Alicia E. Kirchner
Chief, Planning Division
Corps of Engineers, Sacramento District
1325 J Street
Sacramento, California 95814-2922

Dear Ms. Kirchner:

The U.S. Army Corps of Engineers' (Corps) has requested coordination under the Fish and Wildlife Coordination Act (FWCA) for the American River Common Features General Re-evaluation Report (GRR) project. The proposed flood risk management construction would occur along the lower American River and the Sacramento River in Sacramento County, California. The enclosed report constitutes the U.S. Fish and Wildlife Service's draft FWCA report for the proposed project. A draft FWCA report was provided to the Corps and other state and federal resource agencies on September 20, 2013. We did not receive any comments on the draft FWCA report.

If you have any questions regarding this report on the proposed project, please contact Jennifer Hobbs, Fish and Wildlife Biologist, at (916) 414-6541.

Sincerely,

for Jennifer M. Norris
Field Supervisor

Enclosure:

FISH AND WILDLIFE COORDINATION ACT REPORT
AMERICAN RIVER COMMON FEATURES
GENERAL RE-EVALUATION REPORT PROJECT

OCTOBER 2015

BACKGROUND

In February 1986, major storms in northern California caused record flows along the American River. Water releases from Folsom Reservoir into the American River, in combination with high flows on the Sacramento River, almost caused catastrophic flooding to the city of Sacramento and surrounding areas. The result of the February 1986 storms raised concerns over the adequacy of the existing flood control system, which led to a series of investigations to provide additional flood protection to the Sacramento area.

The U.S. Army Corps of Engineers (Corps) completed an initial feasibility study in December 1991 for the American River and Natomas Basin areas. The feasibility report recommended the construction of a concrete gravity flood detention dam just downstream of the confluence of the North and Middle Forks of the American River, and for levee improvements downstream of Folsom Dam. Due to environmental and cost concerns, Congress chose not to authorize the proposed detention dam and instead directed the Corps to supplement the analysis of flood control options considered in the 1991 study.

A supplemental study was completed and presented in the *Supplemental Information Report American River Watershed Project, California*, dated March 1996. The report presented three possible flood control plans: (1) the construction of the concrete gravity flood detention dam recommended in the 1991 report; (2) Folsom Dam improvements; and (3) a stepped release plan for Folsom Dam releases. The report also concluded that levee improvements downstream of Folsom Dam were needed and that these levee improvements were "common" to all three plans. Under the Water Resources Development Act of 1996 (WRDA 96), Congress authorized the American River Common Features Project (Common Features Project), which included levee modifications on both banks of the American River, levee modifications along the east bank of the Sacramento River downstream from the Natomas Cross Canal, installation of streamflow gauges upstream from Folsom Reservoir, modification of the flood warning system along the lower American River, and continued interim reoperation of Folsom Reservoir for flood control.

In 1999, Congress decided to authorize improvements to Folsom Dam to control a 200-year flood event with a peak release of 160,000 cubic feet per second (cfs) from the dam. By doing this, improvements to levees downstream of Folsom Dam could be fine-tuned to work closely with the Folsom Dam improvements being discussed by Congress. Subsequently, the Common Features Project was modified by the Water Resources Development Act of 1999 (WRDA 99) to include additional features so the American River could safely convey an emergency release of 160,000 cfs. Also authorized under WRDA 99 was the Folsom Dam Modification project, which would allow for larger releases from Folsom Dam earlier in a flood event. At the same time, Congress also directed the Corps to review additional modifications to the flood storage of Folsom Dam to maximize the use of the dam for flood damage reduction prior to consideration of any additional storage on the American River. The Folsom Dam Raise project was subsequently authorized by Congress in 2004.

Major construction components for the Common Features Project under the WRDA 96 authorization include construction of seepage remediation along about 22 miles of the American River levees. Under the WRDA 99 authorization, the major construction components include construction of seepage remediation and levee raises along four stretches of the American River. All Common Features Project features authorized under WRDA 96 and WRDA 99 have been constructed or are in design analysis for construction, and the U.S. Fish and Wildlife Service (Service) has previously coordinated with the Corps on the various aspects of the Common Features Project.

Deep under-seepage became a significant concern along the American River levees following a flood event in 1997. Since the levee improvements along the American River were still in the design phase, remediation of deep under-seepage needed to be included in the design plans. This additional effort led to considerable cost increases over what was originally authorized by Congress for the Common Features Project, including the WRDA 99 improvements that had already increased the cost of the original WRDA 96 authorization.

The Folsom Dam Post Authorization Change Report and the Economic Re-evaluation Report for Folsom Dam Improvements revealed that additional levee improvements were needed on the American and Sacramento Rivers in order to truly capture the benefits of the Folsom Dam projects. These levee deficiencies consisted primarily of erosion concerns on the American River, and seepage, stability, erosion, and height deficiencies on the Sacramento River downstream of its confluence with the American River. However, the full extent of these levee deficiencies was not known and additional re-evaluation studies were needed for the flood basins that comprise the city of Sacramento.

The purpose of the Common Features Project is to reduce the flood risk for the city of Sacramento. The following problems were identified within the Sacramento levee system:

- seepage and underseepage;
- levee erosion;
- levee stability;
- levee overtopping;
- access for maintenance and flood fighting;
- vegetation and encroachments;
- releases from Folsom Dam;
- floodplain management; and
- additional upstream storage from existing reservoirs.

DESCRIPTION OF PROJECT AREA

The project area is located along the Sacramento and American River watersheds. The Sacramento River watershed covers 26,000 square miles in central and northern California. Major tributaries of the Sacramento River include the Feather, Yuba, and American Rivers. The American River watershed covers about 2,100 square miles northeast of Sacramento and includes portions of Placer, El Dorado, Alpine, and Sacramento counties. The American River watershed includes Folsom Dam and Folsom Reservoir; inflowing rivers and streams, including the North, South and Middle forks of the American River; and the American River downstream to its confluence with the Sacramento

River in the city of Sacramento. The Sacramento and American rivers form a floodplain covering roughly 110,000 acres at their confluence. This floodplain includes most of the developed portions of the city of Sacramento.

The American River Common Features GRR study area includes: about 12 miles of the north and south banks of the American River immediately upstream of its confluence with the Sacramento River; the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry Creek, Robla Creek, Arcade Creek, and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); the east bank of the Sacramento River downstream from the American River to the town of Freeport, where the levee ties into the Beach Lake levee; and the Sacramento Weir and Bypass, which is located along the north edge of the city of West Sacramento.

Within the greater project area, there are four distinct flood basins: the American River North Basin, the American River South Basin, the Sacramento Bypass and the Natomas Basin. These basins are described in further detail below.

The American River North Basin is located north of the American River and east of the city of Natomas, and includes the North Sacramento and Arden Arcade communities. Project construction in this basin includes the levees on the north bank of the American River, levees on the east bank of NEMDC, and levees along Arcade Creek, Dry/Robla Creek, and the Magpie Creek Diversion Channel.

The American River South Basin is located south of the American River and east of the Sacramento River. Communities protected by these project levees include Downtown Sacramento, Land Park, Pocket-Meadowview, East Sacramento, South Sacramento and Rancho Cordova. Project construction in this basin would be limited to the south bank of the American River and the east bank of the Sacramento River.

The Sacramento Bypass is located in Yolo County, about 4 miles west of the city of Sacramento and along the northern edge of the city of West Sacramento. The Sacramento Weir runs along the west bank of the Sacramento River and connects the river to the Bypass. The Bypass is located in a rural area owned by the State of California and operated as the Sacramento Bypass Wildlife Area.

The Natomas Basin is located in the northern portion of the study area and is located east of the Sacramento River, west of NEMDC, and north of the American River. The Natomas Basin is considered to be a part of the study area, as described by the GRR; however, the proposed measures to raise the height of the Natomas Basin levees were previously analyzed in the Natomas Levee Improvement Program, Phase 4b Landside Improvements Project (NLIP Phase 4b Project) in 2010. Therefore, the Natomas Basin will not be analyzed in this document.

PROJECT DESCRIPTION

The purpose of the Common Features GRR is to determine if there is a Federal interest in modifying the authorized Common Features Project for flood risk management in the greater Sacramento area. National Environmental Policy Act (NEPA) evaluation is required when a major Federal action is under consideration and may have impacts on the quality of the natural and human environment. The Corps has determined that the proposed project may have significant effects on the environment and therefore, an EIS is required.

The Common Features GRR has identified a number of problems associated with the flood risk management system protecting the city of Sacramento and surrounding areas. There is a high probability that flows in the American and Sacramento Rivers would stress the network of levees protecting Sacramento to the point that levees could fail. The consequences of such a levee failure would be catastrophic since the area inundated by flood water is highly urbanized and the flooding could be up to 20 feet deep.

A wide variety of management measures were developed and then evaluated and screened to address the planning objectives to remedy the Sacramento area levee problems. Formulation strategies were then developed to address various combinations of the planning objectives and planning constraints. The formulation strategies used to address the objectives and constraints included measures to reduce flood stages, address seepage and underseepage, address stability, address erosion, address maintenance/emergency response access, and achieve the urban levee level of protection. Based upon these strategies, various combinations of the measures were assembled to form an array of preliminary plans. The preliminary plans were then evaluated, screened, and reformulated, resulting in a final array of alternatives. From this final array of alternatives, a tentatively selected plan was identified.

No Action Alternative

The Corps is required to consider a No Action Alternative as one of the alternatives for selection in order to comply with the requirements of NEPA. With the No Action Alternative, it is assumed that no additional features would be implemented by the Corps or by local interests to achieve the planning objectives over and above those elements of the previously authorized Common Features Project.

Under the No Action Alternative the Corps would not conduct any additional work to address seepage, slope stability, overtopping, or erosion concerns in the Sacramento metropolitan area. As a result, if a high flow event were to occur, the Sacramento area would remain at risk of a possible levee failure.

The urban development within the project area would continue to be at risk of flooding and lives would continue to be threatened. The levees within the study area could fail and result in a catastrophic disaster. If a levee failure were to occur, major government facilities would be impacted until the flood waters recede. Within the study area are many transportation corridors that could be flooded as well if the levees were to fail.

Alternative 1: Fix Levees in Place

Alternative 1 involves the construction of fix-in-place levee remediation measures to address seepage, stability, erosion, and overtopping concerns identified for the American and Sacramento river levees, and the East Side Tributaries. In addition, Alternative 1 would include levee raises for the Natomas Basin, which were analyzed under NEPA in the NLIP Phase 4b Project EIS/EIR in 2010. As a result, this FWCA report incorporates the analysis of the levee raise by reference, but is not discussed within this report.
Due to the urban nature and proximity of existing development within the American River North and South Basins, Alternative 1 proposes fix in place remediation. The purpose of this alternative would be to improve the flood damage reduction system to safely convey flows to a level that

River in the city of Sacramento. The Sacramento and American rivers form a floodplain covering roughly 110,000 acres at their confluence. This floodplain includes most of the developed portions of the city of Sacramento.

The American River Common Features GRR study area includes: about 12 miles of the north and south banks of the American River immediately upstream of its confluence with the Sacramento River; the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry Creek, Robla Creek, Arcade Creek, and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); the east bank of the Sacramento River downstream from the American River to the town of Freeport, where the levee ties into the Beach Lake levee; and the Sacramento Weir and Bypass, which is located along the north edge of the city of West Sacramento.

Within the greater project area, there are four distinct flood basins: the American River North Basin, the American River South Basin, the Sacramento Bypass and the Natomas Basin. These basins are described in further detail below.

The American River North Basin is located north of the American River and east of the city of Natomas, and includes the North Sacramento and Arden Arcade communities. Project construction in this basin includes the levees on the north bank of the American River, levees on the east bank of NEMDC, and levees along Arcade Creek, Dry/Robla Creek, and the Magpie Creek Diversion Channel.

The American River South Basin is located south of the American River and east of the Sacramento River. Communities protected by these project levees include Downtown Sacramento, Land Park, Pocket-Meadowview, East Sacramento, South Sacramento and Rancho Cordova. Project construction in this basin would be limited to the south bank of the American River and the east bank of the Sacramento River.

The Sacramento Bypass is located in Yolo County, about 4 miles west of the city of Sacramento and along the northern edge of the city of West Sacramento. The Sacramento Weir runs along the west bank of the Sacramento River and connects the river to the Bypass. The Bypass is located in a rural area owned by the State of California and operated as the Sacramento Bypass Wildlife Area.

The Natomas Basin is located in the northern portion of the study area and is located east of the Sacramento River, west of NEMDC, and north of the American River. The Natomas Basin is considered to be a part of the study area, as described by the GRR; however, the proposed measures to raise the height of the Natomas Basin levees were previously analyzed in the Natomas Levee Improvement Program, Phase 4b Landside Improvements Project (NLIP Phase 4b Project) in 2010. Therefore, the Natomas Basin will not be analyzed in this document.

PROJECT DESCRIPTION

The purpose of the Common Features GRR is to determine if there is a Federal interest in modifying the authorized Common Features Project for flood risk management in the greater Sacramento area. National Environmental Policy Act (NEPA) evaluation is required when a major Federal action is under consideration and may have impacts on the quality of the natural and human environment. The Corps has determined that the proposed project may have significant effects on the environment and therefore, an EIS is required.

The Common Features GRR has identified a number of problems associated with the flood risk management system protecting the city of Sacramento and surrounding areas. There is a high probability that flows in the American and Sacramento Rivers would stress the network of levees protecting Sacramento to the point that levees could fail. The consequences of such a levee failure would be catastrophic since the area inundated by flood water is highly urbanized and the flooding could be up to 20 feet deep.

A wide variety of management measures were developed and then evaluated and screened to address the planning objectives to remedy the Sacramento area levee problems. Formulation strategies were then developed to address various combinations of the planning objectives and planning constraints. The formulation strategies used to address the objectives and constraints included measures to reduce flood stages, address seepage and underseepage, address stability, address erosion, address maintenance/emergency response access, and achieve the urban levee level of protection. Based upon these strategies, various combinations of the measures were assembled to form an array of preliminary plans. The preliminary plans were then evaluated, screened, and reformulated, resulting in a final array of alternatives. From this final array of alternatives, a tentatively selected plan was identified.

No Action Alternative

The Corps is required to consider a No Action Alternative as one of the alternatives for selection in order to comply with the requirements of NEPA. With the No Action Alternative, it is assumed that no additional features would be implemented by the Corps or by local interests to achieve the planning objectives over and above those elements of the previously authorized Common Features Project.

Under the No Action Alternative the Corps would not conduct any additional work to address seepage, slope stability, overtopping, or erosion concerns in the Sacramento metropolitan area. As a result, if a high flow event were to occur, the Sacramento area would remain at risk of a possible levee failure.

The urban development within the project area would continue to be at risk of flooding and lives would continue to be threatened. The levees within the study area could fail and result in a catastrophic disaster. If a levee failure were to occur, major government facilities would be impacted until the flood waters recede. Within the study area are many transportation corridors that could be flooded as well if the levees were to fail.

Alternative 1: Fix Levees in Place

Alternative 1 involves the construction of fix-in-place levee remediation measures to address seepage, stability, erosion, and overtopping concerns identified for the American and Sacramento river levees, and the East Side Tributaries. In addition, Alternative 1 would include levee raises for the Natomas Basin, which were analyzed under NEPA in the NLIP Phase 4b Project EIS/EIR in 2010. As a result, this FWCA report incorporates the analysis of the levee raise by reference, but is not discussed within this report.

Due to the urban nature and proximity of existing development within the American River North and South Basins, Alternative 1 proposes fix in place remediation. The purpose of this alternative would be to improve the flood damage reduction system to safely convey flows to a level that maximizes net benefits. Table 1 summarizes the levee problems discussed above and the proposed remediation measure for each waterway.

Table 1. Alternative 1 Proposed Levee Improvement Measures by Waterway

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	–	–	Bank Protection, Launchable Rock Trench	–
Sacramento River	Cutoff Wall	Cutoff Wall	Bank Protection, Launchable Rock Trench	Levee Raise
NEMDC	Cutoff Wall	Cutoff Wall	–	Floodwall
Arcade Creek	Cutoff Wall	Cutoff Wall	–	Floodwall
Dry and Robla Creeks	–	–	–	Floodwall
Magpie Creek	–	–	–	Floodwall

In addition to the proposed levee improvement measures shown in Table 1, the following measures and policies would be addressed during construction.

- The Corps' standard levee footprint would be established during construction of structural improvements on all levees that are out of compliance. The standard levee footprint consists of a 20 foot crown width, a 3H:1V waterside slope, and a 2H:1V landside slope, when possible. If the 3H:1V waterside slope is not possible, than a minimum 2H:1V waterside slope would be established instead.

- A 10 foot landside maintenance access would be established, when possible.

- Compliance with Corps levee vegetation requirements would be established. The vegetation requirements include a 15 foot waterside, landside and vertical vegetation-free zone. When possible, a variance would be sought to allow vegetation to remain. If granted, the variance would allow for vegetation to remain on the lower waterside slope and within the waterside 15 foot vegetation-free zone. No vegetation would be permitted on the landside slope.

    - A vegetation variance would be requested to provide compliance for the Sacramento River portion of this project.

    - The erosion measures on the American River is not considered a structural fix, as these measures do not impact the structure of the levee, therefore the vegetation in this portion of the project would not be addressed under the Common Features GRR project. American River vegetation compliance would occur under a System-

1 Seepage, stability, and overtopping measures were addressed in the American River Common Features WRDA 96 and WRDA 99 construction projects.

Wide Improvement Framework by the local sponsors.

  - The East Side Tributaries would be brought into vegetation compliance during construction in those levee reaches.

- Utility encroachments would be brought into compliance with Corps policy. Utilities that penetrate the levee would be removed and replaced with one of two fixes: a surface line over the levee prism or a through-levee line equipped with positive closure devices.

- Private encroachments would be removed by the non-Federal local sponsor or property owner prior to construction.

There would be no proposed measures under Alternative 1 for the Sacramento Bypass. The following sections contain more detailed information on the specific measures proposed by waterway under Alternative 1.

American River

Levees along the American River under Alternative 1 require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed to address erosion on the American River levees: bank protection and a launchable rock trench. Both of these measures are described in detail in the subsections below. These measures would be implemented for all of the proposed alternatives discussed in this document.

Bank Protection

This measure consists of placing rock protection on the river's bank, and in some locations, on the levee slope to prevent erosion. The location of rock placement would be based on site-specific analysis. When necessary, the eroded portion of the bank would be filled and compacted prior to the rock placement. The sites would be prepared by clearing and stripping the site prior to construction. Small vegetation and deleterious materials would be removed. In most cases large vegetation would be permitted to remain at these sites. Temporary access ramps would be constructed, if needed, using imported borrow material that would be trucked to the site.

Revetment would be imported from an offsite location via haul trucks and temporarily stored at a staging area located in the immediate vicinity of the construction site. A loader would be used to move revetment from the staging area to the excavator that would be placing material. The revetment would be placed at a slope varying from 2V:1H to 3V:1H, depending on the site specific conditions. A large rock berm would be placed in the water up to an elevation slightly above the mean summer water surface and a planting trench would be established on the rock berm surface for re-vegetation purposes. An excavator would either be working from the top of bank placing revetment on the bank and in the water, or from on top of the rock berm that is established.

Launchable Rock Trench

The launchable rock filled trench is designed to deploy once erosion has removed the bank material beneath it. All launchable rock trenches would be constructed outside of the natural river channel. The vegetation would be removed from the footprint of the trench and the levee slope prior to excavation. The trench configuration would include a 2H:1V landslide slope and a 1H:1V waterside slope, and would be excavated at the toe of the existing levee. All soil removed during trench excavation would be stockpiled for reuse or disposed of. The bottom of the trench would be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and the amount of rock required.

After excavation, the trench would be filled with revetment that would be imported from an off-site location via haul trucks. After rock placement, the trench would be covered with a minimum of 3 feet of stockpiled soil for a planting berm. Rock placed on the levee slope would be covered with 2 feet of stockpiled soil. All disturbed areas would be reseeded with native grasses and small shrubs where appropriate. Trees would be permitted on the berm if planted outside the specified vegetation free zone.

<u>Sacramento River</u>

Levees along the Sacramento River require improvements to address seepage, stability, and erosion. In addition, these levees require height improvements in order to convey additional flows that exceed the current design levels. To provide access for levee construction, inspection, maintenance, monitoring, and flood-fighting, some properties would need to be acquired.

Where the existing levee does not meet the levee design requirements, slope flattening, crown widening, and/or a levee raise is required. This improvement measure addresses problems with slope stability, geometry, overtopping, and levee access. To begin levee embankment grading, the area would be cleared, grubbed, stripped, and where necessary, portions of the existing embankment would be excavated to allow for bench cuts and keyways to tie in additional embankment fill. Excavated and borrow material from nearby borrow sites would be stockpiled at staging areas. Haul trucks and front end loaders would bring borrow materials to the site, which would then be spread evenly and compacted according to levee design plans.

The existing levee centerline would be shifted landward, where necessary, in order to meet the Corps' current levee footprint requirements; or, in order to construct the levee to the existing footprint, a retaining wall may be constructed at the landside levee toe. This measure would raise the levee landward of the existing levee without reducing the levee crown width or disturbing the waterside slope. Retaining walls would range from 4 to 6 feet high and would require landside slope benching to establish the additional fill into the levee section. The levee crown patrol road would be re-established and a new road at the levee toe would be added 10 feet landward of the retaining wall.

Cutoff Walls

To address seepage concerns, a cutoff wall would be constructed through the levee crown. The cutoff wall would be installed by one of two methods: conventional open trench cutoff walls or deep soil mixing (DSM) cutoff walls. The method of cutoff wall selected for each reach would depend on the depth of the cutoff wall needed to address seepage. The open trench method can be used to install a cutoff wall to a depth of about 85 feet. For cutoff walls of greater depth, the DSM method would be utilized.

Prior to construction of the cutoff wall, the construction site and staging areas would be cleared, grubbed, and stripped. The levee crown would be degraded to about half of the levee height to create a large enough working platform (about 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids.

Open Trench Cutoff Walls

Under the open trench method, a trench 3 feet wide would be excavated at the top of levee centerline and into the subsurface materials up to 85 feet deep with a long boom excavator. As the trench is excavated, it is filled with low density temporary bentonite water slurry to prevent cave in. The soil from the excavated trench is mixed nearby with hydrated bentonite, and in some applications cement. The soil bentonite mixture is backfilled into the trench, displacing the temporary slurry. Once the slurry has hardened, it would be capped and the levee embankment would be reconstructed with impervious or semi-impervious soil.

DSM Cutoff Wall

The DSM method involves the use of a crane that supports a set of two to four mixing augers used to drill through the levee crown and subsurface to a maximum depth of about 140 feet. As the augers are inserted and withdrawn, a cement bentonite grout would be injected through the augers and mixed with native soils. An overlapping series of mixed columns would be drilled to create a continuous seepage cutoff barrier. Once the slurry has hardened, it would be capped and the levee embankment would be reconstructed with impervious or semi-impervious soil.

Bank Protection

Bank protection on the Sacramento River would be addressed by construction of the launchable rock trench method described for the American River above, or by standard bank protection, which consists of placing rock protection on the bank to prevent erosion. This measure entails filling the eroded portion of the bank, when necessary, and installing revetment along the waterside levee slope and streambank, from the streambed to a height determined by site-specific analysis. The sites would be prepared by removing vegetation along the levee slopes at either end of the site for construction of a temporary access ramp if needed. The ramp would then be constructed using imported borrow material that would be trucked onsite.

The placement of rock onto the levee slope would occur from atop the levee and/or from the waterside by means of barges. Rock required within the channel, both below and slightly above the water line at the time of placement, would be placed by an excavator located on a barge. Construction would require two barges: one barge would carry the excavator, while the other barge would hold the stockpile of rock to be placed on the channel slopes. Rock required on the upper portions of the slopes would be placed by an excavator located on top of the levee. Rock placement from atop the levee would require one excavator and one loader for each potential placement site. The loader brings the rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the waterside of the levee.

The revetment would be placed via the methods discussed above on existing banks at a slope varying from 2V:1H to 3V:1H, depending on site specific conditions. After revetment placement has been completed, a small planting berm would be constructed in the rock, when feasible, to allow for some re-vegetation of the site.

NEMDC

The east levee of the NEMDC requires improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A conventional open trench cutoff wall would be constructed at these locations to address these problems. The open trench cutoff walls would be constructed as described for the Sacramento River levee described above.

The NEMDC east levee also has height issues which would be addressed by construction of a floodwall. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown construction. The heights of the floodwalls vary from 1 to 4 feet, as required by water surface elevations. Constructing the floodwall raise would require doweling into the existing concrete floodwall and adding reinforced concrete to the floodwall section. The waterside slope would be re-established to its existing slope and the levee crown would grade away from the wall and be surfaced with aggregate base.

Arcade Creek

The Arcade Creek levees require improvements to address seepage, slope stability, and overtopping when the flood event exceeds the current design. A cutoff wall would also be constructed to address seepage for portions of the creek. There is a ditch adjacent to the north levee at the landside toe which provides a shortened seepage path and could affect the stability of the levee. The ditch would be replaced with a conduit or box culvert and then backfilled. This would lengthen the seepage path and improve the stability of the levee.

The majority of the levees on Arcade Creek have existing floodwalls; however, there remains a height issue in this reach. A 1 to 4 foot floodwall raise would allow the levees to pass flood events greater than the current design level. Construction of the floodwall would be consistent with the description for NEMDC above.

Dry and Robla Creeks

The Dry Creek and Robla Creek levees require improvements to address overtopping for when flood events exceed the design level. Height improvements would be made with a floodwall raise. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown construction. The height of the floodwalls would vary from 1 to 4 feet as required by water surface elevations. Construction of the floodwall would be consistent with the description for NEMDC above. The waterside slope would be re-established to its existing slope and the levee crown would be graded away from the wall and be surfaced with aggregate base.

Magpie Creek Diversion Channel

A number of features are proposed for the Magpie Creek Diversion Channel under Alternative 1. These features include the following:

- Strengthening the existing project levee;
- Construction of a 3 to 4 foot tall floodwall along the top of the existing levee for a distance of about 2,100 feet. Construction of the floodwall would be consistent with the description for NEMDC above;
- Construction of a new 1,000-foot-long levee along Raley Boulevard, south of the Magpie Creek bridge;
- Construction of a 79 acre flood detention basin on both sides of Raley Boulevard, primarily through the purchase of properties to preserve the existing floodplain; and
- Raley Boulevard improvements, including widening the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

Alternative 2: Fix Levees in Place and Widen the Sacramento Weir and Bypass

Alternative 2 would include all of the levee improvements discussed in Alternative 1 above, except for the levee raises along the Sacramento River. Instead of the levee raises, the Sacramento Weir and Bypass would be widened to divert more flows into the Yolo Bypass. The levees along the American River, NEMDC, Arcade Creek, Dry Creek, Robla Creek, and the Magpie Creek Diversion Channel would be improved to address identified seepage, stability, erosion, and height concerns through methods described under Alternative 1 above. The levees along the Sacramento River would be improved to address identified seepage, stability, and erosion concerns through the measures described under Alternative 1 above. Due to the urban nature of the project area and proximity of development to the levees, the majority of the levee repairs would be fixed in place.

In addition, Alternative 2 would include levee raises for the Natomas Basin. The Natomas Basin levee raises are proposed under the Common Features Project GRR for authorization; however, these measures were analyzed under NEPA for the NLIP Phase 4b Project EIS/EIR in 2010.

The following sections contain more detailed information on the specific features and reaches included in this alternative. Table 2 summarizes the levee problems discussed above and the proposed measure for each waterway.

Table 2. Alternative 2 Proposed Remediation Measures by Waterway

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[2]	—	—	Bank Protection, Launchable Rock Trench	—
Sacramento River	Cutoff Wall	Cutoff Wall	Bank Protection, Launchable Rock Trench	Sacramento Bypass and Weir Widening
NEMDC	Cutoff Wall	Cutoff Wall	—	Floodwall
Arcade Creek	Cutoff Wall	Cutoff Wall	—	Floodwall
Dry and Robla Creeks	—	—	—	Floodwall
Magpie Creek	—	—	—	Floodwall, Levee Raise

Sacramento Weir and Bypass

The existing Sacramento Weir and Bypass, which allow high flows in the Sacramento River to be diverted into the Yolo Bypass, would be expanded to roughly twice the current width to accommodate increased bypass flows. The existing north levee of the Sacramento Bypass would be degraded and a new levee would be constructed about 1,500 feet to the north. The existing Sacramento Weir would be expanded to match the wider bypass. The new north levee of the bypass would include a 300-foot-wide seepage berm on the landside, with a system of relief wells. An existing high tide relief well site near the existing north levee would be remediated by the non-Federal sponsor prior to construction.

American River

Measures for the American River levees under Alternative 2 would address erosion. These measures were identified and described under Alternative 1 and would also be included in Alternative 2. Implementation of these measures under Alternative 2 would be consistent with the description in Alternative 1.

East Side Tributaries

Measures for NEMDC, Arcade Creek, Dry Creek, Robla Creek, and the Magpie Creek Diversion Channel under Alternative 2 would address seepage, slope stability, and erosion control. These measures were identified and described in Alternative 1 and would also be included in Alternative 2. Implementation of these measures under Alternative 2 would be consistent with the description in Alternative 1.

---

2 Seepage, stability, and overtopping measures were addressed in the American River Common Features WRDA 96 and WRDA 99 construction projects.

Sacramento River

The measures for the Sacramento River levees under Alternative 2 would be consistent with Alternative 1, with one exception. Under Alternative 1, Sacramento River levee remediation measures were proposed to address seepage, stability, erosion control, and levee height problems. Under Alternative 2, there would be no need to address the levee height problems. Therefore, the measures from Alternative 1 that would be implemented under Alternative 2 for the Sacramento River levees would include: (1) installation of cutoff walls to address seepage concerns; (2) slope reshaping to address stability concerns; and (3) bank protection or launchable rock trench measures to address erosion. The description of these measures can be found above under Alternative 1 for the Sacramento River.

BIOLOGICAL RESOURCES

American River

The American River Parkway (Parkway) contains many vegetation types including riparian scrub, riparian forest, oak woodland, open water, grasslands, and some agriculture. Along the river channel, vegetation is primarily considered shaded riverine aquatic (SRA) cover. Trees adjacent to the channel are mainly oaks and cottonwoods with a thick understory of vines, shrubs, and herbaceous vegetation.

The levee slopes along the American River are primarily covered with grasses and a few scattered trees within the levee structure. Several areas within the Parkway have been used as mitigation sites for the Corps and other agency projects for valley elderberry longhorn beetle. There are also some areas within the Parkway that have been used to compensate for loss of riparian habitat or oak woodlands from projects. Vegetation on the landside of the levee is mostly non-native ornamentals and landscape plantings that were planted beyond the legal property and fence lines of residents.

Habitats in the project area around the American River support various wildlife species. Mammal species include mule deer, coyote, black-tailed jackrabbit, striped skunk, and a variety of rodents. Common bird species include American robin, spotted towhee, dark-eyed junco, black phoebe, California towhee, ash-throated flycatcher, northern flicker, mourning dove, California quail, house finch, American and lesser goldfinches, Bewick's and house wrens, northern mockingbird, yellow-billed magpie, red-winged and Brewer's blackbirds, oak titmouse, and Anna's hummingbird. Common raptors include red-tailed hawk, Cooper's hawk, red-shouldered hawk, American kestrel, and great horned owl. Reptile and amphibian species found within the project area include western fence lizard, gopher snake, western rattlesnake, common kingsnake, Pacific treefrog, and western toad.

The river and small backwater areas provide habitat for many water associated species such as raccoon, beaver, Canada goose, wood duck, common merganser, mallard, black phoebe, great blue heron, belted kingfisher, and common yellowthroat. The levee slopes, which are dominated by annual grassland, provide foraging habitat and cover for California ground squirrel, pocket gopher, and western meadowlark.

The lower American River supports a diverse and abundant fish community; altogether, at least 41 species of fish are known to inhabit the river (USFWS 1986). In recognition of its "outstanding and remarkable" fishery resources, the entire lower American River was included in the Wild and Scenic Rivers System in 1981, which provides some protection for these resources (USFWS 1991). Four anadromous species are important from a commercial and recreational perspective. The lower river supports a large run of fall-run Chinook salmon, a species with both commercial and recreational values. The salmon run is sustained by natural reproduction in the river, and by hatchery production at the Nimbus Salmon and Steelhead Hatchery, operated by the California Department of Fish and Wildlife (CDFW). The average annual production of fall-run Chinook salmon in the American River from 1992-2009 is 109,574 (USFWS 2013).

Steelhead, a popular sport fish, are largely sustained in the river by production from the Nimbus Hatchery, because summer water temperatures often exceed the tolerances of juvenile steelhead, which typically spend about 1 year in the river. American shad and striped bass enter the river to spawn; these two species, introduced into the Sacramento River system in the late 1800s, now support popular sport fisheries. In addition to species of economic interest, the lower American River supports many nongame species, including Sacramento pikeminnow, Sacramento sucker, tule perch, and hardhead (USFWS 1994).

NEMDC

This canal is a narrow channel with many trees in the lower portion. As the canal heads north the channel widens and has less woody vegetation. The levee slopes on the east side of the canal are clear of vegetation due to maintenance practices. The west side of this canal is not part of this project as it is part of the NLIP Phase 4b Project.

Arcade Creek

The levees along Arcade Creek are maintained vegetation free; however, the channel does have some trees and understory. Between Norwood Avenue and Rio Linda Boulevard the channel contains a thick riparian area but vegetation becomes sparse once it passes Rio Linda Boulevard. Due to the urban conditions in this area, wildlife is limited to those similar to the Parkway but in smaller numbers.

Dry and Robla Creeks

The Dry and Robla Creeks area is a wide open space floodplain, with both creeks being contained between the two levees. The creeks maintain sufficient water throughout the year for trees to survive along the channel. There are scattered wetlands located in the floodplain with a higher concentration at the confluence with the NEMDC. The actual levee slopes in this floodplain contain very little vegetation due to maintenance practices. Wildlife in the floodplain is similar to that in the Parkway.

Magpie Creek Diversion Channel

The project area of Magpie Creek Diversion Channel begins in an industrial area where the channel contains primary grasses. Upstream, the area becomes open space before it intersects with Raley Boulevard and additional industrial development. Seasonal wetlands in the area include natural vernal pools and other areas with standing water that provide a similar biological function as natural vernal pools. Wildlife in this area includes jack rabbits, skunks, beavers, and coyotes that also use the surrounding undeveloped area. Avian species that utilize this habitat include herons and waterfowl. Amphibian and reptile species include treefrog and common garter snake.

Sacramento River

Vegetation along the Sacramento River is mostly SRA cover consisting of oaks and cottonwoods with shrub understory. There are intermittent locations along the waterline with no trees due to revetment. The Sacramento River Bank Protection Project has repaired some erosion sites along this section of the river using rock revetment on the slope and creating small vegetated benches. These sites have been planted with riparian vegetation and woody material has been placed in the rock to provide in water habitat for fish species.

Due to the urban development adjacent to the levees in this area, wildlife is limited to small mammals and various avian species. Domestic animals from residents are also often seen along the levees in this basin of the project. Though a narrow riparian corridor, this area does function as a migratory corridor for wildlife as the area to the east is completely developed with housing. It is important to maintain a corridor to provide connectivity along the Sacramento River.

The Sacramento River contains a variety of habitat characteristics that are important to many fish species. Streamside vegetation provides SRA cover and aids in temperature control, streambank stability, and habitat complexity. Cover is used by all life stages of anadromous fish for shelter and provides habitat for salmonids, Sacramento splittail, delta smelt, black bass and sunfish.

Root structures of riparian vegetation can provide bank stability and shelter for juvenile fish. Woody debris can provide shelter from predation and refugia from stream flow. Riparian vegetation also influences the food chain of a stream, providing organic detritus and terrestrial insects. Terrestrial organisms falling from overhanging branches contribute to the food base of the aquatic community. Salmonids in particular are primarily insectivores and feed mainly on drifting food organisms.

In general, the Sacramento River channel provides a migratory pathway to many anadromous fish and provides seasonal rearing habitat to many other native fish species. Native anadromous fish species include Chinook salmon, green and white sturgeon, Pacific and river lamprey, and steelhead. Native resident fish species include delta smelt, hardhead, hitch, prickly sculpin, Sacramento blackfish, Sacramento pikeminnow, Sacramento splittail, Sacramento sucker, threespine stickleback and tule perch. Non-native anadromous species, such as American shad and striped bass, provide recreational sport fishing opportunities. Non-native resident fish species include several species of catfish, black bass, sunfish and minnows. Some non-native species may provide recreational fishing opportunities, such as largemouth, smallmouth, and striped bass, yet these species also prey upon native juvenile species that use nearshore habitats.

Sacramento Bypass and Weir

The Sacramento Bypass is a 360 acre area that is an important cover and feeding area for wildlife during the late fall, winter and early spring. Vegetation varies from scattered trees, such as mature cottonwoods, willows and valley oaks, to a sparsely covered sand soil area on the eastern end. There are also wetlands within the bypass. Game birds, raptors, songbirds, and native mammals are all present in this area.

The footprint of the expanded weir contains 8 acres of scattered trees along the road, railroad tracks, and levee slope. Primary wildlife use this area is avian species, beavers, skunks, and rabbits. The trees along the river provide shade for many native and non-native species. These trees are also used by various avian species for nesting.

Threatened and Endangered Species

Potentially affected federally-listed species within the project area include the valley elderberry longhorn beetle, giant garter snake, delta smelt, Central Valley steelhead, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and green sturgeon. The valley elderberry longhorn beetle, giant garter snake, delta smelt, yellow-billed cuckoo, and least Bell's vireo fall under the jurisdiction of the Service. The National Marine Fisheries Service (NMFS) is responsible for the listed salmonids and green sturgeon.

The riverbank and associated nearshore aquatic area that would be affected by the proposed action constitute portions of the designated critical habitat of the delta smelt. Indirect effects of the proposed action may also extend to other portions of this critical habitat. The Corps completed section 7 consultation with the Service. The consultation is included as Appendix 1.

In addition, the bank protection action area constitutes elements of essential fish habitat (EFH). EFH is the aquatic habitat (water and substrate) necessary to fish for spawning, breeding, feeding and or growth to maturity that will allow a level of production needed to support a long-term, sustainable commercial fishery and contribute to a health ecosystem. Consultation with NMFS regarding EFH is required for all commercially-harvested runs of salmon, including all runs of salmon in the project's action area.

Future Conditions Without the Project (No Action Alternative)

American River

Under the No Action Alternative, the Corps would not participate in construction of the proposed project. There would be no construction related effects to the vegetation and wildlife. However, looking over the past several decades the largest and most frequent flows come down the American River system, some of the floodplain in the Parkway has eroded away. During the 50 year life span of the project it is expected that larger flows would be released from Folsom Dam and sustained for longer periods, leading to potential loss of floodplain and the vegetation on it within the Parkway. While erosion and accretion within the riverine system is a normal and healthy process, Folsom Dam has cutoff sediment supply to the lower American River which creates a sediment starved section of the river. Sediment starvation means that accretion would not occur and the loss of floodplain and its ability to support habitat would be lost. This loss would also cause any wildlife in the area to relocate to other areas where the habitat they need is present. Because we cannot predict when and how large events would occur, it is not possible to determine when the floodplain would erode. The loss of the Parkway vegetation and wildlife habitat would be considered a significant impact.

East Side Tributaries

Under the No Action Alternative, the Corps would not participate in construction of the proposed project. There would be no construction related effects to the vegetation and wildlife. The riparian habitat on Arcade Creek between Norwood Avenue and Rio Linda Boulevard would remain. The other creeks do not contain much vegetation; however, the little vegetation that does exist would not be removed. Wildlife in these creek areas would not be disturbed due to construction activities.

Sacramento River

Under the No Action Alternative, the Corps would not participate in construction of the proposed project. There would be no construction related effects to the vegetation and wildlife. The banks along the Sacramento River are very erosive and without some kind of erosion control measures, the banks would continue to erode during high flows. As the banks of the river erode, vegetation would be lost and the levees could fail. It is likely that in order to save the levee structures, flood fighting activities would occur during a high flow emergency response. Flood fighting is usually performed by placing large rock along the levee slope to stop erosion and prevent levee failure and loss of lives. The placement of the rock could prevent and/or impede future growth of trees and vegetation on the levee slopes.

In the event that flood fighting activities are not successful and a levee failure occurs, all vegetation could be lost and wildlife could be swept away in the flood waters. The loss of vegetation that could occur in a large flood event and the placement of rock along the banks could have significant impacts to vegetation and wildlife, particularly to the functioning of a migratory corridor.

While this area of the project does not provide large patches of habitat, it does serve as a migratory corridor for wildlife from further south in the Sacramento-San Joaquin Delta to areas further north along the Sacramento River, such as the Parkway. Riparian corridors can be especially important for reptiles, amphibians, and small mammals.

Future Conditions With the Project

Impacts to vegetation and wildlife within the project area are evaluated based on data collected from tree surveys conducted in 2011, site visits, Google Earth, and the American River Parkway Plan (Parkway Plan). The goals and objectives of the Parkway Plan and how construction of the project would impact those goals and objectives were considered in the impact analysis. Table 3 summarizes the impacts to vegetation by basin and reach.

Alternative 1: Fix Levees in Place

American River

The construction of rock trenches along the American River would result in the removal of about 65 acres of riparian habitat within the Parkway. This acreage was determined by overlaying the largest possible footprint onto an aerial photograph and calculating the riparian habitat within the footprint. Much of this riparian habitat contains trees that have been in the Parkway for 50 to 100 years or more. The Parkway is the largest remaining riparian corridor in the city of Sacramento. In addition, construction would also impact 135 acres of grassland, which include the levees, patrol roads, and open lands. Project construction along the American River would be intermittent and would occur over a 7 year period. Trees would not be removed all at one time, they would be removed at each trench site as the trench is constructed.

Table 3. Potential Impacts by Flood Basin and Reach

Waterway	Impacts
American River	65 acres of riparian habitat
	135 acres of grassland habitat
East Side Tributaries	2 acres oak woodland
	4 acres of grassland
	10.5 acres riparian
Sacramento River	70 acres of riparian
Sacramento Bypass	300 acres of agricultural fields and drainage canals
	8 acres of riparian vegetation

Most of the 65 acres of riparian habitat is located on land designated by the Parkway Plan as Protected Areas or Nature Study Area. However, the Parkway Plan also allows for flood control activities to be conducted in order to pass 160,000 cfs through the system. Section 4.10 of the Parkway Plan states:

> *Flood control project, including levee protection projects and vegetation removal for flood control purposes, shall be designed to avoid or minimize adverse impacts on the Parkway, including impacts to wildlife and wildlife corridors. To the extent that adverse impacts are unavoidable, appropriate feasible compensatory mitigation shall be part of the project. Such mitigation should be close to the site of the adverse impact, unless such mitigation creates other undesirable impacts.*

Any trees planted would take many years to mature to the level where they provide the same value as those removed. Because there would be many years between when the trees are planted and when they mature to a value of those removed, this impact is considered significant. Construction would likely occur from May through October when birds are nesting. Once the project is authorized and funded, surveys of the project areas would occur to determine if migratory birds are nesting in areas which may be impacted during construction.

East Side Tributaries

Riparain and oak woodland along Arcade Creek and the NEMDC would need to be removed to construct the project. These trees are suitable nesting habitat for many avian species in the area. Surveys would be conducted to determine if any nesting birds are present prior to construction. If nesting birds are located adjacent to the project area, coordination with the resource agencies would occur. Any trees where nesting birds are located would not be removed while they are actively nesting. However, once the young have fledged, the trees may be removed to construct the project. The loss of trees in this area would be considered significant because new plantings would take many years to grow to the value of those removed.

This alternative would result in temporary impacts to about 4 acres of grasses along the creek channels and levee slopes. Once construction is complete, the areas would be planted with a native grass seed mix to prevent erosion and replace the grasses removed for construction. The grasslands are likely to grow back in a single season.

Sacramento River

Under this alternative the existing levee structure would be degraded by one half to create a working platform for slurry wall installation. As the levee is degraded, all vegetation on the top one half would be removed. Levee degradation will result in the loss of 70 acres of riparian habitat. These trees are located on the top half of the levee, so they provide a small amount of SRA cover and habitat for many avian species. They also contribute to the width of the riparian corridor. On average the current width of the riparian corridor along the Sacramento River is 100 feet. Riparian loss will remove about 60 feet of those 100 feet. The construction and planting of the berm as part of the erosion repair will create an additional 25 feet to the width of the riparian corridor. There will still be a net loss of 35 feet from the riparian corridor. The loss of this 35 feet from the width of the riparian habitat can cause increased predation because the narrower corridor will increase edge effects. Additionally, smaller widths of habitat make it more likely that stochastic events will affect the habitat and loss of the vegetation could result in complete removal of the riparian corridor diminishing connectivity. It will be important for the Corps and the non-federal and local sponsors to ensure that the remaining riparian habitat remains, regeneration occurs (it may need to be helped through active planting), and non-native vegetation does not become established within the corridor.

On the waterside of the levee, 930 large trees would be left in place on the lower one-third and rock would be placed around the base of the trees. The trees that would remain in place are scattered over 31,130 linear feet (50 acres). The rock protection around the trees would reduce the potential for erosion and anchor the trees in place to lower the risk of uprooting in high water events. The understory vegetation would be removed to provide a clean surface to place the rock. Excluding the large trees, vegetation in this area is primarily small shrubs, low growing plants of various species, and grasses. Once the rock protection is in place and a planting berm is constructed, the area would be planted with small shrubs. Appropriate plants would be selected to maximize wildlife habitat.

On the landside of the levee all trees would be removed on the levee slope and within 15 feet of the levee toe to comply with the Corps vegetation policy. Within this 15 feet compliance area, a 10-foot wide landside operations, maintenance, and emergency access corridor would be established. There are 670 trees of various species and size within this landside area that would be removed and not be replaced on-site. The removal of these trees is considered significant because it would take many years for the replacement trees to establish to the value of those removed.

The landside slopes are primarily covered with ornamental groundcovers installed by adjacent private property owners. In some places landscaping has been extended beyond the fence or property lines and up the levee slopes. Degrading of the levee would include removal of all vegetation on the upper half of the landside slope. All disturbed areas, including the levee slopes, would be planted with native grasses to prevent erosion. The 15 foot landside vegetation free zone would be maintained vegetation free, except for the native grasses.

The loss of woody vegetation would affect avian species. Surveys would be conducted to determine if any nesting birds are present prior to construction. If nesting birds are located adjacent to the project area, coordination with the resource agencies would occur. Trees where nesting birds are located would not be removed while they are actively nesting.

Alternative 2 – Fix Levees and Widen the Sacramento Weir and Bypass

The footprints of all features in this alternative are the same as Alternative 1 with the added feature of widening the Sacramento Weir and Bypass. Areas that no longer require a raise would still maintain the same footprint since the purpose of the raise would instead be accomplished via the installation of a retaining wall at the toe of the levee. Therefore, the effects to vegetation and wildlife are the same as those for Alternative 1, with the addition of those associated with the Sacramento Weir and Bypass.

Sacramento Weir and Bypass

Habitat within the existing Bypass would remain the same as the existing conditions. The Bypass would be expanded by about 300 acres, which would become open space and would likely become similar habitat for wildlife as the existing Bypass. Operations of the new weir and bypass would be determined after construction is complete. No grading or altering of the lands within the existing bypass would occur as part of this alternative. Since the southern side of the bypass is lowest in elevation, water would naturally flow to the existing area and continue to support existing vegetation and wildlife. Due to the natural flow of water in the Bypass, existing wetlands are not expected to be impacted by construction of the project. There is a potential for additional wetlands to actually develop in the added 300 acres of bypass since the land would no longer be farmed. Conversion of this land back to its natural state would have benefits to other wildlife and could become an expansion of the Sacramento Bypass Wildlife Area.

There are 8 acres of riparian vegetation that would be removed to construct the weir structure. The 8 acre area contains both the Old River Road and Union Pacific Railroad train tracks. Avian species are the primary wildlife in this area with some small animals like fox and coyotes, which pass through the area to access the river. Included within the 8 acres are 1,500 linear feet of vegetation along the Sacramento River which may be removed to allow the river to flow freely into the weir. Both native and non-native fish species use this area of the river. During construction there would be direct effects to wildlife as the human activities associated with the construction would likely cause any wildlife to relocate to other open space lands to avoid the disturbance; however, the expansion of the Sacramento Weir and Bypass would have a positive effect on vegetation and wildlife once construction is complete and lands are converted from farming activities to open space.

DISCUSSION

Service Mitigation Policy

The recommendations provided herein for the protection of fish and wildlife resources are in accordance with the Service's Mitigation Policy as published in the Federal Register 46:15; January 23, 1981).

The Mitigation Policy provides Service personnel with guidance in making recommendations to protect or conserve fish and wildlife resources. The policy helps ensure consistent and effective Service recommendations, while allowing agencies and developers to anticipate Service recommendations and plan early for mitigation needs. The intent of the policy is to ensure protection and conservation of the most important and valuable fish and wildlife resources, while allowing reasonable and balanced use of the Nation's natural resources.

Under the Mitigation Policy, resources are assigned to one of four distinct Resource Categories, each having a mitigation planning goal which is consistent with the fish and wildlife values involved. The Resource Categories cover a range of habitat values from those considered to be unique and irreplaceable to those believed to be much more common and of relatively lesser value to fish and wildlife. However, the Mitigation Policy does not apply to threatened and endangered species, Service recommendations for completed Federal projects or projects permitted or licensed prior to enactment of Service authorities, or Service recommendations related to the enhancement of fish and wildlife resources.

In applying the Mitigation Policy during an impact assessment, the Service first identifies each specific habitat or cover-type that may be impacted by the project. Evaluation species which utilize each habitat or cover-type are then selected for Resource Category analysis. Selection of evaluation species can be based on several criteria, as follows: (1) species known to be sensitive to specific land- and water-use actions; (2) species that play a key role in nutrient cycling or energy flow; (3) species that utilize a common environmental resource; or (4) species that are associated with Important Resource Problems, such as anadromous fish and migratory birds, as designated by the Director or Regional Directors of the Service. Based on the relative importance of each specific habitat to its selected evaluation species, and the habitat's relative abundance, the appropriate Resource Category and associated mitigation planning goal are determined.

Mitigation planning goals range from "no loss of existing habitat value" (i.e., Resource Category 1) to "minimize loss of habitat value" (i.e., Resource Category 4). The planning goal of Resource Category 2 is "no net loss of in-kind habitat value." To achieve this goal, any unavoidable losses would need to be replaced in-kind. "In-kind replacement" means providing or managing substitute resources to replace the habitat value of the resources lost, where such substitute resources are physically and biologically the same or closely approximate those lost. The planning goal of Resource Category 3 is "no net loss of habitat while minimizing loss of in-kind value." To achieve this goal any unavoidable losses will be replaced in-kind or if it is not desirable or possible out-of-kind mitigation would be allowed. The planning goal of Resource Category 4 is "minimize loss of habitat value." To achieve this goal the Service will recommend ways to rectify, reduce, or minimize loss of habitat value.

In addition to mitigation planning goals based on habitat values, Region 8 of the Service, which includes California, has a mitigation planning goal of no net loss of acreage and value for wetland habitat. This goal is applied in all impact analyses.

In recommending mitigation for adverse impacts to fish and wildlife habitat, the Service uses the same sequential mitigation steps recommended in the Council on Environmental Quality's regulations. These mitigation steps (in order of preference) are: avoidance, minimization, rectifying, reducing or eliminating impacts over time, and compensation.

Ten fish and/or wildlife habitats were identified in the project area which had potential for impacts from the project: oak woodland, riparian forest, riparian scrub-shrub, SRA cover, shallow open water, emergent wetland, annual grassland, agriculture (non-rice cultivation), ornamental landscape, and other. The resource categories, evaluation species, and mitigation planning goal for the habitats impacted by the project are summarized in Table 4.

The evaluation species selected for the oak woodland that would be impacted are acorn woodpecker, turkey, and mule deer. Acorn woodpeckers utilize oak woodlands for nearly all their life requisites; 50-60 percent of the acorn woodpecker's annual diet consists of acorns. Acorn woodpeckers can also represent impacts to other canopy-dwelling species. Turkeys forage and breed in oak woodlands and are abundant in the project area. Mule deer also heavily depend on acorns as a dietary item in the fall and spring; the abundance of acorns and other browse influence the seasonal pattern of habitat use by deer. These latter species represent species which utilize the ground component of the habitat and both have important non-consumptive human uses (i.e., wildlife viewing and bird watching). Based on the high value of oak woodlands to the evaluation species, and their declining abundance, the Service has determined oak woodlands which would be affected by the project should be placed in Resource Category 2, with an associated mitigation planning goal of "no net loss of in-kind habitat value or acreage."

The evaluation species selected for the riparian forest that would be impacted by the project are Swainson's hawks, wood ducks, and Bullock's orioles. Riparian forest vegetation provides important cover, and roosting, foraging, and nesting habitat for these species. Large diameter trees also provide nesting sites for species such as wood ducks and Swainson's hawks. Riparian woodland cover-types are of generally high value to the evaluation species, and are overall, extremely scare (less than 2% remaining from pre-development conditions). Therefore, the Service finds that any riparian forest cover-type that would be impacted by the project should be placed in Resource Category 2, with an associated mitigation planning goal of "no net loss of in-kind habitat value or acreage." In addition, the Service's regional goal of no net loss of wetland acreage or habitat values, whichever is greater, would apply to this habitat type.

The evaluation species selected for the riparian scrub-shrub vegetation that would be impacted by the project is the yellow warbler. Riparian scrub-shrub vegetation provides important cover, and roosting, foraging, and nesting habitat for this species. Riparian cover-types are generally of high value to the evaluation species, and are overall extremely scarce (less than 2% remaining from pre-development conditions). Therefore, the Service finds that any riparian scrub-shrub cover-type that would be impacted by the project should be placed in Resource Category 2, with an associated mitigation planning goal of "no net loss of in-kind habitat value or acreage." In addition, the Service's regional goal of no net loss of wetland acreage or habitat values, whichever is greater, would apply to this habitat type.

The evaluation species selected for SRA cover that would be affected by the project are juvenile salmonids (salmon and steelhead) and the heron and egret family (family Ardeidae). Salmonids were selected because large declines in their numbers are among the most important resource issues in the region, and because of their very high commercial and sport fishing values. Herons and egrets were selected because of the Service's responsibilities for their management under the Migratory Bird Treaty Act, their relatively high value for non-consumptive human uses, such as bird watching, and their value as indicator species for the many birds which use SRA cover.

Table 4. Resource categories, evaluation species, and mitigation planning goal for the habitats possibly impacted by the proposed American River Common Features General Re-evaluation Report, Sacramento County, California.

COVER-TYPE	EVALUATION SPECIES	RESOURCE CATEGORY	MITIGATION GOAL
Oak Woodland	Acorn woodpecker Turkey Deer	2	No net loss of in-kind habitat value or acreage.
Riparian Forest	Swainson's hawk Wood duck Bullock's oriole	2	No net loss of in-kind habitat value or acreage.
Riparian Scrub-Shrub	Yellow warbler	2	No net loss of in-kind habitat value or acreage.
SRA Cover	Juvenile salmonids Herons and Egrets	1	No loss of existing habitat value.
Emergent Wetland	Marsh Wren	2	No net loss of in-kind habitat value or acreage.
Shallow Open Water	Egret Sunfish	2	No net loss of in-kind habitat value or acreage.
Annual Grassland	Red-tailed hawk	3	No net loss of habitat value while minimizing loss of in-kind habitat value.
Agriculture (non-rice cultivation)	White-tailed kite California vole	4	Minimize loss of habitat value.
Ornamental Landscape	None	4	Minimize loss of habitat value.
Other	None	4	Minimize loss of habitat value.

In 1992, the Service designated SRA cover that is impacted by bank protection activities within the Sacramento Bank Protection Project action area as Resource Category 1 (USFWS 1992). Under Resource Category 1, habitat to be impacted is high value, unique, and irreplaceable on a national basis or in the eco-region, and the Service's mitigation planning goal is for no loss of existing habitat value.

The evaluation species selected for the emergent wetland cover-type is the marsh wren. Drainage wetland habitat provides important cover, foraging, nesting, and roosting habitat for such water associated birds as well as some amphibians and aquatic mammals. Insects and spiders are taken from vegetation, the wetland floor, and while in flight (Gutzwiller and Anderson 1987). For protection from predators, the marsh wren usually constructs nests in reedy vegetation about 15 inches above water that is 2 to 3 feet deep (Gutzwiller and Anderson 1987). Because of the medium to high value of this habitat to the evaluation species, and its relative scarcity, the Service designates any emergent wetland habitat within the project area as Resource Category 2, with its associated mitigation planning goal of "no net loss of in-kind habitat value or acreage."

The evaluation species selected for the shallow open water cover-type is the egret and sunfish. Shallow, open water is important to a number of regionally important fish and wildlife. For example, wading birds (e.g., herons and egrets) use it for feeding, as do a number of gamefish, including sunfish, catfish and striped bass. It is also part of the critical habitat designated for federally listed delta smelt and Sacramento River winter-run Chinook salmon. Such shallow water is generally removed when typical bank protection is done, especially when the bank is reshaped. The result is likely to be higher velocities and deeper water along the new shoreline. Compounding the problem is the large amount of riprap that has already been placed in the vicinity of the proposed action, thus effectively removing many miles of shallow, open water. In concert with past Sacramento River Bank Protection Project planning, the Service is designating such habitat that would be impacted as Resource Category 2, with an associated planning goal of "no net loss of in-kind habitat value or acreage."

The evaluation species selected for the annual grassland cover-type is the red-tailed hawk, which utilizes these areas for foraging. This species was selected because of the Service's responsibility for their protection and management under the Migratory Bird Treaty Act, and their overall high non-consumptive values to humans. Annual grassland areas potentially impacted by the project vary in their relative values to the evaluation species, depending on the degree of human disturbance, plant species composition, and juxtaposition to other foraging and nesting areas. Therefore, the Service designates the annual grassland cover-type in the project area as Resource Category 3. Our associated mitigation planning goal for these areas is "no net loss of habitat value while minimizing loss of in-kind habitat value."

The evaluation species selected for the agriculture, non-rice cultivation, cover-type is the white-tailed kite (formerly black-shouldered kite) and the California vole. The white-tailed kite in California is a common species of open and cultivated bottomland and is an obligate predator on diurnal small mammals (Faanes and Howard 1987). Movements and nesting of the white-tailed kite is largely governed by concentrations of mice and voles (Faanes and Howard 1987). The California vole is a widespread and common herbivore in California (Brylski 1990), and its abundance and distribution, along with daytime activity, make it an important prey species. Because this habitat is not native, and is managed for crop production unless fallowed, the Service designates the agriculture cover-type in the project area as Resource Category 4. Our associated mitigation planning goal for these areas is "minimize loss of habitat value."

No evaluation species were identified for the ornamental landscape or "other" cover-types. The ornamental landscape is typically vegetation which occurs along the fence line of adjacent private properties and is maintained by individual landowners. The "other" cover-type encompasses those areas which do not fall within the other cover-types such as gravel and paved roads, parking areas, buildings, bare ground, riprap, etc. Generally these cover-types would not provide any significant habitat value for wildlife species. Therefore, the Service designates the ornamental landscape and "other" cover-types in the project area as Resource Category 4. Our associated mitigation planning goal for these areas is "minimize loss of habitat value."

The recommendations below are based on preliminary construction designs provided by the Corps for the Common Features GRR. Once the specific project designs are developed, the Service's recommendations will be refined.

RECOMMENDATIONS

The Service recommends:

1. Avoid the loss of SRA cover by planting native woody vegetation within the bank protection areas. Work with the Service, NMFS, and California Department of Fish and Wildlife (CDFW) to develop planting and monitoring plans, and with DWR and SAFCA to develop a variance to allow vegetation within the Corps' vegetation free zone to remain in place, especially in areas designed for rock slope protection.

2. Woody vegetation that needs to be removed within the construction footprint should be removed during the non-nesting season to avoid affecting active bird nests.

3. Avoid impacts to migratory birds nesting in trees along the access routes and adjacent to the proposed repair sites by conducting pre-construction surveys for active nests along proposed haul roads, staging areas, and construction sites. This would especially apply if construction begins in spring or early summer. Work activity around active nests should be avoided until the young have fledged. The following protocol from the CDFW for Swainson's hawk would suffice for the pre-construction survey for raptors.

   A focused survey for Swainson's hawk nests will be conducted by a qualified biologist during the nesting season (February 1 to August 31) to identify active nests within 0.25 mile of the project area. The survey will be conducted no less than 14 days and no more than 30 days prior to the beginning of construction. If nesting Swainson's hawks are found within 0.25 mile of the project area, no construction will occur during the active nesting season of February 1 to August 31, or until the young have fledged (as determined by a qualified biologist), unless otherwise negotiated with the California Department of Fish and Wildlife. If work is begun and completed between September 1 and February 28, a survey is not required.

4. Avoid future impacts to the site by ensuring all fill material is free of contaminants.

5. Minimize project impacts by reseeding all disturbed areas, including staging areas, at the completion of construction with native forbs and grasses. Reseeding should be conducted just prior to the rainy season to enhance germination and plant establishment. The reseeding mix should include species used by and beneficial for native pollinators. The Service can work with you in developing this seed mix.

6. Minimize the impact of removal and trimming of all trees and shrubs by having these activities supervised and/or completed by a certified arborist.

7. Compensate the loss of oak woodland, riparian forest, riparian scrub-scrub, and emergent wetland at a ratio of at least 2:1. The Corps should work with the Service and other resource agencies on the development of a riparian plan that will evaluate locations for riparian vegetation planting based on land use in the lower American River Parkway, effects from known future projects, such as the reoperation of Folsom Dam, where existing riparian and

valley elderberry longhorn beetle habitat exists, creating and maintaining connectivity between large riparian patches, and coordination with Sacramento County Parks. For the loss of other cover-types, the Corps should work with the Service and other resource agencies on the development of compensation success benchmarks to ensure that goals are achieved.

8. All bank protection areas should be planted with a diverse mix of woody and herbaceous riparian vegetation. Sites should be diverse (a mix of riparian forest and scrub-shrub) and fit into the surrounding landscape. The planting plan should take into account what is missing from the surrounding vegetation and attempt to create heterogeneous habitats. The Corps should develop a baseline map of existing vegetation communities. Given the amount of rock already placed and the amount proposed for placement, this can serve to create diverse and heterogeneous habitats.

9. Include within the planting contract a provision for the contractor to plant understory species after some of the woody canopy has established. Studies have shown that planting late successional understory species after woody species canopy cover has been established provides better success for establishing these understory plants. Incorporating these species within the planting mix provides more diverse habitat for wildlife species (Johnston 2009).

10. Contact the California Department of Fish and Wildlife regarding possible effects of the project on State listed species.

Subject: Formal Consultation on the American River Common Features (AFRC) Project, Sacramento County, California

Dear Ms. Kirchner:

This letter is in response to the U.S. Army Corps of Engineers (Corps) April 3, 2015, request for consultation with the U.S. Fish and Wildlife Service (Service) on the proposed American River Common Features General Reevaluation Report (ARCF GRR) project in Sacramento County, California. You request was received by the Service on April 7, 2015. The Corps originally initiated consultation on June 30, 2014; however, the Service responded on July 23, 2014, with a request for additional information regarding the project description and the effects analysis the Corps had completed. The April 3, 2015, letter and biological assessment began the formal consultation period. This response is provided under the authority of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

The Federal action on which we are consulting is the ARCF GRR, which includes levee improvements and bank protection along the Sacramento River, levee improvements along Arcade, Magpie, and Dry/Robla Creeks, widening the Sacramento Bypass and Weir, and bank protection along the lower American River. Pursuant to 50 CFR 402.12(j), you submitted a biological assessment for our review and requested concurrence with the findings presented therein. These findings conclude that the proposed project may affect and is not likely to adversely affect the vernal pool fairy shrimp (*Branchinecta lynchi*) and vernal pool tadpole shrimp (*Lepidurus packardi*); may affect likely to adversely affect the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), delta smelt (*Hypomesus transpacificus)* (smelt) and its critical habitat; the giant garter snake (*Thamnophis gigas*); and the yellow-billed cuckoo (*Coccyzus americanus occidentalis*). The project is outside of critical habitat designated for the valley elderberry longhorn beetle and critical habitat proposed for the yellow-billed cuckoo.

The Corps previously consulted with the Service on the Magpie Creek Flood Control Project and on September 15, 2004 a biological opinion regarding effects to the vernal pool fairy shrimp, vernal pool tadpole shrimp, and giant garter snake (File # 1-1-04-F-0132) was provided. The project described in the 2004 biological opinion is exactly the same as the Magpie Creek portion of the project description in the Common Features biological assessment. Because the environmental baseline for vernal pool fairy shrimp and vernal pool tadpole shrimp has not changed from the baseline that was analyzed in the 2004 biological opinion and the project description remains the same, effects to and take of vernal pool fairy shrimp and vernal pool tadpole shrimp are addressed i the September 15, 2004, biological opinion. More recent information regarding the status of the habitat along Magpie Creek for giant garter snake has changed from the 2004 biological opinion. This opinion addresses those changes and any potential effects to the giant garter snake.

Seasonal wetlands, which may provide suitable habitat for vernal pool fairy shrimp and vernal pool tadpole shrimp, occur in the vicinity of the Robla Creek woodland mitigation site A, however any vernal pools in this area would be avoided by these activities. The Corps will implement a 250-foot buffer between vernal pools and vegetation planting. Planting activities will be done in the fall when the wetlands are dry and will use best management practices to ensure that sediment does not enter the seasonal wetlands. The Service concurs that with your determination of may affect, not likely to adversely affect vernal pool fairy shrimp and vernal pool tadpole shrimp at the Robla Creek woodland mitigation site A.

This biological opinion is based on information provided in the Corps' letter requesting consultation and the biological assessment. A complete administrative record is on file at the Service's Sacramento Fish and Wildlife Office.

CONSULTATION HISTORY

September 4, 2013: The Service commented on the April 2013 draft biological assessment.

April 8, 2014: The Service commented on the October 2013 draft biological assessment.

June 30, 2014: The Corps initiated section 7 consultation with the Service.

July 23, 2014: The Service sent a letter in response to the Corps initiation requesting additional information.

April 3, 2015: The Corps provided an updated biological assessment with responses to the Service's July 23, 2014, request for additional information.

August 31, 2015: The Corps provided a revised biological assessment that addressed questions the Service had regarding the project description.

BIOLOGICAL OPINION

Description of the Action

Congress directed the Corps to investigate the feasibility of reducing flood risk of the city of Sacramento. The Corps completed feasibility studies in 1991 and 1996, recommending a concrete gravity flood detention dam on the north fork of the American River at the Auburn site along with levee improvements downstream of Folsom Dam. Other plans evaluated in the report were Folsom Dam improvements and a stepped release plan for Folsom Dam releases. These additional plans also included levee improvements downstream of Folsom Dam. Congress recognized that levee improvements were "common" to all candidate plans in the report and that there was a Federal interest in participating in these "common features." Thus, the ARCF Project was authorized in the Water Resources Development Act (WRDA) of 1996 and a decision on Auburn Dam was deferred to a later date. Major construction components of ARCF in the WRDA 1996 authorization included construction of seepage remediation along about 22 miles of American River levees and construction of levee strengthening and raising of 12 miles of Sacramento River levee in Natomas.

Following the 1986 flood, significant seepage was experienced on the Sacramento River from Verona (upstream end of Natomas) at River Mile (RM) 79 to Freeport at RM 45.5. In addition, both the north and south bank of the American River from RM 0 to about RM 11.4 experienced seepage. Seepage on the Sacramento River was so extensive that Congress, soon after the 1986 flood event, funded remediation in the Sacramento Urban Levee Improvement Project (Sac Urban). The Sac Urban Project constructed shallow seepage cutoff walls from Powerline Road in Natomas at approximately RM 64 down to Freeport.

Shortly thereafter, the Sacramento Valley experienced a flood event in 1997. Considerable seepage occurred on the Sacramento River as well as on the American River. Seepage on the American River was expected because remediation measures had yet to be constructed, but the occurrence of significant seepage on the Sacramento River in the reach remediated as part of the Sac Urban Project was alarming and confirmed that deep underseepage was also of significant concern. As a result, seepage remediation on the American River (then in the late 1990s in the design phase) would need to be designed to remediate both through- and deep underseepage.

In 1999, Congress decided not to authorize Auburn Dam, but instead authorized improvements for Folsom Dam. By doing this, improvements to levees downstream of Folsom Dam could be fine-tuned to work closely with the Folsom improvements being discussed by Congress. Therefore, the ARCF project was modified by WRDA 1999 to include additional necessary features for the American River so that it could safely convey the proposed emergency release of 160,000 cubic feet per second (cfs) from Folsom Dam. Major construction components for the ARCF project in the WRDA 1999 authorization include construction of seepage remediation and levee raise along four stretches of the American River, and construction of levee strengthening and raising of 5.5 miles of Natomas Cross Canal levee in Natomas. All American River features authorized in WRDA 1996 and 1999 have been constructed or are in design analysis for construction within a year or two.

The purpose of the ARCF project is to reduce the flood risk for the city of Sacramento. The following problems were identified within the Sacramento levee system:

- Seepage and underseepage;
- Levee erosion;
- Levee stability;
- Levee overtopping;
- Access for maintenance and flood fighting;
- Vegetation and encroachments;
- Releases from Folsom Dam;
- Floodplain management; and
- Additional upstream storage from existing reservoirs.

In order to evaluate the effects to listed species, the Corps looked at the largest foreseeable footprint. As the Corps moves into the design phase of the project, footprint changes will likely reduce the effects to listed species.

The project is designed to allow for the release of 160,000 cubic feet per second (cfs) from Folsom Dam. The levees along the American River are unable to withstand these maximum flows for extended periods of time without increased risk of erosion and potential failure. The exact location where erosion will occur and to what extent erosion will occur during any given event is unknown. Erosion within the American River Parkway will be addressed as part of the Folsom Dam Water Control Manual Update currently under evaluation and a biological assessment is being prepared to initiate section 7 consultation with both the Service and National Marine Fisheries Service (NMFS). Therefore, the effects of erosion along the lower American River and effects of increased Yolo Bypass flooding frequency due to changes in operations from Folsom Dam are not analyzed in this project description. This is because construction of the American River and Sacramento Bypass measures, which are dependent on releases from Folsom Dam, will not occur until after a biological opinion is received for the Water Control Manual Update. Sacramento River and East Side Tributaries measures are necessary to improve the flood risk management system in the Sacramento area regardless of the change in operation at Folsom Dam and are not dependent on Folsom Dam operations for their implementation. As a result, construction in these areas could occur regardless of the Folsom Dam Water Control Manual Update schedule.

The Corps' project involves the construction of fix-in-place levee remediation measures to address seepage, stability, erosion, and height concerns identified for the Sacramento River and American River levees, Natomas East Main Drainage Canal (NEMDC), Arcade, Dry/Robla, and Magpie Creeks (Figure 1). Most height concerns along the Sacramento River will be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass. Due to the urban nature and proximity of existing development within the American River North and South basins the Corps is planning fix in place remediation. This would improve the flood damage reduction system to safely convey flows to a level that maximizes net benefits. Table 1 summarizes the levee problems discussed above and the proposed measure for each waterway.

Sacramento Area Flood Control Agency (SAFCA), the project's local sponsor, will complete some portions of the Federal project. SAFCA is seeking permission from the Corps pursuant to 33 USC §408 (Section 408) for alteration of the Federal levees along the NEMDC and Arcade Creek.

In addition to the proposed levee improvements measures shown in Table 1, the following measures and policies would be addressed during construction:

- The non-Federal (Department of Water Resources (DWR)) will bring the levees into compliance with the Corps' standard levee footprint using a System Wide Implementation Framework (SWIF) process. A SWIF is a plan developed by the levee sponsor(s) and accepted by the Corps to implement system-wide improvements to a levee system (or multiple levee systems within a watershed) to address system-wide issues, including correction of unacceptable inspection items, in a prioritized way to optimize flood risk reduction. The standard levee footprint consists of a 20 foot crown width, 3:1 waterside

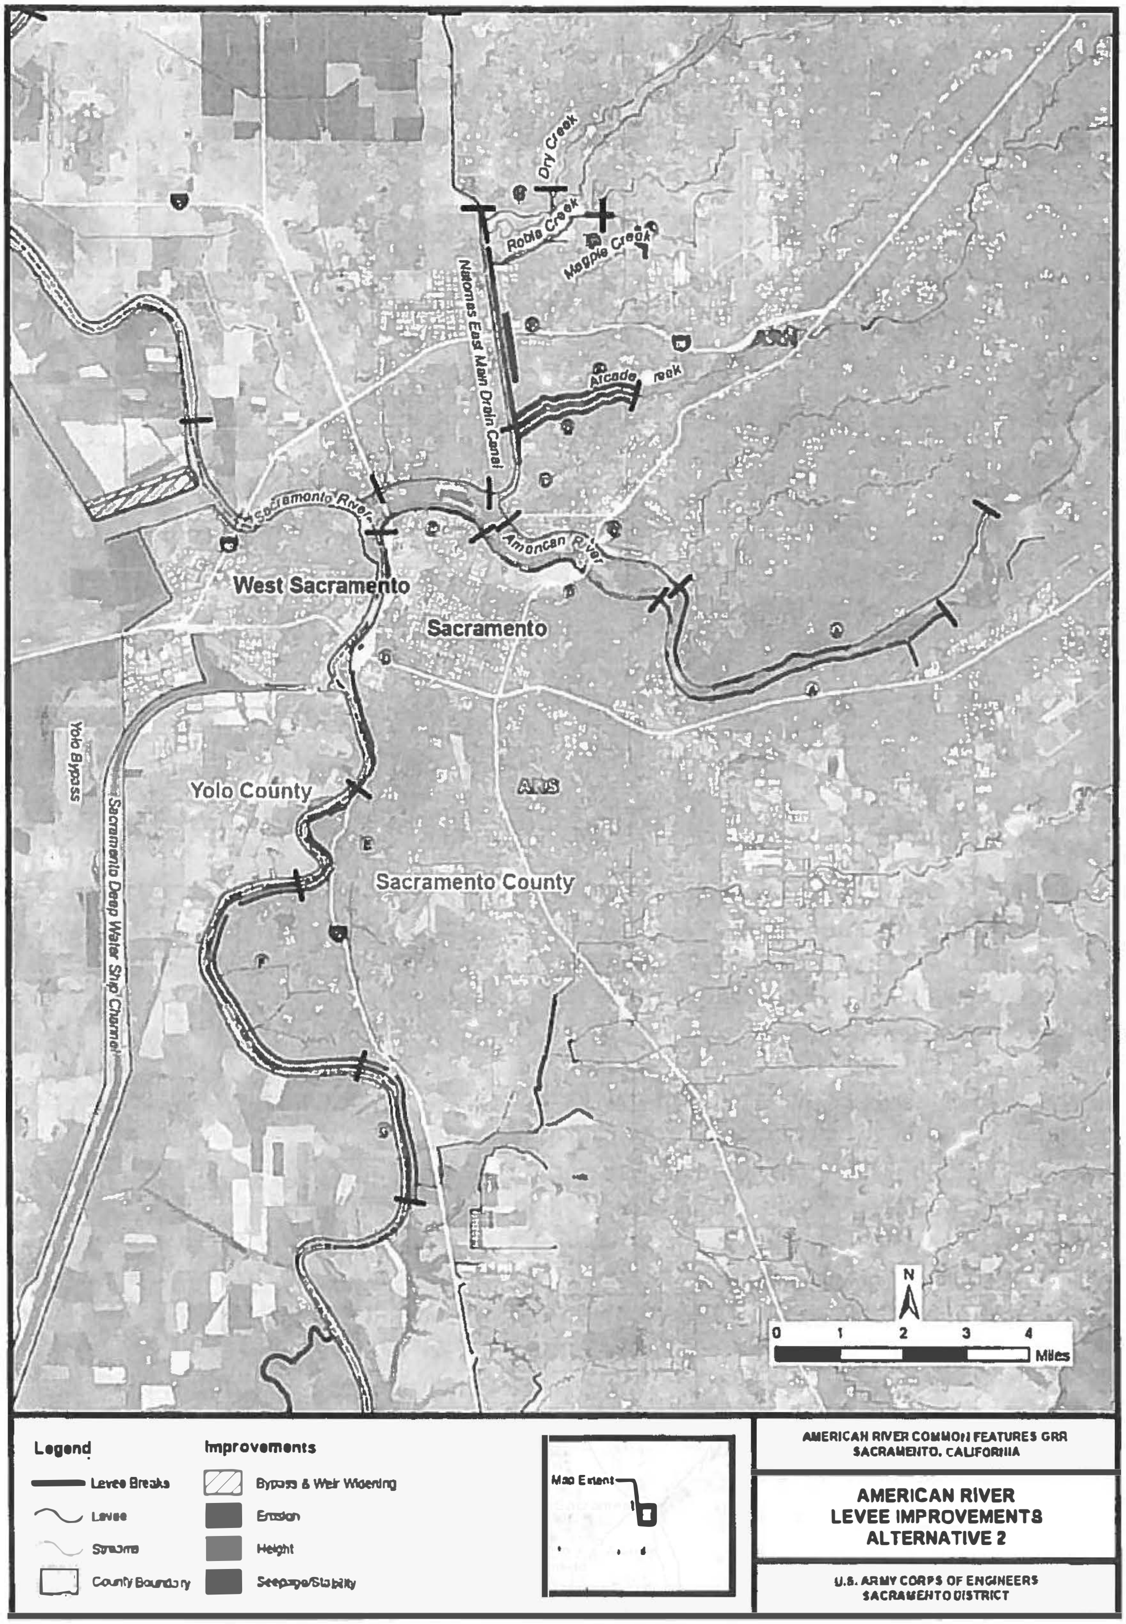

Figure 1. American River Common Features Project Area

Table 1. Remediation by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench (31,000 linear feet)	---
Sacramento River	Cutoff Wall (50,300 linear feet)	Cutoff Wall (50,300 linear feet)	Bank Protection (50,300 linear feet)	Sacramento Bypass and Weir Widening, Levee Raise (1,500 feet)
NEMDC	Cutoff Wall (6,000 linear feet)	Cutoff Wall	---	Floodwall (15,600 linear feet)
Arcade Creek	Cutoff Wall (22,000 linear feet)	Cutoff Wall	---	Floodwall (22,000 linear feet)
Dry/Robla Creeks	---	---	---	Floodwall (2,500 linear feet)
Magpie Creek[2]	---	---	---	Floodwall, Levee Raise

[1]American River seepage, stability, and overtopping measures were addressed in a previous construction project.
[2]In addition to the floodwall, Magpie Creek will include construction of a new levee (3,100 linear feet) along Raley Boulevard south of the creek, and construction of a detention basin on both sides of Raley Boulevard (79 acres). In addition, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

slope and 2:1 landside slope, when possible. If the 3:1 waterside slope is not possible, then a minimum 2:1 waterside slope would be established instead.

- Engineering Technical Letter 1110-2-583 (ETL) vegetation compliance would occur under a SWIF by the local maintaining agency (LMA). The intent of the SWIF is to collaboratively work with the resource agencies and levee sponsors to transition existing levees to Corps standards while maintaining Public Law (PL) 84-99 rehabilitation assistance and adhering to the Act and other environmental laws. The SWIF is a two-step process completed by the applicant that is composed of a letter of intent, which is followed by submission of a SWIF plan. The SWIF process allows eligible local sponsors to implement levee improvements in a prioritized "worst first" way to optimize the achievement of risk reduction. The Corps acknowledges that implementing system-wide improvements will need to be done within a collaborative intergovernmental framework and that it will take time to develop and implement improvements in complex situations. Challenges including ensuring that both environmental and levee safety considerations are adequately served.
- The vegetation requirements for the SWIF include a 15-foot waterside, landside, and vertical vegetation-free zone. Trees that pose an unacceptable risk to levee integrity will be removed and the root balls and roots will be remediated. Trees that do not pose a threat will not be removed. Vegetation on the landside slope would only be removed within the construction

footprint (up to ½ levee degrade) and the remaining vegetation would be dealt with under the SWIF process.

- Utility encroachments will be brought into compliance with Corps policy. Utilities that penetrate the levee would be removed and replaced with one of two fixes: (1) a surface line over the levee prism, or (2) a through-levee line equipped with positive closure devices.
- Private encroachments shall be removed by the non-Federal sponsor prior to construction.
- The Sacramento District of the Corps will pursue a vegetation variance which will allow vegetation on the lower ½ of the levee slope to 15 feet waterward of the waterside levee toe to remain in place. The Sacramento District has conducted an evaluation which examined the safety, structural integrity, and functionality of the levees that will be retained and not compromised if a tree were to fall and result in scouring of the root ball area. The results show that the tree fall and scour did not significantly affect levee performance, and the levee meets Corps seepage and slope stability criteria assuming the entire project is constructed.

American River

Levees along the American River require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed for the American River levees: (1) a maximum of 31,000 linear feet (LF) of bank protection, and (2) a maximum of 65 acres/45,000 LF of launchable rock trench. Both of these measures are described in detail in the subsections below. These numbers are maximized because there is some overlap identified to account for the uncertainty of site-specific conditions. For example, for some reaches both bank protection and launchable rock trench impacts were estimated even though both measures will not be constructed in the same reach.

<u>Bank Protection</u>

This measure consists of placing rock revetment on the river's bank to prevent erosion. It entails installing revetment along the stream bank based on site-specific analysis (Figure 2). When necessary, the eroded portion of the bank will be filled and compacted prior to the rock placement. The sites will be prepared by clearing and stripping of loose material and understory growth prior to construction. In most cases, large vegetation will be permitted to remain at these sites. Temporary access ramps will be constructed, if needed, using imported borrow material that would be trucked on site.

The placement of rock onto the bank will occur from a land based staging area using long reach excavators and loader. The loader brings rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the waterside of the levee.

The revetment will be placed on the existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a planting berm will be constructed in the rock to allow for revegetation of the site. The planting berm varies in width from 5 to 15 feet. In all cases the planting will occur outside the vegetation free zone as required by the ETL.

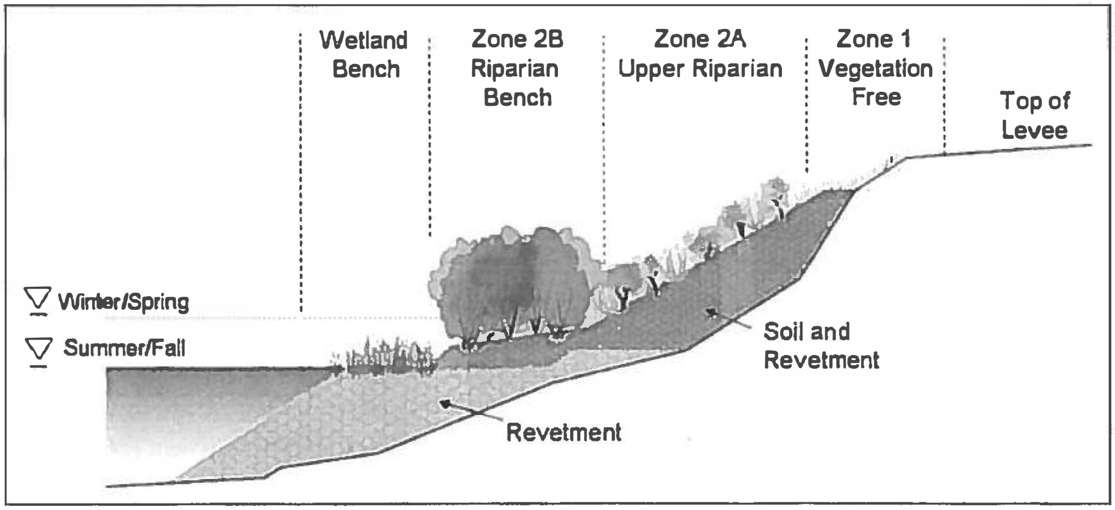

Figure 2. Bank Protection with Planting Bench.

Launchable Rock Trench

For the purposes of this project description, it is assumed that 65 acres of the lower American River will have a launchable rock trench fix. The remainder will be the bank protection described above. This measure includes construction of a launchable rock filled trench, designed to deploy once erosion has removed the bank material beneath it (Figure 3). All launchable rock trenches will be constructed outside of the natural river channel. The vegetation will be removed from the footprint of the trench and the levee slope prior to excavation of the trench. The trench configuration will include a 2:1 landside slope and 1:1 waterside slope and will be excavated at the toe of the existing levee. All soil removed during trench excavation will be stockpiled for potential reuse. The bottom of the trench will be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and amount of rock required.

After excavation, the trench will be filled with revetment that will be imported from an offsite commercial location. After rock placement the trench will be covered with a minimum of 3 feet of the stockpiled soil for a planting berm. Rock placed on the levee slope will be covered with 2 feet of stockpiled soil. All disturbed areas will be reseeded with native grasses and small shrubs where appropriate. Trees and shrubs could be permitted on the trench if planted outside the specified vegetation free zone as required by the ETL.

Sacramento River

Levees along the Sacramento River require improvements to address seepage, stability, and erosion. About 50,300 LF of bank protection and cutoff wall or slope stability work is proposed for the Sacramento River. In addition, these levees require a total of one mile of intermittent height improvements in order to convey additional flows that exceed current design levels.

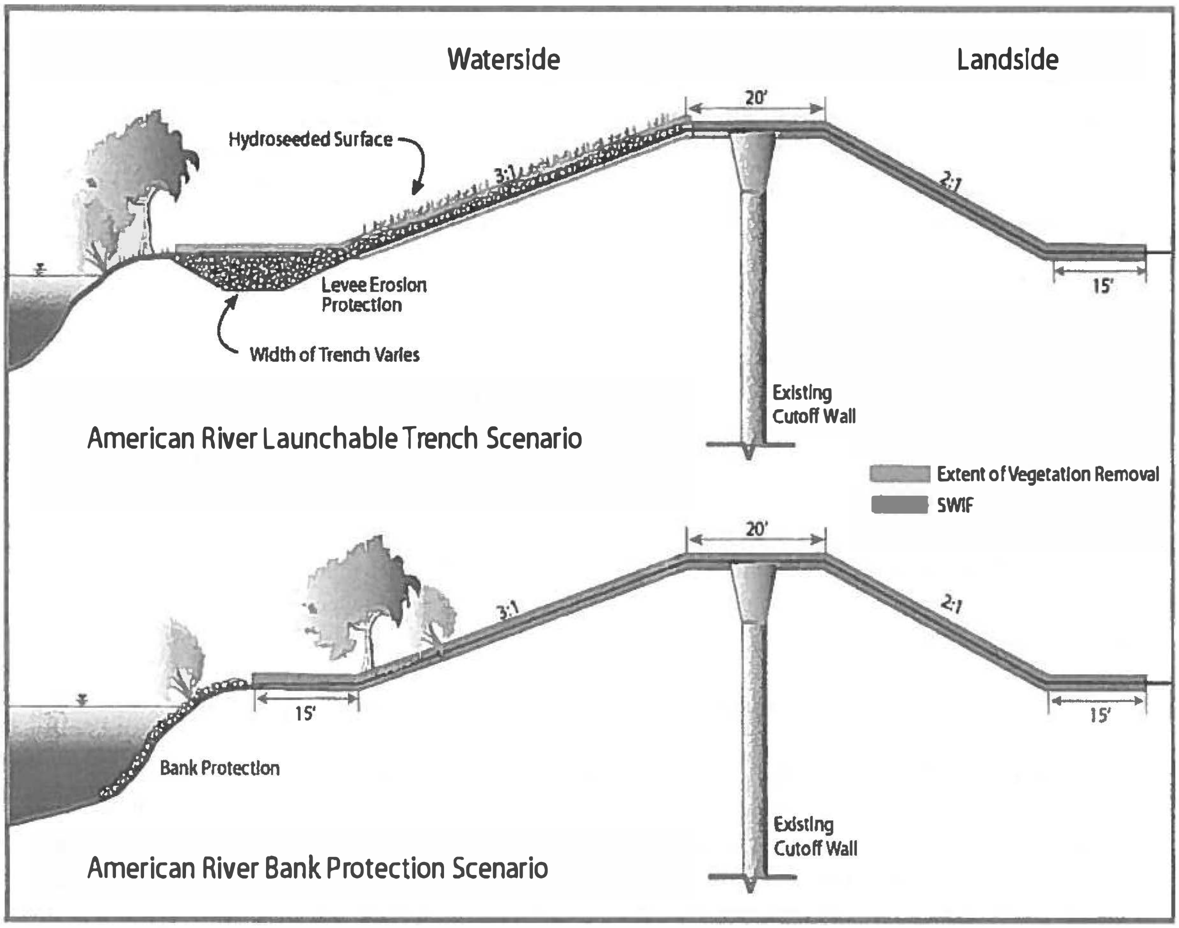

Figure 3. Launchable Rock Trench and Bank Protection.

Where the existing levee does not meet the levee design requirements, as discussed above, slope flattening, crown widening, and/or a minimal amount of levee raise is required. This improvement measure addresses problems with slope stability, geometry, height and levee crest access and maintenance. To begin levee embankment grading, loose material and vegetation understory will be cleared, grubbed, stripped, and where necessary, portions of the existing embankment will be excavated to allow for bench cuts and keyways to tie in additional embankment fill. Excavated and borrow material (from nearby borrow sites) will be stockpiled at staging areas. Haul trucks and front end loaders will bring borrow materials to the site, which will then be spread evenly and compacted according to levee design plans.

The levee will be raised about 1 to 2 feet resulting in the levee footprint extending out a maximum of 5 feet on the landside from the existing levee. The levee crown patrol road will be re-established at the completion of construction.

Cutoff Walls

To address seepage concerns, a cutoff wall will be constructed through the levee crown. The cutoff wall will be installed by one of two methods: (1) conventional open trench cutoff walls, or (2) deep soil mixing (DSM) cutoff walls. The method of cutoff wall selected for each reach will depend on the depth of the cutoff wall needed to address the seepage. The open trench method can be used to install a cutoff wall to a depth of about 85 feet. For cutoff walls of greater depth the DSM method will be utilized.

Prior to any cutoff wall construction method, the construction site and any staging areas will be cleared, grubbed, and stripped. The levee crown will be degraded up to half the levee height to create a large enough working platform (about 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids. This method of slurry wall installation will also reduce the risk of slurry mixture following seepage paths and leaking into the river or into landside properties.

Open Trench Cutoff Wall

Under the open trench method, a trench about 3 feet wide will be excavated at the top of levee centerline and into the subsurface materials up to 85 feet deep with a long boom excavator. As the trench is excavated, it is filled with low density temporary bentonite water slurry to prevent cave in. The soil from the excavated trench is mixed nearby with hydrated bentonite, and in some applications cement. The soil bentonite mixture is backfilled into the trench, displacing the temporary slurry. Once the slurry was hardened, it will be capped and the levee embankment will be reconstructed with impervious or semi-impervious soil.

DSM Cutoff Wall

The DSM method involves a crane supported set of two to four mixing augers used to drill through the levee crown and subsurface to a maximum depth of about 140 feet. As the augers are inserted and withdrawn, a cement bentonite grout will be injected through the augers and mixed with the native soils. An overlapping series of mixed columns will be drilled to create a continuous seepage cutoff barrier. A degrade of up to one half the levee height will be required for construction of the DSM wall. For both methods, once the slurry has hardened it will be capped and the levee embankment will be reconstructed with impervious or semi-impervious soil.

Bank Protection

Proposed bank protection along the Sacramento River will address erosion concerns. Studies have shown that the Sacramento River levees have a medium to high risk of breach due to erosion. Bank protection will be addressed by standard bank protection with planting berm. The standard bank protection measure for the Sacramento River consists of placing rock protection on the bank to prevent erosion. This measure entails filling the eroded portion of the bank, where necessary, and installing revetment along the waterside levee slope and streambank from streambed to a height determined by site-specific analysis. Large trees on the lower half of the waterside slope will be protected in place to retain shaded riverine aquatic (SRA) habitat. The sites will be prepared by removing vegetation along the levee slopes at either end of the site for construction of a temporary access ramp, if needed. The ramp will then be constructed using imported commercial borrow material that will be trucked on site.

The placement of rock onto the levee slope will occur from atop the levee and/or from the waterside by means of barges. Rock required within the channel, both below and slightly above the water line at the time of placement, will be placed by an excavator located on a barge. Construction will require two barges: one barge would carry the excavator, while the other barge will hold the stockpile of rock to be placed on the channel slopes. Rock required on the upper portions of the slopes will be placed by an excavator located on top of the levee. Rock placement from atop the levee will require one excavator and one loader for each potential placement site. The loader brings the rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the waterside of the levee.

The revetment will be placed via the methods discussed above on existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a small planting berm will be constructed in the rock to allow for some revegetation of the site.

Natomas East Main Drain Canal

The east levee of the NEMDC requires 6,000 LF of improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A cutoff wall will be constructed at this location to address the seepage and stability problems. The cutoff wall will be constructed by one of the methods described in the Sacramento River section above. SAFCA is proposing to construct 1,700 LF of cutoff wall beginning just south of the confluence of Arcade Creek and extending south along the NEMDC. The Corps will construct the remaining 4,300 LF of cutoff wall.

Arcade Creek

The Arcade Creek levees require improvements to address seepage, slope stability, and overtopping when the event exceeds the current design. A centerline cutoff wall will be constructed to address seepage along 22,000 LF of the Arcade Creek levees. Levees from Rio Linda Boulevard to Marysville Boulevard will have a cutoff wall constructed at the waterside toe of the levee. Construction of the waterside toe cutoff wall will require constructing a work bench along the toe of the levee. Excavation for the bench will extend deep enough below existing grade to remove organic material and soft, unsuitable foundation soils. Bench excavation will also extend into the existing waterside slope of the levee as needed. Riprap will be placed on the waterside benches after construction of the waterside toe cutoff wall. Some portions of the Arcade Creek north levee will require more substantial excavation and reconstruction of the waterside slope to provide a low permeable seepage levee slope barrier. Bench fill material will be integrated with the slope reconstruction fill to provide an integral seepage barrier with the cutoff wall over the full height of the levee slope. A small section of levee will have a sheet pile cutoff wall at the centerline of the levee, rather than the waterside toe cutoff wall.

There is a ditch adjacent to the north levee at the landside toe which provides a shortened seepage path, and could affect the stability of the levee. The ditch will be replaced with a conduit or box culvert and then backfilled. This will lengthen the seepage path and improve the stability of the levee. Additionally, pressure relief wells will be installed along the landside toe of the levee along the north levee west of Norwood Avenue.

The majority of the Arcade Creek levees have existing floodwalls, however there remains a height issue in this reach. A 1 to 4-foot floodwall will allow the levees to pass flood events greater than the current design level. The floodwall will be placed on the waterside hinge point of the levee and will be designed to disturb a minimal amount of waterside slope and levee crown for construction. The waterside slope will be re-established to its existing slope and the levee crown will grade away from the wall and be surfaced with aggregate base.

Dry and Robla Creeks

The Dry and Robla Creeks levees require improvements to address overtopping when flood events exceed the design level. Height improvements will be made with a new floodwall constructed to a height of 4 to 6 feet along 2,500 LF of the south levee. The floodwall will be placed at the waterside hinge point of the levee and will be designed to disturb a minimal amount of waterside slope and levee crown for construction. Construction of the floodwall will be consistent with the description for Arcade Creek above. The waterside slope will be re-established to its existing slope and the levee crown will grade away from the wall and be surfaced with aggregate base.

Magpie Creek Diversion Canal

The Magpie Creek Diversion Canal project description is the same as was described in the September 15, 2004 biological opinion.

Sacramento Weir and Bypass

The Sacramento Weir was completed in 1916. It is the only weir in the Sacramento River Flood Control Project that is manually operated; all others overflow by gravity on their own. It is located along the right bank of the Sacramento River about 4 miles upstream of the Tower Bridge, and about 2 miles upstream from the confluence with the American River. Its primary purpose is to protect the city of Sacramento from excessive flood stages in the Sacramento River channel downstream of the American River. The weir limits flood stages (water surface elevations) in the Sacramento River to project design levels through the Sacramento/West Sacramento area. Downstream of the Sacramento Weir, the design flood capacity of the American River is 5,000 cfs higher than that of the Sacramento River. Flows from the American River channel during a major flood event often exceed the capacity of the Sacramento River downstream of the confluence. When this occurs, floodwaters flow upstream from the mouth of the American River to the Sacramento Weir.

The project design capacity of the weir is 112,000 cfs. It is currently 1,920 feet long and consists of 48 gates to divert floodwaters to the west through the mile-long Sacramento Bypass to the Yolo Bypass. Each gate has 38 vertical wooden plank "needles" (4 inches thick by 1 foot wide by 6 feet long).

Though the weir crest elevation is 24.75 feet, the weir gates are not opened until the river reaches 27.5 feet at the I Street gage with a forecast to continue rising. This gage is about 1,000 feet upstream from the I Street Bridge and about 3,500 feet upstream from the mouth of the American River. The number of gates to be opened is determined by the National Weather Service/DWR river forecasting team to meet either of two criteria: (1) to prevent the stage at the I Street gage from exceeding 29 feet, or (2) to hold the stage at the downstream end of the weir to 27.5 feet (DWR 2010). The weir gates are then closed as rapidly as practicable once the stage at the weir drops below 25 feet. This provides "flushing" flows to re-suspend sediment deposited in the Sacramento River between the Sacramento Weir and the American River during the low flow periods when the weir is open during the peak of the flood event (DWR 2010).

The Sacramento Weir and Bypass will be expanded to roughly twice their current width to accommodate increased bypass flows. The existing north levee of the Sacramento Bypass will be degraded and a new levee would be constructed 1,500 feet to the north. The existing Sacramento Weir will be expanded to match the wider bypass. At this time, it is not known whether the new segment of weir will be constructed consistent with the 1916 design described above, or whether it will be designed to be a gravity-type weir. The new north levee of the bypass will be designed to be consistent with the existing Sacramento Bypass north levee; however, it will also include a 300-foot-wide seepage berm on the landside with a system of relief wells. A hazardous, toxic, and radiological waste site near the existing north levee will be remediated by the non-Federal sponsor prior to construction.

Operation of the new segment of the Sacramento Weir will occur during high water situations only, when the American River flows exceed 115,000 cfs. The existing Sacramento Weir will be operating at the pre-existing conditions described above. There are not expected to be any water quality impacts, though this has not been specifically modeled. The approximate change in water diversions, which are shown in Table 2, will vary based on the size of the flood event. The frequency of water diversion is expected to be the same, dependent on the stream gage at the I Street Bridge reaching 27.5 feet.

The widened portion of the Sacramento Weir will only be operated when the release from Folsom Dam is above 115,000 cfs. With the Folsom Dam improvements in place, releases from Folsom Dam will be above 115,000 cfs for flood events greater than the 100-year event. Therefore, for events up to and including the 100-year event, only the existing weir will be operated per the criteria previously established. For events greater than the 100-year event, when the release from Folsom Dam will go above 115,000 cfs, the new weir will be opened. Therefore, for events up to the 100-year event there will be no change in flow conditions in the Sacramento and Yolo Bypasses.

Table 2. Comparison of 10-, 100-, and 200-year Frequency Flows under Various Conditions

10-Year Event	Existing Condition	Future Without Project Condition	Future With Project Condition
American River	43,000 cfs	72,000 cfs	72,000 cfs
Sacramento Bypass	50,000 cfs	66,000 cfs	66,000 cfs
Yolo Bypass below Sacramento Bypass	270,000 cfs	296,000 cfs	296,000 cfs
100-Year Event	Existing Condition	Future Without Project Condition	Future With Project Condition
American River	145,000 cfs	115,000 cfs	115,000 cfs
Sacramento Bypass	131,000 cfs	115,000 cfs	115,000 cfs
Yolo Bypass below Sacramento Bypass	555,000 cfs	535,000 cfs	535,000 cfs
200-Year Event	Existing Condition	Future Without Project Condition	Future With Project Condition
American River	320,000 cfs	160,000 cfs	160,000 cfs
Sacramento Bypass	183,000 cfs	149,000 cfs	164,000 cfs
Yolo Bypass below Sacramento Bypass	656,000 cfs	631,000 cfs	643,000 cfs

For the 200-year event, there will be an increase in flows in the Sacramento Bypass of about 15,000 cfs. In the Yolo Bypass, this equates to an increase of about 0.10-foot of water surface elevation. During the 200-year event, the Yolo Bypass is already flooded from levee to levee. The addition of these flows will equate to about 0.5-foot of additional width on the Yolo Bypass levee slopes.

High Hazard Levee Encroachment and Vegetation Removal

The National Flood Insurance Program (NFIP) standards for levee accreditation and the State's ULDC both require removal or modification of encroachments that pose an unacceptably high risk to the performance and safety of a levee either by undermining its structural integrity or by interfering with necessary inspection, operation, and maintenance activities. To address this requirement, SAFCA has identified and evaluated all of the encroachments in the NEMDC, Robla Creek, and Arcade Creek area. Each of these encroachments has been evaluated and based on this evaluation the encroachments have been classified as either:

- High-risk – poses a threat to levee integrity, removable prior to the levee being accredited;
- High-risk – impedes operation, maintenance, and inspection, removable within 3 years after the levee is accredited; or
- Low-risk – not identified as high hazard.

High-risk encroachments to be removed are limited to residential landscaping located at 10 locations along the landside of the south and north levees of Arcade Creek and along the Robla Creek south levee.

Vegetation on levees must be modified or removed if it presents an unacceptable risk to the structural integrity or impedes operation and maintenance of the levee. Eight high-risk trees along Arcade Creek have been identified for removal. All of the trees are either nonnative (7) or snags (1). Five are located on the waterside of the levees. These trees are in addition to any trees that will be removed as a result of implementation of levee improvements in the Arcade Creek area.

Utility Relocation

Existing encroachments and penetrations within the NEMDC and Arcade Creek have been inventoried by SAFCA. Many utilities will be avoided, however some utilities may need to be temporarily removed or relocated prior to construction. Temporary bypass pumping may be required for sanitary sewers. SAFCA and the construction contractors will coordinate with utility owners to manage the utilities in advance of construction. Disturbed utilities will be restored after construction consistent with Central Valley Flood Protection Board requirements.

Stormwater Pollution Prevention

Temporary erosion/runoff best management control measures would be implemented during construction to minimize stormwater pollution resulting from erosion and sediment migration from the construction, borrow, and staging areas. These temporary control measures may include implementing construction staging in a manner that minimizes the amount of area disturbed at any one time; secondary containment for storage of fuel and oil; and the management of stockpiles and disturbed areas by means of earth berms, diversion ditches, straw wattles, straw bales, silt fences, gravel filters, mulching, revegetation, and temporary covers as appropriate. Erosion and stormwater pollution control measures will be consistent with National Pollutant Discharge Elimination System (NPDES) permit requirements and included in a Stormwater Pollution Prevention Plan (SWPPP).

After completion of construction activities, the temporary facilities (construction trailers and batch plants) will be removed and the site would be restored to pre-project conditions. Site restoration activities for areas disturbed by construction activities, including borrow areas and staging areas, will include a combination of regrading, reseeding, constructing permanent diversion ditches, using straw wattles and bales, and applying straw mulch and other measures deemed appropriate.

Borrow Sites, Haul Routes, and Staging Areas

Borrow Sites - It is estimated that a maximum of 1 million cubic yards (cy) of borrow material will be needed to construct the project. Detailed studies of the borrow needs have not been completed. Actual volumes exported from any single borrow site will be adjusted to match demands for fill. Borrow sites will be selected that avoid effects to endangered species or their habitat.

To identify potential locations for borrow material soil maps and land use maps were obtained for a 20-mile radius surrounding the project area. Except as discussed below for Arcade Creek and NEMDC, eventual borrow site selection will include the following criteria: avoid threatened and endangered species effects and habitat, current land use patterns, and soil types.

Excavation limits on the borrow sites will provide a minimum buffer of 50 feet from the edge of the borrow site boundary. From this setback, the slope from existing grade down to the bottom of the excavation will be no steeper than 3:1. Excavation depths from the borrow sites will be determined based on available suitable material. The borrow sites will be stripped of top material and excavated to appropriate depths. Once material is extracted, borrow sites will be returned to their existing use whenever possible, or these lands could be used to mitigate for project effects, if appropriate.

Because SAFCA has completed more detailed design and studies for work along NEMDC and Arcade Creek the borrow site has been selected. Borrow site 2 is located along the east side of the NEMDC north of where the levee repairs will occur. About 27,000 cubic yards of material will be excavated from the 5.5-acre borrow site in order to construct levee improvements along the NEMDC and Arcade Creek. Following borrow activities the site will be contoured to create about 0.5 acre of tule bench, set an elevation the will provide aquatic habitat all year, 1.0 acre of higher bench with seasonal wetlands, that will flood in the winter and spring, and 3.5 acres of native grassland.

Clean rock will be commercially acquired in order to construct the American and Sacramento River bank protection sites. For the Sacramento River, rock will be acquired from a commercial source in the Bay Area and barged up the Sacramento River to the construction sites. Rock for the American river sites will be acquired from a commercial source within a 50-mile radius and will be hauled in trucks to the construction sites.

Haul Routes – Haul routes will be determined during the design phase and will depend on what borrow sites and staging areas are selected. Haul routes will be selected based on existing commercial routes and levee roads. Haul routes will be selected that avoid effects to federally listed species.

For Arcade Creek and NEMDC, haul trucks will leave borrow site 2 and use East Levee Road from the borrow site down to a point just north of the existing Del Paso/Main Avenue Bridge over NEMDC. Temporary bridges crossing the NEMDC and Arcade Creek will be used to allow haul trucks to reach repair sites. Railroad car undercarriages on temporary abutment supports will be one option for temporary bridge crossings.

Staging Areas – Staging areas will be selected that do not require the removal of vegetation or habitat that is used by threatened or endangered species or effect threatened or endangered species. Four potential staging areas have been identified for improvements along Arcade Creek. All four areas will require little preparation other than surface striping and temporary connection roads and ramps to the levee crown. The primary use of staging areas will be for temporary trailers, parking, and material staging. Additionally, there will need to be space to process material and an area where excavated soils and imported soils will be spread out and processed material. Importing, processing, and exporting material for levee reconstruction will be continuous activities once the work flow is established during the start of the construction season. Staging areas will be returned to pre-project conditions following construction activities unless the owner agrees to some grade raising to help dispose of excess construction soils.

Operation and Maintenance

Operation and maintenance (O&M) of the levees in the Sacramento area are the responsibility of the local maintaining agencies, including the American River Flood Control District, the DWR, and the City of Sacramento. The applicable O&M Manual for the Sacramento area levees is the Standard Operation and Maintenance Manual for the Sacramento Flood Control Project. Typical levee O&M in the Sacramento in the Sacramento area currently includes the following actions:

- Vegetation maintenance up to four times a year by mowing or applying herbicide.
- Control of burrowing rodent activity monthly by baiting with pesticide.
- Slope repair, site-specific and as needed, by re-sloping and compacting.
- Patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate.
- Visual inspection at least monthly, by driving on the patrol road on the crown and maintenance roads at the base of the levee.
- Post-construction, groundwater levels will be monitored using the piezometers.

The Corps will work with local maintaining agencies to develop the maintenance activities necessary for long-term operations and maintenance. This will occur during the preconstruction engineering and design phase of the project. The Corps will evaluate if these maintenance activities will affect any Federally-listed species and reinitiate section 7 consultation if there will be adverse effects to listed species. Currently, the Corps only has a project description for activities that will affect valley elderberry longhorn beetle habitat. This is included below.

Following construction, the O&M manual for these reaches will be adjusted to reflect the vegetation variance and the SWIF plan. Under the adjusted O&M manual, large trees that are protected in place under the variance will be allowed to remain on the waterside slopes and additional vegetation will be planted on the planting benches.

Vegetation maintenance includes keeping maintenance roads clear of overhanging branches. Some of the vegetation along the levees includes elderberry shrubs. As part of long-term O&M, elderberry shrubs will be trimmed by the three levee maintenance districts. Table 3 describes the maximum amount of elderberry acreage that will be trimmed each year as a result of O&M. Trimming consists of cutting overhanging branches along the levee slopes on both the landside and waterside. Some shrubs may be located adjacent to the levee with branches hanging over the levee maintenance road. Up to a third of a shrub will be trimmed in a single season. Trimming will occur between November 1 and March 15. Loss of habitat will be offset through the development of a conservation area as described in the conservation measures below. Each year the local maintaining agency will document the amount of valley elderberry longhorn beetle habitat that they have trimmed and report that number to the Corps to ensure compliance with this biological opinion. If the local maintaining agency has a need to exceed the amount of valley elderberry longhorn beetle habitat which needs to be trimmed or affected due to routine maintenance, then they will request the Corps reinitiate consultation on this biological opinion for those actions.

Table 3. O&M by Maintaining Agency

Local Maintaining Agency	Levee Systems Covered	Annual Acreage of Trimmed Elderberry Shrubs*	Total Acreage of Elderberry Shrubs Trimmed over the 50 Year Life of the Project
American River Flood Control District	Lower American River, Dry/Robla Creek, Arcade Creek, NEMDC	0.5	25
Maintenance Area 9	Sacramento River east levee between Sutterville Road and the Beach Lake Levee	0.2	10
City of Sacramento	Sacramento River East Levee between the confluence of the American River and Sutterville Road	0.1	5

*acreage based on an estimated average shrub of 0.027 acre and no more than 1/3 of a shrub trimmed any given year.

Valley Elderberry Longhorn Beetle Habitat

Valley elderberry longhorn beetles are closely associated with elderberry shrubs. In 2011, the Corps conducted surveys and mapped all of the elderberry shrubs on the levees and 15 feet on either side of the levee. Elderberry shrubs were located along the American River and Sacramento River. The Corps counted shrub clusters and used elderberry stem counts from previous projects in the area to estimate a standard number and size of elderberry stems per shrub cluster. Tables 4 and 5 list the stem counts for shrubs along the American River and Sacramento River respectively. While shrubs exist along Arcade Creek or Magpie Creek, the Corps and SAFCA will avoid effects to the beetle by following the conservation measures below.

Table 4. American River Elderberry Shrub Effects and Compensation

Location	Stems	Exit Holes	No. of Stems	Elderberry Ratios	Elderberry Plantings	Associated Native Planting	Associated Native Ratios
riparian	> or = 1" & < or = 3"	no	1,998	2	3,996	3,996	1
		yes	0	4	0	0	2
riparian	> 3" & < 5"	no	790	3	2,370	2,370	1
		yes	16	6	96	192	2
Riparian	> or = 5"	no	312	4	1,248	1,248	1
		yes	23	8	184	368	2
TOTAL			**3,139**		**7,894**	**8,174**	
				total basins or credits=	1,606.8		
				total acres for compensation	66.40		

Table 5. Sacramento River Elderberry Shrub Effects and Compensation

Location	Stems	Exit Holes	No. of Stems	Elderberry Ratios	Elderberry Plantings	Associated Native Plantings	Associated Native Ratios
riparian	> or = 1" & < or = 3"	no	104	2	208	208	1
		yes	0	4	0	0	2
riparian	> 3" & < 5"	no	40	3	120	120	1

		yes	2	8	16	32	2
TOTAL			**163**		**414**	**436**	
				total basins or credits=	85		
				total acres need for compensation	3.51		

Delta Smelt Habitat

The American River lacks suitable turbidity making it unsuitable for delta smelt. Due to the higher temperatures within Arcade Creek, Magpie Creek, and NEMDC it is also unlikely that delta smelt will use these tributaries. Therefore, suitable delta smelt habitat occurs within the Sacramento River in the reach where erosion protection will occur. The Corps has calculated that there will be a complete loss of 14 acres of shallow water habitat due to the placement of riprap and a change of substrate from natural soil to riprap on 32 acres.

Giant Garter Snake Habitat

Giant garter snakes are not known to use large rivers such as the American and Sacramento Rivers. Given the close proximity to urban development, high level of human disturbance, presence of riparian vegetation along the banks of most channel reaches, and lack of extensive marsh or rice to the east, giant garter snakes are unlikely to occur in Arcade Creek, Dry Creek, Robla Creek, Magpie Creek, or the southern section of the NEMDC (south of where Dry Creek enters). North of Dry Creek, the NEMDC has less woody vegetation, less urban development, and large areas of open grassland along the landside of the levee with rice farming occurring to the west of the grasslands. Therefore, there is potential for the snake to occur either in the upland or within the NEMDC north of where Dry Creek enters. Work in this location will involve removal of borrow material at borrow site 2 (5.5 acres of upland habitat).

Habitat for the giant garter snake also exists north of the existing Sacramento Bypass north levee. The land north of the Sacramento Bypass is currently agricultural fields producing row crops and nut orchards. Existing giant garter snake aquatic habitat occurs in drainage ditches and farm canals and the surrounding upland habitat. About 15 acres of aquatic habitat will be filled making it and the associated 30 acres of upland habitat unavailable to the giant garter snake. The Sacramento Bypass also has a toe drain along the levee with 25 acres of aquatic and 50 acres of upland habitat that will be relocated to the toe of the new Sacramento Bypass levee.

Yellow-billed Cuckoo Habitat

Yellow-billed cuckoos use riparian habitat for foraging and nesting. Suitable habitat occurs within the lower American River. The project will affect 65 acres of riparian habitat that could be used by the yellow-billed cuckoo. While riparian habitat occurs along Arcade Creek, Magpie Creek, and NEMDC it is very narrow and cuckoos are not likely to use these areas. Riparian habitat occurs along the Sacramento River and in some areas may be of such a width that a cuckoo could stop and use it during migration, but it is not wide enough to support a nesting pair of cuckoos. The Corps will remove 110 acres of riparian habitat along the Sacramento River and disturb an additional 50 acres of riparian habitat by removing the understory and placing rock around the large trees. The Sacramento Bypass does not have suitable habitat for the yellow-billed cuckoo. But riparian habitat does exist north of the existing Sacramento Weir along the Sacramento River (8 acres). Cuckoos have been observed in the Yolo Bypass in recent years (Ebird 2015).

Conservation Measures

Valley Elderberry Longhorn Beetle

- The Corps assumes complete avoidance of the valley elderberry longhorn beetle when a 100-foot (or wider) buffer is established and maintained around elderberry shrubs.
- When work will occur within the 100-foot buffer, a setback of 20 feet from the dripline of each elderberry shrub will be maintained whenever possible.
- During construction activities, all areas to be avoided will be fenced and flagged.
- Contractors will be briefed on the need to avoid damaging elderberry shrubs and the possible penalties for not complying with these requirements.
- Signs will be erected every 50 feet along the edge of the avoidance area, identifying the area as an environmentally sensitive area.
- Any damage done to the buffer area will be restored.
- Buffer areas will continue to be protected after construction.
- No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used in the buffer areas.
- Elderberry shrubs that cannot be avoided would be transplanted to an appropriate riparian area at least 100 feet from construction activities.
- Elderberry shrubs will be surveyed prior to construction to ensure that the actual effects match the estimated effects of this biological opinion. If the Corps will effect more valley elderberry longhorn beetle habitat than estimated than they will reinitiate consultation with the Service.
- If possible, elderberry shrubs would be transplanted during their dormant season (November through the first two weeks in February). If transplantation occurs during the growing season, increased mitigation will apply.
- Elderberry compensation will be planted in the American River Parkway. The Corps has six existing sites which are offsetting previous Corps flood control projects along the lower American River and near Folsom Dam. The Corps will find areas within the lower American River parkway which will either expand existing compensation areas or provide for connectivity between conserved valley elderberry longhorn beetle habitat. Sites within the lower American River parkway will be coordinated with Sacramento County Parks and the Service during the design phase of the project. Sites will be designed and developed prior to any effects to valley elderberry

longhorn beetle habitat. The Corps will create 69.91 acres of riparian habitat which supports valley elderberry longhorn beetle within the lower American River parkway for the transplantation of elderberry shrubs. In addition, the local sponsors will create an additional 40 acres of land to benefit the valley elderberry longhorn beetle or purchase 40 acres of credits at a Service approved conservation bank to offset the loss of habitat due to trimming of elderberry shrubs along the lower American River, Sacramento River, Dry/Robla Creeks, Arcade Creek, Magpie Creek, and NEMDC.

- Management of these lands will include all measures specified in the Service's conservation guidelines (1999a) related to weed and litter control, fencing, and the placement of signs.
- Monitoring will occur for 10 consecutive years or for 7 non-consecutive years over a 15-year period. Annual monitoring reports will be submitted to the Service.
- Compensation areas will be protected in perpetuity and have a funding source for maintenance (endowment).

Giant Garter Snake

- Unless approved otherwise by the Service, construction will be initiated only during the giant garter snakes' active period (May 1–October 1, when they are able to move away from disturbance).
- Construction personnel will be given a Service-approved worker environmental awareness program.
- A survey for giant garter snakes will be conducted within 24 hours prior to construction beginning in potential giant garter snake habitat. Should there be any interruption in work for greater than 2 weeks, a biologist will resurvey the area within 24 hours prior to the restart of construction.
- Giant garter snakes encountered during construction will be allowed to move away from construction activities on their own.
- Movement of heavy equipment to and from the construction site will be restricted to established roadways. Stockpiling of construction materials will be restricted to designated staging areas, which will be located more than 200 feet away from giant garter snake aquatic habitat.
- Giant garter snake habitat within 200 feet of construction activities will be designated as an environmentally sensitive area and delineated with signs or fencing. This area will be avoided by all construction personnel.
- Habitat temporarily affected for one season (the 5.5 acre borrow site along the NEMDC and the 75 acres along the toe drain of the Sacramento Bypass levee) will be restored after construction by applying appropriate erosion control techniques and replanting/seeding with appropriate native plants. If for any reason construction extends into another active season the Corps will replace the habitat on-site and purchase credits at a ratio of 1:1 at a Service approved conservation bank.
- Habitat temporarily affected for more than three or more seasons will be restored and twice as much habitat will be created.
- Habitat permanently affected in the Sacramento Bypass in the form of drainage ditches and irrigation canals will be compensated for through the purchase of 135 acres of credits at a Service approved conservation bank.
- One year of monitoring will be conducted for the 80.5 acres that are temporarily affected.

- The Corps will purchase credits at a conservation bank prior to any permanent disturbance of giant garter snake habitat.
- A biological monitor will be on-site during all ground disturbing activities at borrow site 2.
- Exclusionary fencing will be placed, at least 10 days prior to the beginning of ground disturbing activities after May 1, to exclude giant garter snakes from entering areas where upland disturbance (borrow site 2 and Sacramento Bypass) will occur during the active season (May 1 to October 1). Prior to fencing installation, the fence line will be mowed (with a minimum height of 6 inches) in order to conduct a surface survey of potential burrows. Fencing will be installed with a minimum of 6 inches buried in the ground and a minimum of 24 inches above ground. Fence staking will be installed on the inside of the exclusion area. One-way escape funnels will be installed every 50 to 100 feet and sealed along the fence line to provide an escape for any giant garter snake that may be within the exclusion area. The fencing will enclose the entirety of the site, or additional exclusionary fencing can be extended 200 to 400 feet beyond the proposed entrance area. The fencing will be inspected before the start of each work day and maintained by the contractor until completion of the project. The fencing will be removed only when project activities are completed.

Yellow-Billed Cuckoo

- Prior to construction, surveys will be conducted to determine the presence of yellow-billed cuckoos within the project area in accordance with any required Service survey protocols and permits at the time of construction.
- If surveys find cuckoos in the area, vegetation removal will be done outside of the cuckoo nesting season.
- Riparian habitat that is removed due to project construction along the American River will be replanted within the American River parkway. The Corps intends to expand existing conserved riparian lands within the parkway that could support the yellow-billed cuckoo. The design of replacement riparian areas will be coordinated with the Service to ensure that the habitat benefits both valley elderberry longhorn beetles and yellow-billed cuckoos.

Fisheries Conservation Measures

- In-water construction activities (e.g., placement of rock revetment) will be limited to the work window of August 1 through November 30. If the Corps wants to work outside of this window they will consult with National Marine Fisheries Service (NMFS) and/or the Service.
- The Corps will purchase 42 acres of delta smelt credits from a Service-approved conservation bank to off-set the loss of 14 acres of shallow water habitat.
- The Corps will purchase an additional 32 acres of delta smelt credits from a Service-approved conservation bank to off-set the loss of spawning habitat due to the placement of riprap on the river bed.
- Erosion control measures (BMPs), including Storm Water Pollution Prevention Program and Water Pollution Control Program, that minimize soil or sediment from entering the river shall be installed, monitored for effectiveness, and maintained

throughout construction operations to minimize effects to federally listed fish and their designated critical habitat.

- Screen any water pump intakes, as specified by NMFS and the Service screening specifications. Water pumps will maintain an approach velocity of 0.2 feet per second or less when working in areas that may support delta smelt.
- The Corps shall include as part of the project, a Riparian Corridor Improvement Plan with the overall goal of maximizing the ecological function and value of the existing levee system within the Sacramento Metropolitan area.

Additional Minimization and Conservation Measures

- Obtain an ETL approved vegetation variance exempting sites from vegetation removal prior to final design and construction phase for the Sacramento River.
- Construction will be scheduled when listed terrestrial and aquatic species will be least likely to occur in the project area. If construction needs to extend into the timeframe that species are present, then coordination/reinitiation with the Service will occur.
- Compensation for impacts to native riparian habitat will occur on a 2:1 basis on-site or in close proximity to the impact area. Riparian vegetation impacted under the SAFCA 408/404 actions will be replaced on a 3:1 canopy cover acreage basis.
- Stockpile all liquid chemicals and supplies at a designated impermeable membrane fuel and refueling station with a 110% containment system.
- Stockpile construction materials such as portable equipment, vehicles, and supplies, at designated construction staging areas and barges, exclusive of any riparian and wetland areas.
- Implement BMPs to prevent slurry from seeping out to the river and require piping systems on the landside of the levee.
- Project related vehicles will observe a 20-mile-per-hour speed limit within construction areas, except on County roads and on State and federal highways.
- Site access will be limited to the smallest area possible in order to minimize disturbance. Litter, debris, unused materials, equipment, and supplies will be removed from the project area daily. Such materials or waste will be deposited at an appropriate disposal or storage site.
- Immediately (within 24 hours) cleanup and report any spills of hazardous materials to the resource agencies. Any such spills, and the success of the efforts to clean them up, shall also be reported in post-construction compliance reports.
- Designating a Service approved biologist as a point-of-contact for any contractor who might incidentally take a living, or find a dead, injured, or entrapped threatened or endangered species. This representative shall be identified to the employees and contractors during an all employee education program conducted by the Corps.

Action Area

The action area is defined in 50 CFR § 402.02, as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action." For the purposes of the effects assessment, the action area encompasses the Sacramento River from the Sacramento Bypass downstream to River Mile 45, the Yolo Bypass south the confluence of the Sacramento Bypass, the lower American River from Arden Way to the confluence of the Sacramento River, Arcade Creek from Marysville Boulevard to the confluence of the NEMDC, the NEMDC from the south Dry

Creek levee to just south of the NEMDC Arcade Creek confluence, the southern Dry Creek levee between Dry Creek Road and Rose Street, the borrow site along the NEMDC, and any borrow sites. Additionally, we are including a buffer of 300 feet from construction to account for effects to listed species due to dust and noise.

Analytical Framework for the Jeopardy Analysis

The following analysis relies on four components to support the jeopardy determination for the giant garter snake, valley elderberry longhorn beetle, yellow-billed cuckoo, and delta smelt: (1) the *Status of the Species*, which evaluates the species' range-wide condition, the factors responsible for that condition, and their survival and recovery needs; (2) the *Environmental Baseline*, which evaluates the condition of the species in the action area, the factors responsible for that condition, and the role of the action area in the species' survival and recovery; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on these species; and (4) the *Cumulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on these species.

In accordance with the implementing regulations for section 7 and Service policy, the jeopardy determination is made in the following manner: the effects of the proposed Federal action are evaluated in the context of the aggregate effects of all factors that have contributed to the current status of the delta smelt, valley elderberry longhorn beetle, giant garter snake, and yellow-billed cuckoo. Additionally, for non-Federal activities in the action area, we will evaluate those actions likely to affect the species in the future, to determine if implementation of the proposed action is likely to cause an appreciable reduction in the likelihood of both its survival and recovery in the wild.

The following analysis places an emphasis on using the rang-wide survival and recovery needs of the delta smelt, valley elderberry longhorn beetle, giant garter snake, and yellow-billed cuckoo, and the role of the action area in providing for those needs as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the jeopardy determination.

Analytical Framework Adverse Modification

This biological opinion does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 CFR 402.2. Instead, we have relied upon the statutory provisions of the Act to complete the following analysis with respect to critical habitat.

In accordance with policy and regulation, the adverse modification analysis in this biological opinion relies on four components: (1) the *Status of the Critical Habitat*, which evaluates the range-wide condition of critical habitat for the delta smelt in terms of primary constituent elements (PCE)s, the factors responsible for that condition, and the intended recovery function of the critical habitat at the provincial and range-wide scale; (2) the *Environmental Baseline*, which evaluates the condition of the critical habitat in the action area, the factors responsible for that condition, and the recovery role of the critical habitat in the action area; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on the PCEs and how that will influence the recovery role of affected critical habitat units and; (4) *Cummulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on the PCEs and how that will influence the recovery role of affected critical habitat units.

For purposes of the adverse modification determination, the effects of the proposed Federal action on the delta smelt critical habitat are evaluated in the context of the range-wide condition of the critical habitat at the provincial and range-wide scales, taking into account any cumulative effects, to determine if the critical habitat range-wide would remain functional (or would retain the current ability for the PCEs to be functionally established in areas of currently unsuitable but capable habitat) to serve its intended recovery role for the delta smelt.

The analysis in this biological opinion places an emphasis on using the intended range-wide recovery function of delta smelt critical habitat and the role of the action area relative to that intended function as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the adverse modification determination.

Status of the Species and Environmental Baseline

Valley Elderberry Longhorn Beetle Status of the Species

Please refer to the *Withdrawl of the Proposed Rule to Remove the Valley Elderberry Longhorn Beetle from the Federal List of Endangered and Threatened Wildlife* (Service 2014) for the current status of the species. Ongoing threats to the valley elderberry longhorn beetle include habitat loss due to flood control projects, development projects, and invasive species. While these threats continue to affect the valley elderberry longhorn beetle throughout its range, to date no project has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the valley elderberry longhorn beetle.

Valley Elderberry Longhorn Beetle Environmental Baseline

The project footprint along both the Sacramento River and the American River contain riparian vegetation. The beetle is known in numerous locations along the American River parkway (CNDD 2015). Suitable habitat for the beetle in the form of elderberry shrubs occurs within the action area along the Sacramento River, the American River, and Arcade Creek.

Sacramento River - Riparian habitat along the Sacramento River, south of the city of Sacramento, occurs in narrow bands along the riverbank and levee. Generally an overstory layer is present composed of cottonwood, sycamore, and oak trees. Shrubs occur as a mid-story layer including buttonbush, blue elderberry, white alder, and Oregon ash. Elderberry shrubs occur randomly along the reach of river proposed for improvements. The Corps has documented at least 73 elderberry shrubs along the Sacramento River reach where construction is proposed. Natural river processes of erosion and accretion effect elderberry shrubs which is the host plant of the valley elderberry longhorn beetle by eroding away bank and potentially elderberry shrubs. Levee maintenance can adversely affect elderberries within this stretch of the Sacramento River either by pruning or drift of herbicides used along the levee slope.

American River – The valley elderberry longhorn beetles have been identfied along the lower American River Parkway in the CNDDB (2015). Additionally, the Corps has designed and built six sites along the lower American River as habitat for the valley elderberry longhorn beetle. These sites extend from RM 0.9 up to RM 21. Levee maintenance can adversely affect elderberry shrubs, though the largest threat to valley elderberry longhorn beetle is fires that have been started in the parkway and burned habitat that supports valley elderberry longhorn beetles.

Delta Smelt Status of Species

Listing Status: The Service proposed to list the delta smelt as threatened with proposed critical habitat on October 3, 1991 (56 FR 50075). The Service listed the delta smelt as threatened on March 5, 1993 (58 FR 12854), and designated critical habitat for this species on December 19, 1994 (59 FR 65256). The delta smelt was one of eight fish species addressed in the *Recovery Plan for the Sacramento–San Joaquin Delta Native Fishes* (Service 1996). This recovery plan is currently under revision. A 5-year status review of the delta smelt was completed on March 31, 2004 (Service 2004). The 2004 review affirmed the need to retain the delta smelt as a threatened species. A 12-month finding on a petition to reclassify the delta smelt was completed on April 7, 2010 (75 FR 17667). After reviewing all available scientific and commercial information, the Service determined that re-classifying the delta smelt from a threatened to an endangered species was warranted, but precluded by other higher priority listing actions (Service 2010).

Distribution: The delta smelt is endemic to the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (Bay-Delta) in California, and is restricted to the area from San Pablo Bay upstream through the Delta in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties (Moyle 2002). Their range extends from San Pablo Bay upstream to Verona on the Sacramento River and Mossdale on the San Joaquin River. The delta smelt was formerly considered to be one of the most common pelagic fish in the upper Sacramento-San Joaquin Estuary.

Description: Live delta smelt are nearly translucent with a steely-blue sheen to their sides and have been characterized to have a pronounced odor reminiscent of cucumber (Moyle 2002). Although delta smelt have been recorded to reach lengths of up to 120 millimeters (mm) (4.7 in) (Moyle 2002), mean fork length of the delta smelt from 1974 to 1991 was measured to be 64.1 ± 0.1 mm. Since then, catch data from 1992 - 2004 showed mean fork length decreased to 54.1 ± .01 mm (Bennett 2005; Sweetnam 1999). Delta smelt are also identifiable by their relatively large eye to head size (Moyle 2002). Delta smelt have a small, translucent adipose fin located between the dorsal and caudal fins.

The delta smelt is one of six species currently recognized in the *Hypomesus* genus (Bennet 2005). Genetic analyses have confirmed that *H. transpacificus* presently exists as a single intermixing population (Stanley *et al.* 1995; Trenham *et al.* 1998; Fisch *et al.* 2011). Within the genus, delta smelt is most closely related to surf smelt (*H. pretiosis*), a species common along the western coast of North America. Despite morphological similarities, the delta smelt is less-closely related to the wakasagi (*H. nipponensis*), an andadromous western Pacific species introduced to Central Valley reservoirs in 1959, and may be seasonally sympatric with delta smelt in the estuary (Trenham *et al.* 1998). Allozyme studies have demonstrated that wakasagi and delta smelt are genetically distinct and presumably derived from different marine ancestors (Stanley *et al.* 1995).

Life History and Biology

Adult-Spawning: Adult delta smelt spawn during the late winter and spring months, with most spawning occurring during April through mid-May (Moyle 2002). Spawning occurs primarily in sloughs and shallow edge areas in the Delta. Delta smelt spawning has also been recorded in Suisun Marsh and the Napa River (Moyle 2002). Most spawning occurs at temperatures between 12-18°C. Although spawning may occur at temperatures up to 22°C, hatching success of the larvae is very low (Bennett 2005).

Fecundity of females ranges from about 1,200 to 2,600 eggs, and is correlated with female size (Moyle 2002). Moyle *et al.* (1992) considered delta smelt fecundity to be "relatively low." However, based on Winemiller and Rose (1992), delta smelt fecundity is fairly haigh for a fish its size. Captive delta smelt can spawn up to 4-5 times. While most adults do not survive to spawn a second season, a few (<5 percent) do (Moyle 2002; Bennett 2005). Those that do survive are typically larger (90-110 mm Standard Length[sdl]) females that may contribute disproportionately to the population's egg supply (Moyle 2002 and references therein). Two-year-old females may have 3-6 times as many ova as first year spawners.

Most of what is known about delta smelt spawning habitat in the wild is inferred from the location of spent females and young larvae captured in the California Department of Fish and Wildlife Spring Kodiak Trawl (SKT) and 20-mm Survey, respectively. In the laboratory, delta smelt spawned at night (Baskerville-Bridges *et al.* 2000; Mager *et al.* 2004). Other smelts, including marine beach spawning species and estuarine populations and the landlocked Lake Washington longfin smelt, are secretive spawners, entering spawning areas during the night and leaving before dawn. If this behavior is exhibited by delta smelt, then delta smelt distribution based on the SKT, which is conducted during daylight hours in offshore habitats, may reflect general regions of spawning activity, but not actual spawning sites.

Delta smelt spawning has only been directly observed in the laboratory and eggs have not been found in the wild. Consequently, what is known about the mechanics of delta smelt spawning is derived from laboratory observations and observations of related smelt species. Delta smelt eggs are 1 mm diameter and are adhesive and negatively buoyant (Moyle 1976, 2002; Mager *et al.* 2004; Wang 1986, 2007). Laboratory observations indicate that delta smelt are broadcast spawners, discharging eggs and milt close to the bottom over substrates of sand and/or pebble in current (DWR and Reclamation 1994; Brown and Kimmerer 2002; Lindberg *et al.* 2003; Wang 2007). Spawning over gravel or sand can also aid in the oxygenation of delta smelt eggs. Eggs that may have been laid in silt or muddy substrates might get buried or smothered, preventing their oxygenation from water flow (Lindberg pers. comm. 2011). The eggs of surf smelts and other beach spawning smelts adhere to sand particles, which keeps them negatively buoyant but not immobile, as the sand may move ("tumble") with water currents and turbulence (Hay 2007). It is not known whether delta smelt eggs "tumble incubate" in the wild, but tumbling of eggs may moderately disperse them, which might induce predation risk within a localized area.

The locations in the Delta where newly hatched larvae are present, most likely indicates spawning occurrence. The 20-mm trawl has captured small (~5 mm sdl) larvae in Cache Slough, the lower Sacramento River, San Joaquin River, and at the confluence of these two rivers (e.g., 20-mm trawl survey 1 in 2005). Larger larvae and juveniles (size > 23 mm sdl), which are more efficintly sampled by the 20-mm trawl gear, have been captured in Cache Slough and the Sacramento Deep Water Ship Channel in July (e.g. 20-mm trawl survey 9 in 2008). Because they are small fish inhabiting pelagic habitats with strong tidal and river currents, delta smelt larval distribution depends on both the spawning area from which they originate and the effect of transport processes caused by flows. Larval distribution is further affected by water salinity and temperature. Hydrodynamic simulations reveal that tidal action and other factors may cause substantial mixing of water with variable salinity and temperature among regions of the Delta (Monson *et al.* 2007). This could result in rapid dispersion of larvae away from spawning sites.

The timing of spawning may affect delta smelt population dynamics. Lindberg (2011) has suggested that smelt larvae that hatch early, around late February, have an advantage over larvae hatched during late spawning in May. Early season larvae have a longer growing season and may be able to grow larger faster during more favorable habitat conditions in the late winter and early spring. An early growing season may result in higher survivorship and a stronger spawning capability for that generation. Larvae hatched later in the season have a shorter growing season which effectively reduces survivorship and spawning success for the following spawning season.

Larval Development: Mager *et al.* (2004) reported that embryonic development to hatching takes 11-13 days at 14-16° C for delta smelt, and Baskerville-Bridges *et al.* (2000) reported hatching of delta smelt eggs after 8-10 days at temperatures between 15-17° C. Lindberg *et al.* (2003) reported high hatching rates of delta smelt eggs in the laboratory at 15° C, and Wang (2007) reported high hatching rates at temperatures between 14-17° C. Hatching success peaks near 15°C (Bennett 2005) and swim bladder inflation occurring at 60-70 days post hatch at 16-17°C (Mager *et al.* 2004). At hatching and during the succeeding three days, larvae are buoyant, swim actively near the water surface, and do not react to bright direct light (Mager *et al.* 2004). As development continues, newly hatched delta smelt become semi-buoyant and sink in stagnant water. However, larvae are unlikely to encounter stagnant water in the wild.

Growth rates of wild-caught delta smelt larvae are faster than laboratory-cultured individuals. Mager *et al.* (2004) reported growth rates of captive-raised delta smelt reared at near-optimum temperatrues (16-17°C). Their fish were about 12 mm long after 40 days and about 20 mm long after 70 days. In contrast, analyses of otoliths indicated that wild delta smelt larvae were 15-25 mm, or nearly twice as long at 40 days of age (Bennett 2005). By 70 days, most wild fish were 30-40 mm long and beyond the larval stage. This suggests there is a strong selective pressure for rapid larval growth in nature, a situation that is typical for fish in general (Houde 1987). Successful feeding seems to depend on a high density of food organisms and turbidity, and increases with stronger light conditions (Baskerville-Bridges *et al.* 2000; Mager *et al.* 2004; Baskerville-Bridges *et al.* 2004). The food available to larval fishes is constrained by mouth gape and status of fin development. Larval delta smelt cannot capture as many kinds of prey as larger individuals, but all life stages have small gapes that limit their range of potential prey. Prey availability is also constrained by habitat use, which affects what types of prey are encountered. Larval delta smelt are visual feeders. They find and select individual prey organisms and their ability to see prey in the water is enhanced by turbidity (Baskerville-Bridges *et al.* 2004). Thus, delta smelt diets are largely comprised of small crustacea that inhabit the estuary's turbid, low-salinity, open-water habitats (i.e., zooplankton). Larval delta smelt have particularly restricted diets (Nobriga 2002). They do not feed on the full array of zooplankton with which they co-occur; they mainly consume three copepods, *Eurytemora affinis*, *Pseudodiaptomus forbesi*, and freshwater species of the family Cyclopidae. Further, the diets of first-feeding delta smelt larvae are largely restricted to the larval stages of these copepods; older, larger life stages of the copepods are increasingly targeted as the delta smelt larvae grow, their gape increases, and they become stronger swimmers.

The triggers for and duration of delta smelt larval movement from spawning areas to rearing areas are not known. Hay (2007) noted that eulachon larvae are probably flushed into estuaries from upstream spawning areas within the first day after hatching, but downstream movement of delta smelt larvae occurs much later. Most larvae gradually move downstream toward the two parts per thousand (ppt) isohaline (X2). X2 is scaled as the distance in kilometers from the Golden Gate Bridge (Jassby *et al.* 1995).

At all life stages, delta smelt are found in greatest abundance in the water column and usually not in close association with the shoreline. They inhabit open, surface waters of the Delta and Suisun Bay, where they presumably aggregate in loose schools where conditions are favorable (Moyle 2002). In years of moderate to high Delta outflow (above normal to wet water years), delta smelt larvae are abundant in the Napa River, Suisun Bay and Montezuma Slough, but the degree to which these larvae are produced by locally spawning fish versus the degree to which they originate upstream and are transported by tidal currents to the bay and marsh is uncertain.

Juveniles: Young-of-the-year delta smelt rear in the low-salinity zone (LSZ) from late spring through fall and early winter. Once in the rearing area growth is rapid, and juvenile fish are 40-50 mm sdl long by early August (Erkkila *et al.* 1950; Ganssle 1966; Radtke 1966). They reach adult size (55-70 mm sdl) by early fall (Moyle 2002). Delta smelt growth during the fall months slows considerably (only 3-9 mm total), presumably because most of the energy ingested is being directed towards gonadal development (Erkkila *et al.* 1950; Radtke 1966).

Delta Smelt Population Dynamics and Abundance Trends

As a consequence of channelization, water operations, and agriculture in the Delta there has been a change to the physical appearance, water salinity, water clarity, and hydrology in the Delta such that most life stages of the delta smelt are now distributed across a smaller area than historically (Arthur *et al.* 1996; Feyrer *et al.* 2007). Wang (1991) noted in a 1989 and 1990 study of delta smelt larval distribution that, in general, the San Joaquin River was used more intensively for spawning than the Sacramento River. Nobriga *et al.* (2008) found that delta smelt capture probabilities in the Summer Townet Survey (TNS) are highest at specific conductance levels of 1,000 to 5,000 $\mu S\ cm^{-1}$ (approximately 0.6 to 3.0 practical salinity unit [psu]). Similarly, Feyrer *et al.* (2007) found a decreasing relationship between abundance of delta smelt in the Fall Midwater Trawl (FMWT) and specific conductance during September through December. The location of the low salinity zone (LSZ) and changes in delta smelt habitat quality in the San Francisco Estuary can be indexed by changes in X2. The LSZ historically had the highest primary productivity and is where zooplankton populations (on which delta smelt feed) were historically most dense (Knutson and Orsi 1983; Orsi and Mecum 1986). However, this has not always been true since the invasion of the overbite clam (Kimmerer and Orsi 1996). The abundance of many local aquatic species has tended to increase in years when winter-spring outflow has high and Z2 was pushed seaward (Jassby *et al.* 1995), implying that the quantity and quality (overall suitability) of estuarine habitat increases in years when outflows are high. However, delta smelt is not one of the species whose abundance has statistically covaried with winter-spring freshwater flows (Stevens and Miller 1983; Moyle *et al.* 1992; Kimmerer 2002a; Bennett 2005).

The distribution of juvenile delta smelt has also changed over the last several decades. During the years 1970 through 1978, delta smelt catches in the TNS survey declined rapidly to zero in the Central and South Delta and have remained near zero since. A similar shift in FMWT catches occurred after 1981 (Arthur *et al.* 1996). This portion of the Delta has also had a long-term trend increase in water clarity during July through December (Arthur *et al.* 1996; Feyrer *et al.* 2007; Nobriga *et al.* 2008).

The CDFW has conducted several long-term monitoring surveys that have been used to index the relative abundance of delta smelt. The 20-mm Survey has been conducted every year since 1995. This survey targets late-stage delta smelt larvae. Most sampling has occurred April-June. The TNS has been conducted nearly every year since 1959. This survey targets 38-mm striped bass, but collects similar-sized juvenile delta smelt. Most sampling has occurred June-August. The Fall Midwater Trawl Survey has been conducted nearly every year since 1967. This survey also targets age-0 striped bass, but collects delta smelt > 40 mm in length. The FMWT samples monthly, September-December. The relative abundance index data and maps of the sampling stations used in these surveys are available at http://www.CDFW.ca.gov/delta/. The methods that underlie the surveys have been described previously (Stevens and Miller 1983; Moyle *et al.* 1992; Dege and Brown 2004). The delta smelt catch data and relative abundance indices derived from these sampling programs have been used in numerous publications (e.g., Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995; Kimmerer 2002b; Dege and Brown 2004; Bennett 2005; Feyrer *et al.* 2007; Sommer *et al.* 2007; Kimmerer 2008; Newman 2008; Nobriga *et al.* 2008; Kimmerer *et al.* 2009; Mac

Nally *et al.* 2010; Thomson *et al.* 2010; Feyrer *et al.* 2011; Maunder and Deriso 2011). These abundance index time series document the long-term decline of the delta smelt.

Early statistical assessments of delta smelt population dynamics concluded that at best, the relative abundance of the adult delta smelt population had only a very weak influence on subsequent juvenile abundance (Sweetnam and Stevens 1993). Thus, early attempts to describe abundance variation in delta smelt ignored stock-recruit effects and researchers looked for environmental variables that were directly correlated with interannual abundance variation (e.g., Stevens and Miller 1983; Moyle *et al.* 1992; Sweetnam and Stevens 1993; Herbold 1994; Jassby *et al.* 1995). Because delta smelt live in a habitat that varies in size and quality with Delta outflow, the authors cited above searched for a linkage between Delta outflow (or X2) and the TNS and FMWT indices. Generally, these analyses did not find strong support for an outflow-abundance linkage. These analyses led to a prevailing conceptual model that multiple interacting factors had caused the delta smelt decline (Moyle *et al.* 1992; Bennett and Moyle 1996; Bennett 2005). It has also recently been noted that delta smelt's FMWT index is partly influenced by explanation for why few analyses could consistently link springtime environmental conditions to delta smelt's fall index.

One published exception to the multi-factor hypothesis was proposed by Gilbert (2010), who posited that nutrient pollution was the root cause of all the food web and fish assemblage changes that caused the decline of delta smelt and other pelagic fishes. However, the statistical approach she used to support her hypothesis was not appropriate and the untransformed data sets do not support this hypothesized chain of consequences stemming solely from wastewater inputs to the Delta (Jassby *et al.* in press). It is now recognized that delta smelt abundance plays an important role in subsequent abundance (Bennett 2005; Maunder and Deriso 2011). Bennett (2005) assessed (1) the influence of adult stock as indexed by the FMWT versus the next generation of juveniles indexed by the following calendar year's TNS; (2) the influence of the juvenile stock indexed by the TNS versus the subsequent adult stock indexed a few months later in the FMWT; (3) the influence of the FMWT on the following year's FMWT and on the FMWT two years later, and (4) he did the same for the TNS data. He concluded that (1) two-year-old delta smelt might play an important role in delta smelt population dynamics, (2) it was not clear wheter juvenile production was a density-independent or density-dependent function of adult abundance, and (3) adult production was a density-dependent function of juvenile abundance and the carrying capacity of the estuary to support this life-stage transition had declined over time. These conclusions are also supported by Maunder and Deriso (2011).

The concept of density-dependence and how it has affected the delta smelt is important because it may be used as a reason not to protect particular life stages from sources of mortality. Bennet (2005) concluded it was (statistically) unclear whether density-dependence occurs between generations. He also noted that the delta smelt indices strongly suggest that density-dependence has occurred, at least over the long-term, during the juvenile stage. The uncertainty about density-dependence between generations results because statistical assessments of the relationship between the adult stock and the next generation of recruits (juveniles_ result in similar fits for linear (density-independent) and nonlinear (density-dependent) relationships (Bennett 2005; Maunder and Deriso 2011).

One reason for this is that delta smelt population dynamics may have changed over time. Previous papers have reported a delta smelt step-decline during 1981-1982 (Kimmerer 2002a; Thomson *et al.* 2010). Prior to this decline, the stock-recruit data are consistent with "Ricker" type density-dependence where increasing adult abundance resulted in decreased juvenile abundance. Since the decline, recruitment has been positively and essentially linearly related to prior adult abundance, suggesting that reproduction has been basically density-independent for about the past 30 years.

This means that since the early 1980s, more adults translates into more juveniles and fewer adults translates into fewer juveniles without being 'compensated for' by density-dependence. In contrast to the transition among generations, the weight of scientific evidence strongly supports the hypothesis that, at least over the history of Interagency Ecological Program (IEP) fish monitoring, delta smelt has experienced density-dependence during the juvenile stage of its life cycle, i.e., between the summer and fall (Bennett 2005; Maunder and Deriso 2011). This has been inferred because, statistically, the FMWT index does not increase linearly with increases in the summer townet index. Rather, the best-fitting relationships between the summer townet index and the FMWT index show that the FMWT indices approach an asymptote as the summer townet increases or possibly even declines at the highest summer townet indices.

From a species conservation perspective, the most relevant aspect of this juvenile density dependence is that the carrying capacity of the estuary for delta smelt has declined (Bennett 2005). Thus, the delta smelt population decline has occurred for two basic reasons. First, the compensatory density-dependence that historically enabled juvenile abundance to rebound from low adult numbers stopped happening. This change had occurred by the early 1980s as described above. The reason is still not known, but the consequence of the change is that for the past several decades, adult abundance drives juvenile production in a largely density-independent manner. Thus, if numbers of adults or adult fecundity decline, juvenile production will also decline (Kimmerer 2011). Second, because juvenile carrying capacity has declined, juvenile production hits a 'ceiling' at a lower abundance than it once did. This limits adult abundance and possibly per capita fecundity, which cycles around and limits the abundance of the next generation of juveniles. The mechanism causing carrying capacity to decline is likely due to the long-term accumulation of deleterious habitat changes, both physical and biological, during the summer-fall (Bennett *et al.* 2008; Feyrer *et al.* 2007; 2011; Maunder and Deriso 2011).

Habitat

The existing physical appearance and hydrodynamics of the Delta have changed substantially from the environment in which native fish species like delta smelt evolved. The Delta once consisted of tidal marshes with networks of diffuse dendritic channels connected to floodplains of wetlands and upland areas (Moyle 2002). The in-Delta channels were further connected to drainages of larger and smaller rivers and creeks entering the Delta from the upland areas. In the absence of upstream reservoirs, freshwater inflow from smaller rivers and creeks and the Sacramento and San Joaquin Rivers were highly seasonal and more strongly and reliably affected by precipitation patterns than they are today. Consequently, variation in hydrology, salinity, turbidity, and other characteristics of the Delta aquatic ecosystem was greater in the past than it is today (Kimmerer 2002a). For instance, in the early 1900s, the location of maximum salinity intrusion into the Delta during dry periods varied from Chipps Island in the lower Delta to Stockton along the San Joaquin River and Merritt Island in the Sacramento River. Operations of upstream reservoirs have reduced spring flows while releases of water for Delta water export and increased flood control storage have increased late summer and fall inflows (Knowles 2002), though Delta outflows have been tightly constrained during late summer-fall for several decades. The following is a brief description of the changes that have occurred to delta smelt's habitat that are relevant to the environmental baseline for this consultation.

Changes to the LSZ: There have been documented changes to the delta smelt's LSZ habitat that have led to present-day, baseline habitat conditions. The close association of delta smelt with the San Francisco estuary LSZ has been known for many years (Stevens and Miller 1983; Moyle *et al.* 1992). Peterson (2003) developed a conceptual model that hypothesized how, "stationary and dynamic components of estuarine habitats" interacted to influence fisheries production in tidal river estuaries.

Peterson's model suggests that when the dynamic and static aspects of estuarine habitat sufficiently overlap, foraging, growth, density, and survival are all high, and that enables fish production to outpace losses to predators. The result is high levels of successful recruitment of new individuals. The model also hypothesizes that when the dynamic and static aspects of an estuarine habitat do not sufficiently overlap, foraging, growth, density, and survival are impaired such that losses to predators increase and recruitment of new individuals decreases. This model was developed specifically for species spawned in marine environments that were subsequently transported into estuaries. However, the concept of X2, which was developed in the San Francisco estuary to describe how freshwater flow affected estuarine habitat (Jassby *et al.* 1995), played a role in the intellectual development of Peterson's model. The Peterson model also provides a useful framework to conceptualize delta smelt's LSZ habitat.

Currently available information indicates that delta smelt habitat is most suitable for the fish when low-salinity water is near 20°C, highly turbid, oxygen saturated, low in contaminants, supports high densities of calanoid copepods and mysid shrimp (Moyle *et al.* 1992; Lott 1998; Nobriga 2002), and occurs over comparatively static 'landscapes' that support sandy beaches and bathymetric variation that enables the fish and their prey to aggregate (Kimmerer *et al.* 2002a; Bennett *et al.* 2002; Hobbs *et al.* 2006). Almost every component listed above has been degraded over time (see below). The Service has determined that this accumulation of habitat change is the fundamental reason or mechanism that has caused delta smelt to decline.

Alterations to estuarine bathymetry and salinity distribution (~ 1850-present): The position of the LSZ, where delta smelt rear, has changed over the years. The first major change in the LSZ was the conversion of the landscape over which tides oscillate and river flows vary (Moyle *et al.* 2010). The ancestral Delta was a large tidal marsh-floodplain habitat totaling approximately 700,000 acres. Most of the historic wetlands within the system were diked and reclaimed for agriculture or other human uses by 1920 (Atwater *et al.* 1979). Channels were dredged deep (~12 meters[m]) to accommodate shipping traffic from the Pacific Ocean and San Francisco Bay to ports in Sacramento and Stockton. These changes left Suisun Bay and the confluence of the Sacramento-San Joaquin Rivers as the largest and most bathymetrically variable places in the LSZ. This region remained a highly productive nursery for many decades (Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995). However, the deepened channels created to support shipping and flood control, requires more freshwater outflow to maintain the LSZ in the large Suisun Bay and River confluence than was once required (Gartrell 2010). The construction of the CVP and SWP not only provided water supply for urban, agricultural and industrial users, but also provided water needed to combat salinity intrusion into the Delta, which was observed by the early 20th century. California's demand for freshwater (keeps) continues to increase, thus seasonal salinity intrusion perpetually reduces the temporal overlap of the LSZ (indexed by X2) within the Suisun Bay (region), especially in the fall (Feyrer *et al.* 2007; 2011). Consequently, the second major habitat change in the Delta has been in the frequency with which the LSZ is maintained in Suisun Bay for any given amount of precipitation. There was a step-decline in the LSZ in 1977 from which it has never recovered for more than a few years at a time. Based on model forecasts of climate change and water demand, this trend is expected to continue (Feyrer *et al.* 2011).

Summer and fall environmental quality has decreased overall in the Delta because outflows are lower and water transparency is higher. These changes may be due to increased upstream water diversions for flooding rice fields (Kawakami *et al.* 2008). The confluence of the Sacramento and San Joaquin Rivers has, as a result, become increasingly important as a rearing location for delta smelt, with physical environmental conditions constricting the species range to a relatively narrow area (Feyrer *et al.* 2007; Nobriga *et al.* 2008). This has increased the likelihood that most of the juvenile population is exposed to chronic and cyclic environmental stressors, or catastrophic events. For instance, all seven delta smelt collected during the September 2007 FMWT survey were captured at statistically significantly higher salinities than what would be expected based upon historical distribution data generated by Feyrer *et al.* (2007). During the same year, the annual bloom of toxic cyanobacteria (Microcystis aeruginosa) spread far downstream to the west Delta and beyond during the summer (Peggy Lehman, pers comm). This has been suggested as an explanation for the anomaly in the distribution of delta smelt relative to water salinity levels (US Bureau of Reclamation 2008).

Bank Protection (Levees): The placement of riprap bank protection has led to the loss of riparian habitat, large woody debris, shallow water habitat, and natural channel migration. Bank stabilization and riprapping has been shown to change natural river processes such as erosion and accretion which reduces habitat complexity; creates a smooth, hydraulically enhanced surface that is not conducive to the habitat requirements of fish including delta smelt; stops woody vegetation from entering the river and reduces the long-term recruitment of large woody debris; inhibits plant growth through a change is substrate; lowers the amount of outside food sources because of the lack of riparian and wetland vegetation for aquatic invertebrates; and increases stream edge velocities which decreases available refuge areas for fish (Service 2000). More than half of the Sacramento River's lower 194 miles have been riprapped, mostly under the Corps Sacramento River bank Protection Project. Today most of the riparian forests and wetlands have been removed and the Sacramento River has been constrained to not allow natural erosion and accretion to occur.

Turbidity: From 1999 to present, the Delta experienced a change in estuarine turbidity that culminated in an estuary-wide step-decline in 1999 (Schoellhamer 2011). For decades, the turbidity of the modified estuary had been sustained by very large sediment deposits resulting mainly from gold mining in the latter 19th century. Sediments continued to accumulate into the mid-20th century, keeping the water relatively turbid even as sediment loads from the Sacramento River basin declined due to dam and levee construction (Wright and Schoellhamer 2005). The flushing of the sediment deposits may also have made the estuary deeper overall and thus a less suitable nursery from the 'static' bathymetric perspective (Schroeter 2008).

Delta smelt are associated with highly turbid waters; there is a negative correlation between the frequency of delta smelt occurrence in survey trawls during the summer, fall and early winter and water clarity. For example, the likelihood of delta smelt occurrence in trawls at a given sampling station decreases with increasing Secchi depth at the stations (Feyrer *et al.* 2007, Nobriga *et al.* 2008). This is very consistent with behavioral observations of captive delta smelt (Nobriga and Herbold 2008). Few daylight trawls catch delta smelt at Secchi depths over 0.5 m and capture probabilities for delta smelt are highest at 0.40 m depth or less. First-feeding delta smelt larvae require relatively turbid (muddy) waters to capture prey, but older fish do not require turbidity to capture prey and very high turbidity may even have some inhibitory effect on prey consumption (Hasenbein *et al.* 2013). Delta smelt may also use turbidity as cover from predators; this was hypothesized based on long-term monitoring of the distribution of fish in the wild (e.g., Feyrer *et al.* 2007) and recently supported by a laboratory experiment (Ferrari *et al.* 2014).

Temperature: Temperature also affects delta smelt distribution. Swanson and Cech (1995) and Swanson *et al.* (2000) indicate delta smelt tolerate temperatures (<8° C to >25° C), however warmer water temperatures >25° C restrict their distribution more than colder water temperatures (Nobriga and Herbold 2008). Delta smelt of all sizes are found in the main channels of the Delta and Suisun Marsh and the open waters of Suisun Bay where the water is well oxygenated and temperatures are usually less than 25° C in summer (Nobriga *et al.* 2008). Currently, delta smelt are subjected to thermally stressful temperatures every summer, and all available regional climate change projections predict central California will be warmer still in the coming decades (Dettinger 2005). We expect warmer estuary temperatures to be yet another significant conservation challenge based on climate change models. Warmer water temperatures would increase delta smelt mortality and constrict suitable habitat throughout the Delta during the summer months. Higher temperatures would shrink delta smelt distribution into the fall, limiting their presence to Suisun Bay and in waters with less than optimal salinities (Brown *et al.* 2013). Water temperatures are presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding the nominal lethal limit of 25°C for short periods. Coldwater fishes begin to have behavioral impairments (Marine and Cech 2004) and lose competitive abilities (Taniguchi *et al.* 1998) prior to reaching their thermal tolerance limits. Thus, the estuary can already be considered thermally stressful to delta smelt and can only become more so if temperatures warm in the coming decades.

Foraging Ecology: Delta smelt feed primarily on small planktonic crustaceans, and occasionally on insect larvae (Moyle 2002). Juvenile-stage delta smelt prey upon copepods, cladocerans, amphipods, and insect larvae (Moyle 2002). Historically, the main prey of delta smelt was the euryhaline copepod *Eurytemora affinis* and the euryhaline mysid *Neomysis mercedis.* The slightly larger *Pseudodiaptomus forbesi* has replaced *E. affinis* as a major prey source of delta smelt since its introduction into the Bay-Delta, especially in summer, when it replaces *E. affinis* in the plankton community (Baxter *et al.* 2008; Moyle 2002). The most common copepod in the estuary now is a small nonnative species, *Limnoithona tetraspina.* It has been suggested that *L. tetraspina* may be an inferior food for pelagic fishes including delta smelt because of its small size and generally sedentary behavior (Bouley and Kimmerer 2006). Experimental studies addressing this issue have suggested that smelt larvae will attack *L. tetraspina* until they grow large enough to successfully capture larger copepods; also, growth rate of delta smelt fed *L. tetraspina* was lower than that of smelt fed the larger copepods (Sullivan *et al.*, unpublished). *L. tetraspina* is sometimes consumed in large numbers by juvenile delta smelt during late summer when this copepod is abundant in the LSZ (Slater and Baxter 2014). *Acartiella sinensis*, a calanoid copepod species that invaded the Delta at the same time as *L. tetraspina*, also occurs at high densities in Suisun Bay and in the western Delta over the last decade. Delta smelt eat these newer copepods, but *Pseudodiaptomus* remains their dominant prey (Baxter *et al.* 2008).

River flows influence estuarine salinity gradients and water residence times and thereby affect both habitat suitability for benthos and the transport of pelagic plankton upon which delta smelt feed. High tributary flow leads to lower residence time of water in the Delta, which generally results in lower plankton biomass (Kimmerer 2004). In contrast, higher residence times, which result from low tributary flows, can result in higher plankton biomass but water diversions, overbite clam grazing (Jassby *et al.* 2002) and possibly contaminants (Baxter *et al.* 2008) remove a lot of plankton biomass when residence times are high. These factors all affect food availability for planktivorous fishes that utilize the zooplankton in Delta channels. Delta smelt cannot occupy much of the Delta anymore during the summer (Nobriga *et al.* 2008). Thus, there is the potential for mismatches between regions of high zooplankton abundance in the Delta and delta smelt distribution now that the overbite clam has decimated LSZ zooplankton densities.

The delta smelt compete with and are prey for several native and introduced fish species in the Delta. The introduced Mississippi silverside may prey on delta smelt eggs and/or larvae and compete for copepod prey (Bennett and Moyle 1996; Bennett 2005). Young striped bass also use the LSZ for rearing and may compete for copepod prey and eat delta smelt. Centrarchid fishes and coded wire tagged Chinook salmon smolts released in the Delta for survival experiments since the early 1980s may potentially also prey on larval delta smelt (Brandes and McLain 2001; Nobriga and Chotkowski 2000). Studies during the early 1960s found delta smelt were only an occasional prey fish for striped bass, black crappie and white catfish (Turner and Kelley 1966). However, delta smelt were a comparatively rare fish even then, so it is not surprising they were a rare prey. Striped bass appear to have switched to piscivorous feeding habits at smaller sizes than they historically did, following severe declines in the abundance of mysid shrimp (Feyrer *et al.* 2003). Nobriga and Feyrer (2008) showed that Mississippi silverside, which is similar in size to delta smelt, was only eaten by subadult striped bass less than 400-mm fork length. While largemouth bass are not pelagic, they have been shown to consume some pelagic fishes (Nobriga and Feyrer 2007).

Other Stressors

Aquatic Macrophytes: For many decades, the Delta's waterways were turbid and growth of submerged plants was apparently unremarkable. That began to change in the mid-1980s, when the Delta was invaded by the non-native plant, *Egeria densa*, a fast-growing aquatic macrophyte that has now taken hold in many shallow habitats throughout the Delta (Brown and Michnuik 2007; Hestir 2010). *Egeria densa* and other non-native species of submerged aquatic vegetation (SAV) grow most rapidly in the summer and late fall when water temperatures are warm (> 20°C) and outflow is relatively low (Hestir 2010). The large canopies formed by these plants have physical and biological consequences for the ecosystem (Kimmerer *et al.* 2008). First, the dense nature of SAV promotes sedimentation of particulate matter from the water column, which increases water transparency that then limits the amount of habitat available for delta smelt (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Second, dense SAV canopies provide habitat for a suite of non-native fishes that occupy the littoral and shallow habitats of the Delta, displacing native fishes (Nobriga *et al.* 2005; Brown and Michniuk 2007). Finally, the rise in SAV colonization over the last three decades has led to a shift in the dominant trophic pathways that fuel fish production in the Delta. Until the latter 1980s, the food web of most fishes was often dominated by mysid shrimp (Feyrer *et al.* 2003) that were subsidized by phytoplankton food sources (Rast and Sutton 1989). Now, most littoral and demeral fishes of the Delta have diets dominated by the epibenthic amphipods that eat SAV detritus or the epiphytic algae attached to SAV (Grimaldo *et al.* 2009).

E. densa and other non-native submerged aquatic vegetation (e.g., *Myriophyllum spicatum*) can affect delta smelt in direct and indirect ways. Directly, submerged aquatic vegetation can over whelm littoral habitats (inter-tidal shoals and beaches) where delta smelt may spawn making them unsuitable for spawning. Indirectly, submerged aquatic vegetation decreases turbidity (by trapping suspended sediment) which has contributed to a decrease in both juvenile and adult smelt habitat (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Increased water transparency may delay feeding and may also make delta smelt more susceptible to predation pressure.

Predators: Delta smelt is a rare fish and has been a rare fish (compared to other species) for at least the past several decades (Nobriga and Herbold 2008). Therefore, it has also been rare in examinations of predator stomach contents. Delta smelt were occasional prey fish for striped bass, black crappie, and white catfish in the early 1960s (Turner and Kelly 1966) but went undetected in a recent study of predator stomach contents (Nobriga and Feyrer 2007). The predator with the highest historical documentation of predation on delta smelt is striped bass (*Morone saxatilis*, Stevens 1963; 1966; Thomas 1967). In these studies, striped bass were confirmed to prey on both juvenile and adult delta smelt. Striped bass are widely distributed in pelagic areas of the San Francisco Bay-Delta and parts of its watershed, and thus striped bass distribution fully encompasses the distribution of delta smelt juveniles and adults (Nobriga *et al.* 2013). Striped bass also tend to aggregate in the vicinity of water diversion structures, where delta smelt are frequently entrained (Nobriga and Feyrer 2007). No inverse correlations between the abundance of striped bass and the relative abundance of delta smelt have been found to date using a variety of statistical approaches (Mac Nally et al 2010; Thomson *et al.* 2010; Maunder and Deriso 2011; Miller *et al.* 2012; Nobriga et al 2013). Although the relative rarity of delta smelt in the estuary food web would presumably make them a n incidental prey item for striped bass, it is possible that striped bass abundance and demand for prey are always high enough to limit delta smelt population growth rate (Nobriga *et al.* 2013).

Fish eggs and larvae can be opportunistically preyed upon by many invertebrate and vertebrate animals. There has always been a very long list of potential predators of delta smelt's eggs and larvae. One of these is the nonnative Mississippi silverside (*Menidia audens*), which like delta smelt is and annual fish with a maximum length near 100 mm (4 inches). Mississippi silversides may be both predators and competitors of delta smelt (Bennett 2005). Mississippi silversides were first introduced to the San Francisco Bay-Delta in the mid-1970s, and have increased dramatically in numbers since the mid-1980s. They forage in schools around the shoreline habitats and tidal marsh channels of the San Francisco Bay-Delta, where they are exceptionally common (Matern *et al.* 2002); Nobriga *et al.* 2005; Gewant and Bollens 2012). They readily consume delta smelt larvae in aquarium tests Bennett (20025_ concluded that "delta smelt are at high risk of eggs or larvae co-occur with schools of foraging silversides."

Another known predator is the largemouth bass are freshwater fish that prefer clear waters along shorelines (littoral habitat) with relatively dense water plants (Nobriga and Feyrer 2007; Brown and Michniuk 2007; Baxter *et al.* 2008). This is a suite of habitat characteristics that is distinctly different from those described above for delta smelt. Thus, unlike delta smelt and striped bass, delta smelt and largemouth bass have different habitat requirements (e.g., Nobriga *et al.* 2005) and their distributions do not strongly overlap. However, there has been a major increase in the Delta's largemouth bass population since the early 1990's that is believed to have been facilitated by the spread of the introduced plant *Egeria densa*, which provides rearing habitat for the bass (Baxter *et al.* 2008). Despite increases in largemouth bass populations and habitat, Nobriga and Feyrer (2007) did not find delta smelt as largemouth bass prey. Nor have more recent and extensive surveys of largemouth bass stomach contents. In captivity however, even young juvenile largemouth bass will attempt to consume delta smelt (Ferrari *et al.* 2014) so they presumably represent a predation threat when the species closely co-occur in the wild. In contrast to the situation for striped bass, several researchers have found inverse correlations between the relative abundance of largemouth bass or multi-species indices that included largemouth bass and the relative abundance of delta smelt (MacNally *et al.* 2010; Thomson *et al.* 2010; Maunder and Deriso 2011). At this time however, there is no way to determine whether these correlations are causative (predation by largemouth bass caused delta smelt to decline) or not (delta smelt simply use different habitats than largemouth bass and delta smelt habitat has decreased whil largemouth bass habitat has increased).

Other potential predators of eggs and larvae of smelt in littoral habitats are yelllowfin goby, entrarchids, and Chinook salmon. Potential native predators of juvenile and adult delta smelt would also have included numerous bird and fish species and this may be reflected in delta smelt's annual life-history. Annual fish species, also known as "opportunistic strategists", are adapted to high mortality rates in the adult stage (Winemiller and Rose 1992). This high mortality is usually due to predation or highly unpredictable environmental conditions, both of which could have characterized the ancestral niche of delta smelt.

Predation is a common source of density-dependent mortality in fish populations (Rose *et al.* 2001). Thus, it is possible that predation was a mechanism that historically generated the density-dependence observable in delta smelt population dynamics that has been noted by Bennett (2005) and Maunder and Deriso (2011). As is the case with other fishes, the vulnerability of delta smelt to predators may be influence primarily by habitat suitability. It is widely documented that pelagic fishes, including many smelt species, experience lower predation risks under turbid water conditions (Thetmeyer and Kils 1995; Utne-Palm 2002; Horpilla *et al.* 2004). Growth rates, a result of feeding success plus water temperature, are also well known to affect fishes' cumulative vulnerability to predation (Sogard 1997).

Competition: It has been hypothesized that delta smelt are adversely affected by competition from other introduced fish species that use overlapping habitats, including Mississippi silversides, (Bennett and Moyle 1995) striped bass, and wakasagi (Sweetnam 1999). Laboratory studies show that delta smelt growth is inhibited when reared with Mississippi silversides (Bennett 2005) but there is no empirical evidence to support the conclusion that competition between these species is a factor that influences the abundance of delta smelt in the wild. There is some speculation that the overbite clam competes with delta smelt for copepod nauplii (Nobriga and Herbold 2008). It is unknown how intensively overbite clam grazing and delta smelt directly compete for food, but overbite clam consumption of shared prey resources does have other ecosystem consequences that appear to have affected delta smelt indirectly.

Microcystis: Large blooms of toxic blue-green algae, *Microcystis aeruginosa*, were first detected in the Delta during the summer of 1999 (Lehman *et al.* 2005). Since then *M. aeruginosa* has bloomed each year, forming large colonies throughout most of the Delta and increasingly down into eastern Suisun Bay. Blooms typically occur between late spring and early fall (peak in the summer) when temperatures are above 20°C. *M. aeruginosa* can produce natural toxins that pose animal and human health risks if contacted or ingested directly. It is unclear whether microcystins and other toxins produced by local blooms are acutely toxic to fishes at current concentrations; however, the toxins accumulate in fish and their prey. During the summer of 2005, Age-0 striped bass and Mississippi silversides that were co-occurring with the *Microcystis* bloom showed various forms of liver damage (Lehman *et al.* 2010). When ingested with food, microcystins have been experimentally shown to cause substantial impairment of health in threadfin shad (Acuna *et al.* 2012). In addition, the copepods that delta smelt eat are particularly susceptible to these toxins (Ger 2008; Ger *et al.* 2010). An investigation of food web effects and fish toxicity concluded that even at low abundances, *M. aeruginosa* may impact estuarine fish productivity through both toxicity and food web impacts (Lehman *et al.* 2010). *M. aeruginosa* is most likely to affect juvenile delta smelt during summer blooms. Microcystis blooms may also decrease dissolved oxygen to lethal levels for fish (Saiki *et al.* 1998), although delta smelt do not strongly overlap the densest *Microcystis* concentrations, so dissolved oxygen is not likely a problem. *Microcystis* blooms are a symptom of eutrophication and high ammonia to nitrate ratios in the water.

Contaminants: Contaminants can change ecosystem functions and productivity through numerous pathways. However, contaminant loading and its ecosystem effects within the Delta are not well understood. Although a number of contaminant issues were first investigated during the Pelagic Organism Decline (POD) years, concern over contaminants in the Delta is not new. There are long-standing concerns related to mercury and selenium levels in the watershed, Delta, and San Francisco Bay (Linville *et al.* 2002; Davis *et al.* 2003). Phytoplankton growth rate may, at times, be inhibited by high concentrations of herbicides (Edmunds *et al.* 1999). New evidence indicates that phytoplankton growth rate is chronically inhibited by ammonium concentrations in and upstream of Suisun Bay (Wilkerson *et al.* 2006, Dugdale *et al.* 2007). Contaminant-related toxicity to invertebrates has been noted in water and sediments from the Delta and associated watersheds (e.g., Kuivila and Foe 1995, Giddings 2000, Werner *et al.* 2000, Weston *et al.* 2004). Undiluted drain water from agricultural drains in the San Joaquin River watershed can be acutely toxic (quickly lethal) to fish and have chronic effects on growth (Saiki *et al.* 1992).

Evidence for mortality of young striped bass due to discharge of agricultural drainage water containing rice herbicides into the Sacramento River (Bailey *et al.* 1994) led to new regulations for

water discharges. Bio assays using caged Sacramento sucker (Catostomus occidentalis) have revealed deoxyribonucleic acid strand breakage associated with runoff events in the watershed and Delta (Whitehead *et al.* 2004). Kuivila and Moon (2004) found that peak desities of larval and juvenile delta smelt sometimes coincided in time and space with elevated concentrations of dissolved pesticides in the spring. These periods of co-occurrence lasted for up to 2-3 weeks, but concentrations of individual pesticides were low and much less than would be expected to cause acute mortality. However, the effects of exposure to the complex mixtures of pesticides actually present are unknown.
Current science suggests the possible link between contaminants and the POD may be the effects of contaminant exposure on prey items, resulting in an indirect effect on the survival of POD species (Johnson *et al.* 2010). The POD investigators initiated several studies beginning in 2005 to address the possible role of contaminants and disease in the declines of Delta fish and other aquatic species. Their primary study consists of twice-monthly monitoring of ambient water toxicity at fifteen sites in the Delta and Suisun Bay. In 2005 and 2006, standard bioassays using the amphipod *Hyalella azteca* had low (<5 percent) frequency of occurrence of toxicity (Werner *et al.* 2008). The results indicated that 2007, a dry year, showed a higher incidence of toxic events than in the previous (wetter) year, 2006 (Werner *et al.* 2010). Parallel testing with the addition of piperonyl butoxide, an enzyme inhibitor, indicated that both organophosphate and pyrethroid pesticides may have contributed to the pulses of toxicity. Most of the tests that were positive for *H. azteca* toxicity have come from water samples from the lower Sacramento River.

Pyrethroids are of particular concern because of their widespread use, and their tendency to be genotoxic (DNA damaging) to fishes at low doses (in the range of micrograms per liter) (Campana *et al.* 1999). The pyrethroid esfenvalerate is associated with delayed spawning and reduced larval survival of bluegill sunfish (*Lepomis macrochirus*) (Tanner and Knuth 1996) and increased susceptibility of juvenile Chinook salmon (*Oncorhynchus tshawytscha*) to disease (Clifford *et al.* 2005). In addition, synthetic pyrethroids may interfere with nerve cell function, which could eventually result in paralysis (Bradbury and Coats 1989; Shafer and Meyer 2004). Weston and Lydy (2010) found the largest source of pyrethroids flowing into the Delta to be coming from the Sacramento Regional Waste water Treatment Plant, where only secondary treatment occurs. Their data not only indicate the presence of these contaminants, but the concentrations found exceeded acute toxicity thresholds for the amphipod *Hyalella azteca*. This is of substantial concern because the use of insecticides flowing into the Delta. Furthermore, this was not the case for the Stockton Wastewater Treatment facility, where tertiary treatment occurs, suggesting that different treatment methods may remove or etain pyretroids differently (Baxter *et al.* 2010).

In conjunction with the POD investigation, larval delta smelt bioassays were conducted simultaneously with a subset of the invertebrate bioassays. The water samples for these tests were collected from six sites within the Delta during May-August of 2006 and 2007. Results from 2006 indicated that delta smelt are highly sensitive to high levels of ammonia, low turbidity, and low salinity. There is some preliminary indication that reduced survival may be due to disease organisms (Werner *et al.* 2008). No significant mortality of larval delta smelt was found in the 2006 bioassays, but there were two instances of significant mortality in June and July of 2007. In both cases, the water samples were collected from sites along the Sacramento River and had relatively low turbidity and salinity levels and moderate levels of ammonia. It is also important to note that no significant *H. azteca* mortality was detected in these water samples. While H. Azteca tests are very useful for detecting biologically relevant levels of water column toxicity for zooplankton, interpretation of the *H. azteca* test results with respect to fish should proceed with great caution. The relevance of the bioassay results to field conditions remains to be determined. Werner *et al.* (2010b) conducted *in situ* testing in the laboratory and compared contaminant sensitivity of delta smelt to common bioassay organisms, including *H. azteca*. The investigations included contaminants commonly observed in the

Delta, such as organophosphate and pyrethroid insecticides, copper, and total ammonia. In the laboratory, delta smelt were 1.8 to >11 times more sensitive thatn fathead minnow to ammonia, copper and all insecticides tested (except permethrin). The invertebrates tested were more sensitive to contaminants than delta smelt or fathead minnows. *Eurytemora affinis* and *Ceriodaphnia dubia* were the most sensitive to total ammonia. *C. dubia* was the most sensitive to copper and organophosphates pesticides. *H. azteca* was the most sensitive test organism to pyrethroids. Toxicity was not detected for the Sacramento River at Hood or the San Joaquin River at Rough and Ready Island during the 2009 in situ testing period. Delta smelt survival was low in treatment and control waters. Werner *et al.* (2010b) concluded that larval smelt may be too sensitive to salinity, temperature and transport stress for *in situ* exposures and recommended using surrogate species in future tests.

Persistent confinement of the spawning population of delta smelt to the Sacramento River increases the likelihood that a substantial portion of the spawners will be affected by a catastrophic event or localized chronic threat. For instance, large volumes of highly concentrated ammonia released into the Sacramento River from the Sacramento Regional County Sanitation District may affect embryo survival or inhibit prey production. Further, agricultural field in the Yolo Bypass and surrounding areas are regularly sprayed by pesticides, and water samples taken from Cache Slough sometimes exhibited toxicity to *H. azteca* (Werner *et al.* 2008; 2010). The thresholds of toxicity for delta smelt for most of the known contaminants have not been determined, but the exposure to a combination of different compounds increases the likelihood of adverse effects. The extent to which delta smelt larvae are exposed to contaminants varies with flow entering the Delta. Flow pulses during spawning increase exposure to many pesticides (Kuivila and Moon 2004) but decrease ammonia concentrations from wastewater treatment plants.

The POD investigations into potential contaminant effects also include the use of biomarkers that have been used previously to evaluate toxic effects on POD fishes (Bennett and Moyle 1996, Bennett 2005). The results to date have been mixed. A pathogen survey of 105 adult delta smelt, sampled from January through May, at several sites in the Delta, found that disease did not appear to overtly influence the health of the surveyed population for that year (Foott and Bigelow 2010). Histopathological and viral evaluation of young longfin smelt collected in 2006 indicated no histological abnormalities associated with exposure to toxics or disease (Foott *et al.* 2006). There was also no evidence of viral infection or high parasite loads. Similarly, young threadfin shad showed no histological evidence of contaminant effects or of viral infections (Foott *et al.* 2006). Parasites were noted in threadfin shad gills at a high frequency but the infections were not considered severe. Both longfin smelt and threadfin shad were considered healthy in 2006. Adult delta smelt collected from the Delta during the winter of 2005 also were considered healthy, showing little histopathological evidence for starvation or disease (Teh 2007). However, there was some evidence of low frequency endocrine disruption. In 2005, nine of 144 (six percent) of adult delta smelt males sampled were intersex, having immature oocytes in their testes (Teh 2007). Bennett (2005) reported that about 10 percent of the delta smelt analyzed for histopathological anomalies in 1999-2000 showed evidence of deleterious contaminant exposure. In contrast, 30-60 percent of these fish had liver glycogen depletion consistent with food limitation.

In contrast, preliminary histopathological analyses have found evidence of significant disease in other species and for POD species collected from other areas of the estuary. Massive intestinal infections with an unidentified myxosporean were found in yellowfin goby (*Acanthogobius flavimanus*) collected from Suisun Marsh. Severe viral infection was also found in Mississippi silverside and juvenile delta smelt collected from Suisun Bay during summer 2005. Lastly, preliminary evidence suggests that contaminants and disease may impair survival of age-0 striped bass. Baxter *et al.* 2008 found high occurrence and severity of parasitic infections, inflammatory conditions, and muscle degeneration in young striped bass collected in 2005; levels were lower in 2006. Several biomarkers of contaminant exposure including P450 activity (i.e., detoxification enzymes in liver), acetylcholinesterase activity (i.e., enzyme activity in brain), and vitellogenin induction (i.e., presence of egg yolk protein in blood of males) were also reported from striped bass collected in 2006 (Ostrach 2008).

Delta smelt can also be exposed to other toxic substances. Recent toxicological research has provided dose-response curves for several contaminants (Connon *et al.* 2009; 2011). This research has also shown that gene expression changes and impairment of delta smelt swimming performance occur at contaminant concentrations lower than levels that cause mortality.

Climate Change: Climate change is likely already impacting the delta smelt. Climate change may affect the delta smelt directly by creating physiological stress, the primary impacts of climate change on the species are expected to be through changes in the availability and distribution of delta smelt habitat.

The terms "climate" and "climate change" are defined by the Intergovernmental Panel on Climate Change (IPCC). The term "climate" refers to the mean and variability of different types of weather conditions over time, with 30 years of being a typical period for such measurements (IPCC 2013a). The term "climate change" thus refers to a change in the mean or variability of one or more measures of climate (for example, temperature or precipitation) that persists for an extended period, whether the change is due to natural variability or human activity (IPCC 2013a). Scientific measurements spanning several decades demonstrate that changes in climate are occurring, and that the rate of change has increased since the 1950s. Examples include warming of the global climate system, and substantial increases in precipitation in some regions of the world and decreases in other regions.

Scientific measurements spanning several decades demonstrate that changes in climate are occurring, and that the rate of change has increased since the 1950s. Examples include warming of the global climate system, and substantial increases in precipitation in some regions of the world and decreases in other regions (for these and other examples, see Solomon *et al.* 2007;; IPCC 2013b;; IPCC 2014). Results of scientific analyses presented by the IPCC show that most of the observed increase in global average temperature since the mid-20th century cannot be explained by natural variability in climate and is "very likely" (defined by the IPCC as 90 percent or higher probability) due to the observed increase in greenhouse gas (GHG) concentrations in the atmosphere as a result of human activities, particularly carbon dioxide emissions from use of fossil fuels (Solomon *et al.* 2007; IPCC 2013b). Further confirmation of the role of GHGs comes from analyses by Huber and Knutti (2011), whom concluded it is extremely likely that approximately 75 percent of global warming since 1950 has been caused by human activities.

Scientists use a variety of climate models, which include consideration of natural processes and variability, as well as various scenarios of potential levels and timing of GHG emissions, to evaluate the causes of changes already observed and to project future changes in temperature and other climate conditions (Meehl *et al.* 2007, entire; Ganguly *et al.* 2009; Prinn *et al.* 2011). All combinations of models and emissions scenarios yield very similar projections of increases in the most common measure of climate change, average global surface temperature (commonly known as global warming), until about 2030. Although projections of the magnitude and rate of warming differ after about 2030, the overall trajectory of all the projections is one of increasing global warming through the end of this century, even for the projections based on scenarios that assume that GHG emissions will stabilize or decline. Thus, there is strong scientific support for projections that warming will continue through the 21st century, and that the magnitude and rate of change will be influenced substantially by the extent of GHG emissions (Meehl *et al.* 2007; Ganguly *et al.* 2009; Prinn *et al.* 2011; IPCC 2013b). See IPCC 2013b (entire), for a summary of other global projections of climate-related changes, such as frequency of heat waves and changes in precipitation.

Current Drought Conditions and Relative Abundance: California is experiencing its fourth consecutive dry water-year due to low rainfall and low snowpack. On January 17, 2014, the Governor of California declared a State of Emergency due to the drought and directed state officials to take all necessary actions to make water immediately available (Office of the Governor 2014). As of June 2015, the Governor's drought declaration remains in place and the current drought conditions are comparable to the driest years on record in California. The severity of California's drought has been exacerbated by record warm temperatures and below-normal precipitation in 2015, resulting in a severely reduced snowpack. During the last two years, Federal and state governments (Bureau of Reclamation and California Department of Water Resources) have taken actions to ensure the reduced water quality and supply does not reach a level of concern for human health and safety, while complying with biological opinions. The actions taken include the 2015 placement of a salinity rock barrier on West False River and numerous Temporary Urgency Change Orders to modify requirements under Decision 1641 to meet certain water quality objectives, reduction of river flows caused by low reservoir storage, and river temperature requirements.

Drought conditions and some drought management actions have decreased suitable and available aquatic habitat in the Delta for delta smelt breeding and survival, thereby reducing the overall population in the Delta. Fish surveys indicate that the relative abundance of delta smelt is very low. In the last five years, the FMWT, TNS, and 20mm survey results have produced some of the lowest adult and larval delta smelt abundance indexes on record (CDFW 2013, 2014, 2015). The 2014 FMWT abundance index which determines the relative population status for the delta smelt was set at 9, which is the lowest index on record. The low index numbers and relatively few occurrences represent the additive impact of drought to the delta smelt and its habitat.

Status of the Delta Smelt Critical Habitat

The Service designated critical habitat for the delta smelt on December 19, 1994 (Service 1994). The geographic area encompassed by the designation includes all water and all submerged lands below ordinary high water and the entire water column bounded by and contained in Suisun Bay (including the contiguous Grizzly and Honker Bays); the length of Goodyear, Suisun, Cutoff, First Mallard (Spring Branch), and Montezuma sloughs; and the existing contiguous waters contained within the legal Delta (as defined in section 12220 of the California Water Code) (Service 1994).

Conservation Role of Delta Smelt Critical Habitat

The Service's primary objective in designating critical habitat was to identify the key components of delta smelt habitat that support successful spawning, larval and juvenile transport, rearing, and adult migration. Delta smelt are endemic to the Bay-Delta and the vast majority only live one year. Thus, regardless of annual hydrology, the Delta must provide suitable habitat all year, every year. Different regions of the Delta provide different habitat conditions for different life stages, but those habitat conditions must be present when needed, and have sufficient connectivity to provide migratory pathways and the flow of energy, materials and organisms among the habitat components. The entire Delta and Suisun Bay are designated as critical habitat; over the course of a year, the entire habitat is occupied.

Description of the Primary Constituent Elements

In designating critical habitat for the delta smelt, the Service identified the following primary constituent elements (PCEs) essential to the conservation of the species:

Primary Constituent Element 1: "Physical habitat" is defined as the structural components of habitat. Because delta smelt is a pelagic fish, spawning substrate is the only known important structural component of habitat. It is possible that depth variation is an important structural characteristic of pelagic habitat that helps fish maintain position within the estuary's low-salinity zone (LSZ) (Bennett *et al.* 2002, Hobbs *et al.* 2006).

Primary Constituent Element 2: "Water" is defined as water of suitable quality to support various delta smelt life stages with the abiotic elements that allow for survival and reproduction. Delta smelt inhabit open waters of the Delta and Suisun Bay. Certain conditions of temperature, turbidity, and food availability characterize suitable pelagic habitat for delta smelt. Factors such as high entrainment risk and contaminant exposure can degrade this PCE even when the basic water quality is consistent with suitable habitat.

Primary Constituent Element 3: "River flow" is defined as transport flow to facilitate spawning migrations and transport of offspring to LSZ rearing habitats. River flow includes both inflow to and outflow from the Delta, both of which influence the movement of migrating adult, larval, and juvenile delta smelt. Inflow, outflow, and Old and Middle Rivers flow influence the vulnerability of delta smelt larvae, juveniles, and adults to entrainment at Banks and Jones. River flow interacts with the fourth primary constituent element, salinity, by influencing the extent and location of the highly productive LSZ where delta smelt rear.

Primary Constituent Element 4: "Salinity" is defined as the LSZ nursery habitat. The LSZ is where freshwater transitions into brackish water; the LSZ is defined as 0.5-6.0 psu (parts per thousand salinity) (Kimmerer 2004). The 2 psu isohaline is a specific point within the LSZ where the average daily salinity at the bottom of the water is 2 psu (Jassby *et al.* 1995). By local convention the location of the LSZ is described in terms of the distance from the 2 psu isohaline to the Golden Gate Bridge (X2); X2 is an indicator of habitat suitability for many San Francisco Estuary organisms and is associated with variance in abundance of diverse components of the ecosystem (Jassby *et al.* 1995, Kimmerer 2002a). The LSZ expands and moves downstream when river flows into the estuary are high. Similarly, it contracts and moves upstream when river flows are low. During the past 40 years, monthly average X2 has varied from San Pablo Bay (45 kilometers) to as far upstream as Rio Vista on the Sacramento River (95 kilometers). At all times of year, the location of X2 influences both the area and quality of habitat available for delta smelt to successfully complete their life cycle. In general, delta smelt habitat quality and surface area are greater when X2 is located in Suisun Bay. Both habitat quality and quantity diminish the more frequently and further the LSZ moves upstream, toward the confluence.

Overview of Delta Smelt Habitat Requirements and the Primary Constituent Elements

Delta smelt live their entire lives in the tidally-influenced fresh- and brackish waters of the San Francisco Estuary (Moyle 2002). Delta smelt are an open-water, or pelagic, species. They do not associate strongly with structure. They may use nearshore habitats for spawning (PCE #1), but free-swimming life stages mainly occupy offshore waters (PCE #2). Thus, the distribution of the population is strongly influenced by river flows through the estuary (PCE #3) because the quantity of fresh water flowing through the estuary changes the amount and location of suitable low-salinity, open-water habitat (PCE #4). This is true for all life stages. During periods of high river flow into the estuary, delta smelt distribution can transiently extend as far west as the Napa River and San Pablo Bay. Delta smelt distribution is highly constricted near the Sacramento-San Joaquin river confluence during periods of low river flow into the estuary (Feyrer *et al.* 2007). In the 1994 designation of critical habitat, the best available science held that the delta smelt population was responding to variation in spring X2.

Alterations to Estuarine Bathymetry (PCE # 1) (~ 1850-present)

The first major change in the LSZ was the conversion of the landscape over which tides oscillate and river flows vary (Nichols *et al.* 1986). The ancestral Delta was a large tidal marsh-floodplain habitat totaling approximately 300,000 acres. Most of the wetlands were diked and reclaimed for agriculture or other human use by the 1920s. The physical habitat modifications of the Delta and Suisun Bay were mostly due to land reclamation and urbanization. Water conveyance projects and river channelization have had some influence on the regional physical habitat by armoring levees with riprap, building conveyance channels like the Delta Cross Channel, storage reservoirs like Clifton Court Forebay, and by building and operating temporary barriers in the south Delta and permanent gates and water distribution systems in Suisun Marsh.

In the 1930s to 1960s, the shipping channels were dredged deeper (~12 m) to accommodate shipping traffic from the Pacific Ocean and San Francisco Bay to ports in Sacramento and Stockton. These changes left Suisun Bay and the Sacramento-San Joaquin river confluence region as the largest and most bathymetrically variable places in the LSZ. This region remained a highly productive nursery for many decades (Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995). However, the deeper landscape created to support shipping and flood control requires more freshwater outflow to maintain the LSZ in the large Suisun Bay/river confluence region than was once required (Gartrell 2010).

Seasonal salinity intrusion reduces the temporal overlap of the LSZ (indexed by X2) with the Suisun Bay region, especially in the fall (Feyrer *et al.* 2007, 2010). Thus, the second major change has been in the frequency with which the LSZ is maintained in Suisun Bay for any given amount of precipitation. This metric showed a step-decline in 1977 from which it has never recovered for more than a few years at a time. Based on model forecasts of climate change and water demand, this trend is expected to continue (Feyrer *et al.* 2011). As such this alteration of PCE # 1 also affects the other PCEs, particularly PCE # 4. The major landscape factor affecting this interaction was the dredging of shipping channels.

Spawning delta smelt require all four PCEs, but spawners and embryos are the life stage that is believed to most require a specific structural component of habitat. Spawning delta smelt require sandy or small gravel substrates for egg deposition (Bennett 2005). The major invasive species effect on physical habitat is the dense growth of submerged aquatic vegetation in the Delta. These plants carpet large areas in parts of the Delta such as Frank's Tract. The vegetation beds act as mechanical filters removing turbidity and possibly other water quality components as the tides and river flows move water over them (Hestir 2010). Thus, the proliferation of submerged aquatic plants has likely also reduced the area of nearshore habitat suitable for delta smelt spawning.

Alterations to Water (PCE # 2)

PCE # 2 is primarily referring to a few key water quality components (other than salinity) that influence spawning and rearing habitat suitability for delta smelt. Research to date indicates that water quality conditions are more important than physical habitat conditions for predicting where delta smelt occur (Feyrer *et al.* 2007; Nobriga *et al.* 2008) probably because delta smelt is a pelagic fish except during its egg/embryo stage. However, the interaction of water quality and bathymetry is thought to generally affect estuarine habitat suitability (Peterson 2003) and there is evidence that delta smelt habitat is optimized when appropriate water quality conditions overlap the Suisun Bay region (Moyle *et al.* 1992; Hobbs *et al.* 2006; Feyrer *et al.* 2011). This is discussed further in the section about PCE # 4 (salinity).

Changing predation pressure (1879 to present): Noting is known about the historical predators of delta smelt or their possible influence on delta smelt. Fish eggs and larvae can be opportunistically preyed upon by many invertebrate and vertebrate animals so there has always been a very long list of potential predators of delta smelt's eggs and larvae. Potential native predators of juvenile and adult delta smelt would also have included numerous bird and fish species and this may be reflected in delta smelt's annual life-history. Annual fish species, also known as "opportunistic strategists", are adapted to high mortality rates in the adult stage (Winemiller and Rose 1992). This high mortality is usually due to predation or highly unpredictable environmental conditions, both of which could have characterized the ancestral niche of delta smelt.

The introduction of striped bass into the San Francisco Estuary in 1879 added a permanently resident, large piscivorous fish to the low-salinity zone: a habitat that is not known to have had an equivalent predator prior to the establishment of striped bass (Moyle 2002). This likely changed predation rates on delta smelt, but there are no data available to confirm this hypothesis. For many decades the estuary supported higher striped bass and delta smelt numbers than it does currently. This is evidence that delta smelt is able to successfully coexist with striped bass.

The current influence of striped bass and other predators on delta smelt population dynamics is also not known mainly because quantitative descriptions of predator impacts on rare prey are extremely difficult to generate. Delta smelt were observed in the stomach contents of striped bass and other fishes in the 1960s (Stevens 1963; Turner and Kelley 1966), but have not been observed in more recent studies (Feyrer *et al.* 2003; Nobriga and Feyrer 2007). Predation is a common source of density-dependent mortality in fish populations (Rose *et al.* 2001). Thus, it is possible that predation was a mechanism that historically generated the density-dependence observed in delta smelt population dynamics (Bennett 2005; Maunder and Deriso 2011). Because it is generally true for fishes, the vulnerability of delta smelt to predators is influenced primarily by habitat conditions. Turbidity may be a key mediatory of delta smelt's vulnerability to predators (Nobriga *et al.* 2005; 2008). Growth rates, an interactive outcome of feeding success and water temperature, are also well known to affect fishes' cumulative vulnerability to predation (Sogard 1997). Thus, predation rate is best characterized as an aspect food web function linked to PCE # 2.

Food web alterations attributable to the overbite clam (1987-present): The next major change to PCE #2 occurred following the invasion of the estuary by overbite clam (*Corbula amurensis*). The overbite clam was first detected in 1986 and from 1987-1990 its influence on the ecosystem became evident. Since 1987, there has been a step-decline in phytoplankton biomass (Alpine and Cloern 1992; Jassby *et al.* 2002). Phytoplankton in the LSZ is an important component of the pelagic food web that delta smelt are a part of because a key part of the diet of delta smelt's prey is phytoplankton. Not only does the overbite clam reduce food for delta smelt's prey, it can also graze directly on the larval stages of the copepods eaten by delta smelt (e.g., Kimmerer *et al.* 1994). The grazing pressure applied by the overbite clam rippled through the historical zooplankton community that fueled fishery production in the LSZ (Kimmerer and Orsi 1996; Orsi and Mecum 1996; Kimmerer 2002b; Feyrer *et al.* 2003). This major change in the way energy moved through the ecosystem has likely facilitated the numerous invasions of the estuary by suppressing the production of historically dominant zooplankton, which increases the opportunity for invasion by other species that are less dependent on high densities of LSZ phytoplankton.

The distribution and abundance of several LSZ fishes have changed since 1987 (Kimmerer 2002b; Kimmereer 2006; Rosenfield and Baxter 2007; Mac Nally *et al.* 2010). Surprisingly, the changes in phytoplankton and zooplankton production have not been as evident for delta smelt as for other organisms (Kimmer 2002b; Kimmerer 2006; Sommer *et al.* 2007; Mac Nally *et al.* 2010). Nonetheless, delta smelt collected in the FMWT have been persistently smaller since the overbite clam invasion (Sweetnam 1999; Bennett 2005). This is evidence for reduced growth rates that could have been caused by food web changes stemming from overbite clam grazing. The Service considers the prey density aspect of the estuarine food web to be a component of PCE #3 ("Water"). The Central Valley Project and State Water Project entrain some food web production (about 4.5 percent on a daily average basis was attributed to all water diversions in the Delta; Jassby *et al.* 2002). However, prey densities have been most strongly affected by clam grazing (Kimmerer *et al.* 1994; Jassby *et al.* 2002). Urban wastewater input, *Microcystis* blooms, and pesticide loads may also impair the production of zooplankton eaten by delta smelt or eaten by delta smelt's prey (Wilkerson *et al.* 2006; Dugdale *et al.* 2007; Jassby 2008; Ger *et al.* 2009; Werner *et al.* 2010).

Proliferation of submerged aquatic vegetation (1980s to present): For many decades, the Delta's waterways were turbid and the growth of submerged plants was apparently unremarkable. That began to change in the mid-1980s, when the Delta was invaded by non-native plant *Egeria densa*, a fast-growing aquarium plant that has taken hold in many shallow habitats (Brown and Michnuik 2007; Hestir 2010). *Egeria densa* and other non-native species of submerged aquatic vegetation (SAV) grow most rapidly in the summer and late fall when water temperatures are warm (>20°C) and outflow is relatively low (Hestir 2010). The large canopies formed by these plants have physical and biological consequences for the ecosystem (Kimmerer *et al.* 2008). First, dense SAV promotes water transparency. Increased water transparency leads to a loss of habitat for delta smelt (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Second, dense SAV canopies provide habitat for a suite of non-native fishes, including largemouth bass, which now dominate many shallow habitats of the Delta and displace native fishes (Nobriga *et al.* 2005; Brown and Michniuk 2007). Finally, SAV colonization over the last three decades has led to a shift in the dominant freshwater food web pathways and that fuel fish production (Grimaldo *et al.* 2009b). It is noteworthy that SAV-dominated habitats are comparatively productive (Nobriga *et al.* 2005; Grimaldo *et al.* 2009b), but most of the productivity they generate remains in the nearshore environment and therefore does not contribute much to pelagic fish production (Grimaldo *et al.* 2009b).

Reduced turbidity (1999-present): The next major change was a change in estuarine turbidity that culminated in an estuary-wide step-decline in 1999 (Schoellhamer 2011). For decades, the turbidity of the modified estuary had been sustained by very large sediment deposits resulting mainly from gold mining in the latter 19th century. The sediments continued to accumulate into the mid-20th century, keeping the water relatively turbid even as sediment loads from the Sacramento River basin declined due to dam and levee construction (Wright and Schoellhamer 2004). The flushing of the sediment deposits may also have made the estuary deeper overall and thus a less suitable nursery from the 'static' bathymetric perspective (Schroeter 2008). Delta smelt larvae require turbidity to initiate feeding (Baskerville-Bridges *et al.* 2004), and as explained above, older fish are thought to use turbidity as cover from predators. Thus, turbidity is an aspect of PCE # 2 which is a necessary water quality aspect of delta smelt's critical habitat.

Dams and armored levees have contributed to the long-term decline in sediment load to the estuary (Wright and Schoellhamer 2004) and to the clearing of estuary water. This is a long-term effect that stemmed from building and maintaining infrastructure. Opportunities to substantively address this change are limited due to the extreme Central Valley flood and water supply risks that will result from decommissioning dams or removing levees.

Changing water temperature (present through long-term climate forecasts): Delta smelt is already subjected to thermally stressful temperatures every summer in the Delta. Water temperatures are presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding the nominal lethal limit of 25°C for short periods. Coldwater fishes begin to have behavioral impairments (Marine and Cech 2004) and lose competitive abilities (Taniguchi *et al.* 1998) prior to reaching their thermal tolerance limits. Thus, the estuary can already be considered thermally stressful to delta smelt and can only become more so if temperatures warm in the coming decades.

All available regional climate change projections predict central California will be warmer still in the coming decades (Dettinger 2005). It is expected that warmer estuary temperatures will be yet another significant conservation challenge (Brown *et al.* 2013; Cloern *et al.* 2011). This is true because they will limit abiotic habitat suitability further than indicated by flow-based projection (e.g., Feyrer *et al.* 2011). In addition, warmer water temperatures mean that higher prey densities will be required just to maintain present-day growth rates, which are already lower than they once were (Sweetnam 1999; Bennett 2005). Water temperature is mainly affected by climate variation, both as air temperature and as flood and drought scale flow variation (Kimmer 2004; Wagner *et al.* 2011).

Sensitivities to contaminants (ongoing): Delta smelt's spawning migration coincides with early winter rains (Sommer *et al.* 2011). This 'first-flush' of inflow to the Delta brings sediment-bound pesticides with it (Bergamaschi *et al.* 2001), and peak densities of larvae and juveniles can co-occur with numerous pesticides (Kuivila and Moon 2004). Bennett (2005) reported that about 10 percent of the delta smelt analyzed for histopathological anomalies in 1999-2000 showed evidence of deleterious contaminant exposure, but this was low compared to the 30-60 percent of these fish that appeared to be food-limited.

Delta smelt can also be exposed to other toxic substances. Recent toxicological research has provided dose-response curves for several contaminants (Connon *et al.* 2009; 2011). This research has also shown the gene expression changes and impairment of delta smelt swimming performance occur at contaminant concentrations lower than levels that cause mortality. Climate scale flow variation (e.g., flood versus drought scale variation) affects the amount of methyl mercury (Darryl Slotton presentation) entering the ecosystem and may have some influence on the meaningful dilution of ammonium from urban wastewater inputs (Dick Dugdale presentation).

Invasive species may also affect PCE #2 by changing contaminant dynamics. For instance, *Microcystis* blooms generate toxic compounds that can kill delta smelt prey (Ger *et al.* 2009) and accumulate in the estuarine food web (Lehman *et al.* 2010). A second example is the biomagnification of selenium in the food web by *Corbula* (Stewart *et al.* 2004). This has been considered a potential issue for the clam's predators – namely sturgeon, splittail, and diving ducks (Richman and Lovvorn 2004; Stewart *et al.* 2004). However, it is not known whether this change in selenium dynamics negatively affects delta smelt and other fishes that do not directly prey on the clams.

Alterations of River Flows (PCE # 3)

This PCE refers to the transport flows that help guide young delta smelt from spawning habitats to rearing habitats, and to flows that guide adult delta smelt from rearing habitats to spawning habitats. Delta outflow also has some influence on delta smelt's supporting food web (Jassby *et al.* 2002; Kimmerer 2002a) and it affects abiotic habitat suitability as well (Feyrer *et al.* 2007; 2011). The latter is expanded upon in the discussion of PCE # 4. The environmental driver with the strongest influence on PCE # 3 is highly dependent on the time-scale being considered. The tide has the largest influence on flow velocities and directions in delta smelt's critical habitat at very short timescales (minutes to days), whereas interannual variation in precipitation and runoff has the largest influence on flows into and through the Delta at very long timescales (years to decades), and sometimes at shorter time scales (days to weeks) during major storm events. Changes to flow regimes can have the largest influence on PCE #3 at timescales of weeks to seasons. This is particularly true during periods of low natural inflow, for instance during the fall and during droughts, and in the south Delta where Old and Middle River flows are often managed using changes in export flow rates.

Entrainment into water export diversions (1951 to present): The amount of water diverted from the estuary has generally increased over time, and most of the increase during the 1950s and 1960s was due to CVP exports and since the latter 1960s, SWP exports. There are two basic potential fishery impacts that result from water diversion from the Delta: ecosystemic impacts and direct entrainment. From the ecosystemic perspective, water diversions are unnatural 'predators' because they 'consume' organisms at every trophic level in the ecosystem from phytoplankton (Jassby *et al.* 2002) to fish (Kimmerer 2008). Unlike natural predators which typically shift their prey use over time in association with changes in prey fish density (Nobriga and Feyrer 2008), fractional entrainment losses of fishes to diversions are functions of water and demand (e.g., Grimaldo *et al.* 2009). Thus, water diversions not only elevate 'predation' mortality in an aquatic system, but they can do so in an atypical, density-independent manner. Diversions and fish collection facilities in the south Delta are very large structures which attract large aggregations of actual predatory fish and prey on smaller species like delta smelt before they reach the fish salvage facilities and within these facilities (Gingras 1997).

Estimated entrainment losses of delta smelt to SWP and CVP diversions can be substantial in some years (Kimmerer 2008). Given the delta smelt's current density-independent population dynamics, even a statistically indiscernible entrainment effect on the population is likely to cause the species to continue to decline (Kimmerer 2011). The entrainment losses of delta smelt are not generally observed until they reach the early juvenile stage (~20-30 mm in length), but combinations of 20-mm Survey distribution data and hydrodynamic modeling provide evidence that their risk of entrainment into the CVP and SWP diversions can be described by any of several indices that integrate Delta inflow and export flow (Kimmerer and Nobriga 2008; Kimmerer 2008; Service 2008; Grimaldo *et al.* 2009).

Delta smelt entrainment losses estimated from survey data and hydrodynamics can also be substantial in some years (Kimmerer 2008), though it is possible that Kimmerer may have overestimated them (Miller 2011). Nonetheless, increasing higher outflow (or lower X2) moves the bulk of the larval population increasingly west, which results in fewer larvae distributed in the south Delta where they are at highest risk of entrainment. At the same time, indices like the export to inflow ratio or Old and Middle river flow are useful metrics for gauging the effect of exports on the south Delta.

The risk of delta smelt entrainment into smaller agricultural irrigation diversions used mainly to irrigate crops within the Delta is also related to flow conditions. These in-Delta irrigation diversions generally have mean flow rates less than 1 cubic meter per second (Nobriga *et al.* 2004). The lower the Delta outflow, the higher the proportion of the young delta smelt population that overlaps the array of irrigation diversions in the Delta (Kimmerer and Nobriga 2008). However, the irrigation diversions are not currently considered to represent a substantial source of mortality because they individually draw small quantities of water relative to channel volumes (Nobriga *et al.* 2004).

In Suisun Marsh, water diversions are largely made to support waterfowl production. Some Suisun Marsh diversions are larger for the size of channels they are in than most of the agricultural irrigation diversions in the Delta. Based on hydrodynamic simulations, proximity to water diversions in the marsh is expected to correlate strongly with entrainment (Culberson *et al.* 2004), and substantial delta smelt losses have been reported when these diversions are not screened (Pickard *et al.* 1982). Entrainment risk for delta smelt in western Suisun Marsh is considered low because the habitat surrounding the diversions is often too saline (Enos *et al.* 2007).
Salinity PCE # 4

The core delta smelt habitat, is the LSZ (Moyle *et al.* 1992; Bennett 2005). The LSZ is where freshwater transitions into brackish water; the LSZ is defined as the area of the estuary where salinity ranges from 0.5-6.0 psu (Kimmerer 2004). This area is always moving due to tidal and river flow variation. The 2 psu isohaline is a specific location within the LSZ where the average daily salinity at the bottom of the water is 2 psu (Jassby *et al.* 1995). By local convention, changes in the location of the LSZ are described in terms of the distance from the Golden Gate Bridge to the 2 psu isohaline (X2); X2 is an indicator of habitat suitability for many of the estuary's organisms and it is associated with variance in abundance of diverse components of the ecosystem (Jassby *et al.* 1995; Kimmerer 2002b; Kimmerer *et al.* 2009). The LSZ expands and moves downstream when river flows into the estuary are high (Kimmerer *et al.* 2009). Similarly, it contracts and moves upstream when river flows are low. During the past 40 years, monthly average X2 has varied from as far downstream of San Pablo Bay (45 km) to as far upstream as Rio Vista on the Sacramento River (95 km).

Larval delta smelt tend to reside somewhat landward (upstream) of X2 (Dege and Brown 2004), but the center of juvenile distribution tends to be very near X2 until the fish start making spawning migrations in the winter (Feyrer *et al.* 2011; Sommer *et al.* 2011). Because of this association between the distribution of salinity in the estuary and the distribution of the delta smelt population, the tidal and river flows that comprise PCE # 3 affect PCE # 4.

The expansion and contraction of the LSZ affects the areal extent of abiotic habitat for delta smelt, both during spring (Kimmerer *et al.* 2009) and fall (Feyrer *et al.* 2007; 2011). In the spring, most delta smelt are larvae or young juveniles and the LSZ is typically maintained over the expansive Suisun Bay region. Thus, abiotic habitat "limitation" is unlikely and no consistent influence of spring X2 variation on later stage abundance estimates has been reported to date (Jassby *et al.* 1995; Bennett 2005; Kimmerer *et al.* 2009). In fact, historical maxima in juvenile abundance according to CDFW's TNS occurred in low outflow years when abiotic habitat area was comparatively low (Kimmerer 2002a; Kimmerer *et al.* 2009).

In contrast, during fall delta smelt are late stage juveniles and for the past decade or more, the LSZ has been persistently constricted by low Delta outflow. Fall habitat conditions affect delta smelt distribution and the concurrent FMWT abundance index (Feyrer *et al.* 2007; 2011). However, the quantitative life cycle models developed to date have not found evidence for a year over year effect of fall LSZ location on delta smelt population dynamics (Mac Nally *et al.* 2010; Thompson *et al.* 2010; Maunder and Deriso 2011).

It is now recognized that some delta smelt occur year-round in the Cache Slough region including the Sacramento Deep Water Shipping Channel and Liberty Island (Kimmerer 2011; Miller 2011; Sommer *et al.* 2011). The latter has been a consistently available habitat only since 1997. This region is often lower in salinity than 0.6 psu, the lower formal limit of the LSZ as defined by Kimmerer (2004). Delta smelt likely use it because it is one of the most turbid habitats remaining in the Delta (Nobriga *et al.* 2005). A recent population genetic study found no evidence that delta smelt inhabiting this region are unique compared to delta smelt using the LSZ-proper (Fisch *et al.*

2011), therefore it is likely that individual delta smelt migrate between the LSZ and the Cache Slough region. This is consistent with the high summer water temperatures observed there, which might compel individual delta smelt to seek out cooler habitats within and outside the Cache Slough region.

Delta Smelt Environmental Baseline

The portions of the Action Area that fall within the range of delta smelt include the Sacramento River east levee, south of Sacramento and the Sacramento Weir. Delta smelt typically migrate up into this area as early as December and move out in the spring and summer. The proposed project contains habitat components that can be used for feeding, spawning, rearing, and movement. Some amount of erosion protection has already occurred within the action area. Additionally, the Corps has a project which will place rock along 31,000 linear feet of the right bank of the Sacramento River immediately across the river and extending upstream from the proposed project footprint. Compensation for the placement of this rock will be through the development of a setback levee that will provide 118 acres of newly created shallow water habitat.

Giant Garter Snake Status of the Species

For the most recent assessment of the species' range-wide status please refer to the *Giant Garter Snake (Thamnophis gigas) 5-year Review: Summary and Evaluation* (Service 2012) for the current status of the species. Ongoing threats to giant garter snake include habitat loss from water transfers, rice fallowing due to drought conditions, habitat disturbance and loss from irrigation and drainage ditch maintenance, climate change, and invasive species. While these threats continue to effect the giant garter snake throughout its range, to date no project has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the giant garter snake.

Giant Garter Snake Environmental Baseline

The *Draft Recovery Plan for the Giant Garter Snake* (Service 1999b) subdivides the range of the species into four recovery units. Each recovery unit includes populations. The action area for the proposed project is located within the Yolo Basin-Willow Slough unit and the American Basin unit. According to the 2012, 5-year review (Service 2012) the abundance and distribution of giant garter snakes has not changed significantly. Within the Action Area habitat loss and fragmentation is the most significant threat to the giant garter snake. Urbanizing areas within the Action Area include Sacramento and West Sacramento. Habitat loss through water transfers and rice fallowing also negatively affects giant garter snakes. In the Sacramento Valley, rice has served as a substitute for the large amounts of historical wetlands that used to exist in the Central Valley. Loss of this habitat has been shown to reduce or exclude giant garter snakes compared to areas which are actively irrigated in rice (Wylie *et al.* 2002a, b, 2004).

Flood control maintenance and agricultural activities can reduce and prevent the establishment of vegetation and burrows needed by the giant garter snake for cover and shelter on canals, levees, and agricultural ditches. This can also reduce the prey base for giant garter snake, affecting their feeding. Additionally, clearing, scraping and/or re-contouring canals, ditches, and levees, destroys burrows and crevices that are used as over-wintering habitat and during the summer for thermoregulation, shedding, and giving birth. These activities are being conducted by local maintaining agencies throughout the Action Area.

Other factors which effect the giant garter snake population in the Action Area include vehicular mortality particularly where canals or aquatic habitat are bordered by roads such as the crown of the levees. Non-native predators such as game fish, bull frogs (*Rana catesbiana*), and domestic cats can affect giant garter snake populations (Service 1999b). This can be particularly detrimental to young and juvenile giant garter snakes. All of the Action Area has non-native predators occurring in it.

Snakes have been located within the Yolo Bypass within 2 miles of the Sacramento Bypass. Numerous irrigation and drainage canals exist which provide connectivity from the Sacramento Bypass and areas that are known to support snakes in the Yolo Bypass. A snake observed 0.5 mile to the west of the NEMDC along Elkhorn Boulevard in 1996 (CNDDB 2015). Borrow site 2's northern boundary is Elkhorn Boulevard on the east side of the NEMDC. Giant garter snakes could be using the NEMDC for aquatic habitat and the surrounding grasslands for uplands.

Western Yellow-Billed Cuckoo Status of the Species

For the most recent assessment of the species range-wide status please refer to the October 3, 2014, *Determination of Threatened Status for the Western Distinct Population Segment of the Yellow-billed Cuckoo (Coccyzus americanus occidentalis)* (79 FR 59991). Ongoing threats to the yellow-billed cuckoo include habitat loss from flood control projects and maintenance, alterations to hydrology, climate change, and invasive species. While these threats continue to affect the yellow-billed cuckoo throughout its range, no project, to date, has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the yellow-billed cuckoo.

Western Yellow-Billed Cuckoo Baseline

Yellow-billed cuckoo detections have occurred most frequently in the upper Sacramento River where levees are setback from the river or do not exist. Additionally, the last 20 years has seen a large amount of riparian restoration occur in the upper Sacramento River. Habitat in the action area tends to be more narrow and linear than in the upper Sacramento River. Levees were constructed close to the bank of the Sacramento River leaving narrow bands of small patch sizes. Construction of the setback levee along the right bank of the Sacramento River as part of the West Sacramento Flood Control Project will provide some wider patches of riparian habitat that will benefit the yellow-billed cuckoo. The American River has a wider floodplain due to levees being setback from the channel. There are some patches large enough to support nesting yellow-billed cuckoos, though cuckoos have not been observed nesting along the American River.

Effects of the Proposed Action

Valley Elderberry Longhorn Beetle

Vegetation removal, including elderberries could cause mortality of any beetle larvae within the elderberry shrub. Transplanting the shrubs between November 1 and February 15, when the shrubs are dormant, will minimize the likelihood of killing larvae within the shrub. Transplanting the shrub could still result in mortality to larvae within the shrub, particularly if the shrub does not survive transplantation. Proper care of the transplants through watering in the initial years can minimize this loss and increase the likelihood that the shrub will survive and provide continued habitat for the valley elderberry longhorn beetle.

Construction that occurs near elderberry shrubs that will be protected in place can kill adult beetles if construction equipment is operating between the months of March and June when valley elderberry longhorn beetles have emerged from the elderberry shrubs and are locating mates for reproduction. Fencing the area which contains riparian habitat, specifically elderberry shrubs, and keeping a minimum of a 20 foot buffer from the dripline of the elderberry shrub will keep construction equipment from driving too close to the shrubs and minimize the number of beetles that might be struck or run over by equipment.

Transplanting elderberry shrubs out of the construction footprint has the potential to affect valley elderberry longhorn beetle dispersal if there is potential to remove large areas of elderberry shrubs. The Corps has provided maps of where existing valley elderberry longhorn beetle habitat exists and where shrubs will be removed due to the project. Along the Sacramento River, 13 elderberry shrubs distributed within 70 acres of riparian habitat will be transplanted as part of the project, however during surveys the Corps has documented an additional 60 elderberry shrubs that will be protected in place along the Sacramento River. The Corps has also proposed to include elderberry shrub plantings along the bank repair footprint where the elevation is suitable so the shrubs are not inundated too frequently. Along the American River, 250 elderberry shrubs distributed within 65 acres of riparian habitat will be transplanted as part of the project. The American River has many conservation sites and the Corps has proposed to offset the removal of elderberry shrubs through development of additional sites and enlargement of existing sites in the lower American River Parkway. The Corps is proposing to create an additional 69.91 acres of habitat for the valley elderberry longhorn beetle in the lower American River Parkway.

Trimming of elderberry shrubs can result in the loss of some habitat for the valley elderberry longhorn beetle. Unlike transplantation however, the shrub remains within the riparian corridor and can provide habitat for the beetle during dispersal. There is potential for one of the pruned stems to contain the larvae of the valley elderberry longhorn beetle. While elderberry shrubs do resprout readily, there is a temporal loss of habitat for the beetle and as part of the maintenance any resprouted stems will be removed in order to provide maintenance equipment access. To offset these effects the local maintaining agencies have proposed to create a 40-acre conservation area for the valley elderberry longhorn beetle. This area will be selected as described in the preceding paragraph. This will ensure habitat connectivity and help with long-term maintenance and monitoring of these lands.

Delta Smelt

Construction along the Sacramento River will place bank protection along a 50,300 linear foot section of the left bank of the Sacramento River. Delta smelt are a pelagic species that is typically found in the center of the channel. However, as described in the status of the species they do spawn on sandy beaches in shallow water habitat (0 to 3 meters) and in this portion of the Sacramento River are found close to the banks. The rock footprint will change the substrate along the 50,300 linear feet of 33 acres of shallow water habitat. Additionally 13 acres are being converted from riverine bank edge to a rock wedge. Construction related effects to individual delta smelt will be avoided because construction is occurring between August 1 and November 30, a time when delta smelt are located further downstream in the Delta and Suisun Bay. Effects due to increasing sediment downstream of the work area will be minimized through the conservation measures involving monitoring water quality during construction to ensure that effects do not extend into the portion of the Delta that delta smelt occupies during the late summer/fall period. Construction to widen the Sacramento Weir will occur on the landside of the existing Sacramento River right bank levee. Upon completion of the weir extension the levee removed between August 1 and November 30 avoiding effects to delta smelt habitat.

The primary negative effect of the project on potential spawning habitat is the change of substrate from sand to riprap. Rock used for bank protection is large enough to retard erosional forces of the river and therefore has interstitial spaces. Should delta smelt spawn over this riprap substrate, it is very likely that any eggs will fall into these interstitial spaces resulting in the loss of eggs and potentially causing fertilization to not occur if the eggs fall into the interstitial spaces. The Corps has proposed to offset this loss of spawning potential in these areas through the purchase of 33 acres of credits at a Service-approved delta smelt conservation bank. The placement of rock will permanently narrow the channel by 13 acres through the change of riverine edge to rock wedge. Rock slope protection limits the lateral mobility of a river channel, increases flow velocities (Sedell *et al.* 1990), limit sediment transport, and eliminates bankside refugia areas (Gregory *et al.* 1991). Rock placement can also affect primary productivity through the loss of vegetation. The Corps will protect large trees in place and plant riparian benches at the conclusion of the rock placement to replace the loss of vegetation. Planting benches and vegetation planting will also help to offset the increased velocities that the bank protection sites will experience due to the smoother rock surface. To offset the complete loss of riverine edge habitat the Corps has proposed to purchase 39 acres of credits at a Service-approved delta smelt conservation bank for a total of 72 acres of credits.

The Corps has proposed to evaluate effects to listed species including delta smelt when long-term maintenance activities for the Sacramento River can be described. If maintenance activities will affect delta smelt the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the delta smelt from any long-term levee maintenance activities.

Delta Smelt Critical Habitat

This opinion on the critical habitat for the delta smelt does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 CFR § 402.02. Instead, we have relied upon the statute and the August 6, 2004, Ninth Circuit Court of Appeals decision in *Gifford Pinchot Task Force v. U. S. Fish and Wildlife Service* (No. 03-35279) to complete the following analysis with respect to the proposed critical habitat.

Implementation of the proposed project will affect PCE #1 Physical Habitat as described under the environmental baseline section above. The placement of rock will change the substrate of shallow water habitat for 46 acres. Any loss of shallow water habitat will be compensated through the purchase of credits at a delta smelt conservation bank. It is expected that planting the sites post-construction will replace any loss of primary productivity within the Sacramento River water column.

Giant Garter Snake

Borrow Site 2 – Upland habitat will be disturbed at borrow site 2 (5.5 acres) when heavy equipment is brought in to remove soil for the Arcade Creek levee repair. Removal of soil from the site will result in the crushing of burrows that snakes use for aestivating and thermoregulation. Fencing the borrow site prior to borrow excavation will minimize the likelihood that snakes will be in the borrow site when construction equipment begins to mobilize. Fencing the site will temporarily (one active season) exclude the use of the area for giant garter snake. This could result in snakes having to move further distances to find upland refugia in the summer months and expose them to predation or other sources of mortality such as being run over by a vehicle on the levee road on the opposite side of the NEMDC. Because the aquatic habitat will not be disturbed by the project, there will not be any effects on the snake's ability to forage.

Upon completion of the project, the site will restored and re-graded to create three habitat types. The creation of additional tule marsh along the edge of the canal will benefit giant garter snakes that may be using the NEMDC as it will provide cover, an area for prey production, and refugia from predators. Additionally, the seasonal wetland bench will only provide aquatic habitat in the winter months when the snake is typically in burrows. The wetland bench will provide some upland habitat for the giant garter snake during the summer when the snake is active in the form of basking habitat and if dried wetland vegetation remains some refugia from predators; however, because the site will be flooded in the winter it will not serve as overwintering habitat for the snake. The remaining 3.5 acres of the borrow site will be restored to native grassland and will function as summer upland refugia and basking and in the winter serve as overwintering habitat for the snake.

Sacramento Bypass – Enlarging the Sacramento Bypass and Weir will result in both permanent and temporary effects to giant garter snake habitat. Construction of the widened bypass will have similar effects to giant garter snake as the work along borrow site 2. Snakes could be crushed by heavy equipment, entombed in refugia when burrows collapse, and exposed to increased predation because they may have to travel further to find habitat that is unavailable to them due to the project. The 25 acres of aquatic habitat and 50 acres of upland habitat that will be temporarily affected because of the relocation of a levee toe drain will be replaced within one year of construction. The Corps has committed to creating a toe drain that closely mimics the existing aquatic and upland habitat along the northern levee of the Sacramento Bypass. The effects of crushing snakes and exposing them to increased predation will be minimized through the use of the conservation measures described in the project description above.

Permanently, 15 acres of aquatic and 30 acres of upland habitat will be lost through the removal of drainage ditches and farm canals in the area that is currently outside of the bypass footprint. The Corps has committed to offsetting the loss of this habitat through the purchase of 135 acres of giant garter snake credits at a Service-approved conservation bank. Conservation banks provide protection, conservation easement, and funding, endowment, in perpetuity for the giant garter snake. These long-term protections and location of the conservation banks all contribute to the long-term recovery of the giant garter snake.

Operation of the expanded Sacramento Weir and Bypass will result in an increase of water surface elevation of approximately 0.5-foot on the levee slopes on either side of the Yolo Bypass. However, when this increase occurs, during a 200-year flood event, the Yolo Bypass levees already contain water up to 21 feet deep. As a result, giant garter snake burrows would likely already be saturated before the additional water associated with the widened Sacramento Bypass is a factor. The additional 0.5-foot resulting from this action would not significantly change the timing or duration of this flooding and would not result in further impacts to giant garter snake habitat.

The Corps has proposed to evaluate effects to listed species including giant garter snake when long-term maintenance activities for the Sacramento Bypass can be described. If maintenance activities will affect giant garter snakes the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the giant garter snake from any long-term levee maintenance activities.

Yellow-Billed Cuckoo

Sacramento River – The Corps is planning on removing 70 acres of riparian habitat along the Sacramento River. The riparian corridor in this section of the Sacramento River is narrow (about 100 feet wide) because the levees were constructed so close to the edge of the channel bank. This is too narrow for the yellow-billed cuckoo to nest, however it is possible for the yellow-billed cuckoo to use this as a stopover when migrating to the Central Valley to breed. Vegetation removal will reduce the width of the riparian corridor from 100 feet to 40 feet on average. The Corps proposal to plant the bank protection sites will create a 25-foot wide planting berm leaving a loss of about 35 feet of riparian corridor. The Corps proposes to offset the loss of the 70 acres of riparian through the creation of 140 acres of riparian habitat along the lower American River.

American River – The construction of launchable rock trench will remove 65 acres of riparian habitat along the lower American River. The lower American River does have habitat patches large enough to support nesting yellow-billed cuckoos. Large patches of habitat will not be removed; rather a strip will be removed adjacent to the levee which could reduce the size of some of the potential nesting areas. To compensate for this the Corps is proposing to plant 130 acres along the lower American River. As described in the conservation measures, the Corps will develop a Riparian Conservation Plan that will determine the best locations to develop additional riparian habitat. The conservation areas will provide both habitat for yellow-billed cuckoo and valley elderberry longhorn. The areas will also ensure that there is a net increase of potential yellow-billed cuckoo nesting habitat along the lower American River Parkway. There will be a temporal loss of habitat because riparian habitat can take up to 20 years to develop.

In addition to the habitat loss for both the Sacramento and American Rivers, construction itself has the potential to adversely affect yellow-billed cuckoos. Construction that occurs when the cuckoo is in the Sacramento Valley has the potential to harass the bird due to noise. To minimize effects to the cuckoo due to construction noise the Corps conservation measure to do protocol level surveys prior to beginning construction will enable the Corps to determine if yellow-billed cuckoos are nesting near the construction footprint. The Corps has committed to avoid construction near an active yellow-billed cuckoo nest. However, cuckoos that could be foraging in the area could be harassed due to construction activities and noise and move to other locations in the lower American River parkway which could expose individual cuckoos to increased predation.

The Corps has proposed to evaluate effects to listed species including yellow-billed cuckoo when long-term maintenance activities for the Sacramento River and American River can be described. If maintenance activities will affect yellow-billed cuckoos the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the yellow-billed cuckoo from any long-term levee maintenance activities.

Cumulative Effects

Cumulative effects include the effects of future State, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

Valley Elderberry Longhorn Beetle

Non-Federal adverse effects to the valley elderberry longhorn beetle include effects from nearby pesticide spraying drifting into valley elderberry longhorn beetle habitat and levee and channel maintenance. In the areas of the urbanized areas of the American and Sacramento Rivers human started fires is by far the largest effect to valley elderberry longhorn beetles. Over the last several years numerous fires have burned portions of the American River Parkway.

Delta Smelt

Adverse effects to delta smelt may result from point and non-point source chemical contaminant discharges within the action area. These contaminants include but are not limited to ammonia and free ammonium ion, numerous pesticides and herbicides from agricultural activities, and oil and gasoline product discharges. Oil and gasoline product discharges may be introduced into the Sacramento River from shipping and boating activities and from urban activities and runoff. Other future, non-Federal actions within the action area that are likely to occur and may adversely affect delta smelt include: the dumping of domestic and industrial garbage that decreases water quality; oil and gas development and production that may affect aquatic habitat and may introduce pollutants into the water; agricultural activities, including burning or removal of vegetation on levees that reduce riparian and wetland habitats that contribute to the quality of habitat used by delta smelt; and livestock grazing activities that may degrade or reduce riparian and wetland habitats that contribute to the quantity and quality of habitat used by delta smelt.

San Francisco Bay-Delta Climate Change

The effects of climate change do not act in isolation; they are anticipated to exacerbate existing threats to delta smelt. We considered the potential effects of climate change on the delta smelt based on projections derived from various modeling scenarios. A series of publications (Feyrer *et al.* 2011; Cloern *et al.* 2011; Brown *et al.* 2013) have modeled future impacts of climate change in the Delta and projected how this will affect delta smelt. These models used the B1 and A2 scenarios from the 2007 IPCC report. Each scenario included both a warmer-wetter and warmer-dryer sub scenario. Modeled predictions presented in these publications are based on current baseline conditions (no increased outflow, no breeching of levees) which may or may not change in the future. Temperature increases are likely to lead to a continued rise in sea level, further increasing salinity which will increasingly restrict delta smelt's already limited geographic range (Feyrer *et al.* 2011; Cloern *et al.* 2011; Brown *et al.* 2013). Higher air temperatures will reduce snowpacks, melt snow earlier in the winter or spring, and increase water temperatures. These changes will likely alter freshwater flows, possibly shifting and condensing the timing and location of delta smelt reproduction (Brown *et al.* 2013).

Projections indicate that temperature and precipitation changes will diminish snowpack, changing the availability of natural water supplies (Reclamation 2011). Warming may result in more precipitation falling as rain and less storage as snow. This would result in increased rain on snow events and increase winter runoff with an associated decrease in runoff for the remainder of the year (Reclamation 2011). Sacramento Valley Ecoregion projections include a 27 percent decrease in annual freshwater flows and earlier snowmelts, with increased freshwater flows in January and February but reduced throughout the rest of the year (PRBO Conservation Science 2011). Earlier seasonal warming increases the likelihood of rain-on-snow events, which are associated with mid-winter floods. Smaller snowpacks that melt earlier in the year may result in increased drought frequency and severity (Rieman and Isaak 2010). Thus overall, these changes may lead to increased frequency of flood and drought cycles during the 21st century (Reclamation 2011).

Sea level rise is likely to increase the frequency and range of saltwater intrusion. Salinity within the northern San Francisco Bay is projected to rise by 4.5 by the end of the century (Cloern *et al.* 2011). Elevated salinity levels could push the position of X2 farther up the estuary if outflows were not increased to compensate for it. Fall X2 mean values are projected to increase by a mean of about 7 km to the area of Antioch for a distance of about 90 km from the Golden Gate Bridge by 2100 (Brown *et al.* 2013). This increase in the position of X2 in the fall is expected to result in a decrease in suitable physical habitat (Brown *et al.* 2013) if current levees and channel structures are maintained. A decrease in spring habitat due to the movement of X2 upstream due to sea level rise is also expected to result from climate change.

We expect warmer estuary temperatures to be yet another significant conservation challenge based on climate change models. Mean annual water temperatures within the upper Sacramento River portion of the Bay-Delta estuary are expected to approach or exceed 14 °C during the second half of this century (Cloern *et al.* 2011). Warmer water temperatures could reduce delta smelt growth, increase delta smelt mortality and constrict suitable habitat within the estuary during the summer months. Due to warming temperatures, delta smelt are projected to spawn an average of 10 to 25 days earlier in the season depending on the location (Brown *et al.* 2013). Also due to expected temperature increases, total number of high mortality days is expected to increase for all IPCC climate change scenarios (Brown *et al.* 2013). The number of stress days is expected to be stable or decrease partly because many stress days will become high mortality days. This could lead to delta smelt being forced to grow under highly stressful conditions during summer and fall with less time to mature because of advanced spawning (Brown *et al.* 2013). Growth rates have been shown to slow as water temperatures increase therefore requiring delta smelt to consume more food to reach growth rates that are normal at lower water temperatures (Rose *et al.* 2013a). Delta smelt are already often smaller than they used to be (Sweetnam 1999; Bennett 2005) and expected temperature increases due to climate change will likely further slow growth rates.

At the same time, warmer water will tend to move the spawning season earlier in the year (Brown *et al.* 2013). That means the fish will have to grow faster still to compensate for that shorter growing season to produce even as many eggs as they do now – and that may already be a serious limitation on their population fecundity (Rose *et al.* 2013b). Higher temperatures may restrict delta smelt distribution into the fall, limiting their presence in Suisun Bay for more than just salinity reasons and force greater inhabitation of cooler high salinity waters (Brown *et al.* 2013). Water temperatures are already presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding 25 °C for short periods.

The delta smelt is currently at the southern limit of the inland distribution of the family Osmeridae along the eastern Pacific coast. That indicates that this region was already about as warm as that fish family can handle. Increased temperatures associated with climate change may result in a habitat in the Bay-Delta that is outside of the species ecological tolerance limits.

Giant Garter Snake

The Service is aware of other projects currently under review by the State, county, and local authorities where biological surveys have documented the occurrence of federally-listed species. These projects include such actions as urban expansion, water transfer projects that may not have a Federal nexus, and continued agricultural development. The cumulative effects of these known actions pose a significant threat to the eventual recovery of the species. Additionally, an undetermined number of future land use conversions and routine agricultural practices are not subject to Federal permitting processes and may alter the habitat or increase incidental take of snakes, and are, therefore, cumulative to the proposed project. For example other cumulative effects include: (1) unpredictable fluctuations in aquatic habitat due to water management and diversions; (2) dredging and clearing of vegetation from irrigation canals; (3) discing or mowing upland habitat; (4) increased vehicular traffic on access roads adjacent to aquatic habitat; (5) use of burrow fumigants on levees and other potential upland refugia; (6) human intrusion into habitat; (7) use of inappropriate plastic erosion control netting (Stuart *et al.* 2001); (8) riprapping or lining of canals and stream banks; (9) fluctuations in acreages of rice production due to market conditions or water availability; (10) ornamental cultivation; (11) routine grounds maintenance of upland habitat; (12) contaminated runoff from agriculture and urbanization; (13) maintenance of non-Federal flood control structures; and (14) predation by feral animals and pets. Specific cumulative effects related to the proposed project include maintenance activities and/or an increased potential for vandalism, which may degrade or destroy habitat or cause unpredictable fluctuations in habitat.

Yellow-Billed Cuckoo

Habitat that is currently occupied by the yellow-billed cuckoo occurs on public and privately owned lands. Activities on non-Federal lands that may affect the yellow-billed cuckoo include the construction and maintenance of recreational hiking and bicycle trails; restoration of native riparian habitat; transportation related projects like construction and maintenance of State, county, and private roads and bridges; flood channel maintenance by the State water resources agencies, and conversion of riparian habitat to agriculture on private lands.

Conclusion

After reviewing the current status of the valley elderberry longhorn beetle, delta smelt, giant garter snake and yellow-billed cuckoo, the environmental baseline for the action area, the effects of the proposed ARFC project, and the cumulative effects on these species, it is the Service's biological opinion that the proposed AFRC project, is not likely to jeopardize the continued existence of these species. The Service reached this conclusion because the project-related effects to the species, when added to the environmental baseline and analyzed in consideration of all potential cumulative effects, will not rise to the level of precluding recovery or reducing the likelihood of survival of the species based on the conservation measures proposed by the Corps including: creating additional riparian habitat for the valley elderberry longhorn beetle and the yellow-billed cuckoo; purchasing credits at conservation banks for giant garter snake and delta smelt; and restoring any temporarily affected habitat to pre-project conditions.

After reviewing the current status of designated critical habitat for delta smelt, the environmental baseline of critical habitat in the action area, the effects of the proposed ARFC project, and the cumulative effects, it is the Service's biological opinion that the proposed ARFC project, as proposed, is not likely to destroy or adversely modify designated critical habitat. The Service reached this conclusion because the project-related effects to the designated critical habitat, when added to the environmental baseline and analyzed in consideration of all potential cumulative effects, will not rise to the level of precluding the function of the delta smelt critical habitat, to serve its intended conservation role for the species based on the Corps proposal to purchase credits at a conservation bank for permanent effects to the substrate of the Sacramento River. The effects to delta smelt critical habitat are small and discrete, relative to the entire area designated, and are not expected to appreciably diminish the value of the critical habitat or prevent it from sustaining its role in the conservation of the delta smelt.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by Service regulations at 50 CFR 17.3 as an intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the same regulations as an act which actually kills or injures wildlife. Harm is further defined to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavior patterns, including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are nondiscretionary, and must be undertaken by the Corps and SAFCA so that become binding conditions of any contract issued for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Corps (1) fails to assume and implement the terms and conditions, or (2) fails to require their contractor or SAFCA or to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the contract, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps must report the progress of the action and its impact on the species to the Service as specified in the incidental take statement [50 CFR §402.14(i)(3)].

Amount or Extent of Take

Valley Elderberry Longhorn Beetle

The Service anticipates that incidental take of valley elderberry longhorn beetle will be difficult to detect due to its life history and ecology. Specifically, valley elderberry longhorn beetles can be difficult to locate due to the fact that a majority of their life cycle is spent in the elderberry shrub and finding a dead or injured individual is unlikely due to their relatively small size. There is a risk of harm, harassment, injury and mortality as a result of the proposed construction activities; therefore, the Service is authorizing take incidental to the proposed action as harm, harassment, injury, and mortality of all valley elderberry longhorn beetles within 263 shrubs that will be transplanted as a result of construction and 40 acres of elderberry shrubs that will be trimmed for maintenance purposes over the project's 50 year life.

Delta Smelt

The Service expects that incidental take of delta smelt will be difficult to detect or quantify for the following reasons: the small size of adults, their occurrence in turbid aquatic habitat makes them difficult to detect, and the low likelihood of finding dead or impaired specimens. The Service anticipates that the extent of incidental take will be minimized due to the proposed conservation measures and low relative abundance. Due to the difficulty in quantifying the number of delta smelt that will be taken as a result of the proposed action, the number of acres of affected habitat becomes a surrogate for the species that will be taken. The Service anticipates that all individual adult delta smelt in the 46 acres of the action area may be subject to incidental take in the form of harm as described in this biological opinion. Incidental take of delta smelt for maintenance activities is not covered in this biological opinion.

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, and other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed during construction activities, including in staging areas and roads carrying vehicular traffic. In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or degraded as a result of the action as a surrogate measure for quantifying individuals.

Therefore, the Service anticipates the number of giant garter snakes that may be found in 125.5 acres of aquatic and upland habitat will be harmed or killed as a result of habitat modification due to the proposed project. Incidental take of giant garter snake for maintenance activities is not covered in this biological opinion.

Yellow-Billed Cuckoo

The Service anticipates that incidental take of yellow-billed cuckoo will be difficult to detect due to its life history and ecology. Specifically, yellow-billed cuckoos can be difficult to locate due to their cryptic appearance and behavior and finding a dead or injured individual is unlikely. There is a risk of harm and harassment as a result of proposed construction activities and operations and maintenance of the restoration plantings; therefore, the Service is authorizing take incidental to the proposed action as harm of all yellow-billed cuckoos within 135 acres. Incidental take of yellow-billed cuckoo for maintenance activities is not covered in this biological opinion.

Effect of the Take

In the accompanying biological opinion, the Service determined that this level of anticipated take is not likely to result in jeopardy to the species or destruction or adverse modification of critical habitat.

Reasonable and Prudent Measures

All necessary and appropriate measure to avoid or minimize effects on the species resulting from implementation of this project have been incorporated into the project's proposed conservation measures. Therefore, the Service believes the following reasonable and prudent measure is necessary and appropriate to minimize incidental take of the species.

1. All conservation measures, as described in the biological assessment and restated here in the Project Description section of this biological opinion, shall be fully implemented and adhered to. Further, this reasonable and prudent measure shall be supplemented by the terms and conditions below.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measure described above. These terms and conditions are nondiscretionary.

1. The Corps shall include full implementation and adherence to the conservation measures as a condition of any permit or contract issued for the project.

2. The Corps will develop a Riparian Planting Plan. The plan will evaluate locations for riparian vegetation planting based on land use in the lower American River Parkway, effects from future projects, such as the reoperation of Folsom Dam, where existing riparian and valley elderberry longhorn beetle habitat exists, creating and maintaining connectivity between large riparian patches, and coordination with Sacramento County Parks. The plan will maximize habitat quality for both the valley elderberry longhorn beetle and the yellow-billed cuckoo.

3. In order to monitor whether the amount or extent of incidental take anticipated from implementation of the project is approached or exceeded, the Corps shall adhere to the following reporting requirements. Should this anticipated amount or extent of incidental take be exceeded, the Corps must immediately reinitiate formal consultation as per 50 CFR 402.16.

   (a) For those components of the action that will result in habitat degradation or modification whereby incidental take in the form of harm is anticipated, the Corps will provide monthly updates to the Service with a precise accounting of the total acreage of habitat impacted. Updates shall also include any information about changes in project implementation that result in habitat disturbance not described in the Project Description and not analyzed in this biological opinion.
   (b) For those components of the action that may result in direct encounters between listed species and project workers and their equipment whereby incidental take in the form of harassment, harm, injury, or death is anticipated, the Corps shall immediately contact the Service's Sacramento Fish and Wildlife Office (SFWO) at (916) 414-6600 to report the encounter. If the encounter occurs after normal working hours, the Corps shall contact the SFWO at the earliest possible opportunity the next working day. When injured or killed individuals of the listed species are found, the Corps shall follow the steps outlined in the Salvage and Disposition of Individuals section below.
   (c) Injured listed species must be cared for by a licensed veterinarian or other qualified person(s), such as a Service-approved biologist. Dead individuals must be sealed in a resealable plastic bag containing a paper with the date and time when the animal was found, the location where it was found, and the name of the person who found it. The bag containing the specimen must be frozen in a freezer located in a secure site, until instructions are received from the Service regarding the disposition of the dead specimen. The Service contact persons are the Habitat Conservation Division Chief at the Sacramento Fish and Wildlife Office at (916) 414-6600; the Assistant Field Supervisor of ESA/Regulatory Division at the Bay Delta Fish and Wildlife Office at (916) 930-5603; and the Resident Agent-in-Charge of the Service's Office of Law Enforcement at (916) 569-8444.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The Service recommends the following actions:

1. The Service recommends the Corps develop and implement restoration measures in areas designated in the Delta Fishes Recovery Plan (Service 1996) the Giant Garter Snake Recovery Plan (1999) and the Valley Elderberry Longhorn Beetle Recovery Plan (1984).

2. The Corps and SAFCA should develop and implement projects that support DWR's Central Valley Flood System Conservation Strategy. This document provides goals and measurable objectives and potential projects which could be implemented in a manner that while improving the riverine ecosystem also will improve the flood system.

In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION - CLOSING STATEMENT

This concludes formal consultation with the Corps on the American River Common Features GRR Project. As provided in 50 CFR §402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained or is authorized by law and:

(a) If the amount or extent of taking specified in the incidental take statement is exceeded;

(b) If new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered;

(c) If the identified action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in the biological opinion; or

(d) If a new species is listed or critical habitat designated that may be affected by the identified action.

If you have any questions regarding this biological opinion, please contact Jennifer Hobbs (jennifer_hobbs@fws.gov or (916) 414-6541) or Doug Weinrich, Assistant Field Supervisor at the letterhead address, (916) 414-6600.

Sincerely,

Jennifer M. Norris
Field Supervisor

American River Common Features GRR

EIS Cultural Resources Appendix

Enclosure 1

Programmatic Agreement

PROGRAMMATIC AGREEMENT
AMONG
THE U.S.ARMY CORPS OF ENGINEERS AND
THE CALIFORNIA STATE HISTORIC PRESERVATION OFFICER
REGARDING THE AMERICAN RIVER COMMON FEATURES PROJECT, SACRAMENTO, SACRAMENTO AND YOLO COUNTIES, CALIFORNIA

WHEREAS, the U.S. Army Corps of Engineers, Sacramento District (Corps), is proceeding to implement aspects of the American River Common Features Project (Project) as authorized in the Water Resources Development Act (WRDA) of 1996, Pub L. No. 104-303, §101(a)(1), 110 STAT. 3658, 3662-3663 (1996), as amended by the WRDA 1999, Pub. L. No. 106-53, Section 366, 113 STAT. 269, 319-320 (1999) and the Energy and Water Development and Related Agencies Appropriations Act of 2008, Pub. L. No. 110-161, Section 130, 121 STAT. 1844, 1947 (2008), and as authorized by Section 7002 of the Water Resources Reform and Development Act (WRRDA) of 2014 (Pub. L. No. 113-121, § 7002, 128 Stat. 1193, 1366); and

WHEREAS, the Project is being developed to provide flood risk management to the City of Sacramento, including areas along the Sacramento and American Rivers, and around and within the Natomas Basin, including the Natomas Cross Canal, the Sacramento Bypass, the Pleasant Grove Creek Canal, the Natomas East Main Drain Canal, Arcade Creek, Dry Creek, Robla Creek, and Magpie Creek located in Sacramento and Yolo Counties, California. The authorized project is a single purpose flood risk management project shown in **Attachment 1** and further described in **Attachment 2**; and

WHEREAS, the Corps proposes to construct levee improvements including, but not limited to: seepage cutoff walls, seepage berms, levee slope flattening, relief wells, adjacent levees, stability berms, drained stability berms, levee raising, floodwalls, bypass widening, riverbank erosion protection, and launchable rock erosion protection; and

WHEREAS the State of California Central Valley Flood Protection Board (CVFPB) is the non-Federal sponsor for the Project and the CVFPB has been invited to be a Concurring Party to this Programmatic Agreement (Agreement); and

WHEREAS, the Corps has determined that the Project activities constitute an Undertaking, as defined in 36 C.F.R. § 800.16(y), and therefore is subject to Section 106 of the National Historic Preservation Act of 1966, 54 U.S.C. § 306108 (NHPA); and

WHEREAS, the Corps has determined that the Project may have an effect on properties that are either listed or eligible for listing in the National Register of Historic Places (NRHP) and has consulted with the California State Historic Preservation Officer (SHPO) pursuant to the NHPA; and

WHEREAS, pursuant to 36 C.F.R. § 800.4(b)(2), the Corps may implement the Project in phases as funding is available and construction authority is provided and, as a result, efforts to identify and evaluate Historic Properties and the determination of effects to those properties may be deferred until more specific project information for each phase is known; and

WHEREAS, this Agreement shall establish the process the Corps shall follow for compliance with 54 U.S.C. § 306108 (formerly 16 U.S.C. § 470f, referred to hereinafter as "Section 106"), taking into consideration the views of the Signatory and Concurring Parties; and

WHEREAS, a total of 69 cultural resources are known to be present within the Area of Potential Effects (APE) and although extensive archaeological inventory has been completed within the APE under other projects, portions of the APE have not been inventoried; and

WHEREAS, the presence of levees, alluvial deposition, and other built environment features have obscured the presence of cultural resources and a full assessment of archaeological sites cannot be made in advance of construction; and

WHEREAS, the levees of the Sacramento and American Rivers are the one known potential Historic Property within the APE that will be affected by the Project; and

WHEREAS, the Corps is aware that there is a high probability for buried cultural resources that may not be identified prior to construction and that also may be eligible for inclusion in the NRHP, and therefore this Agreement documents a framework for managing post-review discoveries per 36 C.F.R. § 800.13; and

WHEREAS, the Corps, with the concurrence of SHPO, has decided to comply with Section 106 of the NHPA for the Undertaking through the execution and implementation of this Programmatic Agreement (Agreement) because the Corps cannot fully determine the effects of the Undertaking on Historic Properties [36 C.F.R. § 800.14(b)(1)(ii)], for all phases and segments of the Project at this time; and

WHEREAS, in accordance with 36 C.F.R. §§ 800.2(c)(2)(ii)(A), 800.3(f)(2), and 800.14(b)(2)(i), the Corps has contacted federal and state recognized Native American Tribes, via letter(s), phone call(s), and meetings, to invite them to consult on the Project and this Agreement, including the Buena Vista Rancheria of the Me-Wuk Indians of California, the Cachil DeHe Band of Wintun Indians of the Colusa Indian Community of the Colusa Rancheria, the Colfax-Todds Valley Consolidated Tribe, the Cortina Wintun Environmental Protection Agency, the El Dorado Miwok Tribe, the Enterprise Rancheria of

Maidu Indians of California, the Ione Band of Miwok Indians of California, the Mechoopda Indian Tribe of Chico Rancheria, the Mooretown Rancheria of Maidu Indians, the Nashville-El Dorado Miwok, the Shingle Springs Band of Miwok Indians, the Strawberry Valley Rancheria, the T'si-Akim Maidu, the United Auburn Indian Community of the Auburn Rancheria, the Wilton Rancheria, the Yocha Dehe Wintun Nation, and interested Native American individuals; the Corps has invited them (and others who may be identified in the future as appropriate Concurring Parties) to participate as Concurring Parties to this Agreement; and the Corps will continue consultation throughout the duration of this agreement; and

WHEREAS, the Corps shall make the terms and conditions of this Agreement part of the conditions of any contracts issued by the Corps for this Project; and

WHEREAS, the definitions set forth in 36 C.F.R. § 800.16 are incorporated herein by reference and apply throughout this Agreement; and

WHEREAS, the definitions for Signatory Parties set forth in 36 C.F.R. § 800.6(c)(1), and the definitions for Concurring Parties set forth in 36 C.F.R. § 800.6(c)(3), are incorporated herein by reference and apply throughout this Agreement; and

WHEREAS, in accordance with 36 C.F.R. § 800.14(b)(3), the Corps notified and invited the Advisory Council on Historic Preservation (ACHP) per 36 C.F.R. § 800.6(a)(1)(C) to participate in consultation to resolve potential adverse effects of the Project, including development of this Agreement, and the ACHP has declined to participate pursuant to 36 C.F.R. § 800.6(a)(1)(iii) in a letter dated August 7, 2012; and

WHEREAS, in accordance with 36 C.F.R. § 800.6(a)(4) and 36 C.F.R. § 800.14(b)(2)(ii), the Corps has notified the public of the Project and provided an opportunity for members of the public to comment on the Project and the Section 106 process as outlined in this Agreement; and

NOW, THEREFORE, the signatories agree that the Undertaking shall be implemented in accordance with the following stipulations in order to take into account the effects of the undertaking on Historic Properties and to satisfy the Corps' Section 106 responsibilities for all individual aspects of the undertaking.

The Corps shall ensure that the following measures are carried out:

STIPULATIONS

I. TIME FRAMES AND REVIEW PROCEDURES

For all documents and deliverables produced in accordance with the stipulations of this Agreement, the Corps shall provide a draft document to the SHPO, Concurring Parties, and Native American interested parties and Tribes for review. Any written comments provided by the SHPO, Concurring Parties, and Native American interested parties and Tribes, within thirty (30) calendar days from the date of receipt, shall be considered in the revision of the document or deliverable. The Corps shall document and report the written comments received for the document or deliverable and how comments were addressed. The Corps shall provide a revised final document or deliverable to the SHPO for concurrence. The SHPO shall have thirty (30) calendar days to respond. Failure of the SHPO, Concurring Parties, and Native American interested parties and Tribes to respond within thirty (30) calendar days of any submittal shall not preclude Corps from moving to the next step in this Agreement.

Should the SHPO object to the final document or deliverable submitted for concurrence, the Corps and SHPO shall consult for a period not to exceed fifteen (15) calendar days following the receipt of the SHPO's written objection in an effort to come to agreement on the issues to which the SHPO has objected. Should the SHPO and the Corps be unable to agree on the issues to which the SHPO has objected, the SHPO and the Corps shall proceed in accordance with **Stipulation XV (Dispute Resolution)**, below. The timeframe to consult to resolve a disagreement or objection may be extended by mutual consent of the Corps and the SHPO.

II. AREA OF POTENTIAL EFFECTS

The APE for Project activities shall include the construction footprint of the activity and a reasonable buffer determined through consultation between SHPO and the Corps, and shall take into account the likelihood of direct and indirect effects to Historic Properties resulting from the Project. **Attachment 1** includes an overall APE map for the Project. Because the Project will occur in phases, it may be necessary to further define the APE for each phase as phases are authorized and funded for design and construction. Prior to activities under **Stipulation IV (Identification and Evaluation)**, the Corps shall submit to the SHPO, Concurring Parties, and Native American interested parties and Tribes a map of the APE for the current phase and a description of the Project activities occurring for that phase, in accordance with **Stipulation I (Timeframes and Review Procedures)**. Revisions to the APE will not necessitate modifications to this Agreement.

A. For purposes of this Agreement, the APE for each phase shall be defined to meet, at a minimum, the following criteria:

The APE for any segment of the levees that are being improved as part of the phase of the Project shall include the levee segment and a corridor extending not less than 150 meters from the landside toe of the levee segment.

B. The APE also shall include:

(1) The extent of all Project construction and excavation activity required to construct flood control facilities and to modify irrigation and drainage infrastructure; and

(2) The additional right-of-way/easements obtained by the Corps as part of the Project's features; and

(3) All areas used for excavation of borrow material and habitat creation; and

(4) All construction staging areas, access routes, spoil areas, and stockpiling areas.

C. After the APE has been defined and consulted on in accordance with **Stipulation II (Area of Potential Effects)** above, construction or other Project activities may require revisions to the APE. If the APE is revised, the Corps shall consult on that revision in accordance with **Stipulation I (Timeframes and Review Procedures)**, and the Corps shall determine the potential for Project activities in a revised APE to affect potential Historic Properties, in accordance with **Stipulation IV (Identification and Evaluation)**.

III. HISTORIC PROPERTIES MANAGEMENT PLAN

The Corps, in consultation with the SHPO, Concurring Parties, and Native American interested parties and Tribes, shall develop a Historic Property Management Plan (HPMP), which provides the framework by which remaining identification, evaluation of eligibility, findings of effect, and resolution of adverse effect efforts to Historic Properties will occur. The HPMP shall include consideration of property types, treatment of property types, expected methodology for identification and evaluation of potential historic properties, potential templates for work plans, provisions for avoidance or protection of historic properties, and consideration for identification and treatment of human remains. The HPMP shall be appended to this Agreement (**Attachment 3)** and will form the basis for any Historic Property Treatment Plans (HPTPs) that may be required for one or more phases of the Project. The HPMP shall be developed after execution of the Agreement, but before construction commences. For the overall Project and individual phases, the HPMP shall be the means for the Corps to comply with 36 C.F.R. § 800.6 and provide standardized methods for dealing with unanticipated discoveries in accordance with 36 C.F.R. § 800.13(a).

The HPMP may be amended and appended to this Agreement without amending the Agreement.

A. Review: The Corps shall submit the Draft HPMP to the SHPO, Concurring Parties, and Native American interested parties and Tribes for review and comment pursuant to **Stipulation I (Timeframes and Review Procedures)**.

B. Historic Property Treatment Plans: The Corps shall consult the SHPO, pursuant to 36 C.F.R. § 800.5, when the Corps has determined that a Project activity will result in adverse effects to a Historic Property. An HPTP specific to the phase of the Project or the Historic Property will be drafted to describe how the Corps intends to resolve adverse effects and that HPTP may be appended to the HPMP. HPTPs shall be consistent with the HPMP and may incorporate by reference historic contexts, methods, procedures, and research designs, as appropriate. When incorporating portions of the HPMP by reference, the HPTP shall at a minimum include the date of the HPMP and where the HPMP is available to be viewed.

(1) An HPTP may address individual or multiple Historic Properties or Historic Property types. An HPTP shall stipulate those actions the Corps shall take to resolve the adverse effects of the Project on Historic Properties within the project phase or specific action specified by the HPTP. For properties eligible under criteria specified in 36 C.F.R. § 60.4 (A) through (D), mitigation other than data recovery may be considered in the treatment plan (e.g., HABS/HAER, oral history, historic markers, exhibits, interpretive brochures or publications, or other means as deemed appropriate by the signatories). In addition to the SHPO, Concurring Parties, and Native American interested parties and Tribes the Corps may invite the interested public, in accordance with **Stipulation XIII (Public Consultation and Public Notice)**, to comment on the means of mitigation, as appropriate. HPTPs shall include specifications (including content and number of copies) for publication of brochures, pamphlets or synthesis reports for distribution to the general public. The Corps shall ensure that all provisions of an HPTP are carried out as stipulated in the HPTP.

(2) Historic Context, Recordation, and Treatment of Levees: The Sacramento and American River levees are a known potential Historic Property within the APE that may be affected by the Project. Sections of the levees have been recorded and evaluated for their individual eligibility for listing in the NRHP but no overall historic context or evaluation of the levee system has been developed. Because the specific project design that may alter the levees will not be developed until after the Project has been approved for design, a determination of effect and, if necessary, an HPTP, cannot be developed until after approval and execution of this Agreement. In order to document the levees for evaluation, the Corps will develop a historic context and HPTP for recordation of the Sacramento and American River levees as historic structures within the APE in order to evaluate the effects of the Project on the levees. If a historic context and/or HPTP for the levees within the APE has already been developed, the Corps may incorporate it as deemed appropriate by the Corps. The HPTP shall consider the levees in the context of the entire Sacramento and American River levee systems. Additionally, the HPTP shall require the development of clear and specific criteria for determining: (1) recordation guidelines for the levees within the APE, (2) contributing and non-contributing elements of the levee system, (3) thresholds of adverse effect, and (4) treatment of adverse effects. The HPTP shall be developed after execution of the Agreement and before construction commences. The Corps shall submit the HPTP for review, in accordance with **Stipulation I (Timeframes and Review Procedures)**.

(3) HPTPs will be submitted and reviewed in accordance with **Stipulation I (Timeframes and Review Procedures)**, except for those HPTPs developed for Historic Properties discovered during construction activities, which shall follow the review timeframes identified in **Stipulation IX (Discovery of Unknown Historic Properties)**. Circulation of an HPTP shall not include a recirculation of the HPMP.

D. Reporting: Reports and other data pertaining to the inventory of Historic Properties and the treatment of effects to Historic Properties will be distributed to Concurring Parties to this Agreement, Native American Tribes, and other members of the public, consistent with **Stipulation XIV (Confidentiality)** of this Agreement, unless parties have indicated through consultation that they do not want to receive a report or data.

E. Amendments/Addendums/Revisions: If an Historic Property type that is not coveredby an existing HPTP is discovered within the APE subsequent to an initial inventory effort for a phase, or if there are previously unexpected effects to an Historic Property, and the Corps and SHPO agree that the Project may adversely affect the Historic Property, the Corps shall submit an addendum to the HPTP or a new HPTP to the SHPO and Concurring Parties for review and comment, and shall follow the provisions of **Stipulation IX (Discovery of Unknown Historic Properties)**. The HPTP may cover multiple discoveries for the same property type.

F. Data Recovery: When data recovery is proposed, the Corps, in consultation with the SHPO, shall ensure that HPTPs are developed consistent with the *Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation* and the ACHP's "Recommended Approach for Consultation on Recovery of Significant Information from Archaeological Sites" (ACHP, May 18, 1999).

G. **Final Phase Report Documenting Implementation of the Historic Properties Treatment Plan(s):** Within one year after the completion of all work for each phase of the Project, the Corps shall submit to the SHPO, Signatory Parties, Concurring Parties, and Native American interested parties and Tribes, a Final Phase Report documenting the results of all work prepared for that phase under the HPTPs, and the information learned from each of the Historic Properties. The submittal of the Final Phase Report shall be in accordance with **Stipulation I (Timeframes and Review Procedures)**.

IV. IDENTIFICATION AND EVALUATION

Should the HPMP not be finalized at the time that a phase of the Project may be proceeding to design and construction, the Corps shall consult with the Signatory Parties before issuing a notice to proceed on any phase of the Project. Should the Signatory Parties agree that the work may proceed, the Corps shall comply with **Stipulation IV A., B., and C. (Identification and Evaluation)** and, as necessary, **Stipulation VI (Determination of Effects)**. The Corps shall complete any identification and evaluation, and as necessary, any evaluation of effects to Historic Properties prior to proceeding with construction. If the Signatory Parties do not agree to proceed with the phase of the Project the Corps shall follow **Stipulation XV (Dispute Resolution)**.

A. **Identification of Potential Historic Properties:** An inventory of Historic Properties within the APE, consistent with the *Secretary of Interior's Standards and Guidelines for Archeology and Historic Preservation* (48 FR 44716–44740) will be initiated for the Project, or for individual phases of the Project, as construction details become available.

Survey recordation shall include features, isolates, and re-recordation of previously recorded sites, as necessary. The survey shall ensure that potential Historic Properties such as historical structures and buildings, historical engineering features, landscapes, viewsheds, and traditional cultural properties (TCPs) with significance to Native American communities, are recorded in addition to archeological sites. Recordation of historic structures, buildings, objects, and sites shall be prepared using the California Department of Parks and Recreation (DPR) 523 Site Record forms.

B. Property Types Exempt from Evaluation: Attachment 4 to this Agreement lists the property types that the Signatories agree shall be exempt from evaluation as determined by the Corps in consultation with the SHPO. The Corps shall evaluate all other identified properties in accordance with **Stipulation IV.C** (**Evaluation of Potential Historic Properties)**.

C. Evaluation of Potential Historic Properties: After recordation on DPR 523 Site Record forms, potential Historic Properties shall be evaluated by a qualified professional for their eligibility for listing in the NRHP consistent with the *Secretary of Interior's Standards for Evaluation*, 36 C.F.R. § 60.4. In accordance with **Stipulation I (Timeframes and Review Procedures),** the Corps shall submit a completed inventory and evaluation for each phase of Project work.

V. GEOTECHNICAL INVESTIGATIONS

For the purposes of gathering engineering data and for project planning, it may be necessary for the Corps to conduct limited geotechnical investigations at areas within the APE.

A. The Corps may conduct geotechnical investigations (e.g., borings, potholing, or trenches) for planning and exploratory efforts. The Corps shall follow Stipulation V.A(1) and (2), or may follow Stipulation V.A(3) if unable to follow Stipulation V.A(1) and (2):

(1) A records and literature search and consultation with Native Americans has been conducted and it has been determined there are no known existing potential Historic Properties located within 50 feet of the areas identified for geotechnical investigations, and an archeological field survey of the areas identified for geotechnical investigations has been conducted and it has been determined there are no known potential Historic Properties present;

(2) A potential Historic Property is identified during the records and literature search or field survey and consultation process as being within an area where geotechnical investigation will occur, and the geotechnical investigation is relocated at least 50 feet outside the site boundaries; or

(3) Provisions for an archeological monitor meeting the qualifications described in **Stipulation VII.C. (Archeological Monitor Standards)** are included in the contract specifications for the geotechnical investigations. As appropriate, or when geotechnical activities may occur in sensitive areas, an archeological monitor will be present for all ground disturbing activities.

B. If potential Historic Properties are discovered during geotechnical investigations, **Stipulation IX (Discovery of Unknown Historic Properties)** shall be followed;

C. A Memorandum for Record shall be written documenting the results of the records and literature search, the archeological field survey, any decisions to relocate geotechnical investigation areas, the determination for inclusion of an archeological monitor for ground disturbing activities, and a record of communication with Native American interested parties and Tribes, as appropriate.

VI. DETERMINATION OF EFFECTS

Avoidance of adverse effects to Historic Properties is the preferred treatment approach. The Corps will consider redesign of Project elements in order to avoid Historic Properties and Project effects that may be adverse. However, it may not be possible to redesign the Project in order to avoid adverse effects to Historic Properties.

The Corps will apply the criteria of adverse effect, pursuant to 36 C.F.R. § 800.5(a)(1), to all Historic Properties within the APE that will be affected by the Project. The Corps shall submit determinations of effects in accordance with **Stipulation I (Timeframes and Review Procedures)**.

If effects to Historic Properties are determined to be adverse, **Stipulation III (Historic Properties Management Plan)**, above, will be followed.

VII. QUALIFICATIONS

A. Professional Qualifications: All technical work required for historic preservation activities implemented pursuant to this Agreement shall be carried out by or under the direct supervision of a person or persons meeting, at a minimum, the *Secretary of Interior's Professional Qualifications Standards* for archeology or history, as appropriate (48 FR 44739). "Technical work" here means all efforts to inventory, evaluate, and perform subsequent treatment such as data recovery excavation or recordation of potential Historic Properties that is required under this Agreement. This stipulation shall not be construed to limit peer review, guidance, or editing of documents by SHPO and associated Project consultants.

B. Historic Preservation Standards: Historic preservation activities carried out pursuant to this Agreement shall meet the *Secretary of Interior's Standards and Guidelines for Archaeology and Historic Preservation* (48 FR 44716-44740), as well as standards and guidelines for historic preservation activities established by the SHPO. The Corps shall ensure that all reports prepared pursuant to this Agreement will be provided to the Signatories, Concurring Parties, and Native American interested parties and Tribes and are distributed in accordance with **Stipulation XIV (Confidentiality),** and meet published standards of the California Office of Historic Preservation, specifically, *Preservation Planning Bulletin* Number 4(a), "Archaeological Resources Management Reports (ARMR): Recommended Contents and Format" (December 1989).

C. Archeological Monitor Standards: Archeological monitoring activities required for exploratory, construction, or construction related ground disturbing activities implemented pursuant to this Agreement shall be carried out by a person meeting, at a minimum, the *Secretary of Interior's Professional Qualifications Standards* for prehistoric or historic archaeology, as appropriate (48 FR 44739). "Archeological monitoring" here includes monitoring ground disturbing activities that have been determined by the Corps to be occurring in areas potentially sensitive for Historic Properties or buried resources.

VIII. NOTICES TO PROCEED WITH CONSTRUCTION

Notices to Proceed may be issued by the Corps for individual construction segments, defined by the Corps in its construction specifications, after a Historic Properties inventory has been completed [per **Stipulation III (Historic Properties Management Plan)** or **Stipulation IV (Identification and Evaluation)**], and prior to treatment of adverse effects on Historic Properties within the APE provided that:

A. A plan to respond to inadvertent archeological discoveries is prepared by the Corps, and approved by SHPO, prior to the commencement of Project activities anywhere in the APE for that phase of the Project; and

B. Project development activities do not encroach within 30 meters (100 feet) of the known boundaries of any Historic Property as determined from archeological site record forms, other documentation, or as otherwise defined in consultation with the SHPO and other parties, as appropriate; and

C. An archeological monitor meeting the professional qualifications as described in **Stipulation VII (Qualifications)**, is present during any Project activities that are anticipated to extend either vertically or horizontally into any areas designated to be archeologically sensitive by the Corps, in consultation with SHPO, except in phases of construction for slurry walls where visual inspection of the construction area cannot be safely or feasibly accomplished.

IX. DISCOVERY OF UNKNOWN HISTORIC PROPERTIES

The Corps is responsible for complying with 36 C.F.R. § 800.13(a) in the event of inadvertent discoveries of Historic Properties during implementation of the Project. The HPMP will provide procedures for complying with post review and inadvertent discoveries of Historic Properties. If the Corps authorizes work before the HPMP is finalized and there is a discovery of an unknown Historic Property, the Corps shall follow 36 C.F.R. § 800.13(b). Additionally, the following procedures shall be followed:

A. Workforce Training: During implementation of Project activities, the Corps, or archeologists meeting the professional qualifications as described in **Stipulation VII (Qualifications)**, will provide training to all construction personnel, before they begin work, regarding proper procedures and conduct in the event that archeological materials are encountered during construction.

B. **Human Remains:** Treatment of human remains is governed by **Stipulation XII (Tribal Consultation and Treatment of Human Remains)**.

X. CURATION

To the extent that curation is determined to be appropriate mitigation to resolve adverse effects to Historic Properties, curation shall be conducted in accordance with 36 C.F.R. § 79, except those materials identified as Native American human remains and items associated with Native American burials. Archeological items and materials from State or privately owned lands shall be maintained in accordance with 36 C.F.R. § 79 until any specified analyses are complete. Although the Native American Graves Protection and Repatriation Act (NAGPRA) (25 U.S.C. § 3001 et seq.) does not apply to this Project, as there is no federally owned or administered property within the APE and the Corps will not be curating cultural materials subject to NAGPRA, this Agreement incorporates by reference the definitions for “human remains” and “funerary objects” set forth in 43 C.F.R § 10.2(d) and those definitions shall apply to actions under this Agreement. Further treatment of human remains is addressed in **Stipulation XII (Tribal Consultation and Treatment of Human Remains)**.

XI. TRIBAL INVOLVEMENT

A. In consultation with Native American interested parties and Tribes, the Corps will make a reasonable and good-faith effort to identify Historic Properties of traditional religious and cultural importance. The Corps shall ensure that consultation with Native American Tribes is initiated early with respect to the Project and continues throughout the Section 106 process.

B. In accordance with the guidance provided in National Register Bulletin 38 and Preservation Brief 36, the Corps will seek comments from all potentially interested Native American interested parties and Tribes in making determinations of NRHP eligibility for any Traditional Cultural Properties (TCPs) and Cultural Landscapes (as defined in Bulletin 38 and Preservation Brief 36). Review of documentation shall be consistent with **Stipulation I (Timeframes and Review Procedures)**.

C. Pursuant to 36 C.F.R. § 800.6(c)(2)-(3), the Corps shall consider requests by Native American Tribes to become Concurring Parties to this Agreement. In accordance with **Stipulation XIV (Confidentiality)**, Concurring Parties to this Agreement will receive documents produced under this Agreement, as appropriate.

D. Native American Tribes may choose not to sign this Agreement as a Concurring Party. Native American Tribes and individuals not acting as Concurring Parties to the Agreement will be contacted when the Corps identifies potential interest in a specific phase or action of the project. The Corps will make a good faith effort to identify any Native American organizations and individuals with interest in the proposed treatment of Historic Properties. The identification effort may include contacting the Native American Heritage Commission (NAHC), using online databases, and using personal and professional knowledge. The Corps will then contact each identified organization and individual by mail, inviting them to consult about the specific treatment of Historic Properties. If interest from the contacted parties is received by the Corps, the Corps will proceed to consult in accordance with **Stipulation XI.A. (Tribal Involvement)**. Further consultation may also be carried out through either letters of notification, public meetings, environmental assessments/environmental impact statements, site visits, and/or other method requested by a Native American interested party and Tribe. Failure of any contacted group to comment within thirty (30) calendar days shall not preclude the Corps from proceeding with the Project.

E. The Corps shall make a reasonable and good-faith effort to ensure that Native American Tribes, acting as either Concurring Parties or those expressing interest in the project, will be invited to participate in the development and implementation of the terms of this Agreement, including, but not limited to, the identification of the APE, identification of potential Historic Properties, determinations of eligibility, findings of effect, and the resolution of adverse effect for those Historic Properties. Review periods shall be consistent with **Stipulation I (Timeframes and Review Procedures)** except in situations involving unanticipated discoveries and treatment, which shall follow the review schedules of **Stipulation IX (Discovery of Unknown Historic Properties)**. The Corps shall ensure that all interested Native American reviewers shall receive copies of all final survey and evaluation reports.

XII. TRIBAL CONSULTATION AND TREATMENT OF HUMAN REMAINS

There is no federally owned property within the designated APE, therefore NAGPRA would not apply. The CVFPB and landowner shall ensure that Native American human remains and grave goods encountered during the Undertaking that are located on state or private land are treated in accordance with the requirements in California State Health and Safety Code, Section 7050.5 and Public Resources Code 5097.98. If Native American human remains are encountered within the context of a National Register eligible archaeological site, a clear means of identifying those remains and grave goods will be described in the HPMP. Any procedures described in the HPTP regarding the handling or treatment of human remains will be coordinated with the landowner to ensure that they are consistent with Public Resources Code 5097.98. In the event that any Native American human remains or associated funerary items are identified, the Most Likely Descendant (MLD), as identified by the Native American Heritage Commission, shall be invited to advise the CVFPB and landowner in the treatment of any Native American human remains and items associated with Native American burials.

XIII. PUBLIC CONSULTATION AND PUBLIC NOTICE

A. Pursuant to 36 C.F.R. § 800.6(c)(2)-(3), the Corps will consider requests by interested parties to become Concurring Parties to this Agreement. Within thirty (30) calendar days of the effective date of this Agreement, the Corps shall consult with the SHPO to compile a list of members of the interested public who shall be provided notice of this Agreement.

B. The interested public will be invited to provide input on the identification, evaluation, and proposed treatment of Historic Properties. This may be carried out through either letters of notification, public meetings, environmental assessment/environmental impact statements, and/or site visits. The Corps shall ensure that any comments received from members of the public are taken under consideration and incorporated where appropriate. Review periods shall be consistent with **Stipulation I (Timeframes and Review Procedures)**. In seeking input from the interested public, locations of Historic Properties will be handled in accordance with **Stipulation XIV (Confidentiality)**. In cases where the release of location information may cause harm to the Historic Property, this information will be withheld from the public in accordance with Section 304 of the NHPA (54 U.S.C. § 307103).

XIV. CONFIDENTIALITY

Confidentiality regarding the nature and location of the archaeological sites and any other cultural resources discussed in this Agreement shall be limited to appropriate Corps personnel, Corps contractors, Native American tribes, the SHPO, and those parties involved in planning, reviewing and implementing this Agreement in accordance with Section 304 of the NHPA (54 U.S.C. § 307103).

XV. DISPUTE RESOLUTION

A. Should any Signatory Party to this Agreement object in writing to any action proposed or carried out pursuant to this Agreement, the Corps will immediately notify the SHPO and the Concurring Parties of the objection and proceed to consult with the objecting party for a period of time, not to exceed thirty (30) calendar days, to resolve the objection. If the objection is resolved through consultation, the Corps may authorize the disputed action to proceed in accordance with the terms of such resolution. If the Corps determines that the objection cannot be resolved, the Corps shall forward all documentation relevant to the dispute to the ACHP. Within forty-five (45) calendar days after receipt of all pertinent documentation, the ACHP shall either:

(1) Advise the Corps that the ACHP concurs in the Corps' proposed response to the objection, whereupon the Corps will respond to the objection accordingly; or

(2) Provide the Corps with recommendations, which the Corps shall consider in reaching a final decision regarding the objection; or

(3) Notify the Corps that the ACHP will comment in accordance with the requirements of Section 106 of the NHPA, and proceed to comment. Any ACHP comment provided in response shall be considered by the Corps, pursuant to the requirements of Section 106 of the NHPA.

B. Should the ACHP not exercise one of the options under **Stipulation XV.A. (Dispute Resolution)** within forty-five (45) calendar days after receipt of all submitted pertinent documentation, the Corps' responsibilities under Section 106 of the NHPA are fulfilled upon implementation of the proposed response to the objection.

C. The Corps shall consider any ACHP recommendation or comment and any comments from the SHPO to this Agreement provided in accordance with this stipulation with reference only to the subject of the objection; the Corps' responsibility to carry out all actions under this Agreement that are not the subjects of the objection shall remain unchanged.

D. The Corps shall provide the SHPO with a written copy of its final decision regarding any objection addressed pursuant to **Stipulation XV.A. (Dispute Resolution)**.

E. At any time during implementation of the measures stipulated in this Agreement should an objection pertaining to the Agreement be raised by a Concurring Party, Native American Tribe, or a member of the public, the Corps shall notify the Signatory and Concurring Parties and take the objection under consideration, consulting with the objecting party and, should the objecting party request, any of the Signatory and Concurring Parties to this Agreement, for no longer than fifteen (15) calendar days. The Corps shall consider the objection, and in reaching its decision, will consider all comments provided by the other parties. Within fifteen (15) calendar days following closure of the comment period, the Corps will render a decision regarding the objection and respond to the objecting party. The Corps will promptly notify the other parties of its decision in writing, including a copy of the response to the objecting party. The Corps' decision regarding resolution of the objection will be final. Following issuance of its final decision, the Corps may authorize the action that was the subject of the dispute to proceed in accordance with the terms of that decision. The Corps' responsibility to carry out all other actions under this Agreement shall remain unchanged.

XVI. NOTICES

A. All notices, demands, requests, consents, approvals or communications from all parties to this Agreement to other parties to this Agreement shall be personally delivered, sent by United States Mail, or emailed, and all parties shall be considered in receipt of the materials five (5) calendar days after deposit in the United States mail, certified and postage prepaid, return receipt requested.

B. Signatory and Concurring Parties agree to accept facsimiles or copies of signed documents and agree to rely upon such facsimiles or copies as if they bore original signatures.

XVII. AMENDMENTS, NONCOMPLIANCE, AND TERMINATION

A. **Amendment:** Any Signatory Party to this Agreement may propose that the Agreement be amended, whereupon the Corps shall consult with the SHPO to consider such amendment. The Agreement may be amended only upon written concurrence of all Signatories.

All attachments to this Agreement, and other instruments prepared pursuant to this agreement including, but not limited to, the Project's description, initial cultural resource inventory report and maps of the APE, the HPMP, HPTPs, and monitoring and discovery plans, may be individually revised or updated through consultation consistent with **Stipulation I (Timeframes and Review Procedures)** and agreement in writing of the Signatories without requiring amendment of this Agreement, unless the Signatories through such consultation decide otherwise. In accordance with **Stipulation XI (Tribal Involvement)** and **Stipulation XIII (Public Consultation and Public Notice)**, the Concurring Parties, interested Native American Tribes, and interested members of the public, will receive amendments to the Project's description, initial cultural resource inventory report and maps of the APE, the HPMP, HPTPs, and monitoring and discovery plans, as appropriate, and copies of any amendment(s) to the Agreement.

B. **Termination:** Only the Signatories may terminate this Agreement. If this Agreement is not amended as provided for in **Stipulation XVII.A. (Amendment)**, or if any Signatory proposes termination of this Agreement for other reasons, the Signatory proposing termination shall notify the other Signatory in writing, explain the reasons for proposing termination, and consult with the other Signatory to seek alternatives to termination, within thirty (30) calendar days of the notification.

Should such consultation result in an agreement on an alternative to termination, the Signatories shall proceed in accordance with that agreement.

Should such consultation fail, the Signatory proposing termination may terminate this Agreement by promptly notifying the other Signatory and Concurring Parties in writing.

Beginning with the date of termination, the Corps shall ensure that until and unless a new agreement is executed for the actions covered by this Agreement, such undertakings shall be reviewed individually in accordance with 36 C.F.R. § 800.4-800.6.

C. Duration: This Agreement shall remain in effect for a period of ten (10) years after the date it takes effect and shall automatically expire and have no further force or effect at the end of this ten-year period unless it is terminated prior to that time. No later than ninety (90) calendar days prior to the expiration date of the Agreement, the Corps shall initiate consultation to determine if the Agreement should be allowed to expire automatically or whether it should be extended, with or without amendments, as the Signatories may determine. Unless the Signatories unanimously agree through such consultation on an alternative to automatic expiration of this Agreement, this Agreement shall automatically expire and have no further force or effect in accordance with the timetable stipulated herein.

XVIII. ANNUAL REPORTING

At the end of every calendar year following the execution of this Agreement, the Corps shall provide all parties to this Agreement a summary report detailing work carried out pursuant to its terms, if any. Such report shall describe progress made implementing the terms of the Agreement as well as include any scheduling changes proposed, any problems encountered, and any disputes and objections received in the Corps' efforts to carry out the terms of this Agreement. Any Signatory party may request to meet with the other Signatories to discuss implementation of this Agreement.

XIX. EFFECTIVE DATE

This Agreement shall take effect on the date that it has been fully executed by the Corps and the SHPO.

EXECUTION of this Agreement by the Corps and the SHPO, its transmittal to the ACHP, and subsequent implementation of its terms evidence that the Corps has afforded the ACHP an opportunity to comment on the undertaking and its effects on Historic Properties, that the Corps has taken into account the effects of the undertaking on Historic Properties, and that the Corps has satisfied its responsibilities under Section 106 of the NHPA and applicable implementing regulations for all aspects of the undertaking.

Attachment 1
U.S. Army Corps of Engineers
American River Common Features (ARCF) Project
Area of Potential Effects (APE)

Attachment 2

American River Common Features Project
Project Description
November 2014

The American River Common Features (ARCF) Project is being developed to provide flood risk reduction to the city of Sacramento, including the Natomas Basin, areas along the North and South banks of the American River, and areas along the East bank of the Sacramento River below the American River. The non-Federal sponsor for the ARCF Project is the State of California Central Valley Flood Protection Board (CVFPB). The Sacramento Area Flood Control Agency (SAFCA) has a Local Cooperation Agreement with the CVFPB. Authorized Local Cooperation Agreements include requirements to: 1) Provide lands, easements, and rights-of-way; 2) Modify or relocate utilities, roads, bridges (except railroad bridges), and other facilities where necessary for the construction of the project; 3) Cost share the project per applicable laws; and 4) Bear all costs of operation, maintenance, repair, rehabilitation and replacement of flood control facilities.

Location

The Sacramento River Watershed covers approximately 26,000 square miles in central and northern California. Shasta Dam impounds the upper Sacramento River Watershed. Major tributaries of the Sacramento River include the Feather, Yuba and American rivers. The American River Watershed covers about 2,100 square miles northeast of the city of Sacramento and includes portions of Placer, El Dorado, Alpine, and Sacramento counties. The American River Watershed includes Folsom Dam and Reservoir; inflowing rivers and streams, including the North, South, and Middle forks of the American River; and the American River downstream to its confluence with the Sacramento River in the city of Sacramento. The Sacramento and American rivers, in the Sacramento area, form a flood plain covering approximately 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento and encompasses the boundaries of the study area. Figure 1 shows the ARCF study area.

Area of Potential Effects (APE)

While the overall ARCF Project study area covers a broad geographic area, the ARCF Project area of potential effects (APE) includes those areas where the project will have potential direct or indirect effects to the character or use of historic properties. The ARCF Project APE includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; the Sacramento Bypass and Sacramento Weir; approximately 4 miles of the Pleasant Grove Creek Canal; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal. The APE is shown in Figure 2.

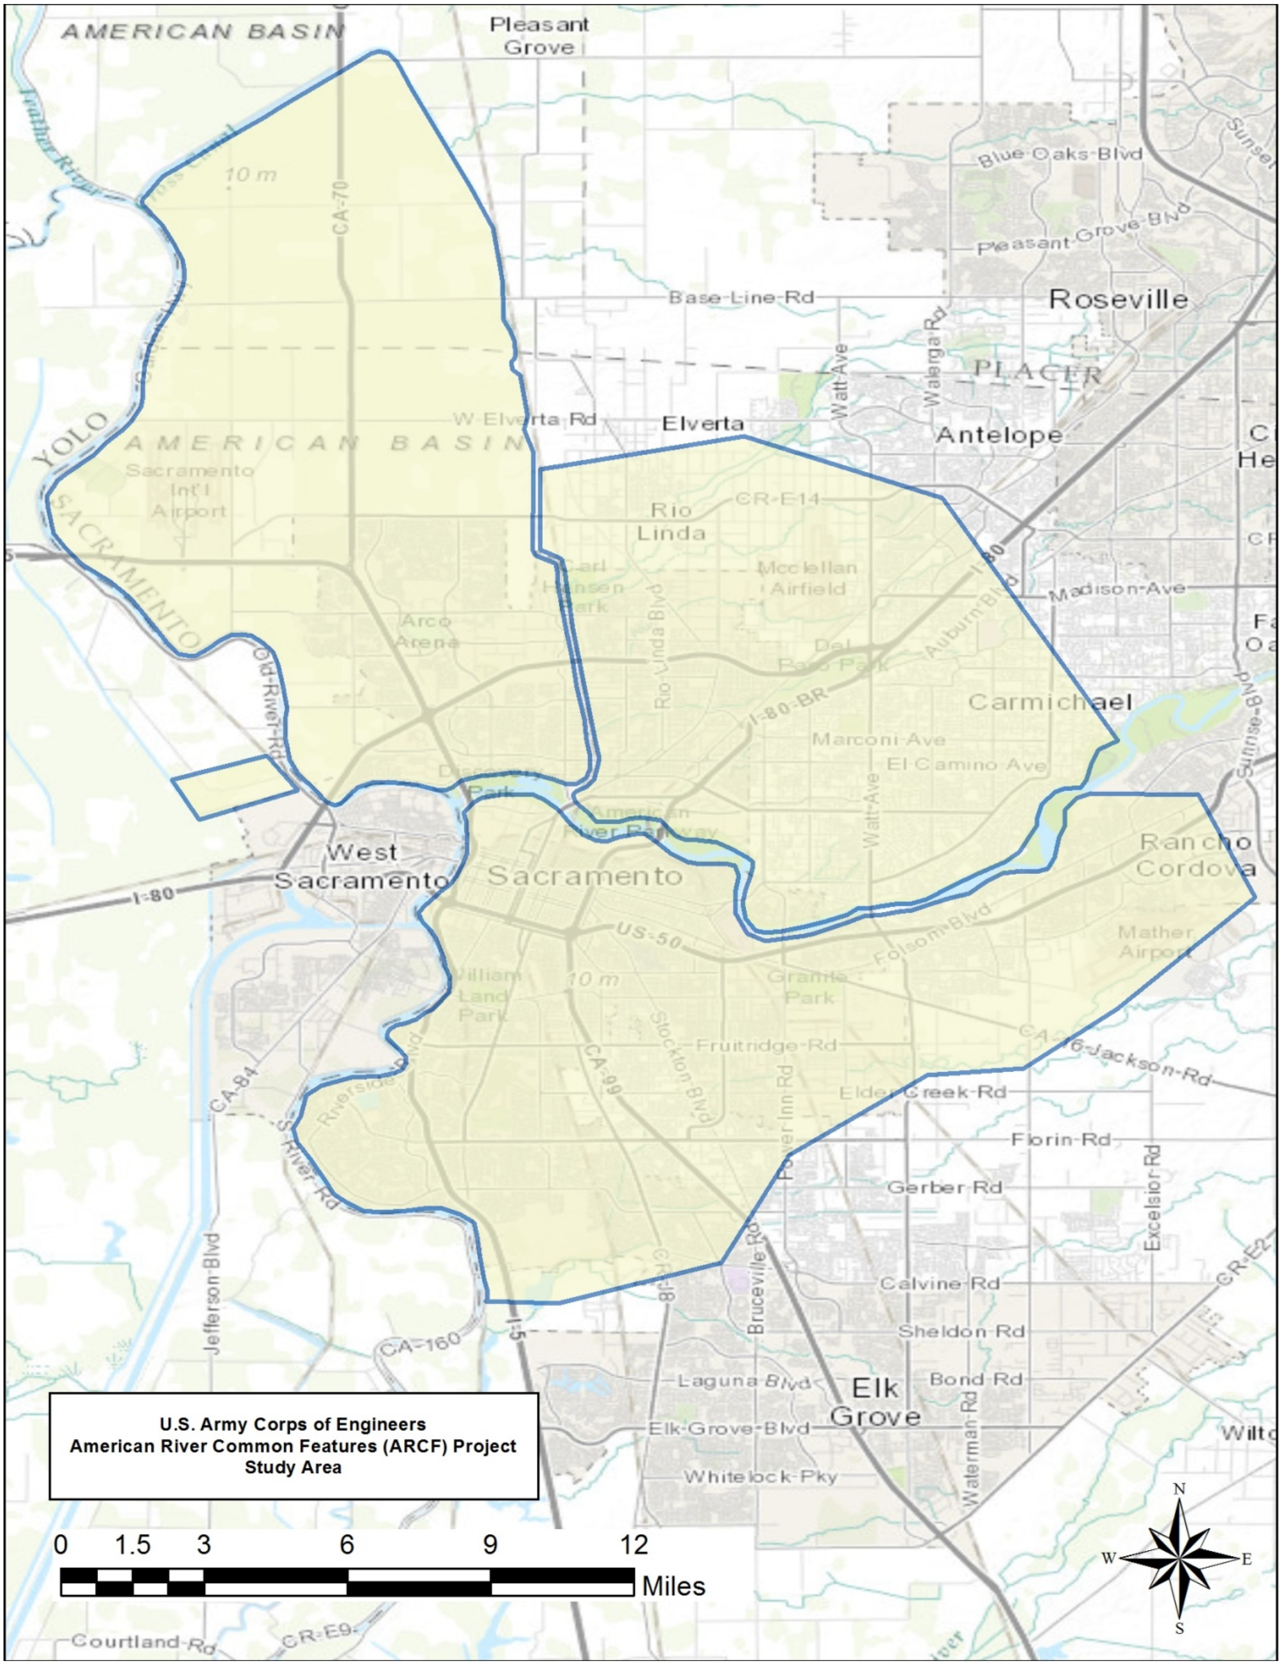

Figure 1. ARCF Project Study Area

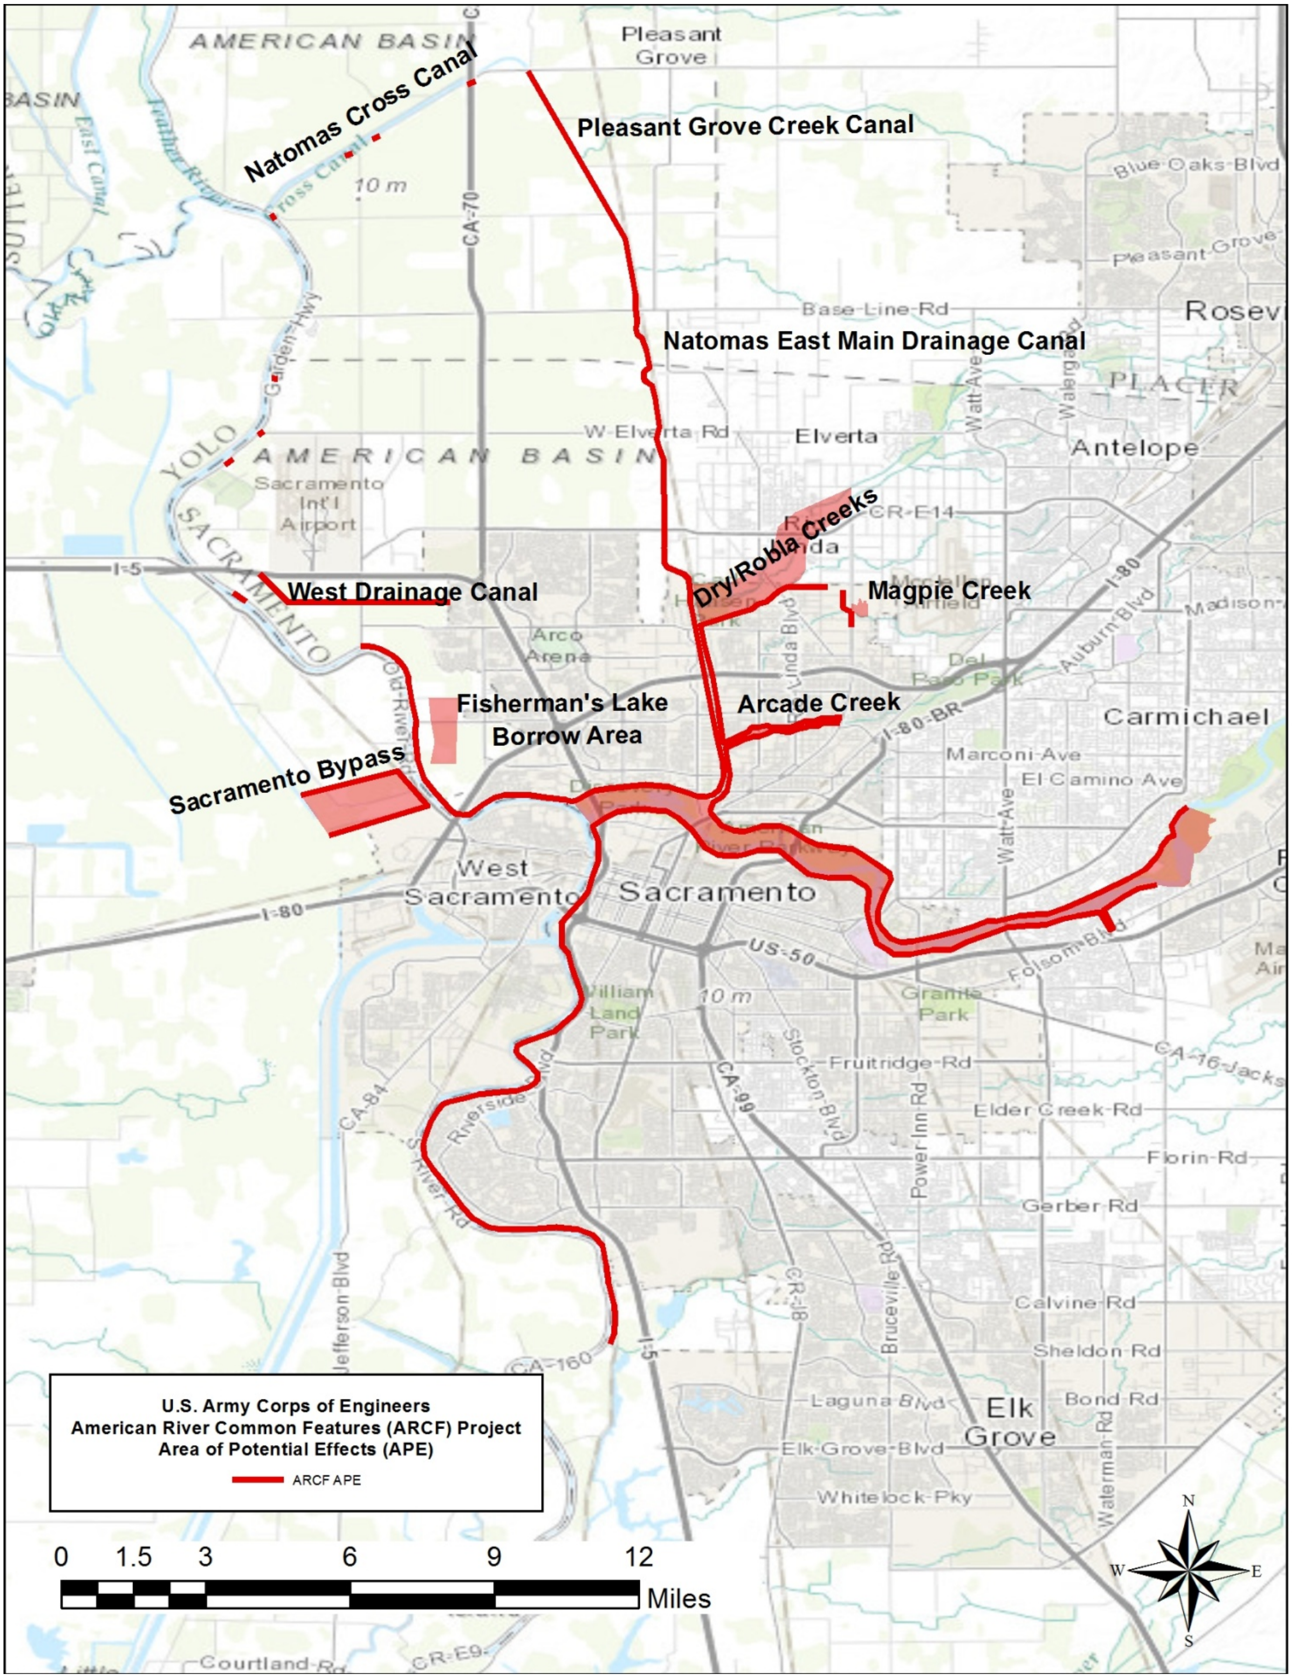

Figure 2. ARCF Project Area of Potential Effects

Project Authorization

The ARCF Project was authorized in the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. Significant changes to the project were approved via the Second Addendum to the Supplemental Information Report of March 2002. Additionally, the Energy and Water Development Appropriations Act of 2004 increased the authorized total cost of the project to $205,000,000. The current estimated cost of the authorized project is $277,563,000.

In the ARCF Project, authorized features are generally located in the Lower American River, Natomas Basin and Sacramento River. All Lower American River features authorized in WRDA 1996 and 1999 have been constructed or are scheduled for construction within the next three years. Construction of authorized Natomas features were deferred as a result of deep underseepage concerns raised after the 1997 flood event in the Sacramento Valley. In 1997, considerable deep underseepage occurred on the Sacramento River in areas that had previously undergone remediation after the 1986 flood event. The previous remediation consisted of shallow seepage cutoff walls and did not account for the deep underseepage problems revealed during the 1997 flood event. Significant seepage on the American River was also observed.

Because of the considerable cost increase of seepage remediation on the American River, all funds appropriated by Congress throughout the late 1990s and the early part of the 2000s were used for construction activities on the Lower American River instead of for design efforts in the Natomas Basin. Additionally, it was recognized that all work in the Natomas Basin would require significantly more features than was anticipated at the time of authorization. Additional levee improvements were also needed on the Sacramento River and the American River below Folsom Dam in order to truly capture the benefits of the Folsom Dam projects and the Common Features project already authorized and constructed. Therefore, the Corps decided that reevaluation studies would be required for the Natomas Basin and city of Sacramento portions of the ARCF Project. This reevaluation is now called the Common Features General Reevaluation Report (CFGRR).

Proposed Measures

In general, levees fail because of one of four reasons: seepage, slope stability, overtopping, and erosion. The CFGRR is looking at reducing the likelihood of having a levee failure in the city of Sacramento as a result of any of these reasons. Methods that were looked at to achieve this goal include, but are not limited to: seepage cutoff wall, seepage berm, levee slope flattening, relief wells, adjacent levee, stability berm, drained stability berm, levee raising, floodwall, bypass widening, riverbank erosion protection, and launchable rock erosion protection. These preliminary methods have been screened and refined to the following final array of measures. The ARCF Project is a single purpose flood risk management project with the measures shown in Table 1 below proposed for implementation. In addition to the measures listed in Table 1, the following measures would be implemented throughout the APE:

- Establish the Corps' standard levee footprint on all levees within the APE that are out of compliance, including a 10-foot-wide landside maintenance access easement.
- Bring utility encroachments, including pump stations, into compliance with Corps policy.
- Remove private encroachments.
- Relocate, as needed, irrigation canals within the Natomas Basin, to include the relocation of the West Drainage Canal south of the Airport Operations Area.
- Remediate the Highway 99/Natomas Cross Canal Bridge.

- Excavation of borrow materials at designated borrow sites, to include the South Fisherman's Lake Borrow Area and the West Lakeside School site in the Natomas Basin.

Table 1. Proposed Measures for the American River Common Features Project.

Waterway/Location	Extent of Action	Proposed Measure
American River	North and south levees from the confluence with the Sacramento River upstream for approximately 12 miles.	• Construct bank protection or launchable rock trenches
American River	North levee from the confluence with the Sacramento River upstream to approximately NEMDC.	• Flatten the levee slope • Install cutoff walls
Sacramento River	East levee from Power Line Road to the American River.	• Construct an adjacent levee with a flattened landside slope • Install cutoff walls • Construct seepage berms • Install relief wells • Construct levee raise • Establish compliance with Corps vegetation requirements for upper 2/3 slopes of the levee.
Sacramento River	East levee from the American River to Morrison Creek.	• Install cutoff walls • Construct bank protection • Construct levee raise • Establish compliance with Corps vegetation requirements for upper 2/3 slopes of the levee.
NEMDC	East levee from Dry/Robla Creek to the American River	• Install cutoff walls • Construct floodwalls • Establish compliance with Corps vegetation requirements.
NEMDC	West levee from Dry/Robla Creek to the American River	• Construct bank protection • Construct levee raise and flatten levee slope • Establish compliance with Corps vegetation requirements.
NEMDC	West levee from Sankey Road to Dry/Robla Creek	• Construct levee raise and flatten levee slope • Install cutoff walls • Establish compliance with Corps vegetation requirements.
Pleasant Grove Creek Canal	West levee	• Construct bank protection • Construct levee raise with a widened levee • Install cutoff walls • Upgrade or remove culverts

Waterway/Location	Extent of Action	Proposed Measure
		• Establish compliance with Corps vegetation requirements.
Arcade Creek	North and south levees from NEMDC to Marysville Boulevard	• Install cutoff walls • Raise floodwalls • Establish compliance with Corps vegetation requirements.
Dry/Robla Creek		• Raise floodwalls • Establish compliance with Corps vegetation requirements.
Magpie Creek Diversion Canal	Upstream of Raley Boulevard	• Construct floodwalls • Establish compliance with Corps vegetation requirements.
Magpie Creek area	South of Raley Boulevard	• Construct new levee
Magpie Creek area	East of Raley Boulevard	• Acquire property to create a flood detention basin • Widen the Raley Boulevard/Magpie Creek bridge and raise the elevation of the roadway • Remove the Don Julio Creek culvert
Sacramento Weir and Bypass	North bypass levee to 1,500 feet north.	• Widen the Sacramento Weir and Bypass by approximately 1,500 feet • Construct a new section of weir and levee • Remove the existing Sacramento Bypass north levee

Construction Activities

While the Corps began its reevaluation studies, SAFCA began final design and construction on certain areas in Natomas. A local sponsor or entity may request permission under Section 408 to alter a Federal project and a Section 404 permit to comply with the Clean Water Act. Generally a local sponsor or entity will request Section 408 permission and will move forward with the funding, planning, and constructing of the Federal project with the intention of seeking later credit under Section 104 for their share of an authorized Federal project. In 2008, the SAFCA requested consideration for a Section 104 credit, permission under Section 408, and requested a Section 404 permit for the Natomas Levee Improvement Project (NLIP). The Natomas Basin portions of the ARCF Project have been divided into a number of construction phases (Figure 3).

Shortly after receiving Section 408 permission and Section 404 approval, SAFCA, in cooperation with the California Department of Water Resources (DWR) and the CVFPB, implemented urgently needed improvements to the Federal project levee system around the Natomas Basin. SAFCA has completed construction for all of Phases 1, 2A, and 3 and is finishing construction of Phase 4a. When complete, SAFCA will have completed levee improvement construction on 18 miles of the 42 miles surrounding the Natomas Basin. The Corps will be constructing the remaining 24 miles of levee improvement once authorization and appropriations are received.

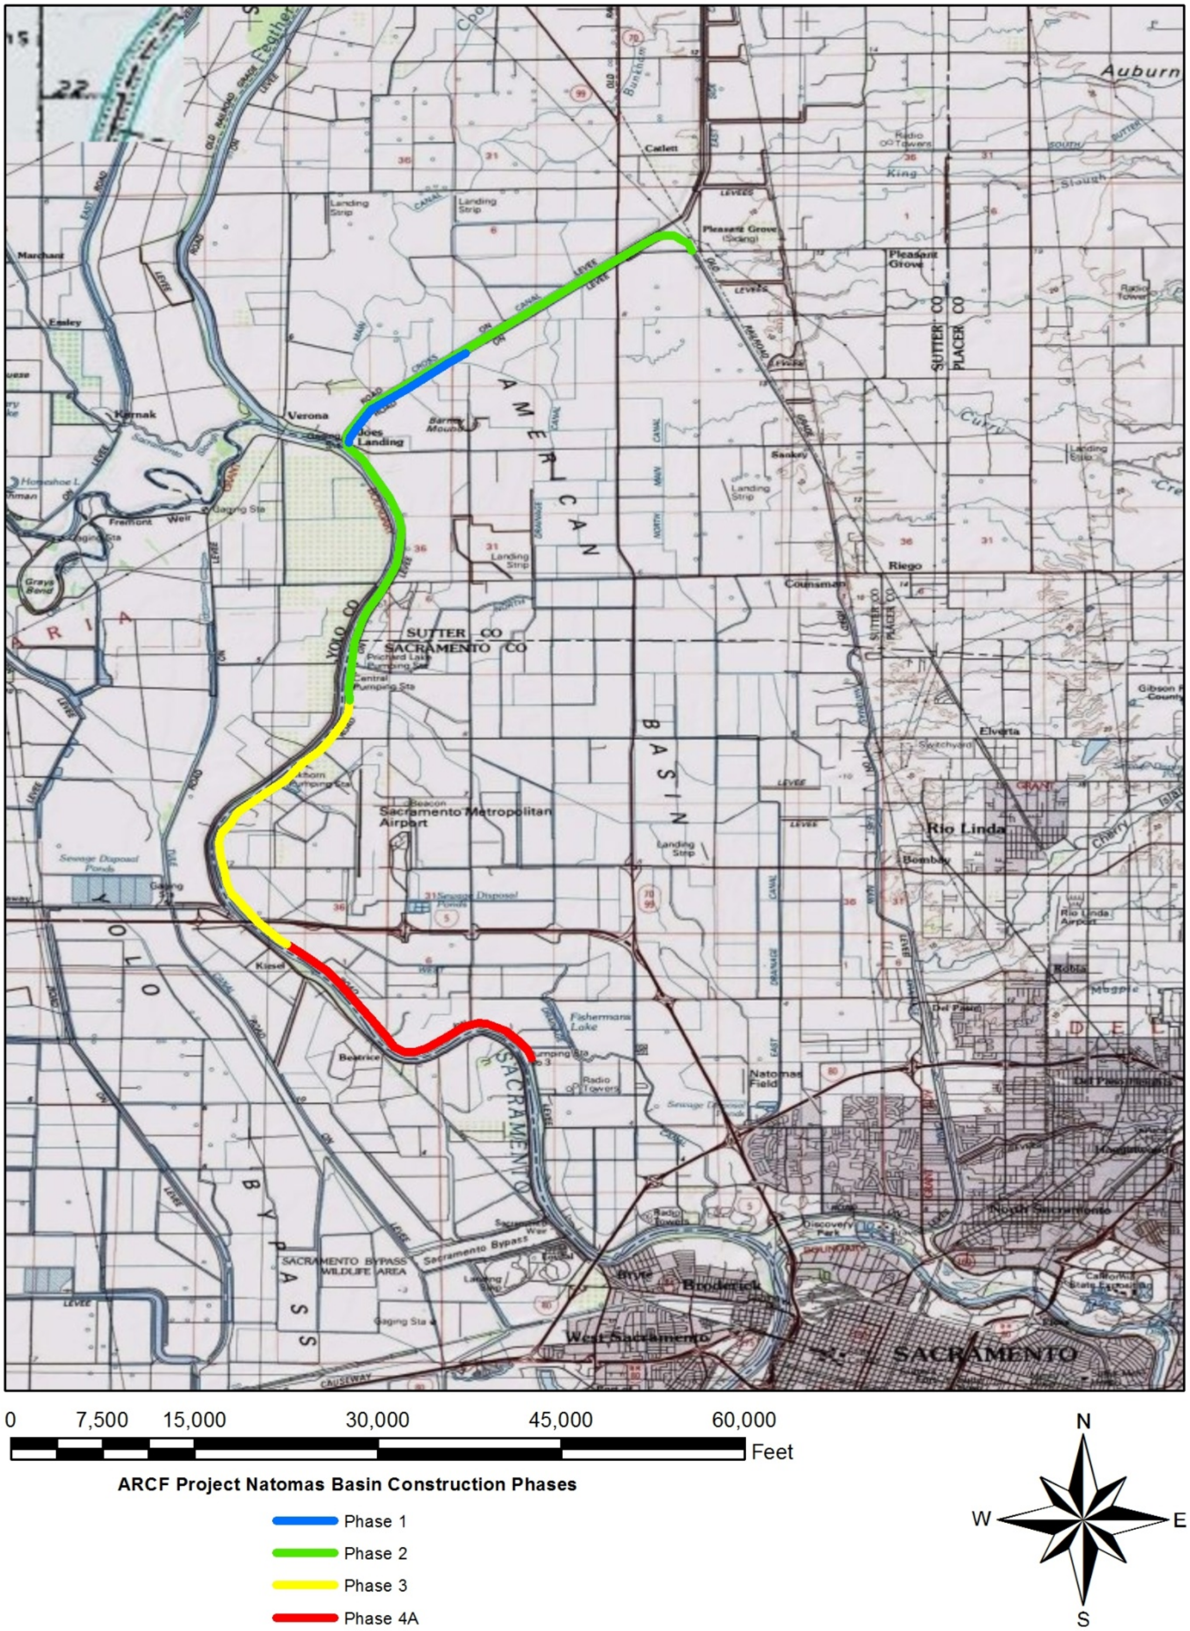

Figure 3. ARCF Project NLIP Construction Phases

Cultural Resources/NEPA Compliance

For NLIP Phases 1, 2, 3, and 4a, SAFCA, DWR and CVFPB were the lead decision makers on the planning, design, environmental and cultural resources compliance, and construction for NLIP. SAFCA contracted with EDAW (now AECOM) to complete EIS/EIRs for the overall Natomas Basin. In order to meet the requirements under the Section 404 permits and Section 408 permissions and because SAFCA planned to seek credit for their share of an authorized Federal project, SAFCA was required to comply with the National Environmental Policy Act of 1969 (NEPA) and the National Historic Preservation Act of 1966, as amended (NHPA).

Section 106 of the NHPA requires Federal agencies to take into account the effects of their undertaking on historic properties and afford the Advisory Council on Historic Preservation a reasonable opportunity to comment on such undertakings. The Code of Federal Regulations 36 CFR § 800 outlines the steps and guidelines a Federal agency must follow in order to comply with Section 106. The NEPA compliance effort in the NLIP Environmental Impact Statement/Environmental Impact Report (EIS/EIR), completed in 2007, provided an overview of the known cultural resources and historic properties within the Natomas Basin and the ARCF study area. The records and literature search identified 175 cultural resources and 285 surveys and inventories conducted within the ARCF study area.

Because of the size of the study area and because the assessment of effects to historic properties could not be completed prior to the signing of the Record of Decision for the EIS/EIR, an alternate method was required to ensure that the construction efforts within the Natomas Basin undertaken by
SAFCA would comply with Section 106 of the NHPA. When effects on historic properties cannot be fully determined prior to approval of an undertaking and when there may be potential adverse effects of a complex or phased project a programmatic agreement (PA) may be executed for the undertaking.

On May 1, 2008, a PA for NLIP was executed between the Corps, SAFCA and the SHPO. The NLIP PA only covered actions under the Section 408 permissions and Section 404 permits within the Natomas Basin for which SAFCA was the construction lead. By executing the PA the NLIP was then in compliance with Section 106 and the signatories to the NLIP PA (the Corps, SAFCA and the SHPO) had an agreed upon series of stipulations that fulfilled the requirements of 36.CFR § 800. The Corps had the responsibility of determining if the actions by SAFCA complied with Section 106 and coordinating concurrence with those determinations with the SHPO. All construction efforts for NLIP Phases 1, 2, 3, and 4a were funded entirely by SAFCA, DWR and CVFPB.

Prior to the construction of Phases 1, 2, 3, and 4a, a series of NEPA compliance documents were completed as supplements to the original EIS/EIR completed in 2007. Phase 1 was covered in an Environmental Assessment/Impact Statement dated November 2007. Phase 2 was covered in a supplement to the EIS/EIR completed in November 2008. Phase 3 was covered in an EIS/EIR completed May 2009. And Phase 4a was covered in a EIS/EIR completed November 2009.

Because construction of Phases 1, 2, 3, and 4a does not address all of the flood risk concerns in the Natomas Basin, it does not provide complete flood protection for the entire Natomas Basin. Due to funding constraints with SAFCA, DWR and CVFPB, construction of the remaining perimeter of the Natomas Basin will not be completed under the Section 408 permissions and Section 404 permits. Therefore, as part of our reevaluation efforts (CFGRR), the Corps is implementing completion of the remaining phases in the Natomas Basin, as well as the other portions of the ARCF Project as the Federal lead on the project. The remaining Natomas construction was covered under NEPA/CEQA in the NLIP Phase 4b EIS/EIR in October 2010. The Corps will also be preparing a NEPA/CEQA document for the CFGRR for those activities not covered in the previous NEPA/CEQA documents.

Although the NLIP PA covered Section 106 compliance for the entirety of possible construction activities in the Natomas Basin, the roles and responsibilities of the NLIP PA designated SAFCA as responsible for the execution of inventories, surveys, recordation of sites, determinations of eligibility, and development of historic properties treatment plans and mitigation measures. The NLIP PA includes the Corps and SAFCA in roles as regulatory authority but with no involvement in the production of technical studies or determinations of effect.

The previously completed EIS/EIRs are applicable for overall NEPA compliance for the Natomas Basin. However, in order for the Corps to be in compliance with Section 106 of the NHPA, and due to the changing roles and responsibilities and authorities, a new PA will need to be developed and executed for the remaining construction activities the Corps will undertake in the Natomas Basin as well as the other authorized project features for the rest of the ARCF Project.

Similar to the NLIP PA, the ARCF PA will outline the steps the Corps, as the lead Federal agency for NEPA, will take in order to comply with Section 106 of the NHPA. The ARCF PA must be executed in advance of any construction activities the Corps may undertake for the ARCF Project.

Attachment 3

Historic Properties Management Plan

Historic Properties Management Plan (HPMP) shall include:

I. Introduction and Description of the Undertaking
   a. Overview and Executive Summary
   b. Purpose and Application of the HPMP
   c. Regulatory context
   d. Description of the Undertaking

II. General Standards and Procedures
   a. Professional Qualifications
   b. Documentation Standards
   c. Dissemination and Confidentiality of Information
   d. Permits and Rights of Entry
   e. Curation

III. Background Information
   a. Records and Literature Search
   b. Archaeological Sensitivity Assessment Procedure
   c. Correspondence with Knowledgeable Individuals and Groups
   d. American Indian Outreach

IV. Historic Context
   a. Prehistoric Resource Types
   b. Historic Resource Types
   c. Environmental Context
      i. Regional Surface Geology
      ii. Regional Geomorphology
      iii. Climate
      iv. Flora and Fauna
   d. Cultural Context
      i. Prehistoric Archaeology
      ii. Ethnographic Context
      iii. Historic Context

V. Identification of Historic Properties
   a. General Methods
   b. Evaluation
   c. Documentation

VI. American Indian Consultation Procedures
   a. American Indians and Organizations as Concurring Parties
   b. American Indians and Organizations as Non-Concurring Parties

VII. Assessment of Effects
   a. Criteria of Adverse Effect
   b. Finding of Effect

Attachment 4

Property Types Exempt from Evaluation

This attachment defines categories of properties that do not warrant evaluation pursuant to Stipulation IV.B of this Agreement. Only individuals meeting the Secretary of the Interior's Professional Qualification Standards pursuant to Stipulation VII.A of this agreement are authorized to determine whether properties meet the requirements of this attachment and are therefore exempt from evaluation and consultation with SHPO. Exempted properties may be documented, if documentation is warranted, at a level commensurate with the nature of the property (e.g., DPR 523 Primary Form, Location Map, memo). The Corps Cultural Resources staff shall make any final determinations on level of documentation required under this agreement.

Exempt Property Type 1: Archaeological Property Types and Features

1. Isolated prehistoric finds consisting of fewer than three items per 100 m^2
2. Isolated historic finds consisting of fewer than three artifacts per 100 m^2 (several fragments from a single glass bottle, and similar vessels are to be counted as one artifact)
3. Refuse scatters less than 50 years old (scatters containing no material that can be dated with certainty as older than 50 years old)
4. Features less than 50 years old (those known to be less than 50 years old through map research, inscribed dates, etc.)
5. Isolated refuse dumps and scatters over 50 years old that lack specific associations
6. Isolated mining prospect pits
7. Placer mining features with no associated structural remains or archaeological deposits
8. Foundations and mapped locations of buildings or structures more than 50 years old with few or no associated artifacts or ecofacts, and with no potential for subsurface archaeological deposits

Exempt Property Type 2: Minor, Ubiquitous, or Fragmentary Infrastructure Elements

The following list does not apply to properties 50 years old or older that could be potentially important, nor does it apply to properties that may contribute to the significance of larger historic properties such as districts or cultural landscapes.

Water Conveyance and Control Features

- Natural bodies of water providing a water source, conveyance, or drainage
- Modified natural waterways

- Concrete-lined canals less than 50 years old and fragments of abandoned canals
- Roadside drainage ditches and secondary agricultural ditches
- Small drainage tunnels
- Flood storage basins
- Reservoirs and artificial ponds
- Levees and weirs
- Gates, valves, pumps, and other flow control devices
- Pipelines and associated control devices
- Water supply and waste disposal systems
- Rip-rap

Recent Transportation or Pedestrian Facilities

- Railroad grades converted to other uses, such as roads, levees, or bike paths
- Bus shelters and benches
- Vista points and rest stops
- Bike paths, off-road vehicle trails, equestrian trails, and hiking trails
- Parking lots and driveways

Highway and Roadside Features

- Isolated segments of bypassed or abandoned roads
- Retaining walls
- Highway fencing, soundwalls, guard rails, and barriers
- Drains and culverts, excluding culverts assigned a Caltrans bridge number
- Cattle crossing guards
- Roadside landscaping and associated irrigation systems
- Signs and reflectors
- Telecommunications services, including towers, poles, dishes, antennas, boxes, lines, cables, transformers, and transmission facilities
- Utility services, including towers, poles, boxes, pipes, lines, cables, and transformers
- Oil and gas pipelines and associated control devices

Adjacent Features

- Fences, walls, gates, and gateposts

- Isolated rock walls and stone fences
- Telephone booths, call boxes, mailboxes, and newspaper receptacles
- Fire hydrants and alarms
- Markers, monuments, signs, and billboards
- Fragments of bypassed or demolished bridges
- Temporary roadside structures, such as seasonal vendors' stands
- Pastures, fields, crops, and orchards
- Corrals, animal pens, and dog runs
- Open space, including parks and recreational facilities
- Building and structure ruins and foundations less than 50 years old

Movable or Minor Objects

- Movable vehicles
- Stationary vehicles less than 50 years old or moved within the last 50 years
- Agricultural, industrial and commercial equipment and machinery
- Sculpture, statuary, and decorative elements less than 50 years old or moved within the last 50 years

American River Common Features GRR

EIS Cultural Resources Appendix

Enclosure 2

Section 106 Consultation Record

American River Common Features Project SHPO, ACHP, Sponsor Consultation Record*

***May not include all communication for project.**

12/31/15

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
2/1/2012	Outgoing Letter	ACHP	Reid Nelson	Inform ACHP of proposed project, process to be followed, ask for participation in PA.
2/1/2012	Outgoing Letter	SHPO	Milford Donaldson	Request comments on APE, proposed efforts to identify historic properties, plan to develop PA.
4/11/2012	Outgoing Email	State of CA	Erin Brehmer, Mary Hadden	Transmittal of draft PA for sponsor review, request comments.
4/13/2012	Incoming Email	State of CA	Erin Brehmer	Acknowledgement of receipt of PA and will sent to CVFPP and DWR cultural staff.
5/22/2012	Outgoing Email	State of CA	Erin Brehmer	Request timeframe for CVFPP and DWR review of PA.
6/13/2012	Incoming Email	State of CA	Erin Brehmer	Transmittal that DWR had no comments on PA and CVFPP transmittal of comments.
6/20/2012	Outgoing Phone Call	CVFPP	James Herota	Discussed CVFPP comments on PA, explained that CEQA specific language would not be included.
6/20/2012	Outgoing Email	State of CA	Erin Brehmer	Responses to CVFPP PA comments.
6/21/2012	Incoming Email	CVFPP	James Herota	Receipt of additional Native American contacts from CVFPP.
7/16/2012	Outgoing Letter	SHPO	Milford Donaldson, Susan Stratton, Dwight Dutsche	Letter transmitting PA for review and comment, determination of the APE, potential adverse effects, resolution of adverse effects through a PA, suggest meeting.
7/16/2012	Outgoing Letter	ACHP	Reid Nelson	Letter transmitting PA for review and comment, request notification if ACHP plans to participate in the PA.
7/16/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche	Email transmittal of 7/16/12 formal letter.
7/16/2012	Outgoing Email	ACHP	Tom McCulloch	Email transmittal of 7/16/12 formal letter.
7/27/2012	Incoming Email	ACHP	Tom McCulloch	Acknowledgement of receipt of 7/16/12 letter, ask if ACHP participation is needed, ask if comments on PA needed.
7/27/2012	Outgoing Email	ACHP	Tom McCulloch	Request any comments from the ACHP on PA, ACHP participation in PA probably not needed unless ACHP thinks so after reading submitted information.
8/7/2012	Incoming Letter	ACHP	Raymond Wallace	ACHP decline to participate in PA, request final signed and executed PA once completed.
8/7/2012	Outgoing Email	ACHP	Tom McCulloch	Request for any comments on PA, acknowledge letter from ACHP declining to participate.
8/14/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche	Follow up to 7/16/12 formal letter and email requesting comments on PA, proposing a meeting, transmittal of ACHP declining to participate.
9/17/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche	Follow up to 7/16/12 formal letter, follow up emails on 7/16/12 and 8/14/12 requesting comments on PA and date for when comments would be available.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
10/10/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche	Email request for consultation meeting with SHPO to include PDT (Dan Tibbitts and Sara Schultz) to discuss project and PA.
10/23/2012	Consultation Meeting	SHPO	Susan Stratton, Dwight Dutsche, Dan Tibbitts, Melissa Montag	Consultation meeting to discuss project and PA, SHPO provided comments on the PA.
10/25/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche	Email addressing comments from 10/23/12 meeting, transmittal of revised PA, request concurrence on PA acceptability, propose meeting in November.
10/29/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche, Brendan Greenaway, Dan Tibbitts, Melissa Montag	Email request for follow up consultation meeting to 10/23/12 meeting and 10/25/12 email and changes/revisions to PA.
11/5/2012	Consultation Meeting	SHPO	Susan Stratton, Dwight Dutsche, Brendan Greenaway, Dan Tibbitts, Sara Schultz, Melissa Montag	Consultation meeting to discuss project and PA, SHPO requested a Historic Properties Management Plan be included in PA.
11/7/2012	Outgoing Email	SHPO	Susan Stratton, Dwight Dutsche, Brendan Greenaway, Dan Tibbitts, Sara Schultz	Transmittal of current draft of PA after incorporating comments from 11/5/12 meeting, communication of project schedule and long term phasing, requested comments on draft PA by 12/31/12.
1/14/2013	Outgoing Email	SHPO	Brendan Greenaway	Email transmittal of draft PA sent 11/7/12, request comments from SHPO.
1/14/2013	Incoming Email	SHPO	Brendan Greenaway	Acknowledgement of 1/14/13 transmittal, no comments from SHPO yet. Will review, suggested sending draft PA to concurring parties.
1/14/2013	Outgoing Email	SHPO	Brendan Greenaway	Acknowledgement of 1/14/13 email from SHPO.
1/30/2013	Outgoing Email	SHPO	Susan Stratton, Brendan Greenaway	Transmittal of draft HPMP for SHPO review and comment.
2/11/2013	Outgoing Email	DWR	Jacqueline Wait	Transmittal of draft PA to sponsor, provided project information, CVFPP comments from 2012, requested comments on draft PA.
2/11/2013	Outgoing Email	SAFCA	Peter Buck	Email to inquire who at SAFCA would review PA.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
2/12/2013	Incoming Email	SAFCA	Peter Buck	Acknowledgement of 2/11/12, request PA be sent to Mr. Buck.
2/12/2013	Outgoing Email	SAFCA	Peter Buck	Transmittal of draft PA for SAFCA review.
3/14/2013	Incoming Email	SHPO	Brendan Greenaway	Acknowledgement of draft HPMP sent 1/30/13, agreed document was acceptable.
3/19/2013	Incoming Email	SAFCA	Peter Buck	Email informing Corps that draft PA is still being reviewed by SAFCA counsel.
4/10/2013	Outgoing Email	DWR	Jacqueline Wait	Follow up email to 2/11/13 email transmitting electronic documents again and requesting comments on draft PA by 5/20/13.
4/11/2013	Incoming Email	SAFCA	Peter Buck	Transmittal of SAFCA comments on draft PA.
6/13/2013	Incoming Email	SHPO	Brendan Greenaway	Queried status of PA.
6/13/2013	Outgoing Email	SHPO	Brendan Greenaway	Informed SHPO that the PA is undergoing additional review by Native Americans, ACHP has declined to participate and Corps would appreciate any comments SHPO may have on draft PA. Told SHPO of general project schedule.
6/13/2013	Incoming Email	SHPO	Brendan Greenaway	Acknowledgment of 6/13/13 email.
9/19/2013	Outgoing Email	DWR	Erin Brehmer, Jacqueline Wait	Transmittal of EIS Cultural Resources section for State/Sponsor CEQA review.
9/19/2013	Outgoing Email	DWR	Jacqueline Wait	Transmittal of Archaeological Sensitivity Analysis for State/Sponsor review.
6/12/2014	Outgoing Email	DWR	Brehmer, David Martasian, Wait	Transmittal of updated EIS/EIR Cultural Resources appendix and current version of final draft of the PA.
6/13/2014	Outgoing Email	SHPO	Brendan Greenaway	Transmittal of final draft of PA for SHPO review, summarized consultation efforts with DWR, ACHP, and tribes so far.
6/13/2014	Incoming Email	SHPO	Brendan Greenaway	Acknowledgement of 6/13/14 email transmittal. Stated SHPO will review once current draft of PA has been circulated to tribes. Asked for the review period for tribes on the current draft.
6/13/2014	Outgoing Email	SHPO	Brendan Greenaway	Response to SHPO email above, stating current review of draft PA for tribes is 30 days and that the tribes received the draft PA for a 45 day review period in 2013.
6/13/2014	Incoming Email	SHPO	Brendan Greenaway	Restated SHPO will review following the current 30 day review period. Asked to provide any response to the 30 day review period once it has passed.
6/13/2014	Outgoing Letter	SHPO	Brendan Greenaway	Outgoing letter (hand delivered) to SHPO. Requests that the SHPO concur on the Corps' determination of the APE, plans to identify cultural resources through sensitivity assessment, and provide comments on the final draft of the PA.
6/13/2014	Outgoing Letters	DWR, ACHP	Jacqueline Wait, Reid Nelson	Copy furnished (with enclosures) 6/13/14 letter to SHPO for DWR and ACHP files.
6/16/2014	Outgoing Email	SHPO	Brendan Greenaway	Response to 6/13/14 email, mentioned the Corps would like to execute the PA this fall, offered to arrange for site visit or hold a meeting to provide additional information that could help with SHPO's review.
6/17/2014	Incoming Email	SHPO	Brendan Greenaway	Response to 6/16/14 email that a field trip might be a good idea, asked for what and where the field trip could cover.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
6/17/2014	Outgoing Email	SHPO	Brendan Greenaway	Response to 6/17/14 email that the field trip could cover four locations where the Corps is proposing work to show the scope of the effort, provide information on the construction, as well as future efforts to identify cultural resources in accordance with the PA. Requested three available dates to schedule a site visit.
6/17/2014	Incoming Email	SHPO	Brendan Greenaway	Will check schedules for attendance for site visit to include Jessica Tudor and Susan Stratton.
6/26/2014	Outgoing Email	SHPO	Brendan Greenaway	Follow up to email from 6/17/14 to suggest 7/31/14 for a field visit, possibly to include stops for West Sac Project as well.
7/2/2014	Incoming Email	SHPO	Jessica Tudor	Ms. Tudor requested list of comments from Mr. Dutsche on the draft PA, and what comments may have been addressed, or not.
7/3/2014	Outgoing Email	SHPO	Jessica Tudor	Response to 7/2/14 email, provided Ms. Tudor with email from Ms. Montag to SHPO on 10/25/12 that addressed comments from SHPO and provided a new draft of the PA. Provided information that no written comments have been received, though the SHPO did suggest the development of a HPMP as an attachment to the PA, to be developed later. Also suggested the field visit, possibly for 7/31/14.
7/3/2014	Incoming Email	SHPO	Jessica Tudor	Requested information on proposed field trip on 7/31/14, as well as the timeline for the review of the draft PA, APE, and historic properties identification efforts.
7/3/2014	Outgoing Email	SHPO	Jessica Tudor	Response to 7/3/14 email, provided logistical information on proposed field trip, that the review of the draft PA can take place in a few weeks but preferably prior to field trip on 7/31/14, and the Corps' plan to release the draft PA with the draft EIS/EIR in mid-August, preferably with comments from SHPO incorporated and comments from tribes considered (if they have been received).
7/3/2014	Incoming Email	SHPO	Jessica Tudor	Ms. Tudor said she is available for field visit on 7/31/14, will check with Ms. Stratton and Mr. Greenaway on their availability.
7/3/2014	Outgoing Email	SHPO	Jessica Tudor	Forwarded 7/31/14 field visit meeting request to Ms. Tudor.
7/3/2014	Incoming Email	SHPO	Jessica Tudor	Accepted 7/31/14 field visit meeting request.
7/22/2014	Outgoing Email	DWR	Erin Brehmer, David Martasian, Jacqueline Wait	Sent email to let DWR that UAIC has requested to meet with the Corps regarding the project and PA. Asked that DWR check and confirm availability on August 4th or 5th. Asked for a response ASAP.
7/22/2014	Incoming Email	DWR	David Martasian	Acknowledged 7/22/14 email, said would check and respond ASAP.
7/22/2014	Outgoing Email	DWR	David Martasian	Acknowledged 7/22/14 email from Mr. Martasian.
7/25/2014	Incoming Email	DWR	Erin Brehmer	Response to 7/22/14 email, Ms. Wait has recommended that Anecita Agustinez attend the meeting for DWR and is available on August 5th.
7/28/2014	Incoming Phone Call	DWR	Erin Brehmer	Ms. Brehmer called to follow up to 7/25/14 email, left voice message.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
7/29/2014	Outgoing Phone Call	DWR	Erin Brehmer	Ms. Montag called Ms. Brehmer to discuss the potential meeting on August 5th, asked if Ms. Wait was planning to attend since much of the discussion may center on the project PA and Section 106 requirements. Ms. Brehmer said it was recommended that Ms. Agustinez attend for DWR.
7/29/2014	Outgoing Meeting Request	DWR	Erin Brehmer, David Martasian, Jacqueline Wait, Anecita Agustinez	Sent placeholder meeting request for 8/5/14 meeting with DWR and UAIC.
7/29/2014	Outgoing Email	SHPO	Jessica Tudor	Email to Ms. Tudor that field visit on 7/31/14 has to be cancelled due to logistical reasons. Asked for availability the week of August 11th or 18th.
7/29/2014	Incoming Email	SHPO	Jessica Tudor	Response to 7/29/14 email that those dates are generally open for Ms. Tudor.
7/31/2014	Outgoing Email	SHPO	Jessica Tudor	Asked Ms. Tudor if 8/13/14 or 8/14/14 would work better for the field visit.
7/31/2014	Incoming Email	SHPO	Jessica Tudor	Ms. Tudor responded that either date would work.
7/31/2014	Outgoing Meeting Request	SHPO	Jessica Tudor, Susan Stratton, Brendon Greenaway	Sent meeting request for field visit on 8/13/14.
7/31/2014	Incoming Email	SHPO	Jessica Tudor	Accepted 8/13/14 field visit request.
7/31/2014	Incoming Email	SHPO	Susan Stratton	Declined 8/13/14 field visit request.
7/31/2014	Incoming Email	SHPO	Jessica Tudor	Requested Word version of final draft of PA.
8/1/2014	Outgoing Email	SHPO	Jessica Tudor	In response to 7/31/14 email, sent Word version of final draft of PA.
8/1/2014	Outgoing Email	DWR	Erin Brehmer, David Martasian, Jacqueline Wait, Anecita Agustinez	Revised placeholder meeting sent on 7/29/14 to meeting times for meeting with UAIC on 8/5/14.
8/1/2014	Incoming Email	DWR	David Martasian	Accepted 8/5/14 meeting request.
8/4/2014	Incoming Email	DWR	Erin Brehmer	Accepted 8/5/14 meeting request.
8/4/2014	Incoming Email	DWR	Jacqueline Wait	Accepted 8/5/14 meeting request.
8/4/2014	Incoming Email	DWR	Anecita Agustinez	Declined 8/5/14 meeting request.
8/5/2014	Consultation Meeting	Corps, DWR, Tribes	David Martasian, Erin Brehmer, Jacqueline Wait	Consultation meeting held with UAIC and SSBMI.
8/8/2014	Incoming Email	SHPO	Jessica Tudor, Susan Stratton	Comments provided on draft PA sent 8/1/14.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
9/2/2014	Outgoing Email	DWR	David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez	Sent link to Doodle poll to schedule next meeting with UAIC and SSBMI for late October/early November. Requested response to poll by 9/17/14. Welcomed receiving any comments on the draft programmatic agreement.
9/4/2014	Incoming Email	DWR	David Martasian	Responded to Doodle poll.
11/17/2014	Outgoing Email	SHPO	Jessica Tudor	Sent track changes version of draft PA responding to comments sent 8/8/14, included additional language and current version of PA that will be included with draft EIS/EIR to be released to the public in mid-December. Suggested a face-to-face meeting to resolve any lingering issues before moving to a final draft of PA.
12/10/2014	Outgoing Email	DWR	David Martasian, Erin Brehmer, Jacqueline Wait	Sent current versions of cultural resources sections from the EIS/EIR to ask if DWR has any comments or changes needed in order to comply with CEQA because the EIS/EIR will be going to the CVFPB in January for approval for public release. Stated that comments would be needed in early January to make any changes.
7/1/2015	Outgoing Email	SHPO	Jessica Tudor	Sent an updated version of the PA with comments addressed (similar to 11/17/14 version) as well as merged changes as a result of consultation with tribes. Suggested a meeting to discuss and that the Corps would like to execute the PA around September.
8/6/2015	Outgoing Email	SHPO	Jessica Tudor, Anmarie Medin	Transmittal of updated clean draft of the PA with comments addressed. Suggested meeting to go over changes and edits, if needed, as the Corps is working to execute the PA in September.
9/10/2015	Meeting	SHPO	Anmarie Medin, Julianne Polanco	Signing and execution of final PA for ARCF Project.
10/30/2015	Outgoing Email	ACHP	Brian Lusher	Transmittal of signed and executed PA to the ACHP.
10/30/2015	Outgoing Email	SHPO	Jessica Tudor, Anmarie Medin	Transmittal of list of potential concurring parties to transmit notice of PA, requested a response from SHPO within two weeks.
11/2/2015	Incoming Letter	ACHP	Brian Lusher	Acceptance and acknowledgement of the PA by the ACHP.
11/9/2015	Incoming Email	SHPO	Jessica Tudor	In response to 10/30/15 email, Ms. Tudor suggested adding the Society for California Archaeology and potential historical societies/museums to the mailing list of possible concurring parties.
11/17/2015	Outgoing Email	SHPO	Jessica Tudor, Anmarie Medin	In response to 11/9/15 email, Ms. Montag stated the Society of California Archaeology and several historical societies have been added as potential concurring parties to the PA and if SHPO thinks of any additional parties to let the Corps know.
11/30/2015	Incoming Email	SHPO	Jessica Tudor	Acknowledgement of 11/17/15 email.

American River Common Features Project Native American Consultation Record*

*****May not include all communication for project.

12/31/15

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
5/4/2011	Outgoing Letters	Mechoopda Indian Tribe of Chico Rancheria (MITCR), Shingle Springs Bank of Miwok Indians (SSBMI), Strawberry Valley Rancheria (SVR), Tsi-Akim Maidu (TAM), United Auburn Indian Community (UAIC), Wilton Rancheria (WR), Nashville-El Dorado Miwok (NEDM), Ione Band of Miwok Indians (IBMI), El Dorado Miwok Tribe (EDMT), Enterprise Rancheria of Maidu Indians (ERMI), Buena Vista Rancheria (BVR)	Various	Letter to Native American tribes with potential interest in the American River Common Features (ARCF) Project area of potential effects (APE) informing them of upcoming geotech borings and upcoming Programmatic Agreement (PA).
5/9/2011	Incoming Letter	MITCR	Mike DeSpain	Response letter from 5/4/11 letter expressing tribe's concerns about possible cultural resources sites, unaware of sites within the project area. Requested that is cultural resources are found that a funded tribal monitor be put in place.
6/2/2011	Incoming Letter	UAIC	Marcos Guerrero	Response letter from 5/4/11 letter expressing tribe's concerns about possible cultural resources sites impacted by development. Requested copies of archeological reports produced for the project, future environmental documents, and opportunity for UAIC consultants to accompany Corps during field surveys. Request to set up a field visit and concurring party status on
6/24/2011	Incoming Email	UAIC	Marcos Guerrero	Request initiation of Native American consultation for Natomas Levee Improvements Project (NLIP) and American River Common Features (ARCF) Project. Request environmental and cultural reports.
9/13/2011	Incoming Phone Call	SSBMI	Angela Rivera	Phone call requesting additional information on geotechnical investigations mentioned in 5/4/11 letter.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
9/13/2011	Outgoing Email	SSBMI	Angela Rivera	Follow up to 9/13/11 phone call, email transmittal of information on geotechnical investigations, committed to sending PA for comments when draft is ready.
9/19/2013	Incoming Email	SSBMI	Angela Rivera	Acknowledgement of 9/13/11 email transmittal, expressed interest in PA.
1/31/2012	Incoming Email	UAIC	Marcos Guerrero	Request construction schedule for NLIP Phase 4 and ARCF Project.
2/1/2012	Outgoing Email	UAIC	Marcos Guerrero	Clarification that NLIP Phase 4 will be pulled into ARCF Project and that construction schedule will be after environmental process, executing a PA, signed Chief's report, and Congressional authorization.
2/2/2012	Incoming Email	UAIC	Marcos Guerrero	Acknowledge receipt of information from 2/2/12 email, request to meet regarding ARCF and the PA.
4/3/2012	Incoming Letter	SSBMI	Daniel Fonseca	Request to meet regarding the project, to be added as a consulting party to identify TCPs in APE, and requested environmental and cultural reports.
4/25/2012	Outgoing Letter	SSBMI	Daniel Fonseca	Acknowledgement of 4/3/12 letter and plan to contact for a meeting and consult with the SSBMI on the ARCF Project.
4/25/2012	Outgoing Letter	UAIC	Gregory Baker, Marcos Guerrero	Acknowledgement of 5/9/11 request that UAIC be included survey efforts, as a concurring party to agreement documents, copies of reports, and to schedule a meeting.
4/25/2012	Outgoing Email	UAIC	Gregory Baker, Marcos Guerrero	Email transmittal of 4/25/12 letter and to schedule a tribal consultation meeting.
4/25/2012	Outgoing Email	SSBMI	Daniel Fonseca, Crystal Dilworth	Email transmittal of 4/25/12 letter and to schedule a tribal consultation meeting, suggested dates.

Letter providing project information, determination of possible affects, transmittal of PA for tribal review and comment, request for involvement and review within 45 days.
6/13/2013	Incoming Letter	BVR	Rhonda Pope	Letter received 6/20/13 communicating the BVR comments on the draft PA, concerns about aspects of the PA and past tribal consultation efforts.
6/14/2013	Incoming Email	BVR	Roselynn Lwenya	Transmittal of attendee list requested in 6/3/13 email, noted postal mailing of comments from BVR on the PA.
6/18/2013	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Acknowledge receipt of 6/14/13 email, responded to request for records and literature searches by noting confidentiality agreements with CHRIS.
6/19/2013	Incoming Phone Call	TAM	Grayson Coney	Mr. Coney called to express the interest of the T'Si-akim Maidu in the ARCF PA. He asked to be included in future EIS correspondence and said the tribe would be interesting in signing the PA as a concurring party. He also expressed that the tribe feels it would be the MLD for the project and that tribal monitors may be required. Conversation was documented in a telephone

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
7/9/2013	Incoming Letter	Yocha Dehe Wintun Nation	Marshall McKay	Letter received 7/12/13 in response to 6/6/13 letter to tribes asking for comments on draft PA. The tribe reviewed the project and concluded it is not within the aboriginal territories of the tribe and declined comment on the project or the PA.
7/15/2013	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Outgoing email in response to receipt of 6/13/13 letter from the tribe. Acknowledged receipt, plan to address comments from tribe, and request dates to meet to consult on project again at a later date.
9/13/2013	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Requested dates to meet with Buena Vista in late October/early November regarding ARCF Project, PA, continuing consultation with the tribe.
9/18/2013	Incoming Email	UAIC	Marcos Guerrero	Contacted the Corps in regard to the Common Features Remaining Sites construction project and asked about status of the ARCF GRR PA.
9/18/2013	Outgoing Email	UAIC	Marcos Guerrero	Reply to 9/18/13 email, provided information that the PA is still in draft form, EIS is expected to be out for public review in the fall (UAIC and Shingle Springs will receive the EIS and draft PA for additional review) and PA is not expected to be signed until 2014, with construction to come in following years.
10/9/2013	Outgoing Phone Call		Rose Enos	Called regarding 6/6/13 letter and was told Ms. Enos was not available and to call back later.
10/9/2013	Outgoing Phone Call		April Wallace Moore	Called regarding 6/6/13 letter and spoke to Ms. Moore. She requested that a monitor be present during construction and to be kept up to date on the project.
10/9/2013	Outgoing Phone Call	CTVCT	Judith Marks	Called and left message regarding 6/6/13 letter.
10/9/2013	Outgoing Phone Call	CTVCT	Pamela Cubbler	Called regarding 6/6/13 letter, Ms. Cubbler indicated she would like to meet, suggested possible dates in late October.
10/9/2013	Outgoing Phone Call	IBMI	Anthony Burris	Called regarding 6/6/13 letter, message on phone said "the number is not assigned yet," unable to leave message.
10/9/2013	Outgoing Phone Call	SSBMI	Sam Daniels	Called regarding 6/6/13 letter, left message.
10/9/2013	Outgoing Phone Call	WR	Andrew Franklin	Called regarding 6/6/13 letter, was told to email Andrew Franklin.
10/9/2013	Outgoing Email	WR	Andrew Franklin	Emailed regarding 6/6/13 letter and as directed from 10/9/13 phone call to Mr. Franklin.
10/9/2013	Outgoing Email	WR	Steven Hutchason	Emailed regarding 6/6/13 letter.
10/9/2013	Outgoing Phone Call	ERMI	Art Angle	Called regarding 6/6/13 letter, was told to email Ren Reynolds.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
10/9/2013	Outgoing Email	ERMI	Ren Reynolds	Emailed regarding 6/6/13 and as directed from 10/9/13 phone call to Mr. Angle.
10/9/2013	Outgoing Email	SVR	Cathy Bishop	Emailed regarding 6/6/13 letter.
10/9/2013	Outgoing Email		Kesner Flores	Emailed regarding 6/6/13 letter.
10/9/2013	Outgoing Email	CBWI		Emailed regarding 6/6/13 letter.
10/10/2013	Outgoing Email		Randy Yonemura	Sent email regarding 6/6/13 letter and regarding project and comments on the PA.
10/10/2013	Outgoing Phone Call		Rose Enos	Called regarding 6/6/13 letter and following up from 10/9/13 call and was told Ms. Enos was not available and to call back later.
10/16/2013	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Follow up to 9/13/13 email requesting dates to meet with Buena Vista in late October/early November regarding ARCF Project, PA, continuing consultation with the tribe.
10/18/2013	Outgoing Phone Call	CTVCT	Pamela Cubbler	Follow up to 10/9/13 phone call to schedule a meeting with the CTVCT and Ms. Cubbler. Left message.
10/18/2013	Outgoing Email	IBMI	Randy Yonemura, Yvonne Miller, IMBI Cultural Heritage	Follow up to previous attempts (last 5/20/13) to set up a meeting with the IBMI. Follow up to emails 5/20/13, 4/29/13, 4/22/13.
10/18/2013	Outgoing Phone Call		Rose Enos	Called following up from 6/6/13 letter and 10/9/13 and 10/10/13 phone calls. Ms. Enos stated she is concerned about burials and construction and asked to be kept on our mailing list and to be informed as the project moves forward. She did not want to meet with the Corps at this time.
10/18/2013	Outgoing Phone Call	BVR	Roselynn Lwenya	Follow up to 10/16/13 email requesting dates to meet with Buena Vista regarding the project, PA, continuing consultation with the tribe.
10/18/2013	Outgoing Phone Call	CTVCT	Judith Marks	Follow up to 6/6/13 letter and 10/9/13 phone call message.
10/18/2013	Outgoing Phone Call	IMBI	Anthony Burris	Follow up to 6/6/13 letter and 10/9/13 phone call, unable to leave message because message said "the number is not assigned yet."
10/18/2013	Outgoing Phone Call	SSBMI	Sam Daniels	Follow up to 6/6/13 letter and 10/9/13 phone call message, left message asking for SSBMI to contact the Corps if they have comments, concerns, or would like to meet.
10/18/2013	Outgoing Phone Call	WR	Steven Hutchason	Follow up to 10/9/13 email, Mr. Hutchason expressed interest in commenting on the PA, asked for a Word version to provide track changes. Ms. Montag committed to sending a Word version of the PA after current OC review and asked the WR to contact the Corps with any additional comments, concerns, or requests to meet.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
10/18/2013	Outgoing Phone Call	SVR	Cathy Bishop	Follow up to 6/6/13 letter and 10/9/13 email to try and leave a phone call message. Voice message on phone would not allow leaving a message.
10/18/2013	Outgoing Phone Call		Kesner Flores	Follow up to 6/6/13 letter and 10/9/13 email, Mr. Flores expressed an interest in reviewing the project area to determine if it is within his interest area. Ms. Montag committed to sending a Word version of the PA for review after current OC review is completed and a new draft is ready.
10/18/2013	Outgoing Phone Call	CBWI	Charlie Wright	Follow up to 6/6/13 letter and 10/9/13 email, left voice message with Chairman Charlie Wright.
11/15/2013	Incoming Phone Call	IBMI	Randy Yonemura	Phone call requesting that the Corps meet with the Bureau of Indian Affairs (Gerald Jones) regarding the Common Features Project and general requirements the Corps may have on water projects.
11/15/2013	Outgoing Phone Call	Bureau of Indian Affairs (BIA)	Gerald Jones	Spoke with Gerald Jones to get clarification on the proposed Corps/BIA/Ione Band meeting. Requested proposed agenda for proper coordination with Corps management.
11/19/2013	Outgoing Email	IBMI, BIA	Yonemura, Jones	Follow up to phone conversations on 11/15/13, requested agenda or discussion topics, proposed dates for a meeting. Provided contact information for Jane Rinck and Mark Gilfillan to coordinate if needed.
5/7/2014	Incoming Email	UAIC	Marcos Guerrero	Asked if the Corps has an electronic version of the Common Features PA.
5/13/2014	Outgoing Email	UAIC	Marcos Guerrero	Response to 5/7/14 email that a current draft of the Common Features PA is still being worked on, taking into account comments received so far and that Ms. Montag will be in touch when that draft is available for review.
6/5/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	As requested in emails dated 9/18/13 and 5/7/14, provided the draft PA and attachments in electronic form for review and comment. Mentioned an official letter will be transmitted soon with a review period in that letter. Asked to provide any questions or concerns, or interest in scheduling a meeting.
6/5/2014	Outgoing Email	WR	Steven Hutchason	As requested phone call on 10/18/13, provided the draft PA and attachments in electronic form for review and comment. Mentioned an official letter will be transmitted soon with a review period in that letter. Asked to provide any questions or concerns, or interest in scheduling a meeting.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
6/5/2014	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Follow up to most recent email on 10/18/13, provided the draft PA and attachments in electronic form for review and comment. Mentioned an official letter will be transmitted soon with a review period in that letter. Asked to provide any questions or concerns, or interest in scheduling a meeting. Asked for three available dates in June and July to schedule a meeting.
6/5/2014	Outgoing Email		Kesner Flores	As requested phone call on 10/18/13, provided the draft PA and attachments in electronic form for review and comment. Mentioned an official letter will be transmitted soon with a review period in that letter. Asked to provide any questions or concerns, or interest in scheduling a meeting.
6/5/2014	Outgoing Email	WR	Steven Hutchason	Follow up to 6/5/14 email, earlier email did not attach PA attachments. Resent with PA attachments.
6/5/2014	Outgoing Email	BVR	Roselynn Lwenya, Rhonda Pope	Follow up to 6/5/14 email, earlier email did not attach PA attachments. Resent with PA attachments.
6/5/2014	Outgoing Email		Kesner Flores	Follow up to 6/5/14 email, earlier email did not attach PA attachments. Resent with PA attachments.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
6/12/2014	Outgoing Letters	SVR, IMBI, UAIC, TAM, CTVCT, SSBMI, WR, MITCR, EDMT, ERMI, BVR, Cachil DeHe, MRMI, NEDM, CBWI	Cathy Bishop, Anthony Burris, Jason Camp, Grayson Coney, Pamela Cubbler, Sam Daniels, Mary Daniels-Tarango, Michael DeSpain, Rose Enos, Kesner Flores, Daniel Fonseca, Nicholas Fonseca, Andrew Franklin, Reno Franklin, Marcos Guerrero, Steven Hutchason, Roselynn Lwenya, Judith Marks, Yvonne Miller, Ambar Mohammed, Eileen Moon, April Wallace Moore, Glenda Nelson, Rhonda Morningstar Pope, Dennis Ramirez, Guy Taylor, Cosme Valdez, Gene Whitehouse, Charlie Wright, Randy Yonemura	Letters providing final draft of PA, summarized previous actions to consult in April/June 2013, provided sensitivity assessment for review/comment, detailed previous Section 106 consultation efforts with SHPO, ACHP, CVFPP DWR, and tribes, communication with the public via letter, requested involvement in the PA as a potential concurring party, requested comments for consideration for the final PA, interest in scheduling a meeting, and to inform the Corps if there is interest in signing the PA as a Concurring Party and any edits to signature block.
6/20/2014	Incoming Email	UAIC	Marcos Guerrero	In response to 6/5/14 email, Mr. Guerrero asked if an MOA or addendum for sites within the APE with a high potential for adverse effects could be included with the PA, as well as if a map with sensitivity areas UAIC would like to have monitored could be included.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
6/23/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Response to 6/20/14 email to iterate that the PA is the Corps' planned process to comply with Section 106, identify historic properties, and determine adverse effects once the project is authorized and that an MOA or addendum would be premature since historic properties have not yet been identified. Further iterated that the Corps welcomes UAIC's assistance identifying sensitive areas and would appreciate any information the tribe is willing to share.
6/26/2014	Outgoing Letters	BVR	Rhonda Pope, Roselynn Lwenya	Received 6/12/14 letters back as undeliverable. Re-dated letters to 6/26/14 and sent by mail again.
6/30/2014	Outgoing Email		Kesner Flores	Received hard copy of 6/12/14 letter back as unclaimed. Sent email to ask Mr. Flores for an address to re-send the hard copies to. Provided electronic copies of the documents (Letter to Mr. Flores, letter to SHPO, Word version of draft PA) sent in 6/12/14 postal mailing.
7/1/2014	Incoming Email	UAIC	Marcos Guerrero	Requested to meet regarding the project to share UAIC maps and to start to identify the need to ground truth locations. Requested to meet the week of July 21st.
7/1/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Replied to 7/1/14 email from Mr. Guerrero that Ms. Montag is not available the week of the 21st, but would be available the week of the 14th, or the 28th or 29th. Or could scheduled for August. Also requested that UAIC let Ms. Montag know if they would like other Corps personnel to attend meeting.
7/14/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Follow up to email sent on 7/1/14 to inquire if Mr. Guerrero would still like to schedule a meeting. Provided July 16-18, 28, 29, August 4-6 as available, or could schedule for later in August.
7/15/2014	Incoming Email	UAIC	Marcos Guerrero, Jason Camp	Response to 7/14/14 email, suggested 7/29/14 to meet.
7/15/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Confirmed 7/29/14 would likely work, asked who from the Corps UAIC would like to have present at the meeting so Ms. Montag can coordinate.
7/15/2014	Incoming Email	UAIC	Marcos Guerrero, Jason Camp	Mr. Guerrero suggested the Corps PM and those in charge at SAFCA attend the 7/29/14 meeting.
7/15/2014	Returned Mailing	TAM	Grayson Coney	Received 6/12/14 letters back as unclaimed.
7/15/2014	Outgoing Phone Call	TAM	Grayson Coney	Called Mr. Coney to confirm mailing address, he confirmed the correct mailing and was out of town.
7/15/2014	Outgoing Letter	TAM	Grayson Coney	Resent 6/12/14 letter and draft PA.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
7/15/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Reply to 7/15/14 email that Corps PM is not available on 7/29/14, suggested 8/1 or 8/4-8/6. Also explained that DWR is the non-Federal sponsor the ARCF Project and offered to coordinate their attendance at meeting, depending on UAIC's preference.
7/16/2014	Returned Mailing		Randy Yonemura	Received 6/12/14 letters back as unclaimed.
7/16/2014	Outgoing Phone Call		Randy Yonemura	Called and left message that 6/12/14 letter was returned and requested a current address to send the letter and final draft PA to.
7/16/2014	Outgoing Email		Randy Yonemura	Sent 6/12/14 letter, enclosures, and copy of 6/12/14 SHPO letter by email to email addresses on file. Asked if Mr. Yonemura has any questions or would like to discuss to contact Ms. Montag.
7/18/2014	Incoming Email		Randy Yonemura	Mr. Yonemura asked that the document be re-sent to him on 7/24/14. Prefers a hard copy be sent.
7/18/2014	Incoming Phone Call		Randy Yonemura	Mr. Yonemura asked that the document be re-sent to him on 7/24/14. Ms. Montag confirmed it will be sent by mail on 7/24/14. Mr. Yonemura said he would review the documentation and get back in touch with Ms. Montag.
7/22/2014	Incoming Email	UAIC	Marcos Guerrero	Reply to 7/15/14 email, suggested 8/4/14 or 8/5/14 for a meeting with the Corps and UAIC, agreed that DWR should be invited to attend.
7/22/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Andrew Godsey	Reply to 7/22/14 email, Ms. Montag said she would coordinate with DWR for availability for a 8/4/14 or 8/5/14 meeting. Noted that Mr. Guerrero included Mr. Godsey on his 7/22/14 and asked if UAIC is requesting a joint meeting with SSBMI invited to attend.
7/24/2014	Outgoing Letter		Randy Yonemura	Re-sent via USPS 6/12/14 mailing as Mr. Yonemura requested during phone call on 7/18/14 be sent on 7/24/14.
7/24/2014	Outgoing Email		Randy Yonemura	Followed up with email to Mr. Yonemura letting him know the 6/12/14 letter was re-sent in today's mail, as he requested.
7/28/2014	Incoming Email	UAIC	Marcos Guerrero	Email from Mr. Guerrero asking if there was still a meeting scheduled for 7/29/14 (which had been previously discussed to be moved to either 8/4/14 or 8/5/14).
7/29/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Andrew Godsey	Response to 7/28/14 email that Ms. Montag thought the 8/4/14 or 8/5/14 were the meeting dates being discussed. Suggested 8/5/14 and asked Mr. Guerrero to respond with an available time.
7/31/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Andrew Godsey	Follow up to 7/29/14 email to ask if 8/5/14 will work for a meeting, and the time UAIC would like to meet.
8/1/2014	Incoming Email	UAIC	Marcos Guerrero	Response to 7/31/14 email suggesting 10AM for meeting on 8/5/14.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
8/1/2014	Outgoing Meeting Request	UAIC, SSBMI	Marcos Guerrero, Jason Camp, Andrew Godsey	Sent meeting request for 8/5/14 for 10AM-12PM at UAIC offices in Auburn. Suggested the Corps would bring information on the project, the PA, and that DWR is planning to attend. Requested that UAIC indicate if there is specific information they are interested in or agenda items they want to discuss that they let Ms. Montag known.
8/1/2014	Incoming Email	UAIC	Marcos Guerrero	Accepted 8/5/14 meeting request.
8/4/2014	Incoming Email	UAIC	Melodi McAdams	Requested GIS shape files for APE to prepare for meeting on 8/5/14.
8/4/2014	Outgoing Email	UAIC	Melodi McAdams, Marcos Guerrero, Jason Camp	Sent GIS shape files of APE as requested, emphasized that the APE is very approximate and will be refined during planning and design for construction and potentially as a result of future environmental and cultural resources investigations.
8/4/2014	Incoming Email	UAIC	Melodi McAdams	Acknowledgement of receipt of 8/4/14 email with GIS shape files.
8/5/2014	Incoming Email	UAIC	Marcos Guerrero	Requested that Ms. Montag bring archeological site maps and a brief overview of cultural resources in the APE. Indicated UAIC's interest in discussing site eligibility, burial plans, and potential adverse effects.
8/5/2014	Consultation Meeting	UAIC, SSBMI, USACE, DWR	Peter Wakeland, Jason Camp, Melodi McAdams, Marcos Guerrero, Josh Stewart, Donald Rey, Andrew Godsey, Kara Perry, Dan Tibbitts, Melissa Montag, David Martasian, Erin Brehmer, Jacqueline Wait	Meeting with UAIC and SSBMI to discuss concerns of the tribes regarding the ARCF Project including treatment of burials, efforts to identify cultural resources of significance to the tribes, tribal monitors, the draft programmatic agreement. All parties agreed regular scheduled meetings would help ease the process along, comments on the programmatic agreement were requested from the tribes by late September for consideration in the version included in the draft EIS/EIR.
8/5/2014	Outgoing Email	SSBMI	Andrew Godsey, Kara Perry	As requested during consultation meeting with UAIC and SSBMI on 8/5/14, transmitted electronic version of the PA and attachments. The previous draft version of the PA was also transmitted via email on 5/23/13 and 6/5/13.
8/5/2014	Outgoing Email	UAIC	Melodi McAdams, Marcos Guerrero, Jason Camp	Requested meeting attendee list from 8/5/14 meeting with UAIC, SSBMI, Corps and DWR.
8/6/2014	Outgoing Email	SSBMI	Andrew Godsey, Kara Perry	Re-send of 8/5/14 email with draft PA attachments. Email sent on 8/5/14 did not attach the PA attachments correctly.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
8/7/2014	Incoming Email	UAIC	Melodi McAdams	Reply to 8/5/14 email request, sent meeting attendees list from 8/5/14 meeting.
8/19/2014	Incoming Letter	UAIC	Marcos Guerrero	(Letter received 10/16/14) Follow up letter from 8/5/14 consultation meeting requesting the Corps and DWR provide UAIC with: pre-burial plan, confidentiality and data sharing agreement, tribal signatory status on PA, tribal preference on scientific analysis, contractor selection, compensation for tribal monitors and information from tribes.
9/2/2014	Outgoing Email	UAIC, SSBMI	Marcos Guerrero, Jason Camp, Andrew Godsey	Sent link to Doodle poll to schedule next meeting with UAIC and SSBMI for late October/early November. Requested response to poll by 9/17/14. Welcomed receiving any comments on the draft programmatic agreement.
9/3/2014	Incoming Email	UAIC	Marcos Guerrero	Responded with available dates for next meeting, asked when comments on PA are due.
9/3/2014	Outgoing Email	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Dan Tibbitts, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez	Replied to 9/3/14 email from Mr. Guerrero that the last comment review period for the draft of the PA closed July 12, 2014, but that review of the draft is still open. The draft EIS/EIR will include comments received up to August 2014.
9/3/2014	Incoming Email	SSBMI	SSBMI	Responded to Doodle poll with available dates.
9/4/2014	Outgoing Email	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Dan Tibbitts, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez	Asked potential meeting attendees to double check their available dates since to date with six respondents there is not a date that lines up for a meeting from October 31-November 19.
9/24/2014	Outgoing Meeting Request	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Dan Tibbitts, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez	Sent meeting request for 11/3/14 10:00-12:00 meeting at Corps offices.
9/24/2014	Incoming Email	DWR	David Martasian	Declined 11/3/14 meeting request.
9/24/2014	Incoming Email	DWR	Anecita Agustinez	Accepted 11/3/14 meeting request.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
9/24/2014	Incoming Email	UAIC	Marcos Guerrero	Accepted 11/3/14 meeting request.
9/24/2014	Incoming Email	DWR	Erin Brehmer	Accepted 11/3/14 meeting request.
10/1/2014	Incoming Email	DWR	Jacqueline Wait	Declined 11/3/14 meeting request.
10/28/2014	Outgoing Email	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Dan Tibbitts, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez	Sent DRAFT meeting agenda for 11/3/14, requested any additional topics for discussion ASAP.
10/31/2014	Incoming Email	SSBMI	Kara Perry	Accepted 11/3/14 meeting request.
10/31/2014	Incoming Email	SSBMI	Cynthia Franco	Accepted 11/3/14 meeting request.
11/3/2014	Consultation Meeting	UAIC, SSBMI, DWR	Marcos Guerrero, Kara Perry, Cynthia Franco, Erin Brehmer, Anecita Agustinez	Consultation meeting to discuss ongoing ARCF project schedule and activities, outstanding topics: pre-burial plan, confidentiality and data sharing agreement, tribal signatory status on PA, tribal preference on scientific analysis, contractor selection, compensation for tribal monitors and information from tribes. Proposed a field visit of Natomas area in January.
11/6/2014	Incoming Email	UAIC	Marcos Guerrero	Asked to be sent the RFP for ARCF cultural services, asked if the tribe would be able to submit a bid and asked to be integrated into this process.
11/7/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Josh Garcia	In response to 11/6/14 email, Ms. Montag stated cultural resources work under the ARCF PA is not moving forward for several months or longer, will likely be awarded under the Planning IDIQ. Provided information that a new Planning IDIQ is likely to be advertised in the next 30-60 days, that the Corps is looking for a firm to address multiple disciplines (planning, environmental, economics, cultural), to check https://www.fbo.gov/ for listings of federal contracts, and further information cannot be provided because it could be perceived as providing a potential contractor an unfair advantage. For further information, suggested contacting Josh Garcia as the Planning IDIQ COR.

11/7/2014	Outgoing Meeting Request	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Kara Perry, Cynthia Franco, Dan Tibbitts, Sara Schultz, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez, Mark Gilfillan	Sent meeting request for 1/6/15 field visit to Natomas Basin.
11/7/2014	Outgoing Meeting Request	UAIC, SSBMI, DWR	Jason Camp, Marcos Guerrero, Andrew Godsey, Kara Perry, Cynthia Franco, Dan Tibbitts, Sara Schultz, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez, Mark Gilfillan	Sent backup meeting request for 1/13/15 field visit to Natomas Basin.
11/7/2014	Incoming Email	SSBMI	Kara Perry	Accepted 1/6/15 and 1/13/15 meeting requests.
11/7/2014	Incoming Email	DWR	Jacqueline Wait	Accepted 1/6/15 and 1/13/15 meeting requests.
11/7/2014	Incoming Email	USACE	Sara Schultz	Accepted 1/6/15 and 1/13/15 meeting requests.
11/7/2014	Incoming Email	USACE	Dan Tibbitts	Accepted 1/6/15 and 1/13/15 meeting requests.
11/7/2014	Incoming Email	UAIC	Marcos Guerrero	Accepted 1/6/15 and 1/13/15 meeting requests.
11/7/2014	Incoming Email	USACE	Mark Gilfillan	Accepted 1/6/15 meeting, declined 1/13/15 meeting.
11/10/2014	Incoming Email	SSBMI	Cynthia Franco	Accepted 1/6/15 meeting request.
11/12/2014	Incoming Email	DWR	Erin Brehmer	Accepted 1/6/15 and 1/13/15 meeting requests.
11/12/2014	Incoming Email	DWR	Anecita Agustinez	Accepted 1/6/15 and 1/13/15 meeting requests.
12/1/2014	Incoming Email	SSBMI	Daniel Fonseca	Accepted 1/6/15 meeting request.
12/17/2014	Incoming Email	UAIC	Marcos Guerrero	In response to 6/5/14 email transmittal of electronic version of draft PA, UAIC submitted track changes of comments on the document.
12/18/2014	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams, Donald Rey	In response to 12/17/14 email, thanked Mr. Guerrero for providing UAIC comments on the draft PA.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
12/29/2014	Outgoing Email		Jason Camp, Marcos Guerrero, Andrew Godsey, Kara Perry, Cynthia Franco, Dan Tibbitts, Sara Schultz, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez, Mark Gilfillan	Sent updated meeting request for 1/6/15 field visit. Included meeting location, information on weather, tentative agenda.
12/29/2014	Incoming Email	UAIC	Marcos Guerrero	Accepted 1/6/15 meeting request.
1/5/2015	Incoming Email	UAIC	Jason Camp	Accepted 1/6/15 meeting request.
1/6/2015	Field Visit	UAIC, SSBMI, DWR, RD1000	Melissa Montag, Dan Tibbitts, Jason Camp, Marcos Guerrero, Donald Rey, Melodi McAdams, Kara Perry, Cynthia Franco, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez, Paul Devereux	Field visit of Natomas Basin, beginning south on Garden Highway with stops at San Juan Road, at pump station, Natomas Cross Canal, Pleasant Grove Creek Canal, Natomas East Main Drain Canal. Corps staff provided information on past NLIP work completed, types of alternatives being considered for Natomas, plans for compliance with Section 106.
1/6/2015	Outgoing Email	UAIC, SSBMI, DWR, RD1000	Melissa Montag, Dan Tibbitts, Jason Camp, Marcos Guerrero, Donald Rey, Melodi McAdams, Kara Perry, Cynthia Franco, David Martasian, Erin Brehmer, Jacqueline Wait, Anecita Agustinez, Paul Devereux	Ms. Montag transmitted the meeting attendance sheet for the 1/6/15 meeting and stated she would look to April to schedule the next quarterly meeting. Provided the general information that the draft EIS/EIR for the ARCF GRR will be released for public review soon and UAIC and SSBMI are on the mailing list to receive copies. Ms. Montag asked that if there is anything to discuss before the next meeting to please get in contact with her.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
1/8/2015	Consultation Meeting	SSBMI	Kara Perry, Cynthia Franco	Met with SSBMI representatives to specifically address Natomas Reach H borings, but also touched on overall ARCF GRR topics. Ms. Perry requested an electronic copy of the draft PA (previously emailed to Andrew Godsey 5/23/13 and Mr. Godsey and Ms. Perry on 8/61/14).
1/8/2015	Outgoing Email	SSBMI	Kara Perry, Cynthia Franco, Mark Gilfillan	Email transmittal of ARCF draft PA and PA attachments as requested in 1/8/15 consultation meeting. Explained that the PA covers Natomas activities, as well as future work in other basins, welcomed comments from the tribe.
1/8/2015	Outgoing Email	SSBMI	Kara Perry, Cynthia Franco, Mark Gilfillan	Resent 1/8/15 email with PA attachments only.
1/8/2015	Incoming Phone Call	BVR	Roselynn Lwenya	Ms. Lwenya returned a phone call regarding work for the ARCF Reach H project. Included in the conversation, Ms. Montag expressed that if BVR would like to meet to discuss the ARCF projects or any other Corps projects to notify the Corps. Ms. Lwenya stated she would provide this information to the BVR board and would respond to Ms. Montag if the tribe would like to meet.
3/17/2015	Outgoing Email	BVR, IBMI, SSBMI, UAIC, WR, MITCR, CWEPA, TAM, ERMI, NEDM,	Anthony Burris, Jason Camp, Grayson Coney, Michael DeSpain, Kesner Flores, Daniel Fonseca, Nicholas Fonseca, Reno Franklin, Marcos Guerrero, Steven Hutchason, Roselynn Lwenya, Yvonne Miller, Rhonda Morningstar Pope, Dennis Ramirez, Cosme Valdez, Randy Yonemura	Transmitted link to webpage where draft EIS/EIR and GRR are available for review from March 20 to May 4. Provided information on public workshop meetings. Sent by email to those addresses available, stated a letter and CD would also be sent by mail.
3/17/2015	Incoming Email		Kesner Flores	3/17/15 email to Mr. Flores returned as undeliverable.
3/17/2015	Incoming Email	ERMI	ERMI	3/17/15 email to main info address for ERMI returned as undeliverable.
3/17/2015	Incoming Email	NEDM	Cosme Valdez	3/17/15 email to Mr. Valdez returned as undeliverable.
3/17/2015	Incoming Email	TAM	TAM	3/17/15 email to main info address for TAM returned as undeliverable.
3/17/2015	Incoming Email	UAIC	Marcos Guerrero	In response to 3/17/15 email, requested the confidential cultural resources appendix and any survey, inventory, or evaluation reports.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
3/19/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	In reply to 3/17/15, stated there is not confidential information in the cultural resources appendix relating to cultural resources and that the Corps has not yet conducted any survey, inventory or evaluation for the Common Features Project. Transmitted the archaeological sensitivity assessment.
3/19/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	Transmitted GIS shape files as was requested in February 2015 UAIC Outreach Day. These GIS shape files were previously sent 8/4/15.
3/19/2015	Incoming Email	UAIC	Melodi McAdams	In reply to 3/19/15, acknowledged receipt of GIS shape files.
3/23/2015	Incoming Email	UAIC	Marcos Guerrero	Asked for the MMRP for the Common Features and Marysville Ring Levee Projects.
3/24/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	In reply to 3/23/15 email, asked for definition of MMRP.
3/24/2015	Incoming Email	UAIC	Marcos Guerrero	MMRP is Mitigation and Monitoring Report Plan, as part of EIR.
3/24/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Provided contact information for DWR staff POCs for Common Features and Marysville Ring Levee Projects.
4/13/2015	Outgoing Email and Poll	UAIC, SSBMI, DWR	Marcos Guerrero, Jason Camp, Andrew Godsey, Daniel Fonseca, Kara Perry, Cynthia Franco	Email request to set up next quarterly meeting with UAIC and SSBMI in May. Proposed five different days/times to possibly meet, asked for any agenda topics to be forwarded.
4/13/2015	Incoming Poll Response	SSBMI		Responded with availability in poll.
4/14/2015	Incoming Poll Response	UAIC	Marcos Guerrero	Responded with availability in poll.
4/16/2015	Incoming Email	UAIC	Marcos Guerrero	Email with comments from UAIC on the DEIS/DEIR.
4/17/2015	Outgoing Meeting Request	UAIC, SSBMI, DWR	Marcos Guerrero, Jason Camp, Andrew Godsey, Daniel Fonseca, Kara Perry, Cynthia Franco	Sent meeting request for meeting on 5/19/15 from 10AM-12PM for next quarterly meeting with UAIC and SSBMI. Agenda to come.
4/17/2015	Incoming Email	SSMBI	Cynthia Franco, Kara Perry	Accepted meeting request for 5/19/15 meeting.
4/17/2015	Incoming Email	UAIC	Marcos Guerrero	Accepted meeting request for 5/19/15 meeting.
4/17/2015	Incoming Email	UAIC	Marcos Guerrero	Received comments on DEIS/DEIR from UAIC.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
4/20/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Acknowledged receipt of comments from 4/17/15.
4/20/2015	Incoming Email	UAIC	Marcos Guerrero	Asked when the comment period for DEIS/DEIR ends.
4/20/2015	Outgoing Email	UAIC	Marcos Guerrero	Responded to 4/20/15 email that comment period for DEIS/DEIR ends 5/4/15.
4/20/2015	Incoming Email	UAIC	Jason Camp	Accepted meeting request for 5/19/15 meeting.
4/21/2015	Incoming Email	UAIC	Marcos Guerrero	Asked if UAIC can be an invited signatory to the PA.
4/21/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	Replied to 4/21/15 email that Ms. Montag would have to get back to Mr. Guerrero regarding this question.
4/29/2015	Outgoing Email	UAIC	Marcos Guerrero	Provided information that comment review period on the DEIS/DEIR has been extended two weeks until 5/18/15.
5/15/2015	Outgoing Email	UAIC, SSBMI, DWR	Marcos Guerrero, Jason Camp, Andrew Godsey, Daniel Fonseca, Kara Perry, Cynthia Franco	Sent draft meeting agenda for 5/15/15, requested any additional topics for discussion.
5/18/2015	Incoming Letter	UAIC	Gene Whitehouse	Letter to Colonel Farrell requesting Government to Government consultation, notification to the Corps about sites of importance to the tribe in the project area, requesting signatory party status on the PA.
5/19/2015	Consultation Meeting	UAIC, SSBMI, DWR	Marcos Guerrero, Jason Camp, Melodi McAdams, Kara Perry, Cynthia Franco	Scheduled consultation meeting. Topics included an update on the EIS/EIR, draft PA. Requested to know if the tribes have any information on sites or areas of interest within the project area. Tribes expressed concerns about sharing information on sites with the Corps, and with indicating any information on sites of importance. Asked about the project phasing and construction. Corps staff reiterated that phases in Natomas Basin are at early stages of design and suggested those designs could be shared with the tribes so they could determine what concerns the tribes may have. Shape files for current design phases will be sent to tribes and a follow up meeting in July or August to discuss those phases. Mr. Guerrero and Mr. Camp asked if UAIC will be invited as a signatory, Ms. Montag stated that decision is still being considered by the Corps.
5/27/2015	Incoming Email	UAIC	Marcos Guerrero	Email requesting maps of areas currently being consulted on and designed for the project in the Natomas area. Stated UAIC would like to schedule a follow up meeting and field visit to show areas they are most concerned with and to discuss TCPs and historic properties.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
5/27/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp	In reply to 5/27/15 email, stated that GIS shape files have been requested internally but not received and will be forwarded on as soon as they are available. Stated the Corps is very interested in hearing the concerns from UAIC and continuing to discuss TCPs and historic properties.
6/16/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	Provided PDF of project areas for Natomas Reach I, shape files for project areas, and information/description on those areas. Requested potential dates to meet in July, who the tribe would like present at the meeting.
6/16/2015	Outgoing Email	SSBMI	Kara Perry, Cynthia Franco, Daniel Fonseca	Provided PDF of project areas for Natomas Reach I, shape files for project areas, and information/description on those areas. Requested potential dates to meet in July, who the tribe would like present at the meeting.
6/26/2015	Incoming Email	UAIC	Marcos Guerrero	In reply to 6/16/15 email, Mr. Guerrero suggested 7/6/15 as a possible meeting date and expressed concerns about the proposed APE. Stated no other tribes needed to be in attendance at meeting on 7/6/15.
6/26/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	In reply to 6/26/15 email, Ms. Montag stated she would coordinate the 7/6/15 date and would get back to UAIC.
6/30/2015	Outgoing Meeting Request	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	Sent meeting request for site visit for Natomas Reach I for 7/6/15.
7/1/2015	Incoming Email	UAIC	Marcos Guerrero	Accepted 7/6/15 meeting request.
7/1/2015	Incoming Email	UAIC	Jason Camp	Accepted 7/6/15 meeting request.
7/7/2015	Outgoing Letter	UAIC	Gene Whitehouse	Letter requesting additional details and specific information regarding comments from UAIC in 4/16/15 email.
8/6/2015	Consultation Meeting	UAIC/Corps	Bill Welsh, Mike Kynett (Corps), Mark Boedker (Corps), Robin Rosenau (Corps), Marcos Guerrero, Melodi McAdams (UAIC), Donald Skip Rey (UAIC)	Staff-to-staff level consultation meeting regarding Natomas Reach I project and ARCF DEIS/DEIR, sites of concern to the tribe, construction activities of concern to the tribe. Additional topics included involvement of the tribe in surveying and monitoring, reporting, preferences on data recovery and curation, professional qualifications.
8/10/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	Sent comment responses to DEIS/DEIR and requested clarification/correction on notes taken during 8/6/15 consultation meeting with UAIC. Requested responses by 8/14/15.

Date	Type of Contact	Organization	Person Contacted	Contents of Communication
8/17/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Melodi McAdams	Transmitted meeting minutes from 8/6/15 meeting, attached email and document from 8/10/15 and requested any comments no later than 8/19/15.
8/24/2015	Outgoing Letter	UAIC	Gene Whitehouse	In response to 5/18/15 letter from UAIC, committed to continuing Government to Government consultation through Corps' Tribal Liaison, invited UAIC be be a concurring party on the PA.
11/30/2015	Incoming Email	UAIC	Marcos Guerrero	Mr. Guerrero asked if the Corps would still accept comments from UAIC on the draft EIS/EIR, despite comments being due 5/18/15.
12/7/2015	Outgoing Letters	Cortina Wintun, SVR, WR, CVTCT, Cachil Dehe, Mooretown Rancheria, Mechoopda, UAIC, TAM, SSBMI, NEDM, IBMI, ERMI, EDM, BVR, interested Native Americans	Various chairpersons, as well as Kesner Flores, Randy Yonemura, Rose Enos.	Letter transmitting the signed and executed PA and requesting parties to sign as concurring parties if they choose to.
12/31/2015	Outgoing Email	UAIC	Marcos Guerrero, Jason Camp, Courtney Coyle, Melodi McAdams, Jane Rinck, Mark Gilfillan	In response to 11/30/15 email, Ms. Montag stated that although the comment review period on the draft EIS/EIR is closed and the final document is being prepared, the Corps welcomes any comments from the tribe at any time, and anticipates extensive interactions with tribes for cuture environmental compliance efforts and while executing the stipulations of the PA.

State Historic Preservation Officer
Office of Historic Preservation
P.O. Box 942896
Sacramento, California 94296-0001

Dear Mr. Donaldson:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project near Sacramento, California. The ARCF Project is being developed to reduce flood risk to the City of Sacramento, including the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River. The ARCF Project is a part of the Common Features General Reevaluation Report. The non-Federal sponsor for the ARCF Project is the State of California Central Valley Flood Protection Board.

Pursuant to 36 CFR Part 800.3 we are initiating the Section 106 process for the ARCF Project and we are asking for your concurrence with our determination of the area of potential effects (APE) for the ARCF Project in accordance with 36 CFR Part 800.4(a)(1). We are also asking for your comments on our proposed efforts to identify historic properties pursuant to 36 CFR Part 800.4. We are also proposing to develop a programmatic agreement (PA) for the ARCF Project in accordance with 36 CFR Part 800.14(b).

The Corps has undertaken or has been the regulatory agency for multiple efforts to reduce flood risk in the region and the Sacramento and American River watersheds. Many of these efforts have resulted from authority given in the Water Resources Development Acts of 1996 and 1999. Because of the complex nature of these different studies and efforts, we have prepared a short summary document describing the authorizations for the projects in the region, what has been constructed, what agency or partner completed the construction, previous compliance with the National Historic Preservation Act of 1966, as amended, and the National Environmental Policy Act of 1969, and the planned future activities within the watersheds (Enclosure 1).

The APE for the ARCF Project includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; approximately 18 miles of the east bank of the Sacramento River immediately downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; approximately 5 miles of the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; approximately 8 miles of the Natomas East Main Drainage Canal; approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison

Creek; approximately 1.5 miles of the north and south banks of Dry/Robla Creeks; and approximately 2 miles of the north and south banks of Arcade Creek. The APE is shown in Enclosure 2.

We have completed a records and literature search of the APE at the North Central Information Center at California State University, Sacramento and at the Northeast Information Center at California State University, Chico in 2008. The records and literature search identified 136 cultural resources and 285 surveys and inventories conducted within and nearby the ARCF Project APE. Portions of the APE have been previously surveyed but the majority of the APE has not been intensively surveyed for cultural resources in the last ten years.

Because the APE for the ARCF Project covers a large geographic area and is largely located along rivers, which have been shown to be sensitive for buried resources, we are developing two predictive models to extrapolate archaeological sensitivity over un-surveyed portions of the APE. The first model will be a general model of site locations that will anticipate the likelihood that any one or more spots in the study area will be in an archaeological site. The second model will highlight portions of the study area where we would be more or less likely to find buried archaeological materials. Once the predictive models have been completed we plan to demonstrate their accuracy through field testing. Ultimately we plan to use the predictive models to assist with planning and evaluating alternatives to avoid adverse effects to cultural resources whenever and wherever possible.

A number of possible measures may be considered in order to reduce the flood risk to the City of Sacramento. The measures under consideration are described in Enclosure 1. Because the ARCF Project will be a complex undertaking that may be constructed in multiple phases and may result in adverse effects to historic properties, we are proposing to develop a PA to govern the implementation of our compliance efforts. We are working on a draft PA and plan to coordinate the execution of the PA with you and other potential signatory and concurring parties.

We obtained a list of potentially interested Native Americans from the Native American Heritage Commission and contacted them in letters dated May 4, 2011 to inquire if they have knowledge of locations of archeological sites, or areas of traditional cultural value or concern in or near the ARCF Project APE. Both the United Auburn Indian Community of the Auburn Rancheria and the Mechoopda Indian Tribe of Chico Rancheria have contacted us and expressed interest in the ARCF Project. We plan to continue to communicate with those tribes, as well as others that may have an interest in the ARCF Project as we comply with Section 106 and develop a PA.

Pursuant to 36 CFR Part 800.4(a)(1), we request your comments on our preliminary determination of the APE for the ARCF Project. We also request any comments your office may have of our proposed efforts to identify historic properties under 36 CFR Part 800.4 and our plan to develop a PA in accordance with 36 CFR Part 800.14(b). We would like to schedule a meeting to meet with you and your staff to discuss the ARCF Project and answer any questions your may have about the project or our proposed Section 106 compliance efforts.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Alicia E. Kirchner
Chief, Planning Division

Sacramento, California 94296-0001

JUL 16 2012

Dear Mr. Donaldson:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to transmit a draft programmatic agreement (PA) for the proposed American River Common Features (ARCF) Project near Sacramento, California. The ARCF Project is being developed to reduce flood risk to the City of Sacramento, including the Natomas Basin, areas along the north and south banks of the American River, and the east bank of the Sacramento River. The ARCF Project is a part of the Common Features General Reevaluation Report. The non-Federal sponsor for the ARCF Project is the State of California Central Valley Flood Protection Board.

We previously contacted you in a letter dated February 1, 2012, asking for your concurrence with our determination of the area of potential effects (APE), for your comments on our proposed efforts to identify historic properties, and to inform you of our proposed plan to develop a PA for the ARCF Project (Enclosure 1). The ARCF Project will be a complex undertaking that may be constructed in multiple phases, the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and it may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a PA to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 2).

Included as attachments to the PA are a map of the APE (Enclosure 2, Attachment 1) and a project description for the ARCF Project (Enclosure 2, Attachment 2). We have also contacted the Advisory Council on Historic Preservation to ask for their comments on the proposed ARCF Project. They have also received the draft PA for their review and comment.

On several prior occasions we have been in contact with potentially interested Native Americans, asking for their participation in the Section 106 compliance efforts for the ARCF Project. We have met with the United Auburn Indian Community of the Auburn Rancheria and Shingle Springs Band of Miwok Indians on the ARCF Project. As we develop the PA and comply with Section 106, we will continue to involve these tribes, as well as other tribes identified by the Native American Heritage Commission as having an interest in the APE.

Pursuant to 36 CFR § 800.14(b)(2)(i), we request your involvement in the development of the PA for the ARCF Project. We ask that you review the enclosed PA and provide us with comments within 45 days. Additionally, we would like to schedule a time to meet with you and your staff to discuss the ARCF Project and answer any questions you may have about the project or our proposed Section 106 compliance efforts.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Alicia E. Kirchner

JUN 1 2 2014

Dr. Carol Roland-Nawi
State Historic Preservation Officer
Department of Parks and Recreation
Office of Historic Preservation
1725 23rd Street, Suite 100
Sacramento, CA 94296-0001

Dear Dr. Roland-Nawi:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended (NHPA), we are writing to continue consultation on the American River Common Features (ARCF) Project near Sacramento, California. The U.S. Army Corps of Engineers (Corps) is authorized to reduce flood risk to the City of Sacramento and the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The ARCF Project is a part of the Common Features General Reevaluation Report. The State of California Central Valley Flood Protection Board (CVFPP), in cooperation with the Sacramento Area Flood Control Agency (SAFCA), is the non-Federal sponsor for the ARCF Project.

We have previously contacted your office in letter dated February 1, 2012, which documented our determination of the area of potential effects (APE), and requested comments on our efforts to identify historic properties and our plan to develop a programmatic agreement (PA). In a letter July 16, 2012, we transmitted the draft PA for review and requested comments, provided an update of consultation with the Advisory Council on Historic Preservation (ACHP) and potentially interested Native American tribes, and requested to meet on the ARCF Project. Staff from my office met with Ms. Susan Stratton, Mr. Dwight Dutsche, and Mr. Brendan Greenaway of your office in meetings on October 29, 2012 and November 5, 2012 to discuss the ARCF Project and the planned efforts to comply with Section 106 of the NHPA. Previous consultation with your office on the ARCF Project is included in Enclosure 1.

Pursuant to 36 CFR Part 800.3 we are requesting your concurrence with our determination of the area of potential effects (APE) for the ARCF Project in accordance with 36 CFR Part 800.4(a)(1). We are also providing information on our efforts to identify historic properties pursuant to 36 CFR Part 800.4 and we are providing the most recent final draft of the PA for the ARCF Project for your final review and comment before we plan to execute the PA. The final draft of the PA is included in Enclosure 2.

The Corps has undertaken or has been the regulatory agency for multiple efforts to reduce flood risk in the region and the Sacramento and American River watersheds. Many of these efforts have resulted from authority given in the Water Resources Development Acts of 1996 and 1999. Because of the complex nature of these different studies and efforts, we have prepared a short summary document describing the authorizations for the projects in the region, what has been constructed, what agency or partner completed the construction, previous compliance with the National Historic Preservation Act of 1966, as amended, and the National Environmental Policy Act of 1969, and the planned future activities within the watersheds (Enclosure 2, Attachment 4).

We have determined that the APE for the ARCF Project includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; the Sacramento Bypass and Sacramento Weir; approximately 4 miles of the Pleasant Grove Creek Canal; approximately 8 miles of the Natomas East Main Drainage Canal; approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal. Most of the activities planned for the ARCF Project will be confined to the levees or the immediately adjacent river banks near the levees, however, the APE for the ARCF Project includes areas within the American River Parkway and along Dry and Robla Creeks because it is anticipated that there may be visual or landscape impacts to potential historic properties in those areas. The APE is shown in Enclosure 2, Attachment 3.

We have completed a records and literature search of the APE at the North Central Information Center at California State University, Sacramento and at the Northeast Information Center at California State University, Chico in 2006 and 2007, and updated in 2010 and 2013. The records and literature search identified 61 known cultural resources within and nearby the ARCF Project APE. Portions of the APE have been previously surveyed but the majority of the APE has not been intensively surveyed for cultural resources in the last ten years.

Because the APE for the ARCF Project covers a large geographic area and is mostly located along rivers, which have been shown to be sensitive for buried resources, we have developed two predictive models to extrapolate archaeological sensitivity over un-surveyed portions of the APE. The first model is a general model of site locations that anticipates the likelihood that any one or more spots in the study area will be in an archaeological site. The second model highlights portions of the APE where we would be more or less likely to find buried archaeological materials. Ultimately we plan to use the predictive models to assist with planning and evaluating alternatives to avoid adverse effects to cultural resources whenever and wherever possible. The models and detailed information on the archaeological sensitivity assessment are included in Enclosure 3. We request any comments you may have on the archaeological sensitivity assessment.

A number of possible measures may be considered in order to reduce the flood risk to the City of Sacramento. The measures under consideration are described in Attachment 4 of Enclosure 2. Because the ARCF Project will be a complex undertaking that may be constructed in multiple phases and may result in adverse effects to historic properties, we have developed a PA to govern the implementation of our compliance efforts. The PA has been provided to your office, the ACHP, CVFPP, Department of Water Resources (DWR), SAFCA, and potentially interested American Indian Tribes and interested American Indian individuals for review and comment. In a letter dated August 7, 2012, the ACHP declined to participate in consultation for the ARCF Project (Enclosure 2, Attachment 2). Comments were received from the CVFPP, DWR, SAFCA, and American Indian Tribes and have been considered in this current final draft of the PA.

In April 2013, letters to 100 historical societies, museums, state historic parks, associations with historic interests, local city and county groups, and groups of various prehistoric and historic interests were sent providing a description and map of the project and requesting information on cultural resources within the APE. One response, from the Center for Sacramento History, was received, noting they would keep our letter on file. In accordance with 36 CFR § 800.14(b)(2)(ii), we will also provide the final draft PA with the forthcoming Environmental Impact Statement/Environmental Impact Report which will be released for public review this summer.

We obtained a list of potentially interested American Indian tribes and interested American Indian individuals from the Native American Heritage Commission and contacted them in 2011, 2012, and 2013 to inquire if they have knowledge of locations of archeological sites, or areas of traditional cultural value or concern in or near the ARCF Project APE. The United Auburn Indian Community of the Auburn

Rancheria (UAIC), the Shingle Springs Band of Miwok Indians (SSBMI), the Mechoopda Indian Tribe of Chico Rancheria, the Ione Band of Miwok Indians, and the Buena Vista Rancheria (BVR) have contacted us and expressed interest in the ARCF Project. We have met with the UAIC, the SSBMI, and the BVR and we plan to continue to communicate with those tribes, as well as others that may have an interest in the ARCF Project as we execute the PA in compliance with Section 106 of the NHPA. A consultation log of communications with American Indian tribes and American Indian individuals for the ARCF Project is included as Enclosure 4.

Pursuant to 36 CFR Part 800.4(a)(1), we request your comments on our determination of the APE for the ARCF Project. We also request any comments your office may have of our efforts to identify historic properties under 36 CFR Part 800.4 and any comments you may have on the final draft of the PA for the ARCF Project which was developed in accordance with 36 CFR Part 800.14(b).

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

for ~~Al~~icia E. Kirchner

Washington, DC 20004

FEB 01 2012

Dear Mr. Nelson:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended (NHPA), we are writing to inform you of the proposed American River Common Features (ARCF) Project near Sacramento, California, and to request your participation in the ARCF Project. The ARCF Project is being developed by the U.S. Army Corps of Engineers (Corps) to reduce flood risk to the city of Sacramento. The reaches of the ARCF project include the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River. The ARCF Project will be described in the Common Features General Reevaluation Report. The non-Federal sponsor for the ARCF Project is the State of California Central Valley Flood Protection Board (CVFPB).

Because the ARCF Project will be a complex undertaking that may be constructed in multiple phases; covers a large geographic area largely located along rivers, which has been shown to be sensitive for buried resources; and may result in adverse effects to historic properties, we are proposing to develop a programmatic agreement (PA) to govern the implementation of our compliance efforts. We want to make every effort to include all parties with an interest in the project and those agencies with responsibilities under Section 106 of the NHPA. We are writing to provide you with information on the proposed project, to inform you of the process we plan to follow, and to potentially include your participation in accordance with 36 CFR § 800.2(a)(4)(b)(1).

The Corps has undertaken, or has been the regulatory agency, for multiple efforts to reduce flood risk in the region and the Sacramento and American River watersheds. Many of these efforts have resulted from authority given in the Water Resources Development Acts of 1996 and 1999. Because of the complex nature of these different studies and efforts, we have prepared a summary document describing the authorizations for the projects in the region; what has been constructed, and by whom; previous compliance with the NHPA and the National Environmental Policy Act of 1969; and the planned future activities within the watersheds (Enclosure 1).

The area of potential effects (APE) for the ARCF Project includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; approximately 18 miles of the east bank of the

Sacramento River from immediately downstream of the Natomas Cross Canal (NCC) to the confluence with the American River; approximately 5 miles of the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; approximately 8 miles of the Natomas East Main Drainage Canal; approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately 1.5 miles of the north and south banks of Dry/Robla Creeks; and approximately 2 miles of the north and south banks of Arcade Creek. The APE is shown in Enclosure 2.

Because of the possible adverse effects, and due to the complex, multi-phase nature of the ARCF Project, we are developing a PA that will include stipulations for determination of the APE for different phases of the project, identification of historic properties, evaluation of historic properties, determination of effects to historic properties, preparation of historic properties treatment plans, public participation, and communication with Native Americans. Pursuant to 36 CFR § 800.6(a)(1) after the PA has undergone coordination with the non-Federal sponsor, the CVFPB, and the State Historic Preservation Office, we plan to send a draft of the PA to you and ask for your review and comment.

We invite any comments you may have on the proposed ARCF Project. Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

E. Scott Clark

JUL 16 2012

Dear Mr. Nelson:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to transmit a draft programmatic agreement (PA) for the proposed American River Common Features (ARCF) Project near Sacramento, California. The ARCF Project is being developed to reduce flood risk to the City of Sacramento, including the Natomas Basin, areas along the north and south banks of the American River, and the east bank of the Sacramento River. The ARCF Project is a part of the Common Features General Reevaluation Report. The non-Federal sponsor for the ARCF Project is the State of California Central Valley Flood Protection Board.

We previously contacted you in a letter dated February 1, 2012, inviting your comments on the proposed project and informing you of the proposed process we plan to follow, to include the development of a PA for the ARCF Project (Enclosure 1). The ARCF Project will be a complex undertaking that may be constructed in multiple phases, the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and it may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a PA to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 2).

Included as attachments to the PA are a map of the area of potential effects (APE) (Enclosure 2, Attachment 1) and a project description for the ARCF Project (Enclosure 2, Attachment 2). We have also contacted the California State Historic Preservation Officer to ask for their comments on the proposed ARCF Project. They have also received the draft PA for their review and comment.

On several prior occasions we have been in contact with potentially interested Native Americans, asking for their participation in the Section 106 compliance efforts for the ARCF Project. We have met with the United Auburn Indian Community of the Auburn Rancheria and Shingle Springs Band of Miwok Indians on the ARCF Project. As we develop the PA and comply with Section 106, we will continue to involve these tribes, as well as other tribes identified by the Native American Heritage Commission as having an interest in the APE.

Pursuant to 36 CFR § 800.14(b)(2)(i), we request your involvement in the development of the PA for the ARCF Project. We ask that you review the enclosed PA and provide us with comments within 45 days. Additionally, we ask you to notify us if you plan to formally participate in the execution of the PA.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Alicia E. Kirchner

Dear Ms. Montag:

The Advisory Council on Historic Preservation (ACHP) has received the Programmatic Agreement (PA) for the above referenced project. In accordance with Section 800.6(b)(1)(iv) of the ACHP's regulations, the ACHP acknowledges receipt of the PA. The filing of the PA, and execution of its terms, completes the requirements of Section 106 of the National Historic Preservation Act and the ACHP's regulations.

We appreciate your providing us with a copy of the PA and will retain it for inclusion in our records regarding this project. Should you have any questions or require additional assistance, please contact Brian Lusher at (202) 517-0221 or via e-mail at blusher@achp.gov.

Mr. Dennis Ramirez, Chairperson
Mechoopda Indian Tribe of Chico Rancheria
125 Mission Ranch Boulevard
Chico, California 95926

Dear Mr. Ramirez:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of proposed geotechnical explorations for the American River Common Features General Reevaluation (Common Features) Project. The Sacramento Area Flood Control Agency (SAFCA) has implemented and constructed prior phases of the Common Features Project and the U.S. Army Corps of Engineers, Sacramento District (Corps) is now proceeding with future planned phases of the project. The overall Common Features Project is located in Sacramento and Sutter Counties along the Sacramento River, the American River, the Natomas Cross Canal (NCC), the Pleasant Grove Cross Canal (PGCC), and the Natomas East Main Drain Canal (NEMDC).

Enclosure 1 outlines the entire Common Features Project, including portions previously constructed by SAFCA. The Common Features Project is divided into three regions shown on Enclosure 1: the Natomas Basin (NAT) shown in yellow, American River North (ARN) shown in blue, and American River South (ARS) shown in purple. NAT Reaches C and D were entirely constructed by SAFCA, as well as a portion of NAT Reach B, some of which is presently still under construction.

As part of the Corps' exploratory phase for the remaining reaches of the Common Features Project we are planning to complete a series of geotechnical explorations in the late spring, summer, and fall of 2011 along various project reaches. Along NAT Reach A, a total of 8 cone penetrometer tests (CPT) and 15 geotechnical borings at and adjacent to the Sacramento and American Rivers levees will be completed between May and September. The maximum depth of the borings and CPTs would be 100 feet and all borings and CPTs would be backfilled. The boring locations and CPTs for NAT Reach A are shown red dots on Enclosure 2. Although there are no known prehistoric resources located within the areas identified for borings and CPTs, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil.

Within NAT Reach B, a total of 4 CPTs and 13 geotechnical borings along the Sacramento River levee crown and in adjacent agricultural fields will be completed between July and September. The maximum depth of the borings and CPTs would be 100 feet and all borings and CPTs would be backfilled. The boring locations and CPTs for NAT Reach B are shown as red dots on Enclosure 3. Although there are no known prehistoric resources located within the

areas identified for borings and CPTs, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil.

Along NAT Reaches E, F, G, and H, a total of 45 CPTs at the PGCC and NEMDC levee toe and 16 geotechnical borings along the levee crown and in adjacent agricultural fields will be completed between May and October. The maximum depth of the borings and CPTs would be 100 feet and all borings and CPTs would be backfilled. The boring locations and CPTs for NAT Reaches E, F, G, and H are shown as blue and red dots on Enclosure 4. There are no known prehistoric resources located within the areas identified for borings and CPTs. Because the borings and CPTs are planned to occur within a heavily disturbed area along a manmade feature we do not plan to have an archeological monitor present during the geotechnical borings and CPTs along NAT Reaches E, F, G, and H.

Within ARN Reaches A and B and ARS Reaches A and B, three different types of geotechnical explorations are scheduled to be completed between August and September. These explorations include trenching, waterside berm borings, and in-channel borings. Enclosure 5 shows the probable locations of the various explorations along the American River. Shown as red lines in Enclosure 5, a total of 15 trenches will be dug to a maximum depth of 15 feet below the existing ground surface and a total linear footage of 150 feet at each location. Shown as red dots in Enclosure 5, a total of 10 waterside berm borings will be drilled to a maximum depth of 50 feet below the existing ground surface. And shown as blue dots in Enclosure 5, a total of 10 in-channel borings will be drilled to a maximum depth of 25 feet within the American River Channel.

There are no known prehistoric resources located within the areas identified for the trenching, waterside berm borings and in-channel borings. Prior to beginning the geotechnical explorations along Reaches A and B of ARN and ARS we will complete an archeological field investigation of the locations of the explorations. In the event that cultural resources are identified during the archeological field investigation, we will relocate those explorations to avoid possible sites. A qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil for the trenching and borings.

For all of the geotechnical explorations located at NAT A, B, E, F, G and H; ARN Reaches A and B; and ARS Reaches A and B, as well as for all future geotechnical explorations for the Common Features Project, in the event of an unanticipated discovery during the explorations all activity within the vicinity of the find would cease and a qualified archeologist would examine the find to determine treatment.

We are sensitive to traditional cultural properties and sacred sites, and make every effort to avoid them. Please let us know if you have knowledge of locations of archeological sites, or areas of traditional cultural interest or concern. If you are interested in further communication regarding exploratory efforts or our continuing efforts to comply with Section 106 of the National Historic Preservation Act of 1966, as amended, we ask that you notify us. In accordance with 36 C.F.R. § 800.14 we plan to develop a Programmatic Agreement (PA) in order to initiate the Section 106 process early in the planning process for the Common Features Project and we will be contacting you in the future to determine your interest in involvement in the PA as a concurring party. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814-2922.

We request that you reply within 30 days of receipt of this letter. If you have any questions of comments, please contact Ms. Montag, Historian, at (916) 557-7907.

Sincerely,

E. Scott Clark

Alicia E. Kirchner

As part of the Corps' exploratory phase for the remaining reaches of the Common Features Project we are planning to complete a series of geotechnical explorations in the late spring, summer, and fall of 2011 along various project reaches. Along NAT Reach A, a total of 8 cone penetrometer tests (CPT) and 15 geotechnical borings at and adjacent to the Sacramento and American Rivers levees will be completed between May and September. The maximum depth of the borings and CPTs would be 100 feet and all borings and CPTs would be backfilled. The boring locations and CPTs for NAT Reach A are shown red dots on Enclosure 2. Although there are no known prehistoric resources located within the areas identified for borings and CPTs, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil.

Within NAT Reach B, a total of 4 CPTs and 13 geotechnical borings along the Sacramento River levee crown and in adjacent agricultural fields will be completed between July and September. The maximum depth of the borings and CPTs would be 100 feet and all borings and CPTs would be backfilled. The boring locations and CPTs for NAT Reach B are shown as red dots on Enclosure 3. Although there are no known prehistoric resources located within the

Re: American River Common Features General Reevaluation Project

Dear Ms. Montag,

I am writing in response to your letter that we received on May 5th. This letter indicates that you are proposing geotechnical explorations for the American River Common Features General Reevaluation (Common Features) Project. This is said to take place in Sacramento and Sutter Counties.

The Tribe is very concerned with the preservation of any Native American Archaeological or Cultural Sites within the project area, or which may be impacted as a result of project activities (pursuant to 14 CCR § 895.1) These sites include, but are not limited to: village sites, camp sites, petroglyphs, prehistoric trails, quarries, milling stations, cemeteries, ceremonial sites, or traditional cultural sites and properties. We are not aware of any cultural resources in the planned project area. If during project activities any cultural resources are found, we ask you to stop activities and that a funded monitor be placed on site for the remainder of the project.

It is also the Tribe's position that extreme care be taken to preserve all watersheds, all Riparian Habitat Conservation Areas; and in general, the prohibition of any project activities which would diminish water quality.

We appreciate your notification. Please also contact Shingle Springs Rancheria and United Auburn Indian Community because this may also be their ancestral area. If there is any other assistance that I can provide during this process, please do not hesitate to contact me.

Thank you.

Subject: The American River Common Features General Re-evaluation Project

Dear Ms. Montag,

Thank you for requesting information regarding the above referenced project. The United Auburn Indian Community (UAIC) of the Auburn Rancheria is comprised of Miwok and Southern Maidu (Nisenan) people whose tribal lands are within Placer County and ancestral territory spans into El Dorado, Nevada, Sacramento, Sutter, and Yuba counties. The UAIC is concerned about development within its aboriginal territory that has potential to impact the lifeways, cultural sites, and landscapes that may be of sacred or ceremonial significance. We appreciate the opportunity to comment on this and other projects in your jurisdiction.

In order to ascertain whether or not the project could affect cultural resources that may be of importance to the UAIC, we would like to receive copies of any archaeological reports that have been, or will be, completed for the project. We also request copies of future environmental documents for the proposed project so that we have the opportunity to comment on potential impacts and proposed mitigation measures related to cultural resources. The UAIC would also like the opportunity to have our cultural consultants accompany you during the field survey. The information gathered will provide us with a better understanding of the project and cultural resources on site and is invaluable for consultation purposes.

The UAIC's preservation committee would like to set up a fieldvisit and consult about the proposed project. The UAIC would like to be concurring party on any sort of treatment plans, programmatic agreements, or memorandum of agreements. Thank you again for taking these matters into consideration, and for involving the UAIC early in the planning process. We look forward to reviewing the aforementioned documents as requested and setting up a meeting. Please contact Marcos Guerrero, cultural resources specialist, at (530) 883-2364 or email at mguerrero@auburnrancheria.com if you have any questions.

Sincerely,

Gregory S. Baker,
Tribal Administrator

RE: American River Common Features Project in Sacramento County

Dear Alicia E. Kirchner

The Most likely Descendant, Daniel Fonseca would like to initiate consultation process with the Department of the Army for the American River Common Features project located in Sacramento County. Among other things, we would like this consultation to address the cultural and historic resource issues, pursuant to the regulations implementing Section 106 of the National Historic Preservation Act.

Prior to meeting we would like to request any and all completed record searches and or surveys that were done in or around the project area up to and including environmental, archaeological and cultural reports.

Please let this letter serve as a formal request for the Shingle Springs Band of Miwok Indians to be added as a consulting party in identifying any Traditional Cultural Properties (TCPs) that may exist within the project's Area of Potential Effects (APE).

Please contact Crystal Dilworth, Cultural Resource Office Manager at 530-698-1471 to schedule a consultation meeting pursuant to Section 106 of the NHPA.

Sincerely,

Daniel Fonseca
Cultural Resources Director

Mr. Daniel Fonseca
Cultural Resources Director
Shingle Springs Band of Miwok Indians
Shingle Springs Rancheria
P.O. Box 1340
Shingle Springs, California 95682

Dear Mr. Fonseca:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to continue consultation on the American River Common Features General Reevaluation (Common Features) Project. We previously contacted you in reference to geotechnical explorations for this Project in a letter dated May 4, 2011. The U.S. Army Corps of Engineers, Sacramento District (Corps) has previously authorized work under the American River Common Features Project and additional levee improvements are being evaluated as part of the Project. The State of California is the non-Federal partner on the Project. The overall Project is located in Sacramento and Sutter Counties along the Sacramento River, the American River, the Natomas Cross Canal, the Pleasant Grove Creek Canal, the Natomas East Main Drain Canal, Arcade Creek, and Dry/Robla Creeks (Enclosure).

We received your letter dated April 3, 2012, where you requested to meet with us on the project in order to address cultural and historic issues. You also requested to be formally added as a consulting party in identifying any Traditional Cultural Properties (TCPs) within the Project's Area of Potential Effect (APE), and you requested completed records searches, surveys, and environmental, archaeological and cultural reports.

We look forward to meeting with you on the Project. As you requested, Ms. Melissa Montag of my office will contact Ms. Crystal Dilworth to schedule a consultation meeting. We will make every effort to avoid archeological sites, TCPs, areas of traditional cultural value, interest, or concern and your input during the early stages of planning for the Project is valuable in our efforts to identify historic properties within the Project APE.

You may request previously completed records searches, surveys, and archaeological and cultural reports from within the APE from the Northeast Information Center at California State University, Chico for Sutter County and the North Central Information Center at California State University, Sacramento for Sacramento County. You may also make a Freedom of Information Act (FOIA) request for those documents within our agency records to SPK-FOIA@usace.army.mil. If you have questions about submitting a FOIA request, please contact Ms. Phyllis Svetich, FOIA/Privacy Act Officer, at (916) 557-7236 or Phyllis.M.Svetich@usace.army.mil. Also included with this letter is a disc that includes various available environmental documents for the Project APE. Many other related documents are available at http://www.safca.org/Programs_Natomas.html. We will add you to our mailing this to receive relevant future documents within the Project APE.

We will be contacting you soon with information on additional geotechnical explorations we are planning within the Project APE. In accordance with 36 CFR § 800.14 we are developing a Programmatic Agreement (PA) in order to initiate the Section 106 process early in the planning process for the Project and we will be contacting you to determine your interest in involvement in the PA as a consulting or concurring party. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or comments, please contact Ms. Montag, Historian, at (916) 557-7907. For specific Project questions please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372.

Sincerely,

Alicia E. Kirchner

MAY 11 2012

Ms. Rhonda Morningstar Pope, Chairperson
Buena Vista Rancheria
P.O. Box 162283
Sacramento, California 95816

Dear Ms. Pope :

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to keep you informed of our continued geotechnical exploration work for the American River Common Features Project (Common Features) following our initial consultation with you in a letter dated May 4, 2011. The overall Common Features Project is located in Sacramento and Sutter Counties along the Sacramento River, the American River, the Natomas Cross Canal, the Pleasant Grove Cross Canal, and the Natomas East Main Drain Canal, Arcade Creek, and Dry/Robla Creeks.

As part of the U.S. Army Corps of Engineers' (Corps) exploratory phase for the Common Features Project, we are completing a series of geotechnical explorations. The work will consist of soil testing to depths of 80 feet, soil surface testing of erodibility, in-channel borings, trenching, and various geophysical surveys. The geotechnical borings will occur at 23 locations along the American River between river miles 0.0 and 22.4 while the trenching will occur at five locations between river miles 5 and 14. The borings will be taken in various locations along the toe and bench within the American River Parkway. The sonic drilling method will be used to collect continuous samples for geologic and engineering characteristics at all sites.

Additionally, 12 of the locations will include a second boring using the air rotary cased hammer method to collect undisturbed samples. Trenching will consist of excavating an area 15 feet deep and 150 feet long to perform a visual verification of the soil patterns. The maximum depth for borings will not exceed 80 feet and all borings and trenches will be backfilled upon completion. Enclosed is a map of the proposed locations for the geotechnical borings (shown as blue and white dots) and trenching (outlined in red) testing locations.

A comparison between the records search and the map of the boring/testing locations indicates that there are no known sites at any of these locations. An archaeological field investigation of the specific geotechnical exploration locations will be completed prior to any ground disturbing activities. In the event that cultural resources are identified during the archeological field investigation, we will relocate those explorations to avoid possible sites. Although there are no known prehistoric resources located within the areas identified for borings and testing locations, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil at every testing location.

For all the geotechnical explorations located on the American River, as well as for all future geotechnical explorations for the Common Features Project, in the event of an unanticipated discovery during the explorations all activity within the vicinity of the find would cease and a qualified archeologist would examine the find to determine treatment.

We are sensitive to traditional cultural properties and sacred sites, and make every effort to avoid them. Please let us know if you have knowledge of locations of archeological sites, or areas of traditional cultural interest or concern within the locations identified for the borings and testing. If you are interested in further communication regarding exploratory efforts or our continuing efforts to comply with Section 106 of the National Historic Preservation Act of 1966, as amended, we ask that you notify us. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814-2922.

Sincerely,

Alicia E. Kirchner

The overall Common Features Project is located in Sacramento and Sutter Counties along the Sacramento River, the American River, the Natomas Cross Canal, the Pleasant Grove Cross Canal, and the Natomas East Main Drain Canal, Arcade Creek, and Dry/Robla Creeks.

As part of the U.S. Army Corps of Engineers' (Corps) exploratory phase for the Common Features Project, we are completing a series of geotechnical explorations. The work will consist of soil testing to depths of 80 feet, soil surface testing of erodibility, in-channel borings, trenching, and various geophysical surveys. The geotechnical borings will occur at 23 locations along the American River between river miles 0.0 and 22.4 while the trenching will occur at five locations between river miles 5 and 14. The borings will be taken in various locations along the toe and bench within the American River Parkway. The sonic drilling method will be used to collect continuous samples for geologic and engineering characteristics at all sites.

Additionally, 12 of the locations will include a second boring using the air rotary cased hammer method to collect undisturbed samples. Trenching will consist of excavating an area 15 feet deep and 150 feet long to perform a visual verification of the soil patterns. The maximum depth for borings will not exceed 80 feet and all borings and trenches will be backfilled upon completion. Enclosed is a map of the proposed locations for the geotechnical borings (shown as blue and white dots) and trenching (outlined in red) testing locations.

A comparison between the records search and the map of the boring/testing locations indicates that there are no known sites at any of these locations. An archaeological field investigation of the specific geotechnical exploration locations will be completed prior to any ground disturbing activities. In the event that cultural resources are identified during the archeological field investigation, we will relocate those explorations to avoid possible sites. Although there are no known prehistoric resources located within the areas identified for borings and testing locations, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil at every testing location.

Mr. Daniel Fonseca
Cultural Resources Director
Shingle Springs Band of Miwok Indians
Shingle Springs Rancheria
P.O. Box 1340
Shingle Springs, California 95682

Dear Mr. Fonseca:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to keep you informed of our continued geotechnical exploration work for the American River Common Features Project (Common Features) following our initial consultation with you in a letter dated May 4, 2011. The overall Common Features Project is located in Sacramento and Sutter Counties along the Sacramento River, the American River, the Natomas Cross Canal, the Pleasant Grove Cross Canal, and the Natomas East Main Drain Canal, Arcade Creek, and Dry/Robla Creeks.

As part of the U.S. Army Corps of Engineers' (Corps) exploratory phase for the Common Features Project, we are completing a series of geotechnical explorations. The work will consist of soil testing to depths of 80 feet, soil surface testing of erodibility, in-channel borings, trenching, and various geophysical surveys. The geotechnical borings will occur at 23 locations along the American River between river miles 0.0 and 22.4 while the trenching will occur at five locations between river miles 5 and 14. The borings will be taken in various locations along the toe and bench within the American River Parkway. The sonic drilling method will be used to collect continuous samples for geologic and engineering characteristics at all sites.

Additionally, 12 of the locations will include a second boring using the air rotary cased hammer method to collect undisturbed samples. Trenching will consist of excavating an area 15 feet deep and 150 feet long to perform a visual verification of the soil patterns. The maximum depth for borings will not exceed 80 feet and all borings and trenches will be backfilled upon completion. Enclosed is a map of the proposed locations for the geotechnical borings (shown as blue and white dots) and trenching (outlined in red) testing locations.

A comparison between the records search and the map of the boring/testing locations indicates that there are no known sites at any of these locations. An archaeological field investigation of the specific geotechnical exploration locations will be completed prior to any ground disturbing activities. In the event that cultural resources are identified during the archeological field investigation, we will relocate those explorations to avoid possible sites. Although there are no known prehistoric resources located within the areas identified for borings and testing locations, a qualified archeological monitor will be present during ground disturbing activities for the first 20 feet of previously undisturbed soil at every testing location.

For all the geotechnical explorations located on the American River, as well as for all future geotechnical explorations for the Common Features Project, in the event of an unanticipated discovery during the explorations all activity within the vicinity of the find would cease and a qualified archeologist would examine the find to determine treatment.

We are sensitive to traditional cultural properties and sacred sites, and make every effort to avoid them. Please let us know if you have knowledge of locations of archeological sites, or areas of traditional cultural interest or concern within the locations identified for the borings and testing. If you are interested in further communication regarding exploratory efforts or our continuing efforts to comply with Section 106 of the National Historic Preservation Act of 1966, as amended, we ask that you notify us. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814-2922.

Sincerely,

Alicia E. Kirchner

Ms Melissa Montag (CESPK-PD-RC)
U.S Army Corps of Engineers,
1325 J Street, Sacramento CA 95814-2922

Dear Ms Melissa Montag,

We are in receipt of a letter dated May 11, 2012 from Alicia E. Kirchner, Chief, Planning Division informing us of the continued geotechnical exploration work for the American River Common Features Project.

As per your request, Buena Vista Rancheria is interested in continued consultation with U.S Army Corps of Engineers pursuant to Section106 of the National Historic Preservation Act of 1966. In order for us to better understand the project we would like to request additional information on the full range of proposed project activities for which the drilling and trenching is being proposed, including detail project descriptions with maps and photographs. We also request the schedule for the proposed borings and trenching, and a site visit. Buried archeological deposits and other cultural resources could be present at some drilling and trenching sites that could potentially be impacted by proposed project activities.

In addition, Buena Vista Rancheria would like to review the results of your records search concerning cultural resources including archeological sites and other resources of interest and concern to American Indians. The Tribe requests to be involved in developing the scope of work, sampling strategy and research design, as well as field investigations, laboratory analysis, and report writing for the proposed archeological investigations Please provide a schedule for your proposed cultural resources studies. A site visit to the proposed study area is requested, as well.

Buena Vista Rancheria is pleased that the Department of the Army plans to have a qualified archaeologist on site during geotechnical exploration excavations. We request that you consider having the Tribe's Cultural Monitors present during the borings and trenching and all related activities involving substantial ground disturbing actions, in addition to the field investigations mentioned above.

We look forward to receiving additional project information from you to review prior to a site visit, as well as working with you to develop the studies to investigate cultural resources of interest and concern to the American Indian people in the project area of potential effect.

If you have any questions regarding this letter feel free to call me at telephone number (916) 491-0011.

Respectfully,

Roselynn Lwenya, PhD
Tribal Historic Preservation Officer and
Environmental Resources Director

JUL 12 2012

Dear Ms. Lwenya:

In response to your letter dated June 21, 2012 and in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to keep you informed of our continued work for the American River Common Features General Reevaluation (Common Features) Project. The area of potential effects for the Common Features Project is shown on Enclosure 1. The geotechnical borings, for which we originally consulted with you back in May, will no longer be occurring as planned. However, we are still moving forward with the Section 106 consultation process for the overall Common Features Project and we would like to keep you informed of our upcoming efforts on the project.

A draft programmatic agreement will be available soon. In accordance with 36 CFR Part 800.14(b)(2)(i), you will be invited to review this document as a concurring party. Additionally, in accordance with 36 CFR Part 800.2, we would like to propose the prospect of setting up a meeting with you to discuss our current and future Section 106 compliance efforts for the Common Features Project. We will be contacting you soon to schedule a consultation meeting.

We are sensitive to traditional cultural properties and sacred sites, and make every effort to avoid them. If you have any questions or concerns, please feel free to contact us. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814-2922. For specific project questions please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372.

Sincerely,

Alicia E Kirchner

APR 05 2013

Ms. Rhonda Morningstar Pope, Chairperson
Buena Vista Rancheria
P.O. Box 162283
Sacramento, California 95816

Dear Ms. Pope:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Included as attachments to the draft PA are a map of the APE (Enclosure 3, Attachment 1) and a draft project description for the ARCF Project (Enclosure 3, Attachment 3). We have contacted the Advisory Council on Historic Preservation and the State Historic Preservation Officer to ask for their comments on the proposed ARCF Project. They have also received the draft PA for their review and comment.

Pursuant to 36 CFR § 800.14(b)(2)(i), we request your involvement in the development of the PA for the ARCF Project. We ask that you review the enclosed draft PA and provide us with comments within 45 days. Additionally, if you would like to meet with us so that we may answer any questions you may have about ARCF Project, our proposed Section 106 compliance efforts, or the draft PA, we ask that you contact us to schedule a meeting.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation for the ARCF Project, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Alicia E. Kirchner
Chief, Planning Division

Mr. Ambar Mohammed
Cachil DeHe Band of Wintun Indians of the
Colusa Indian Community of the Colusa Rancheria
3730 State Highway 45 # B
Colusa, California 95932

Dear Mr. Mohammed:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Dear Mr. DeSpain:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Mr. Dennis Ramirez, Chairperson
Mechoopda Indian Tribe of Chico Rancheria
125 Mission Ranch Boulevard
Chico, California 95926

Dear Mr. Ramirez:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Dear Ms. Lwenya:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area the Sacramento and American rivers form a flood plain covering roughly 110,000 acres in their confluence. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

JUN 06 2013

Dear Mr. Angle:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area, the Sacramento and American rivers form a flood plain covering roughly 110,000 acres. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Included as attachments to the draft PA are a map of the APE (Enclosure 3, Attachment 1) and a draft project description for the ARCF Project (Enclosure 3, Attachment 3). We have contacted the Advisory Council on Historic Preservation and the State Historic Preservation Officer to ask for their comments on the proposed ARCF Project. They have also received the draft PA for their review and comment.

Pursuant to 36 CFR § 800.14(b)(2)(i), we request your involvement in the development of the PA for the ARCF Project. We ask that you review the enclosed draft PA and provide us with comments within 45 days. Additionally, if you would like to meet with us so that we may answer any questions you may have about ARCF Project, our proposed Section 106 compliance efforts, or the draft PA, we ask that you contact us to schedule a meeting.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation for the ARCF Project, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Alicia E. Kirchner

Ms. April Wallace Moore
19630 Placer Hills Road
Colfax, California 95713

JUN 06 2013

Dear Ms. Moore:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to inform you of the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to provide flood risk reduction to the City of Sacramento and the Natomas Basin pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

In the Sacramento area, the Sacramento and American rivers form a flood plain covering roughly 110,000 acres. The flood plain includes most of the developed portions of the city of Sacramento. The ARCF Project area of potential effects (APE) includes approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; intermittent sites along the east bank of the Sacramento River downstream of the Natomas Cross Canal (NCC) down to the confluence with the American River; intermittent sites on the south bank of the NCC immediately upstream of the confluence with the Sacramento River; approximately 4 miles of the Pleasant Grove Creek Canal; the Sacramento Bypass and Sacramento Weir; approximately 8 miles of the Natomas East Main Drainage Canal (NEMDC); approximately 15 miles of the east bank of the Sacramento River downstream of the American River down to Morrison Creek; approximately ½ mile of the south bank of Dry/Robla Creeks; approximately 2 miles of the north and south banks of Arcade Creek; and approximately ½ mile of the Magpie Creek Diversion Canal (Enclosure 1).

The ARCF Project is a single purpose flood risk management project with the measures described in Enclosure 2 proposed for implementation. The ARCF Project APE is within an area known to be sensitive for prehistoric and historic cultural resources. The Corps has determined that ARCF Project will be a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties. As a result, pursuant to 36 CFR § 800.14(b), we have drafted a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project. The draft PA is enclosed for your review and comment (Enclosure 3).

Melissa Montag, Senior Environmental Manager/Historian
U.S. Army Corps of Engineers
Cultural, Recreation & Social Assessment Section (CESPK-PD-RC)
1325 J Street
Sacramento, CA 95814-2922

Re: American River Common Features Project - Draft Programmatic Agreement

Dear Ms. Montag:

I am writing on behalf of the Buena Vista Rancheria of Me-Wuk Indians (BVR) to express concerns and share comments about the enclosed American River Common Features Project Draft Programmatic Agreement (PA).

This draft PA requests tribal governments to concur with procedural documents that have not yet been prepared, such as the Historic Properties Management Plan (HPMP) and the Historic Properties Treatment Plans (HPTPs). This is problematic for a couple reasons. First, tribes were not involved in determining the area of potential effect (APE), the presence of historic properties, the effect of the undertaking on historic properties, or the identification of resources having spiritual and cultural significance to American Indians. Further, despite requests, BVR has been denied adequate information and documentation on known historic properties within the APE.

BVR believes that the draft PA was prepared with inadequate tribal government to government consultation, as required under Section 106 of the National Historic Preservation Act and Executive Order 13175. BVR has only received copies of letters sent to other agencies and letters of invitation to initiate consultation. Substantive government to government consultation at the earliest possible stage is crucial in order for consultation to be meaningful.

The meeting between representatives of the Army Corps and BVR, on May 29, 2013, is an example of how the process should work, and BVR looks forward to many more opportunities to consult with the U.S. Army Corps of Engineers on local projects.

If you have any questions regarding our comments please feel free to contact Roselynn Lwenya, Ph.D., Environmental Resources Director, at (916) 491-0011.

RE: ARCF Project

Dear Ms. Montag:

Thank you for your project notification letter and programmatic agreement (PA) dated, June 6th, 2013, regarding cultural information on or near the proposed ARCF project, Sacramento area, CA. We appreciate your effort to contact us.

The Cultural Resources Department has reviewed the project and concluded that it is not within the aboriginal territories of the Yocha Dehe Wintun Nation. Therefore, we respectively decline any comment on this project or the PA.

Should you have any questions, please feel free to contact the following individual:

Mr. James Sarmento
Cultural Resources Manager
Yocha Dehe Wintun Nation
Office: (530) 723-0452, Email: jsarmento@yochadehe-nsn.gov

Please refer to identification number YD-06202013-01 in any correspondences concerning this project.

Thank you for providing us with this notice and the opportunity to comment.

Sincerely,

Marshall McKay
Tribal Chairman

Environmental Resources Branch

JUN 1 2 2014

Ms. Cathy Bishop
Chairperson
Strawberry Valley Rancheria
1540 Strader Avenue
Sacramento, California 95815

Dear Ms. Bishop:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to continue consultation with you regarding the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to reduce flood risk to the City of Sacramento and the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The ARCF Project is a part of the Common Features General Reevaluation Report. The State of California Central Valley Flood Protection Board (CVFPP), in cooperation with the Sacramento Area Flood Control Agency (SAFCA), is the non-Federal sponsor for the ARCF Project.

We most recently contacted you via a letter dated June 6, 2013 wherein we:

a. Provided the ARCF Project area of potential effects (APE) and project description.

b. Provided the Corps' determination that the ARCF Project is a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties.

c. Provided the Corps' determination, pursuant to 36 CFR § 800.14(b), that a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project would be the means for the Corps to comply with Section 106 of the National Historic Preservation Act of 1966, as amended.

d. Requested your involvement in the development of the PA for the ARCF Project.

e. Enclosed the ARCF Project draft PA for your review and comment.

We are providing the most recent final draft of the PA for the ARCF Project for your final review and comment before we plan to execute the PA. The final draft of the PA is included in Enclosure 1. We have prepared a short summary document describing the authorizations for the projects in the region, what has been constructed, what agency or partner completed the construction, previous compliance with the National Historic Preservation Act of 1966, as amended, and the National Environmental Policy Act of 1969, and the planned future activities within the watersheds (Enclosure 1, Attachment 4). The APE for the ARCF Project is further described and shown in Enclosure 1, Attachment 3.

Because the APE for the ARCF Project covers a large geographic area and is mostly located along rivers, which have been shown to be sensitive for buried resources, we have developed two predictive models to extrapolate archaeological sensitivity over un-surveyed portions of the APE. The first model is a general model of site locations that anticipates the likelihood that any one or more spots in the study area will be in an archaeological site. The second model highlights portions of the APE where we would be more or less likely to find buried archaeological materials. Ultimately we plan to use the predictive models to assist with planning and evaluating alternatives to avoid adverse effects to cultural resources whenever and wherever possible. The models and detailed information on the archaeological sensitivity assessment are included in Enclosure 2. We request any comments you may have on the archaeological sensitivity assessment.

The PA has been provided to the State Historic Preservation Officer (SHPO), the Advisory Council on Historic Preservation (ACHP), CVFPP, Department of Water Resources (DWR), SAFCA, and potentially interested American Indian Tribes and interested American Indian individuals for review and comment. In a letter dated August 7, 2012, the ACHP declined to participate in consultation for the ARCF Project (Enclosure 1, Attachment 2). Comments were received from the CVFPP, DWR, SAFCA, and American Indian Tribes and have been considered in this current final draft of the PA. A consultation log of communications with American Indian tribes and American Indian individuals for the ARCF Project is included as Enclosure 3.

In April 2013, letters to 100 historical societies, museums, state historic parks, associations with historic interests, local city and county groups, and groups of various prehistoric and historic interests were sent providing a description and map of the project and requesting information on cultural resources within the APE. One response, from the Center for Sacramento History, was received, noting they would keep our letter on file. In accordance with 36 CFR § 800.14(b)(2)(ii), we will also provide potentially interested American Indian Tribes and interested American Indian individuals and the groups and agencies listed above the final draft PA with the forthcoming Environmental

Impact Statement/Environmental Impact Report which will be released for public review this summer.

Pursuant to 36 CFR § 800.14(b)(2)(i), we have requested your involvement in the development of the PA for the ARCF Project. As a potential Concurring Party to the PA, we ask that you review the enclosed final draft PA and archaeological sensitivity assessment and provide us with comments within 30 days. Any comments on the draft final PA received during the review period will be considered for the final PA. If you would like to meet with us so that we may answer any questions you may have about ARCF Project, our proposed Section 106 compliance efforts, or the draft PA, we ask that you contact us to schedule a meeting. Additionally, we request that you inform us if you are interested in signing the PA as a Concurring Party and if there are any required alterations to your signature page of the PA.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. If you have any questions or would like additional information about the Section 106 compliance and consultation for the ARCF Project, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

For Alicia E. Kirchner

Mr. Grayson Coney
Tsi-Akim Maidu
P.O. Box 1316
Colfax, California 95713

Dear Mr. Coney:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to continue consultation with you regarding the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to reduce flood risk to the City of Sacramento and the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The ARCF Project is a part of the Common Features General Reevaluation Report. The State of California Central Valley Flood Protection Board (CVFPP), in cooperation with the Sacramento Area Flood Control Agency (SAFCA), is the non-Federal sponsor for the ARCF Project.

We most recently contacted you via a letter dated June 6, 2013 wherein we:

a. Provided the ARCF Project area of potential effects (APE) and project description.

b. Provided the Corps' determination that the ARCF Project is a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties.

c. Provided the Corps' determination, pursuant to 36 CFR § 800.14(b), that a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project would be the means for the Corps to comply with Section 106 of the National Historic Preservation Act of 1966, as amended.

d. Requested your involvement in the development of the PA for the ARCF Project.

e. Enclosed the ARCF Project draft PA for your review and comment.

Plymouth, California 95669

Dear Ms. Miller:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, we are writing to continue consultation with you regarding the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to reduce flood risk to the City of Sacramento and the Natomas Basin and areas along the north and south banks of the American River as well as the east bank of the Sacramento River pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999. The ARCF Project is a part of the Common Features General Reevaluation Report. The State of California Central Valley Flood Protection Board (CVFPP), in cooperation with the Sacramento Area Flood Control Agency (SAFCA), is the non-Federal sponsor for the ARCF Project.

We most recently contacted you via a letter dated April 5, 2013 wherein we:

a. Provided the ARCF Project area of potential effects (APE) and project description.

b. Provided the Corps' determination that the ARCF Project is a complex undertaking that may be constructed in multiple phases, that the effects on historic properties cannot be fully determined prior to the approval of the undertaking, and that the ARCF Project may result in adverse effects to historic properties.

c. Provided the Corps' determination, pursuant to 36 CFR § 800.14(b), that a programmatic agreement (PA) to establish a framework for the resolution of potential adverse effects that may result from implementation of the ARCF Project would be the means for the Corps to comply with Section 106 of the National Historic Preservation Act of 1966, as amended.

d. Requested your involvement in the development of the PA for the ARCF Project.

e. Enclosed the ARCF Project draft PA for your review and comment.

MIWOK United Auburn Indian Community
MAIDU of the Auburn Rancheria

Gene Whitehouse, Chairman | John L. Williams, Vice Chairman | Danny Rey, Secretary | Brenda Adams, Treasurer | Calvin Moman, Council Member

August 19, 2014

Ms. Melissa Montag
U.S. Army Corp of Engineers
Sacramento District
1325 J Street
Sacramento California 95814-29922

Subject: American River Commons Features (ARCF) Project

Dear Melissa Montag,

Thank you for requesting information regarding the above referenced project. The United Auburn Indian Community (UAIC) of the Auburn Rancheria is comprised of Miwok and Southern Maidu (Nisenan) people whose tribal lands are within Placer County and whose service area includes El Dorado, Nevada, Placer, Sacramento, Sutter, and Yuba counties. The UAIC is concerned about development within its aboriginal territory that has potential to impact the lifeways, cultural sites, and landscapes that may be of sacred or ceremonial significance. We appreciate the opportunity to comment on this and other projects in your jurisdiction.

In order to ascertain whether or not the project could affect cultural resources that may be of importance to the UAIC, we would like to receive copies of any archaeological reports that have been, or will be, completed for the project. We also request copies of future environmental documents for the proposed project so that we have the opportunity to comment on potential impacts and proposed mitigation measures related to cultural resources. Finally, we would like the opportunity to have our tribal monitors accompany you during the field survey. The information gathered will provide us with a better understanding of the project and cultural resources on site and is invaluable for consultation purposes.

Our preservation committee has identified many cultural resources within your project area and in close proximity, and would like to request a site visit to confirm their locations and meet with you regarding this project. In addition, we have several specific requests that arose out of your meeting with our committee members and staff on August 5, 2014. We ask that the USACE and DWR provide the UAIC with:

- A confidentiality and/or data sharing agreement;
- A burial plan;
- A Historic Properties Treatment Plan that is approved before ground disturbing activities begin;
- A confederacy agreement between the tribes that wish to consult on the project;
- Signatory status on the Programmatic Agreement.

Tribal Office 10720 Indian Hill Road Auburn, CA 95603 (530) 883-2390 FAX (530) 883-2380

Each of these is crucial to ensuring that the many cultural resources within your project area are protected and that any disturbance to the resources is minimized.

We will begin preparing comments to the PA and look forward to meeting with you again so that we can maintain an open dialogue. Thank you again for taking these matters into consideration, and for involving the UAIC early in the planning process. We look forward to reviewing the documents we requested. Please contact Marcos Guerrero, Cultural Resources Manager, at (530) 883-2364 or by email at mguerrero@auburnrancheria.com if you have any questions.

Sincerely,

Gene Whitehouse,
Chairman

NOV 20 2014

Mr. Charlie Wright
Chairperson
Cortina Wintun Environmental Protection Agency
P.O. Box 1630
Williams, California 95987

Dear Mr. Wright:

The U.S. Army Corps of Engineers (Corps), along with its non-Federal sponsors, the Central Valley Flood Protection Board (CVFPB) and Sacramento Area Flood Control Agency (SAFCA), are conducting geotechnical study as a part of the American River Watershed Common Features Project Natomas Basin, specifically Reach H, which extends from Northgate Boulevard to the Natomas East Main Drainage Canal (NEMDC) Stormwater Pump Station. Authorization for the Common Features project is provided by Section 7002 of Water Resources Reform and Development Act (WRRDA) (PL 113-121) of 2014. As part of these studies, soil borings will be performed to collect, classify, and test soil samples along the American River and NEMDC near Sacramento, California. Additionally, in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 CFR § 800.4, and as part of efforts to identify historic properties, the Corps will collect samples of organic matter (e.g. charcoal, wood) encountered during the studies for radiocarbon dating. This work is expected to occur between December 2014 and February of 2015.

The geotechnical study consists of drilling thirty eight (38) soil borings within the levee prism, levee toe, waterside berm, or adjacent field along the American River and NEMDC. The borings will be performed by a truck mounted drill rig or hand auger. There will be a total of eleven (11) borings using a truck or track mounted drill rig and twenty-seven (27) hand augers taking place. The borings will be up to 8 inches in diameter and up to 80 feet deep, and the augers will be up to 8 inches in diameter and up to 15 feet deep. The main access and travel paths to the boring and auger locations would be from the existing levee roads, levee access ramps, bike paths, and adjacent streets. After boring and augering is complete all holes/excavations will be backfilled and the surface returned to pre-work conditions. Enclosed is a map of the proposed boring and augering locations and a table describing the activities (Enclosures 1 and 2).

A records search and archeological survey completed on October 14, 2014 revealed that the locations for the geotechnical study have been previously subjected to cultural resources inventory twice and that there are no known prehistoric resources located

within or adjacent to the locations for the geotechnical study. Although there are three previously recorded historic-era features (NEMDC west levee, Del Paso Road, and Northgate Boulevard) within the area, none will be affected by the geotechnical study. A recent archeological field verification of the boring and augering locations did not result in the identification of previously unknown prehistoric resources. A single, isolated, potentially historic-era feature was identified in the NEMDC channel just north of San Juan Road, but it is located outside the area planned for the geotechnical study. However, in the event of an unanticipated discovery during the borings or augering, all work at the location of the discovery would stop and both the State Historic Preservation Officer and tribes would be notified.

Previous consultation with Native American tribes on other Corps projects in the vicinity of the geotechnical study locations has noted the area is potentially sensitive for cultural resources. As a result, an archeological monitor meeting 36 CFR § 61 and the Secretary of the Interior's Professional Qualifications Standards for Archeology will inspect the available soil for the presence of cultural resources and will collect samples of organic matter from a variety of subsurface sediments for radiocarbon dating in order to better understand the age of alluvial deposits and inform the Corps' assessments of the probability of encountering buried archaeological sites.

We are sensitive toward the protection of traditional cultural properties and sacred sites, and make every effort to avoid them. Please let us know if you have knowledge of locations of archeological sites, sacred sites, or areas of traditional cultural value or concern in or near the locations identified for the borings and augering. Correspondence may be sent to: Ms. Melissa Montag (CESPK-PD-RC), U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814. If you have any questions or would like additional information, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil.

Sincerely,

Alicia E. Kirchner

Mr. Kesner Flores
P.O. Box 1047
Wheatland, California 95692

Dear Mr. Flores:

The U.S. Army Corps of Engineers (Corps), along with its non-Federal sponsors, the Central Valley Flood Protection Board (CVFPB) and Sacramento Area Flood Control Agency (SAFCA), are conducting geotechnical study as a part of the American River Watershed Common Features Project Natomas Basin, specifically Reach H, which extends from Northgate Boulevard to the Natomas East Main Drainage Canal (NEMDC) Stormwater Pump Station. Authorization for the Common Features project is provided by Section 7002 of Water Resources Reform and Development Act (WRRDA) (PL 113-121) of 2014. As part of these studies, soil borings will be performed to collect, classify, and test soil samples along the American River and NEMDC near Sacramento, California. Additionally, in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 CFR § 800.4, and as part of efforts to identify historic properties, the Corps will collect samples of organic matter (e.g. charcoal, wood) encountered during the studies for radiocarbon dating. This work is expected to occur between December 2014 and February of 2015.

The geotechnical study consists of drilling thirty eight (38) soil borings within the levee prism, levee toe, waterside berm, or adjacent field along the American River and NEMDC. The borings will be performed by a truck mounted drill rig or hand auger. There will be a total of eleven (11) borings using a truck or track mounted drill rig and twenty-seven (27) hand augers taking place. The borings will be up to 8 inches in diameter and up to 80 feet deep, and the augers will be up to 8 inches in diameter and up to 15 feet deep. The main access and travel paths to the boring and auger locations would be from the existing levee roads, levee access ramps, bike paths, and adjacent streets. After boring and augering is complete all holes/excavations will be backfilled and the surface returned to pre-work conditions. Enclosed is a map of the proposed boring and augering locations and a table describing the activities (Enclosures 1 and 2).

A records search and archeological survey completed on October 14, 2014 revealed that the locations for the geotechnical study have been previously subjected to cultural resources inventory twice and that there are no known prehistoric resources located

Mr. Dennis Ramirez
Chairperson
Mechoopda Indian Tribe of Chico Rancheria
125 Mission Ranch Boulevard
Chico, California 95926

Dear Mr. Ramirez:

The U.S. Army Corps of Engineers (Corps), along with its non-Federal sponsors, the Central Valley Flood Protection Board (CVFPB) and Sacramento Area Flood Control Agency (SAFCA), are conducting geotechnical study as a part of the American River Watershed Common Features Project Natomas Basin, specifically Reach H, which extends from Northgate Boulevard to the Natomas East Main Drainage Canal (NEMDC) Stormwater Pump Station. Authorization for the Common Features project is provided by Section 7002 of Water Resources Reform and Development Act (WRRDA) (PL 113-121) of 2014. As part of these studies, soil borings will be performed to collect, classify, and test soil samples along the American River and NEMDC near Sacramento, California. Additionally, in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 CFR § 800.4, and as part of efforts to identify historic properties, the Corps will collect samples of organic matter (e.g. charcoal, wood) encountered during the studies for radiocarbon dating. This work is expected to occur between December 2014 and February of 2015.

The geotechnical study consists of drilling thirty eight (38) soil borings within the levee prism, levee toe, waterside berm, or adjacent field along the American River and NEMDC. The borings will be performed by a truck mounted drill rig or hand auger. There will be a total of eleven (11) borings using a truck or track mounted drill rig and twenty-seven (27) hand augers taking place. The borings will be up to 8 inches in diameter and up to 80 feet deep, and the augers will be up to 8 inches in diameter and up to 15 feet deep. The main access and travel paths to the boring and auger locations would be from the existing levee roads, levee access ramps, bike paths, and adjacent streets. After boring and augering is complete all holes/excavations will be backfilled and the surface returned to pre-work conditions. RE: Formal Request for Government-to-Government Consultation, American River Watershed Common Features General Reevaluation Report, Draft Environmental Impact Statement/Environmental Impact Report, March 2015

Dear Colonel Farrell,

The United Auburn Indian Community (UAIC) is sending this letter to the U.S. Army Corps of Engineers (USACE) requesting formal Government-to-Government Consultation for the American River Common Features (ARCF) Project, located in Sacramento County. The primary purpose of government-to-government consultation as described in Federal Executive Order 13175 "Consultation and Coordination with Indian Tribal Governments" is to ensure that the UAIC is given the opportunity to provide meaningful and timely input regarding proposed USACE actions that uniquely or significantly affect our burial and sacred sites and places.

With this letter, the UAIC is notifying the USACE that unique or significant historic properties will be adversely affected by your project-related planned and proposed levee improvements. Early identification of Tribal concerns will allow the USACE to consider alternatives to avoid and minimize potential impacts to our burial sites and cultural resources. The UAIC would like to be a signatory party to the Programmatic Agreement and be involved early and often as the project planning, alternatives, and documentation are developed and refined.

The UAIC understands and has concerns regarding the confidentiality of information on areas or resources of religious, traditional and cultural importance to the Tribe. We would be happy to discuss these concerns and develop procedures to ensure the confidentiality of such information is strictly maintained.

Your timely response will greatly assist us in being able to have our concerns incorporated into project planning and the Final EIR/EIS. Please contact Marcos Guerrero, Cultural Resources Manager, at (530) 883-2364 or email at mguerrero@auburnrancheria.com if you have any questions.

Sincerely,

Gene Whitehouse,
Chairman

Mr. Gene Whitehouse
Chairperson
United Auburn Indian Community of the Auburn Rancheria
10720 Indian Hill Road
Auburn, California 95603

Dear Mr. Whitehouse:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended (NHPA), we are writing to continue our consultation with you regarding the proposed American River Common Features (ARCF) Project. The U.S. Army Corps of Engineers (Corps) is authorized to reduce flood risk to the City of Sacramento and the Natomas Basin, and areas along the north and south banks of the American River, as well as the east bank of the Sacramento River, pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999 and the Water Resources Reform and Development Act of 2014. In addition to the work contained in these authorizations, a General Reevaluation Report is being prepared to identify the extent of Federal interest in additional levee improvements in the greater Sacramento area. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

As a result of your stated interest in the ARCF Project, and in compliance with Section 106 of the NHPA, we have been meeting with the United Auburn Indian Community of the Auburn Rancheria (UAIC) quarterly with the most recent meeting occurring on May 19, 2015. We also received your email dated April 16, 2015, wherein you provided several comments on the ARCF Draft Environmental Impact Statement/Draft Environmental Impact Report. Based on several of your comments we request any specific information the UAIC may be able to provide in order to ensure that the Corps completely and accurately understands the UAIC's issues and concerns with the ARCF Project:

a. Comment 1: What specific design features would the UAIC prefer be incorporated to reduce the potential for direct cultural impacts?

b. Comment 2: Please provide specific information on the tribal values the UAIC would like considered under construction timing, project and alternatives screening criteria, environmental commitments for cultural resources, social effects, and environmental justice.

c. Comment 2: Please provide specific information on how the UAIC should be identified as a viewer group for visual impacts.

d. Comment 5: Please provide specific information on tribal cultural values, sanctified cemeteries, and/or cultural landscapes that the Corps should consider.

e. Comment 7: Please provide specific information on how the UAIC believes there will be cumulative effects or effects to cultural resources and/or cultural landscapes across several phases or projects over wide geography.

f. Comment 11: Please provide information on how the UAIC believes vibration or compression effects on cultural resources should be considered.

g. Comment 11: Please provide specific information on the vegetation the UAIC considers to be native or cultural plants, their relationships to burial mounds or tribal cultural landscapes, and the impacts the UAIC believes should be considered.

h. Comment 11: Please provide information on traditional cultural properties and cultural landscapes and the importance of place, setting, and landscape to the UAIC.

We welcome your input on any of the subjects above, or any other information the UAIC would be willing to provide that the Corps may take into consideration while preparing the Final Environmental Impact Statement/Final Environmental Impact Report (FEIS/FEIR). If there is information you would like us to consider but not include in the FEIS/FEIR we welcome the opportunity to discuss accommodating those kinds of requests as well. In order to allow time to consider this information, please provide any responses within 15 calendar days of receipt of this letter.

Correspondence may be sent to Ms. Melissa Montag, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922.

If you have any questions or would like additional information about the Section 106 compliance and consultation for the ARCF Project, please contact Ms. Montag at (916) 557-7907 or by email at: Melissa.L.Montag@usace.army.mil. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

AUG 24 2015

Mr. Gene Whitehouse
Chairperson
United Auburn Indian Community of the Auburn Rancheria
10720 Indian Hill Road
Auburn, California 95603

Dear Mr. Whitehouse:

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended (NHPA) and the U.S. Army Corps of Engineers, Sacramento District (Corps), Tribal Consultation Policy (Nov. 1, 2012), we are writing to continue consultation with you regarding the proposed American River Common Features (ARCF) Project. The Corps is authorized to reduce flood risk to the City of Sacramento, the Natomas Basin, areas along the north and south banks of the American River, and the east bank of the Sacramento River, pursuant to the Water Resources Development Act (WRDA) of 1996 with additional authority provided in WRDA 1999 and the Water Resources Reform and Development Act of 2014. We are further pursuing additional authorization of levee and flow conveyance improvements. The State of California Central Valley Flood Protection Board, in cooperation with the Sacramento Area Flood Control Agency, is the non-Federal sponsor for the ARCF Project.

We received your letter dated May 18, 2015 in which you requested formal Government-to-Government Consultation, notified the Corps that historic properties will be adversely affected by the ARCF Project, and requested that the Corps invite the UAIC to sign the ARCF Project Programmatic Agreement (PA) as a signatory party. The Corps' Tribal Liaison, Mark Gilfillan, has been in contact with your staff to initiate formal Government-to-Government Consultation and to reiterate our commitment to working closely and openly with the UAIC to provide meaningful and timely input regarding the Corps' ARCF Project.

I have given your request careful consideration and would like to invite the tribe to join our PA as a concurring party. With the role as a concurring party, along with my staff working closely and cooperatively with yours, it is my sincere hope and intent to address our mutual concerns regarding any adverse effects to historic properties. As a concurring party, the tribe reserves the ability to object to the manner in which the PA is implemented, if at any point you believe that your voice is not being heard. My goal is that your ideas and concerns are addressed as part of implementation of the PA throughout this project. I share your concerns regarding potential adverse effects to historic properties, and I am committed to ensuring that our project avoids or minimizes to the maximum extent any adverse effects through implementation of the PA and throughout construction of the project.

We look forward to continuing consultation with the UAIC on the ARCF Project. Correspondence may be sent to Mr. Dan Tibbitts, Project Manager, U.S. Army Corps of Engineers, Sacramento District, 1325 J Street, Sacramento, California 95814-2922. I am looking forward to meeting with you to further engage in Government-to-Government Consultation for the ARCF Project. Please contact Mark Gilfillan, Corps Tribal Liaison, at (970) 243-1199 x15, or by email at: Mark.A.Gilfillan@usace.army.mil to further coordinate a Government-to-Government Consultation meeting. Please contact Mr. Dan Tibbitts, Project Manager, at (916) 557-7372 with any specific project questions.

Sincerely,

Dear Ms. Cubbler:

We thank you for your interest in the American River Common Features Project (Project). The U.S. Army Corps of Engineers, Sacramento District (Corps), is proceeding to implement aspects of the Project as authorized in the Water Resources Development Act (WRDA) of 1996, as amended by the WRDA 1999 and the Energy and Water Development and Related Agencies Appropriations Act of 2008, and as authorized by Section 7002 of the Water Resources Reform and Development Act of 2014. At this time, we are submitting the signed Programmatic Agreement for your records and to invite you to sign the document as a concurring party.

Please return an original signed copy of the appropriate signature page if you wish to participate in this agreement as a concurring party. The signed page and/or any questions or comments may be directed to Ms. Melissa Montag, CESPK-PD-RC, U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814; email at Melissa.L.Montag@usace.army.mil; or telephone at (916) 557-7907.

Dear Sir or Madam:

We thank you for your interest in the American River Common Features Project (Project). The U.S. Army Corps of Engineers, Sacramento District (Corps), is proceeding to implement aspects of the Project as authorized in the Water Resources Development Act (WRDA) of 1996, as amended by the WRDA 1999 and the Energy and Water Development and Related Agencies Appropriations Act of 2008, and as authorized by Section 7002 of the Water Resources Reform and Development Act of 2014. At this time, we are submitting the signed Programmatic Agreement for your records and to invite you to sign the document as a concurring party.

Please return an original signed copy of the appropriate signature page if you wish to participate in this agreement as a concurring party. The signed page and/or any questions or comments may be directed to Ms. Melissa Montag, CESPK-PD-RC, U.S. Army Corps of Engineers, 1325 J Street, Sacramento, California 95814; email at Melissa.L.Montag@usace.army.mil; or telephone at (916) 557-7907.

Sincerely,

Mark T. Z

Air Quality Technical Appendix

AIR QUALITY

The air quality emissions analysis for the ARCF GRR was developed based on several interrelated assumptions and constraints:

- The project will require 14 separate years to construct the required features;
- Project funding will be limited to $100 million per construction year;
- The project will receive $100 million per construction year;
- In any given year, approximately 85% of the funding will be applied toward construction;
- A construction season is six months (April 15 to October 15);
- Construction will begin in 2015;
- All required administrative, legal, real estate and environmental clearances/approvals will be acquired prior to initiation of construction.
- All project plans and specifications will require that construction contractors use only off-road equipment that implements the Sacramento Metropolitan Air Quality Management Districts' (SMAQMD) Enhanced Exhaust Control Practices and only use on-road hauling equipment that was manufactured in 2010, or later.
- If the off-road equipment and on-road hauling specifications stated above are not met, it cannot be assured that the project air emissions can meet the Federal *de minimis* standards.

It was determined through internal discussions, as well as discussions with staff from the SMAQMD, that the most reasonable approach to determine if the project was to be in compliance with Federal and local standards was to base the evaluation on a "worst case scenario" construction year.

The project team determined that construction in the second year within Reach F of the American River South basin would be the construction season that would result in the most combined air emissions. Reach F was chosen because it is the single longest reach (5 miles) in the entire Common Features Project, and due to design, constructability and funding constraints, will take 3 1/3 years to construct. This would allow for 1.5 miles of construction in years 1 through 3, with the last 0.5 miles to be completed in the fourth year. The following construction activities are scheduled for this reach: clearing of trees and vegetation, degrading and excavation of the levee, construction of two types of seepage control slurry cutoff walls (conventional slot-trench and deep soil mixing), construction of a retaining wall to allow corrections to the levee height and width, reconstruction of the levee, relocation of utilities, and delivery and installation of rip-rap on the waterside slope. The second year of construction in Reach F was chosen because the slurry cutoff walls must be allowed to cure until the following construction season before the rip-rap is placed. Under this scenario, the rip-rap would be placed on the slopes of the segment completed in the first year of construction, while all other construction activities are being conducted in the second year segment. The staggering of construction years for the placement of rip-rap would continue until Reach F would be completed.

In close coordination with SMAQMD, the Corps uses their Road Construction Emissions Model (RCEM), as it was designed to calculate air emissions for linear projects. The construction activities listed above were broken out into 19 individual sub-tasks based on information developed by Corps engineering and cost-estimating staff. Using the RCEM, a model run was conducted for each sub-task, with one exception: the barging of rip-rap material to the project site. In this case, information for barging material was developed, in close coordination with SMAQMD staff, for similar activities being conducted for the Joint Federal Project (JFP). It was agreed that it is reasonable to use this information for the purposes of a feasibility-level study. Although calculations for the JFP involved smaller harbor craft than that assumed for the Common Features project, SMAQMD staff determined that it was reasonable to extrapolate the air emissions data by increasing the horsepower, daily hours and number of days in the JFP model to calculate specific emissions data (ROG, CO, NOx, PM and CO_2) for the Common Features project.

In order to provide a means of comparison for future decision-making purposes, the delivery and placement task was also calculated using the assumption that same amount of material to be barged to the project site, would be trucked to the site in the same period of time. Those results are shown in Tables 1a and 2a (calculated in pounds per day under local standards) and 1b and 2b (calculated in tons per construction project under Federal standards). Note that neither version of this scenario (barging or trucking rip-rap) would be able to perform consistently under the local standard for NOx (Tables 1a and 2a), however, the trucking alternative would require a lower overall mitigation fee cost. In the case of the Federal *de minimis* standards (Tables 1b and 2b) the alternative that involves trucking the rip-rap is within the Federal de minimis standard, even without mitigation, while the barging alternative would likely meet the standard using the mitigation provided by the implementation of Enhance Exhaust Control Practices for off-road equipment and only using on-road hauling equipment that was manufactured in 2010, or later.

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Clear Vegetation)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	4.5	22.7	194.3	71.2	4.2	67.0	16.6	2.7	13.9	38,067.8
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	4.5	22.7	194.3	71.2	4.2	67.0	16.6	2.7	13.9	38,067.8
Total (tons/construction project)	0.0	0.0	0.3	0.1	0.0	0.1	0.0	0.0	0.0	62.8

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 3910

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Clear Vegetation)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	2.0	10.3	88.3	32.4	1.9	30.5	7.6	1.2	6.3	17,303.6
Total (megagrams/construction project)	0.0	0.0	0.3	0.1	0.0	0.1	0.0	0.0	0.0	57.0

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 2989

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (C&G Clear Vegetation)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.2	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	3910.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.02
Grading/Excavation	0.15	0.09
Drainage/Utilities/Sub-Grade	0.00	0.06
Paving	0.00	0.03
Totals	0.15	0.20

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	50.00	30	
Round trips/day		196	
Vehicle miles traveled/day (calculated)			9775

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Strip to Spoils)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	13.7	66.8	272.4	75.4	8.4	67.0	20.7	6.8	13.9	40,202.0
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	13.7	66.8	272.4	75.4	8.4	67.0	20.7	6.8	13.9	40,202.0
Total (tons/construction project)	0.0	0.0	0.1	0.0	0.0	0.0	0.0	0.0	0.0	22.1

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 3040

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Strip to Spoils)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 2324

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (C&G Strip to Spoils)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.1	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	3040.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.01
Grading/Excavation	0.05	0.05
Drainage/Utilities/Sub-Grade	0.00	0.03
Paving	0.00	0.02
Totals	0.05	0.10

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	50.00	30	
Round trips/day		152	
Vehicle miles traveled/day (calculated)			7600

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Strip to Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	10.5	51.7	129.2	72.4	5.4	67.0	18.8	4.9	13.9	12,179.0
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	10.5	51.7	129.2	72.4	5.4	67.0	18.8	4.9	13.9	12,179.0
Total (tons/construction project)	0.0	0.1	0.2	0.1	0.0	0.1	0.0	0.0	0.0	20.1

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 2520

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Strip to Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-

Maximum (kilograms/day)	4.8	23.5	58.7	32.9	2.4	30.5	8.6	2.2	6.3	5,535.9
Total (megagrams/construction project)	0.0	0.1	0.2	0.1	0.0	0.1	0.0	0.0	0.0	18.2

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported (meters^3/day)-> 1927

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a
yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (C&G Strip to Stockpile)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.2	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	2520.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.02
Grading/Excavation	0.15	0.09
Drainage/Utilities/Sub-Grade	0.00	0.06
Paving	0.00	0.03
Totals	0.15	0.20

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	2.00	30	
Round trips/day		126	
Vehicle miles traveled/day (calculated)			252

Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (C&G Tree Removal) Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	Total PM10 (lbs/day)	Exhaust PM10 (lbs/day)	Fugitive Dust PM10 (lbs/day)	Total PM2.5 (lbs/day)	Exhaust PM2.5 (lbs/day)	Fugitive Dust PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	1.4	9.0	33.4	1.0	1.0	-	0.8	0.8	-	5,303.2
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	1.4	9.0	33.4	1.0	1.0	-	0.8	0.8	-	5,303.2
Total (tons/construction project)	0.0	0.0	0.2	0.0	0.0	-	0.0	0.0	-	29.2

Notes:

Project Start Year ->	2016
Project Length (months) ->	1
Total Project Area (acres) ->	28
Maximum Area Disturbed/Day (acres) ->	7
Total Soil Imported/Exported (yd^3/day)->	1505

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Notes:

Project Start Year ->	2016
Project Length (months) ->	1
Total Project Area (hectares) ->	11
Maximum Area Disturbed/Day (hectares) ->	3
Total Soil Imported/Exported ($meters^3$/day)->	1151

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (C&G Tree Removal)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.5	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	1505.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.05
Grading/Excavation	0.50	0.23
Drainage/Utilities/Sub-Grade	0.00	0.15
Paving	0.00	0.08
Totals	0.50	0.50

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	40.00	30	
Round trips/day	25.00	75	
Vehicle miles traveled/day (calculated)			1000

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

END OF DATA ENTRY SHEET

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Cutoff Wall DSM)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	16.9	100.5	155.6	75.4	8.4	67.0	21.6	7.7	13.9	18,598.4
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	16.9	100.5	155.6	75.4	8.4	67.0	21.6	7.7	13.9	18,598.4
Total (tons/construction project)	0.9	5.5	8.6	2.1	0.5	1.7	0.8	0.4	0.3	1,022.9

Notes: Project Start Year -> 2016

Project Length (months) -> 5

Total Project Area (acres) -> 28

Maximum Area Disturbed/Day (acres) -> 7

Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Cutoff Wall DSM)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-

Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	7.7	45.7	70.7	34.3	3.8	30.5	9.8	3.5	6.3	8,453.8
Total (megagrams/construction project)	0.8	5.0	7.8	1.9	0.4	1.5	0.7	0.4	0.3	927.8

Notes: Project Start Year -> 2016

Project Length (months) -> 5

Total Project Area (hectares) -> 11

Maximum Area Disturbed/Day (hectares) -> 3

Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Cutoff Wall DSM)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	5.0	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.50
Grading/Excavation	5.00	2.25
Drainage/Utilities/Sub-Grade	0.00	1.50
Paving	0.00	0.75
Totals	5.00	5.00

Hauling emission default values can be overridden in cells C45 through C46.

Notes: Project Start Year -> 2016

Project Length (months) -> 2

Total Project Area (hectares) -> 11

Maximum Area Disturbed/Day (hectares) -> 3

Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a
yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Cutoff Wall SCB)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	1.5	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.15
Grading/Excavation	1.50	0.68
Drainage/Utilities/Sub-Grade	0.00	0.45
Paving	0.00	0.23
Totals	1.50	1.50

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip		30	
Round trips/day		0	
Vehicle miles traveled/day (calculated)			0

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Fill from Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	4.5	24.0	56.3	69.4	2.4	67.0	16.1	2.2	13.9	6,281.3
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	4.5	24.0	56.3	69.4	2.4	67.0	16.1	2.2	13.9	6,281.3
Total (tons/construction project)	0.1	0.4	0.9	0.5	0.0	0.5	0.1	0.0	0.1	96.7

Notes: Project Start Year -> 2016

Project Length (months) -> 1

Total Project Area (acres) -> 28

Maximum Area Disturbed/Day (acres) -> 7

Total Soil Imported/Exported (yd^3/day)-> 3030

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Fill from Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	2.0	10.9	25.6	31.6	1.1	30.5	7.3	1.0	6.3	2,855.1
Total (megagrams/construction project)	0.1	0.3	0.8	0.5	0.0	0.4	0.1	0.0	0.1	87.7

Notes: Project Start Year -> 2016

Project Length (months) -> 1

Total Project Area (hectares) -> 11

Maximum Area Disturbed/Day (hectares) -> 3

Total Soil Imported/Exported ($meters^3$/day)-> 2317

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Fill from Stockpile)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	1.4	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	3030.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.14
Grading/Excavation	1.40	0.63
Drainage/Utilities/Sub-Grade	0.00	0.42
Paving	0.00	0.21
Totals	1.40	1.40

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	2.00	30	
Round trips/day		152	
Vehicle miles traveled/day (calculated)			303

Maximum (pounds/day)	8.5	41.5	196.0	72.8	5.8	67.0	18.4	4.5	13.9	32,565.1
Total (tons/construction project)	0.0	0.1	0.5	0.1	0.0	0.1	0.0	0.0	0.0	89.6

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 2810

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Cohesive Fill)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 2148

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Cohesive Fill)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.3	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	2810.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.03
Grading/Excavation	0.25	0.11
Drainage/Utilities/Sub-Grade	0.00	0.08
Paving	0.00	0.04
Totals	0.25	0.25

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	50.00	30	
Round trips/day		141	
Vehicle miles traveled/day (calculated)			7025

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Random Fill)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	6.7	34.2	176.2	71.8	4.8	67.0	17.5	3.6	13.9	30,691.0
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	6.7	34.2	176.2	71.8	4.8	67.0	17.5	3.6	13.9	30,691.0
Total (tons/construction project)	0.0	0.1	0.6	0.1	0.0	0.1	0.0	0.0	0.0	101.3

Notes: Project Start Year ->	2016
Project Length (months) ->	0
Total Project Area (acres) ->	28
Maximum Area Disturbed/Day (acres) ->	7
Total Soil Imported/Exported (yd^3/day)->	2760

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Random Fill)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	3.1	15.5	80.1	32.7	2.2	30.5	8.0	1.6	6.3	13,950.4
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	3.1	15.5	80.1	32.7	2.2	30.5	8.0	1.6	6.3	13,950.4
Total (megagrams/construction project)	0.0	0.1	0.5	0.1	0.0	0.1	0.0	0.0	0.0	91.9

Notes: Project Start Year ->	2016
Project Length (months) ->	0
Total Project Area (hectares) ->	11
Maximum Area Disturbed/Day (hectares) ->	3
Total Soil Imported/Exported ($meters^3$/day)->	2110

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Random Fill)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.3	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	2760.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.03
Grading/Excavation	0.30	0.11
Drainage/Utilities/Sub-Grade	0.00	0.08
Paving	0.00	0.04
Totals	0.30	0.25

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of Soil Hauling Defaults	Default Values				
User Input						
Miles/round trip	50.00	30				
Round trips/day		138				
Vehicle miles traveled/day (calculated)			6900			
Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	1.2	9.3	17.5	67.6	0.6	67.0	14.5	0.5	13.9	2,377.0
Total (tons/construction project)	0.0	0.4	0.7	1.2	0.0	1.2	0.3	0.0	0.2	94.1

Notes: Project Start Year -> 2016
Project Length (months) -> 4
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Rip Rap - Barge+)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Notes: Project Start Year -> 2016
Project Length (months) -> 4
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported (meters^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Rip Rap - Barge+)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	3.6	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	0.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.36
Grading/Excavation	3.60	1.62
Drainage/Utilities/Sub-Grade	0.00	1.08
Paving	0.00	0.54
Totals	3.60	3.60

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip		30	
Round trips/day		0	
Vehicle miles traveled/day (calculated)			0

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Rip Rap - Truck) Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	Total PM10 (lbs/day)	Exhaust PM10 (lbs/day)	Fugitive Dust PM10 (lbs/day)	Total PM2.5 (lbs/day)	Exhaust PM2.5 (lbs/day)	Fugitive Dust PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	4.9	25.9	160.9	71.0	4.0	67.0	16.8	2.8	13.9	30,116.1
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	4.9	25.9	160.9	71.0	4.0	67.0	16.8	2.8	13.9	30,116.1
Total (tons/construction project)	0.2	1.0	6.4	1.4	0.2	1.2	0.4	0.1	0.2	1,192.6

Notes: Project Start Year -> 2016
Project Length (months) -> 4
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 3200

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Rip Rap - Truck) Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	2.2	11.8	73.1	32.3	1.8	30.5	7.6	1.3	6.3	13,689.1
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	2.2	11.8	73.1	32.3	1.8	30.5	7.6	1.3	6.3	13,689.1
Total (megagrams/construction project)	0.2	0.9	5.8	1.2	0.1	1.1	0.3	0.1	0.2	1,081.7

Notes: Project Start Year -> 2016
Project Length (months) -> 4
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 2446

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Rip Rap - Truck)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	3.6	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	3200.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	40.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.36
Grading/Excavation	3.60	1.62
Drainage/Utilities/Sub-Grade	0.00	1.08
Paving	0.00	0.54
Totals	3.60	3.60

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of						
User Input	Soil Hauling Defaults	Default Values					
Miles/round trip	90.00	30					
Round trips/day		80

Maximum (pounds/day)	6.2	27.7	167.0	71.7	4.7	67.0	17.4	3.5	13.9	29,263.7
Total (tons/construction project)	0.0	0.1	0.7	0.1	0.0	0.1	0.0	0.0	0.0	128.8

Notes:	Project Start Year ->	2016
	Project Length (months) ->	0
	Total Project Area (acres) ->	28
	Maximum Area Disturbed/Day (acres) ->	7
	Total Soil Imported/Exported (yd^3/day)->	2755

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Sand)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust

Notes:	Project Start Year ->	2016
	Project Length (months) ->	0
	Total Project Area (hectares) ->	11
	Maximum Area Disturbed/Day (hectares) ->	3
	Total Soil Imported/Exported ($meters^3$/day)->	2106

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Sand)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.4	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	2755.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.04
Grading/Excavation	0.40	0.16
Drainage/Utilities/Sub-Grade	0.00	0.11
Paving	0.00	0.05
Totals	0.40	0.36

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	50.00	30	
Round trips/day		138	
Vehicle miles traveled/day (calculated)			6887.5

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Topsoil Fill)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	5.9	29.9	148.9	71.2	4.2	67.0	17.1	3.1	13.9	25,646.0
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	5.9	29.9	148.9	71.2	4.2	67.0	17.1	3.1	13.9	25,646.0
Total (tons/construction project)	0.0	0.1	0.5	0.1	0.0	0.1	0.0	0.0	0.0	84.6

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 2830

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Import Topsoil Fill)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Import Topsoil Fill)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.3	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	2830.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.03
Grading/Excavation	0.30	0.11
Drainage/Utilities/Sub-Grade	0.00	0.08
Paving	0.00	0.04
Totals	0.30	0.25

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of					
User Input	Soil Hauling Defaults	Default Values				
Miles/round trip	40.00	30				
Round trips/day		142				
Vehicle miles traveled/day (calculated)			5660			
Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86
Emission rate (grams/trip)	0.00	0.00	0.00	0.00	0.00	0.00
Pounds per day	2.0	102.9	8.7	2.1	1.2	20942.7
Tons per contruction period	0.01	0.34	0.03	0.01	0.00	69.11

Worker commute default values can be overridden in cells C60 through C65.

	User Override of Worker					
Worker Commute Emissions	Commute Default Values	Default Values				
Miles/ one-way trip		20				
One-way trips/day		2				
No. of employees: Grubbing/Land Clearing	0.00	10				
No. of employees: Grading/Excavation		15				
No. of employees: Drainage/Utilities/Sub-Grade	0.00	11				
No. of employees: Paving	0.00	13

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (Retaining Wall - Concrete)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	4.0	19.6	146.3	70.6	3.6	67.0	16.3	2.4	13.9	28,259.0
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	4.0	19.6	146.3	70.6	3.6	67.0	16.3	2.4	13.9	28,259.0
Total (tons/construction project)	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.0	0.0	31.1

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 1580

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (Retaining Wall - Concrete)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	1.8	8.9	66.5	32.1	1.6	30.5	7.4	1.1	6.3	12,845.0
Total (megagrams/construction project)	0.0	0.0	0.1	0.0	0.0	0.0	0.0	0.0	0.0	28.2

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 1208

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type

Project Name	ARCF ARS Reach F-Year 2 (Retaining Wall - Concrete)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.1	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	1580.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	9.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.01
Grading/Excavation	0.10	0.05
Drainage/Utilities/Sub-Grade	0.00	0.03
Paving	0.00	0.02
Totals	0.10	0.10

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	40.00	30	
Round trips/day		176	
Vehicle miles traveled/day (calculated)			7022.222222

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2

Maximum (pounds/day)	1.1	5.2	13.1	67.7	0.7	67.0	14.6	0.6	13.9	1,559.8
Total (tons/construction project)	0.0	0.1	0.2	0.5	0.0	0.5	0.1	0.0	0.1	25.7

Notes: Project Start Year -> 2016
Project Length (months) -> 2
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Retaining Wall - Form & S Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)

Maximum (kilograms/day)	0.5	2.4	6.0	30.8	0.3	30.5	6.6	0.3	6.3	709.0
Total (megagrams/construction project)	0.0	0.1	0.2	0.5	0.0	0.5	0.1	0.0	0.1	23.3

Notes: Project Start Year -> 2016
Project Length (months) -> 2
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Input Type

Project Name	ARCF ARS Reach F-Year 2 (G&E Retaining Wall - Form & Steel)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	1.5	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.15
Grading/Excavation	1.50	0.68
Drainage/Utilities/Sub-Grade	0.00	0.45
Paving	0.00	0.23
Totals	1.50	1.50

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of Soil Hauling Defaults	Default Values				
User Input						
Miles/round trip	40.00	30

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E to Spoils) Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	Total PM10 (lbs/day)	Exhaust PM10 (lbs/day)	Fugitive Dust PM10 (lbs/day)	Total PM2.5 (lbs/day)	Exhaust PM2.5 (lbs/day)	Fugitive Dust PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	18.3	89.6	335.9	77.8	10.8	67.0	22.9	9.0	13.9	47,017.6
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	18.3	89.6	335.9	77.8	10.8	67.0	22.9	9.0	13.9	47,017.6
Total (tons/construction project)	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.0	0.0	25.9

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 4090

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E to Spoils) Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	8.3	40.7	152.7	35.4	4.9	30.5	10.4	4.1	6.3	21,371.7
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	8.3	40.7	152.7	35.4	4.9	30.5	10.4	4.1	6.3	21,371.7
Total (megagrams/construction project)	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.0	0.0	23.5

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported (meters^3/day)-> 3127

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E to Spoils)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.1	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	4090.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.01
Grading/Excavation	0.05	0.02
Drainage/Utilities/Sub-Grade	0.00	0.02
Paving	0.00	0.01
Totals	0.05	0.05

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip	40.00	30	
Round trips/day	205.00	205	
Vehicle miles traveled/day (calculated)			8200

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

END OF DATA ENTRY SHEET

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E to Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	11.2	55.5	139.6	72.7	5.7	67.0	19.1	5.2	13.9	13,161.5
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	11.2	55.5	139.6	72.7	5.7	67.0	19.1	5.2	13.9	13,161.5
Total (tons/construction project)	0.2	0.9	2.1	0.6	0.1	0.5	0.2	0.1	0.1	202.7

Notes: Project Start Year -> 2016

Project Length (months) -> 1

Total Project Area (acres) -> 28

Maximum Area Disturbed/Day (acres) -> 7

Total Soil Imported/Exported (yd^3/day)-> 2920

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E to Stockpile)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	5.1	25.2	63.4	33.0	2.6	30.5	8.7	2.4	6.3	5,982.5
Total (megagrams/construction project)	0.2	0.8	1.9	0.5	0.1	0.4	0.2	0.1	0.1	183.8

Notes: Project Start Year -> 2016

Project Length (months) -> 1

Total Project Area (hectares) -> 11

Maximum Area Disturbed/Day (hectares) -> 3

Total Soil Imported/Exported ($meters^3$/day)-> 2232

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E to Stockpile)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	1.4	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported	2920.0	yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.14
Grading/Excavation	1.40	0.63
Drainage/Utilities/Sub-Grade	0.00	0.42
Paving	0.00	0.21
Totals	1.40	1.40

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of					
User Input	Soil Hauling Defaults	Default Values				
Miles/round trip	2.00	30				
Round trips/day	146.00	146				
Vehicle miles traveled/day (calculated)			292			
Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Surfacing) Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	Total PM10 (lbs/day)	Exhaust PM10 (lbs/day)	Fugitive Dust PM10 (lbs/day)	Total PM2.5 (lbs/day)	Exhaust PM2.5 (lbs/day)	Fugitive Dust PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	14.5	64.3	331.0	77.5	10.5	67.0	22.1	8.2	13.9	55,317.2
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	14.5	64.3	331.0	77.5	10.5	67.0	22.1	8.2	13.9	55,317.2
Total (tons/construction project)	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.0	0.0	30.4

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 8228

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (G&E Surfacing) Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	6.6	29.2	150.4	35.2	4.8	30.5	10.1	3.7	6.3	25,144.2
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	6.6	29.2	150.4	35.2	4.8	30.5	10.1	3.7	6.3	25,144.2
Total (megagrams/construction project)	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.0	0.0	27.6

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 6291

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (G&E Surfacing)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.1	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	8228.0	yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.01
Grading/Excavation	0.05	0.05
Drainage/Utilities/Sub-Grade	0.00	0.03
Paving	0.00	0.02
Totals	0.05	0.10

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values	
Miles/round trip		30	
Round trips/day		411	
Vehicle miles traveled/day (calculated)			12342

Hauling Emissions	ROG	NOx	CO	PM10	PM2.5	CO2
Emission rate (grams/mile)	0.16	8.25	0.70	0.17	0.10	1679.86

Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	2.1	11.3	24.7	101.7	1.2	100.5	22.0	1.1	20.9	2,399.7
Total (tons/construction project)	0.0	0.0	0.0	0.1	0.0	0.1	0.0	0.0	0.0	4.0

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (Utilities #1) Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-

Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (kilograms/day)	1.0	5.1	11.2	46.2	0.6	45.7	10.0	0.5	9.5	1,090.8
Total (megagrams/construction project)	0.0	0.0	0.0	0.1	0.0	0.1	0.0	0.0	0.0	3.6

Notes: Project Start Year -> 2016
Project Length (months) -> 0
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model — Version 7.1.2

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (Utilities #1)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	0.2	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.02
Grading/Excavation	0.15	0.09
Drainage/Utilities/Sub-Grade	0.00	0.06
Paving	0.00	0.03
Totals	0.15	0.20

Please note: You have entered a different number of months than the project length shown in cell C13.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions	User Override of					
User Input	Soil Hauling Defaults	Default Values				
Miles/round trip		30				
Round trips/day		0				
Vehicle miles traveled/day (calculated)			0			
Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

Road Construction Emissions Model, Version 7.1.2

Emission Estimates for -> ARCF ARS Reach F-Year 2 (Utilities #2)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	-	-	-	-	-	-	-	-	-	-
Grading/Excavation	1.1	5.1	11.7	101.2	0.7	100.5	21.5	0.6	20.9	1,263.8
Drainage/Utilities/Sub-Grade	-	-	-	-	-	-	-	-	-	-
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	1.1	5.1	11.7	101.2	0.7	100.5	21.5	0.6	20.9	1,263.8
Total (tons/construction project)	0.0	0.1	0.3	1.2	0.0	1.2	0.3	0.0	0.2	33.4

Notes: Project Start Year -> 2016
Project Length (months) -> 2
Total Project Area (acres) -> 28
Maximum Area Disturbed/Day (acres) -> 7
Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> ARCF ARS Reach F-Year 2 (Utilities #2)				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Notes: Project Start Year -> 2016
Project Length (months) -> 2
Total Project Area (hectares) -> 11
Maximum Area Disturbed/Day (hectares) -> 3
Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.2

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	ARCF ARS Reach F-Year 2 (Utilities #2)	
Construction Start Year	2016	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	2.4	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	1.5	miles
Total Project Area	28.0	acres
Maximum Area Disturbed/Day	6.7	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported		yd^3/day
Soil Exported		yd^3/day
Average Truck Capacity	20.0	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months
Grubbing/Land Clearing	0.00	0.24
Grading/Excavation	2.40	1.08
Drainage/Utilities/Sub-Grade	0.00	0.72
Paving	0.00	0.36
Totals	2.40	2.40

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values				
Miles/round trip		30				
Round trips/day		0				
Vehicle miles traveled/day (calculated)			0			

Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

END OF DATA ENTRY SHEET

Additional air quality analysis for the proposed Sacramento Weir and Bypass Widening is performed separately due to the spatial separation between the Sacramento Weir and the additional portion of the project in Alternatives 1 and 2. It should be noted that the Sacramento Weir and Bypass Widening portion of the project is only proposed under Alternative 2.

The air quality emissions analysis for the Sacramento Weir and Bypass Widening was developed based on the following assumptions:

- The Sacramento Weir and Bypass Widening would be constructed as three phases over three years: the Weir, the new levee, and the deconstruction of the old levee;
- The Sacramento Weir would be constructed on dry land on the portion of land between the railroad property and the Old River Road;
- The Old River Road and the railroad would be realigned onto the new weir crown under a separate construction agreement;
- The existing weir would remain in place, and a small transitional island would remain between the new weir and the existing weir;
- The new levee would be constructed using soil existing in the Sacramento Bypass, and no new soil would be imported from other borrow sites.

Sacramento Weir Widening

The construction and design for the proposed widening of the Sacramento Weir has not yet been determined. For the purpose of air quality analysis, it is assumed that the new portion of the weir would be constructed with cement formed on site, requiring haul trucks of both cement and treated wood for the forms. At the peak of construction, as many as 20 trucks could deliver cement or other materials in a day; however, for the purposes of air quality analysis it is anticipated that an average of 5 haul trucks per day would deliver materials to the site over a six month period. Waste materials would be exported on as as-needed basis. The construction of the weir would also include a new section of railroad tracks and a new segment of road in order to connect the existing Yolo Shortline Railroad and the existing Old River Road across the weir. It is currently assumed that the Yolo Shortline Railroad and the Old River Road would remain active during construction, and the only closures and detours would occur when the old section is connected with the new; however, it is possible that the Yolo Shortline Railroad would be closed during construction due to the proximity of the railroad to the footprint of the new weir section. If the railroad requires closure during construction, the goods normally transported by rail could be rerouted onto large cargo trucks; however, the potential emissions from rerouting rail goods onto trucks are outside the scope of this analysis. Construction design, additional traffic analysis, and additional air quality analysis would be conducted during the PED phase.

Construction of the Sacramento Weir and Bypass portion of Alternative 2 is assumed to take place over three years in three different phases: construction of the new levee, construction of the new weir, and demolition of the old levee. For the purposes of air quality analysis, several assumptions associated with each of these phases have been made.

It is assumed that the construction of the new levee segment would utilize soil available either from the existing bypass area or from the area that will be integrated into the new, larger bypass. This nearby borrow source would eliminate the use of haul trucks; therefore, the model analysis included in Appendix D reflects no haul trucks for this portion of construction. Large construction equipment such as scrapers would be needed in order to take the soil from the source to the site of the new levee. Upon completion of the new levee, a new road to take the place of County Road 126 would be constructed on the levee crown. Although construction is assumed to take place over a single construction season (approximately 6 months), the complete design may determine that additional time is needed to construct this portion of the project. Additional analysis may be needed at that time.

It is assumed that the construction of the new portion of the weir would be of similar design and materials of the existing weir and would therefore consist mostly of concrete formed on site. It is currently unknown how many cement trucks would be needed for the actual construction of the weir; however, for the purposes of air quality analysis it is assumed that approximately five loads of cement would be delivered to the site daily for the duration of the six month construction project. Additional analysis would be performed once the design of the new weir is completed. Upon completion of the new weir, a new segment of road and railroad would be constructed on the top of the weir and connected to the existing Old River Road and Yolo Shortline Railroad.

Upon completion of the new levee and the new weir, the existing levee would be deconstructed and the soil from the degraded levee would be redistributed across the entire bypass area in order to encourage positive drainage toward the Yolo Bypass. Additionally, the segment of land that is currently between the existing Yolo Shortline Railroad and the Sacramento River would be lowered in order to connect the new section of the widened Sacramento Bypass to the Sacramento River. Soil removed from this segment of land would also be redistributed across the entire bypass area in order to meet elevation requirements as determined by future design. It is assumed that the majority of the existing river bank would remain in place; however, some vegetation and large trees could be removed. Full analysis of these potential impacts would be performed once the design is completed. Due to the large amount of soil that would be displaced and redistributed in this phase of work, as many as 20 scrapers could be in use at one time during the peak of construction; however, it is not anticipated that any soil would be brought in or removed from the site using haul trucks. The model analysis included in Appendix D reflects no haul trucks for this portion of construction.

Table 5. Estimated Air Emissions for the Sacramento Bypass Existing Levee Removal and Soil Redistribution.

Construction Year	Annual Emissions in Tons					Maximum Daily Emissions in Pounds

General Conformity *de Minimis* Threshold	25	25	100	100	100					
Exceed Threshold?	No	No	No	No	No					

Maximum daily emissions are estimated for ROG, NO_X, PM_{10}, and $PM_{2.5}$ to evaluate emissions against YSAQMD thresholds. Those results are shown in Table 6. Construction-related emissions from the Sacramento Weir and Bypass Widening portion of the project would exceed the YSAQMD's emission threshold for NO_X. The actual emissions may be reduced by reducing the number and type of large construction vehicles utilized on site at one time and by following the mitigation measures as recommended by SMAQMD; however, the overall construction emissions under the alternative would likely exceed the thresholds and would therefore result in a significant effect. The Corps would be required to pay an off-site mitigation fee for NO_X emissions in the SVAB in order to reduce the effect to a less-than-significant level.

Exceed Threshold?	No	No	No	No	No					

Although Alternative 2 would reduce the number of levee raises along the Sacramento River compared to Alternative 1, for the purposes of air quality analysis the emissions estimates are assumed to be the same as Alternative 1. Alternative 1 summarizes the maximum daily emissions estimated for ROG, NO_X, PM_{10}, and $PM_{2.5}$ under the construction emissions that would result in the most combined air emission. As shown in Table 6, the greatest potential emissions impacts would occur during the demolition of the old levee due to the large number of scrapers and other large construction equipment to displace and redistribute soil. These emissions are combined with the previously analyzed emissions from Alternative 1 in Tables 7 and 8, below.

General Conformity *de Minimis* Threshold	25	25	100	100	100					
Exceed Threshold?	No	No	No	No	No					

Maximum daily emissions are estimated for ROG, NO_X, PM_{10}, and $PM_{2.5}$ to evaluate emissions against SMAQMD, YSAQMD, and BAAQMD thresholds under the barge delivery scenario. Those results are shown in Table 8. Construction-related emissions under Alternative 1 would exceed the SMAQMD's and BAAQMD's emission thresholds for NO_X. Therefore, construction of the alternative with barge delivery would result in a significant effect and the Corps would be required to pay an off-site mitigation fee for NO_X emissions in the SVAB. Payment of these mitigation fees would reduce the impacts to a less-than-significant level. Borrow activities and barge delivery emissions would not exceed YSAQMD thresholds; however, the addition of the Sacramento Weir and Bypass Widening portion of Alternative 2 would exceed the YSAQMD's emission threshold for NO_X. The actual emissions may be reduced by reducing the number and type of large construction vehicles utilized on site at one time and by following the mitigation measures as recommended by SMAQMD; however, the overall construction emissions under the alternative would likely exceed the thresholds and would therefore result in a significant effect. The Corps would be required to pay an off-site mitigation fee for NO_X emissions in the SVAB in order to reduce the effect to a less-than-significant level. Since less than 50 percent of borrow activities emissions could occur in FRAQMD, it was assumed FRAQMD thresholds would not be exceeded. Borrow activities emissions associated with potential borrow site located north of the project site were captured in the SMAQMD off-site soil estimations.

Table 8. Estimated Air Emissions for the Barge Delivery Scenario With Bypass Widening.

Maximum Area Disturbed/Day (hectares) ->	2
Total Soil Imported/Exported (meters ^{3}/day)->	0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model

Version 7.1.5.1

Data Entry Worksheet

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Input Type		
Project Name	Sac Bypass Widening: NEW LEVEE	
Construction Start Year	2021	Enter a Year between 2009 and 2025 (inclusive)
Project Type	1	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	6.00	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	2.00	miles
Total Project Area	20.00	acres
Maximum Area Disturbed/Day	4.00	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	0.00	yd^3/day
Soil Exported	0.00	yd^3/day
Average Truck Capacity	20	yd^3 (assume 20 if unknown)

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months	2005	%	2006	%	2007	%
Grubbing/Land Clearing	0.50	0.60	0.00	0.00	0.00	0.00	0.00	0.00
Grading/Excavation	3.00	2.70	0.00	0.00	0.00	0.00	0.00	0.00
Drainage/Utilities/Sub-Grade	1.00	1.80	0.00	0.00	0.00	0.00	0.00	0.00
Paving	1.50	0.90	0.00	0.00	0.00	0.00	0.00	0.00
Totals	6.00	6.00						

NOTE: soil hauling emissions are included in the Grading/Excavation Construction Period Phase, therefore the Construction Period for Grading/Excavation cannot be zero if hauling is part of the project.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions **User Input**	User Override of Soil Hauling Defaults	Default Values
Miles/round trip		30
Round trips/day		0
Vehicle miles traveled/day (calculated)	0	

Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

Paving	3.9	39.7	34.1	1.7	1.7	-	1.6	1.6	-	7,332.4
Maximum (pounds/day)	13.8	114.4	129.7	46.1	6.1	40.0	13.8	5.5	8.3	23,724.5
Total (tons/construction project)	0.7	5.9	6.6	2.5	0.3	2.2	0.7	0.3	0.5	1,214.9

Notes: Project Start Year ->	2022
Project Length (months) ->	6
Total Project Area (acres) ->	10
Maximum Area Disturbed/Day (acres) ->	4
Total Soil Imported/Exported (yd^3/day)->	120

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> Sac Bypass Widening: WEIR ONLY Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	Total PM10 (kgs/day)	Exhaust PM10 (kgs/day)	Fugitive Dust PM10 (kgs/day)	Total PM2.5 (kgs/day)	Exhaust PM2.5 (kgs/day)	Fugitive Dust PM2.5 (kgs/day)	CO2 (kgs/day)

Notes: Project Start Year ->	2022
Project Length (months) ->	6
Total Project Area (hectares) ->	4
Maximum Area Disturbed/Day (hectares) ->	2
Total Soil Imported/Exported (meters ^{3}/day)->	92

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model Version 7.1.5.1

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Input Type		
Project Name	Sac Bypass Widening: WEIR ONLY	
Construction Start Year	2022	Enter a Year between 2009 and 2025 (inclusive)
Project Type	3	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	6.00	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	0.30	miles
Total Project Area	10.00	acres
Maximum Area Disturbed/Day	4.00	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	100.00	yd^3/day
Soil Exported	20.00	yd^3/day
Average Truck Capacity	20	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months	2005	%		2006	%	2007	%
Grubbing/Land Clearing	0.50	0.60	0.00		0.00	0.00	0.00	0.00	0.00
Grading/Excavation	4.00	2.70	0.00		0.00	0.00	0.00	0.00	0.00
Drainage/Utilities/Sub-Grade	0.50	1.80	0.00		0.00	0.00	0.00	0.00	0.00
Paving	1.00	0.90	0.00		0.00	0.00	0.00	0.00	0.00
Totals	6.00	6.00							

NOTE: soil hauling emissions are included in the Grading/Excavation Construction Period Phase, therefore the Construction Period for Grading/Excavation cannot be zero if hauling is part of the project.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values
Miles/round trip	30.00	30
Round trips/day		6
Vehicle miles traveled/day (calculated)		180

Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

Road Construction Emissions Model, Version 7.1.5.1

Emission Estimates for -> Sac Bypass Widening: BYPASS				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (English Units)	ROG (lbs/day)	CO (lbs/day)	NOx (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	PM2.5 (lbs/day)	CO2 (lbs/day)
Grubbing/Land Clearing	6.1	60.4	56.6	42.7	2.7	40.0	10.7	2.4	8.3	12,519.5
Grading/Excavation	30.3	271.8	297.2	52.4	12.4	40.0	19.7	11.3	8.3	58,683.4
Drainage/Utilities/Sub-Grade	5.0	44.7	43.3	42.2	2.2	40.0	10.3	2.0	8.3	9,199.0
Paving	-	-	-	-	-	-	-	-	-	-
Maximum (pounds/day)	30.3	271.8	297.2	52.4	12.4	40.0	19.7	11.3	8.3	58,683.4
Total (tons/construction project)	1.5	13.1	14.2	3.0	0.6	2.4	1.1	0.5	0.5	2,821.0

Notes: Project Start Year -> 2023
Project Length (months) -> 6
Total Project Area (acres) -> 320
Maximum Area Disturbed/Day (acres) -> 4
Total Soil Imported/Exported (yd^3/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sum of exhaust and fugitive dust emissions shown in columns K and L.

Emission Estimates for -> Sac Bypass Widening: BYPASS				Total	Exhaust	Fugitive Dust	Total	Exhaust	Fugitive Dust	
Project Phases (Metric Units)	ROG (kgs/day)	CO (kgs/day)	NOx (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM10 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	PM2.5 (kgs/day)	CO2 (kgs/day)

Notes: Project Start Year -> 2023
Project Length (months) -> 6
Total Project Area (hectares) -> 130
Maximum Area Disturbed/Day (hectares) -> 2
Total Soil Imported/Exported ($meters^3$/day)-> 0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns H and I. Total PM2.5 emissions shown in Column J are the sume of exhaust and fugitive dust emissions shown in columns K and L.

Road Construction Emissions Model **Version 7.1.5.1**

Data Entry Worksheet

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells C10 through C25.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Input Type		
Project Name	Sac Bypass Widening: BYPASS	
Construction Start Year	2023	Enter a Year between 2009 and 2025 (inclusive)
Project Type	2	1 New Road Construction 2 Road Widening 3 Bridge/Overpass Construction
Project Construction Time	6.00	months
Predominant Soil/Site Type: Enter 1, 2, or 3	2	1. Sand Gravel 2. Weathered Rock-Earth 3. Blasted Rock
Project Length	4.00	miles
Total Project Area	320.00	acres
Maximum Area Disturbed/Day	4.00	acres
Water Trucks Used?	1	1. Yes 2. No
Soil Imported	0.00	yd^3/day
Soil Exported	0.00	yd^3/day
Average Truck Capacity	20	yd^3 (assume 20 if unknown)

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells C34 through C37.

Construction Periods	User Override of Construction Months	Program Calculated Months	2005	%	2006	%	2007	%
Grubbing/Land Clearing	1.00	0.60	0.00	0.00	0.00	0.00	0.00	0.00
Grading/Excavation	4.00	2.70	0.00	0.00	0.00	0.00	0.00	0.00
Drainage/Utilities/Sub-Grade	1.00	1.80	0.00	0.00	0.00	0.00	0.00	0.00
Paving	0.00	0.90	0.00	0.00	0.00	0.00	0.00	0.00
Totals	6.00	6.00						

NOTE: soil hauling emissions are included in the Grading/Excavation Construction Period Phase, therefore the Construction Period for Grading/Excavation cannot be zero if hauling is part of the project.

Hauling emission default values can be overridden in cells C45 through C46.

Soil Hauling Emissions

User Input	User Override of Soil Hauling Defaults	Default Values
Miles/round trip		30
Round trips/day		0
Vehicle miles traveled/day (calculated)		0

Hauling Emissions	**ROG**	**NOx**	**CO**	**PM10**	**PM2.5**	**CO2**

APPENDIX E
SECTION 404(b)(1) WATER QUALITY EVALUATION
AMERICAN RIVER COMMON FEATURES
GENERAL REEVALUATION REPORT
SACRAMENTO, CALIFORNIA

This document constitutes the Statement of Findings, and review and compliance determination according to the Section 404(b)(1) Guidelines for the proposed project described in the American River Common Features Environmental Impact Statement/Environmental Impact Report (EIS/EIR) issued by the Sacramento District. This analysis has been prepared in accordance with the Section 404(b)(1) Guidelines, 40 CFR Part 230 and the U.S. Army Corps of Engineers (Corps) Planning Guidance Notebook, Engineer Regulation (ER) 1105-2-100.

I. Project Description

a. Proposed Project

The American River Common Features General Reevaluation Report (ARCF GRR) is a cooperative effort by the Corps, the Central Valley Flood Protection Board, the non-federal sponsor, and the Sacramento Area Flood Control Agency, the local sponsor. The Corps completed the ARCF GRR final Environmental Impact Assessment/Environmental Impact Report (EIS/EIR) in September 2015. The final EIS/EIR will be referenced throughout the document to describe the existing conditions in the study area, as well as some potential impacts of the proposed project and the other alternatives.

The ARCF EIS/EIR identifies a number of problems associated with the flood risk management system protecting the city of Sacramento and surrounding areas. There is a high probability that flood flows in the American River and Sacramento River will stress the network of levees protecting Sacramento to the point that levees could fail. The consequences of such a levee failure would be catastrophic, since the area inundated by flood waters is highly urbanized and the flooding could be up to 20 feet deep.

No Action Alternative

The No Action Alternative, under NEPA, is the expected future without-project condition. Under CEQA, the No Action Alternative is the existing condition at the time the notice of preparation was published (February 28, 2008) as modified by what would reasonably be expected to occur in the foreseeable future if the project were not approved. The No Action Alternative assumes that no work would be completed by the Corps and the study area would continue to be at a very high risk of levee failure and subsequent flooding of the Sacramento Metropolitan area. This area includes the California State Capitol and many other State and Federal Agencies. For the purposes of this 404(b)(1) analysis, the No Action Alternative is also the no fill alternative. Under the no fill alternative, no measures would be proposed to place fill material in waters of the U.S. As a result, under the no fill alternative, the levee system's identified erosion problem would not be addressed, and the Sacramento area would remain at risk of a levee failure.

Alternative 1 – Improve Levees

Alternative 1 involves the construction of fix-in-place levee remediation measures to address seepage, slope stability, erosion, and overtopping concerns identified for the American River and Sacramento River, Natomas East Main Drainage Canal (NEMDC), Arcade Creek, and Magpie Creek levees. Table 1 summarizes the measures proposed under Alternative 1.

Table 1. Alternative 1 – Proposed Levee Improvement Measures by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench	---
Sacramento River	Cutoff Wall	Cutoff Wall, Geotextile, Slope Flattening	Bank Protection, Launchable Rock Trench	Levee Raise
NEMDC	Cutoff Wall	Cutoff Wall	---	Floodwall/Levee Raise
Arcade Creek	Cutoff Wall	Cutoff Wall, Geotextiles	---	Floodwall/Levee Raise
Dry/Robla Creeks	---	---	---	Floodwall
Magpie Creek[2]	---	---	---	Floodwall/New Levee/Detention Basin

Notes: [1]American River seepage, stability, and overtopping measures were addressed in the ARCF WRDA 1996 and 1999 construction projects. [2]In addition to the listed measures, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

Figure 1 shows the reaches where seepage, slope stability, erosion, and overtopping measures would be required.

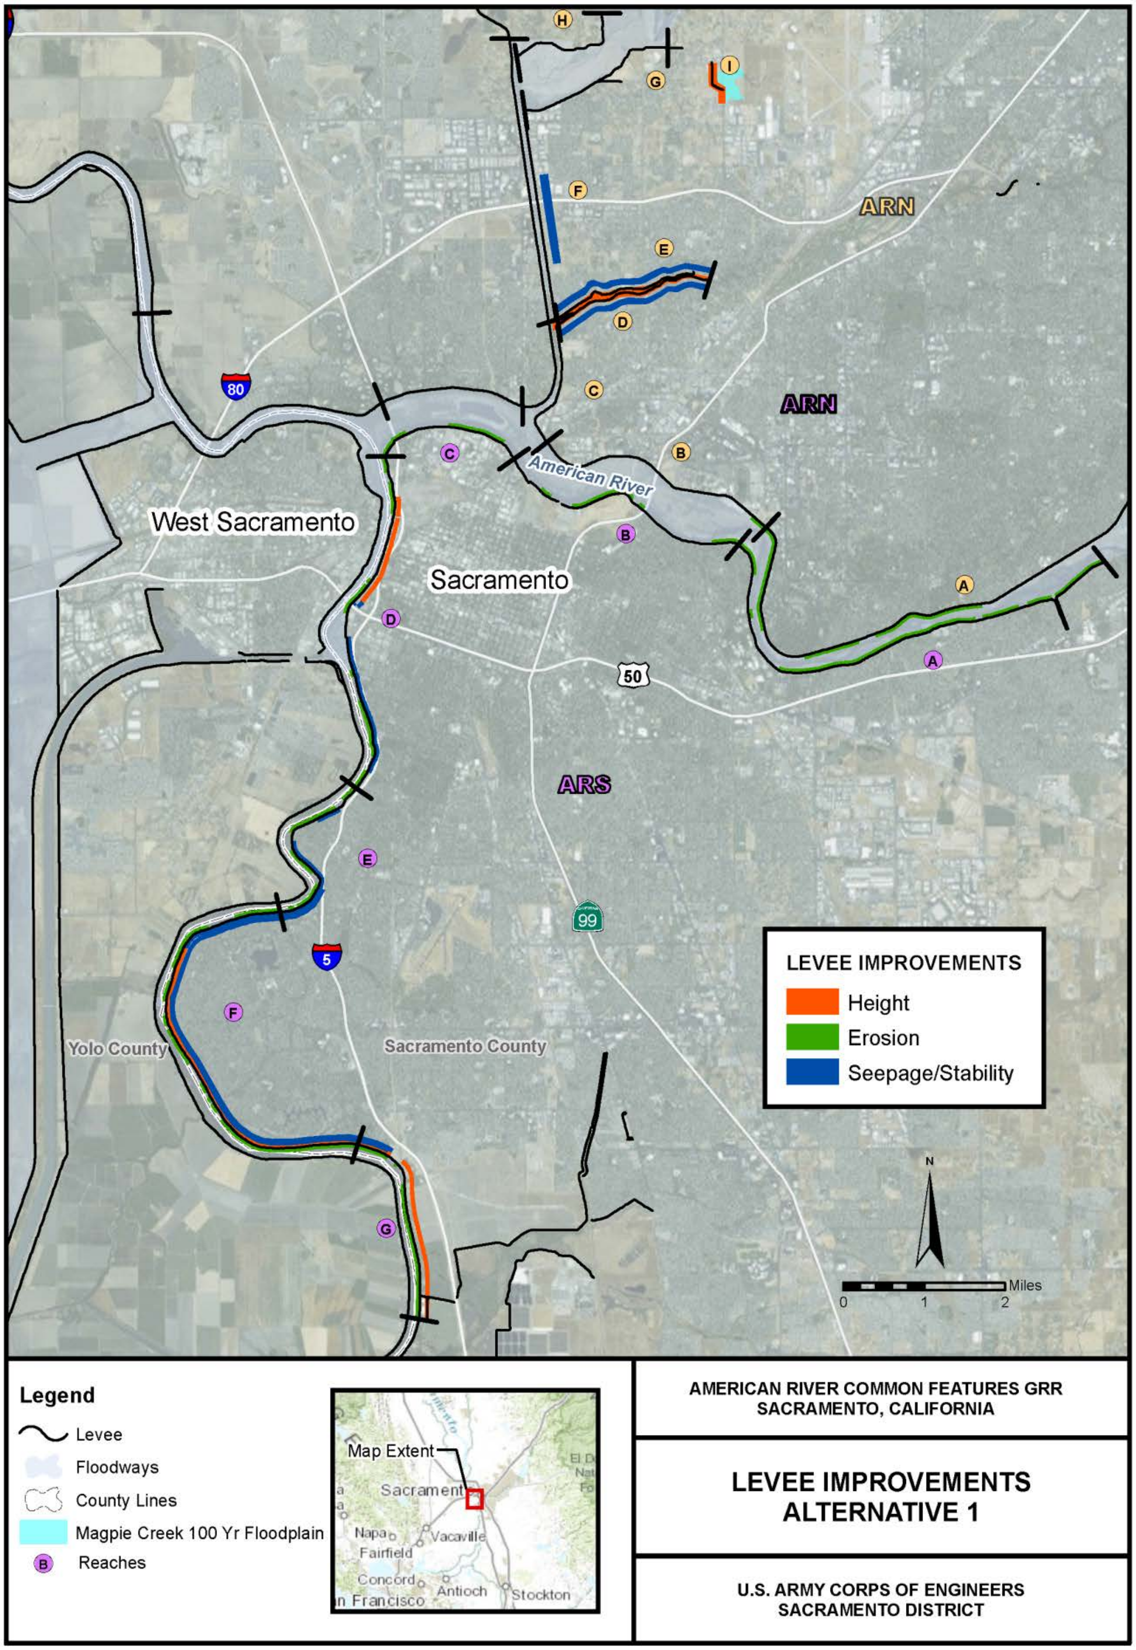

Figure 1. Alternative 1 Proposed Measures.

The proposed project would require discharge of fill material into waters of the U.S. The following subsections describe the measures proposed for Alternative 1 and identify any possible discharge of fill material associated with each measure.

Seepage and Slope Stability Measures

To address seepage concerns, a cutoff wall would be constructed through the levee crown. The cutoff wall would be installed by one of two methods: (1) conventional open trench cutoff walls, or (2) deep soil mixing (DSM) cutoff walls. The method of cutoff wall construction selected for each reach would depend on the depth of the cutoff wall needed to address the seepage. The open trench method can be used to install a cutoff wall to a depth of approximately 80 feet. For cutoff walls of greater depth, the DSM method would be utilized. Prior to construction of the cutoff wall, the construction site and any staging areas would be cleared, grubbed, and stripped. The levee crown would be degraded up to half the levee height to create a large enough working platform (approximately 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids.

This measure is proposed along the Sacramento River, the east bank of the NEMDC, and Arcade Creek. Because seepage and slope stability measures would be installed directly into the levee as a cutoff wall, no fill material would be placed into waters of the U.S. by implementing this measure.

Erosion Protection

Erosion protection along the American River and Sacramento River would be addressed via either the launchable rock trench method or by standard bank protection. There are no erosion protection measures proposed for the East Side Tributaries. The erosion protection measures would involve the placement of fill into waters of the U.S. Construction methods for the bank protection and launchable rock trench measures are described in Section h below.

Overtopping Measures

Levee raises are proposed for the Sacramento River and the East Side Tributaries to address the potential for floodwaters overtopping the levees. For the Sacramento River, Arcade Creek, and NEMDC, there would be no placement of fill into waters of the U.S., because levee raises would be conducted primarily on the crown and landside of the levees and would be designed to avoid placement of fill in the waterways. At Magpie Creek, there is the potential for approximately 0.25-acre of vernal pool habitat on the landside of the levee to be permanently impacted by construction of a levee raise. Construction methods for the levee raise are described in Section h below.

Alternative 2 – Improve Levees and Widen the Sacramento Weir and Bypass

Alternative 2 includes all of the measures proposed under Alternative 1, with the exception of the approximately 7 miles of levee raises on the Sacramento River. Instead, under Alternative 2, the Sacramento Weir and Bypass would be widened to lower the water surface elevations on the Sacramento River to a level that would only require approximately 1 mile of levee raises and would divert more flows into the Yolo Bypass. Table 2 shows the measures that would be implemented under Alternative 2. Figure 2 shows the project area and extent of proposed measures under Alternative 2.

Table 2. Alternative 2 - Proposed Levee Improvement Measures by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench	---
Sacramento River	Cutoff Wall	Cutoff Wall, Geotextile, and Slope Flattening	Bank Protection, Launchable Rock Trench	Sacramento Bypass and Weir Widening
NEMDC	Cutoff Wall	Cutoff Wall	---	Floodwall/Levee Raise
Arcade Creek	Cutoff Wall	Cutoff Wall, Geotextile	---	Floodwall/Levee Raise
Magpie Creek[2]	---	---	---	Floodwall/New Levee/Detention Basin

Note: [1] American River seepage, stability, and overtopping measures were addressed in the American River Common Features, WRDA 1996 and 1999 construction projects.
[2]In addition to the listed measures, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

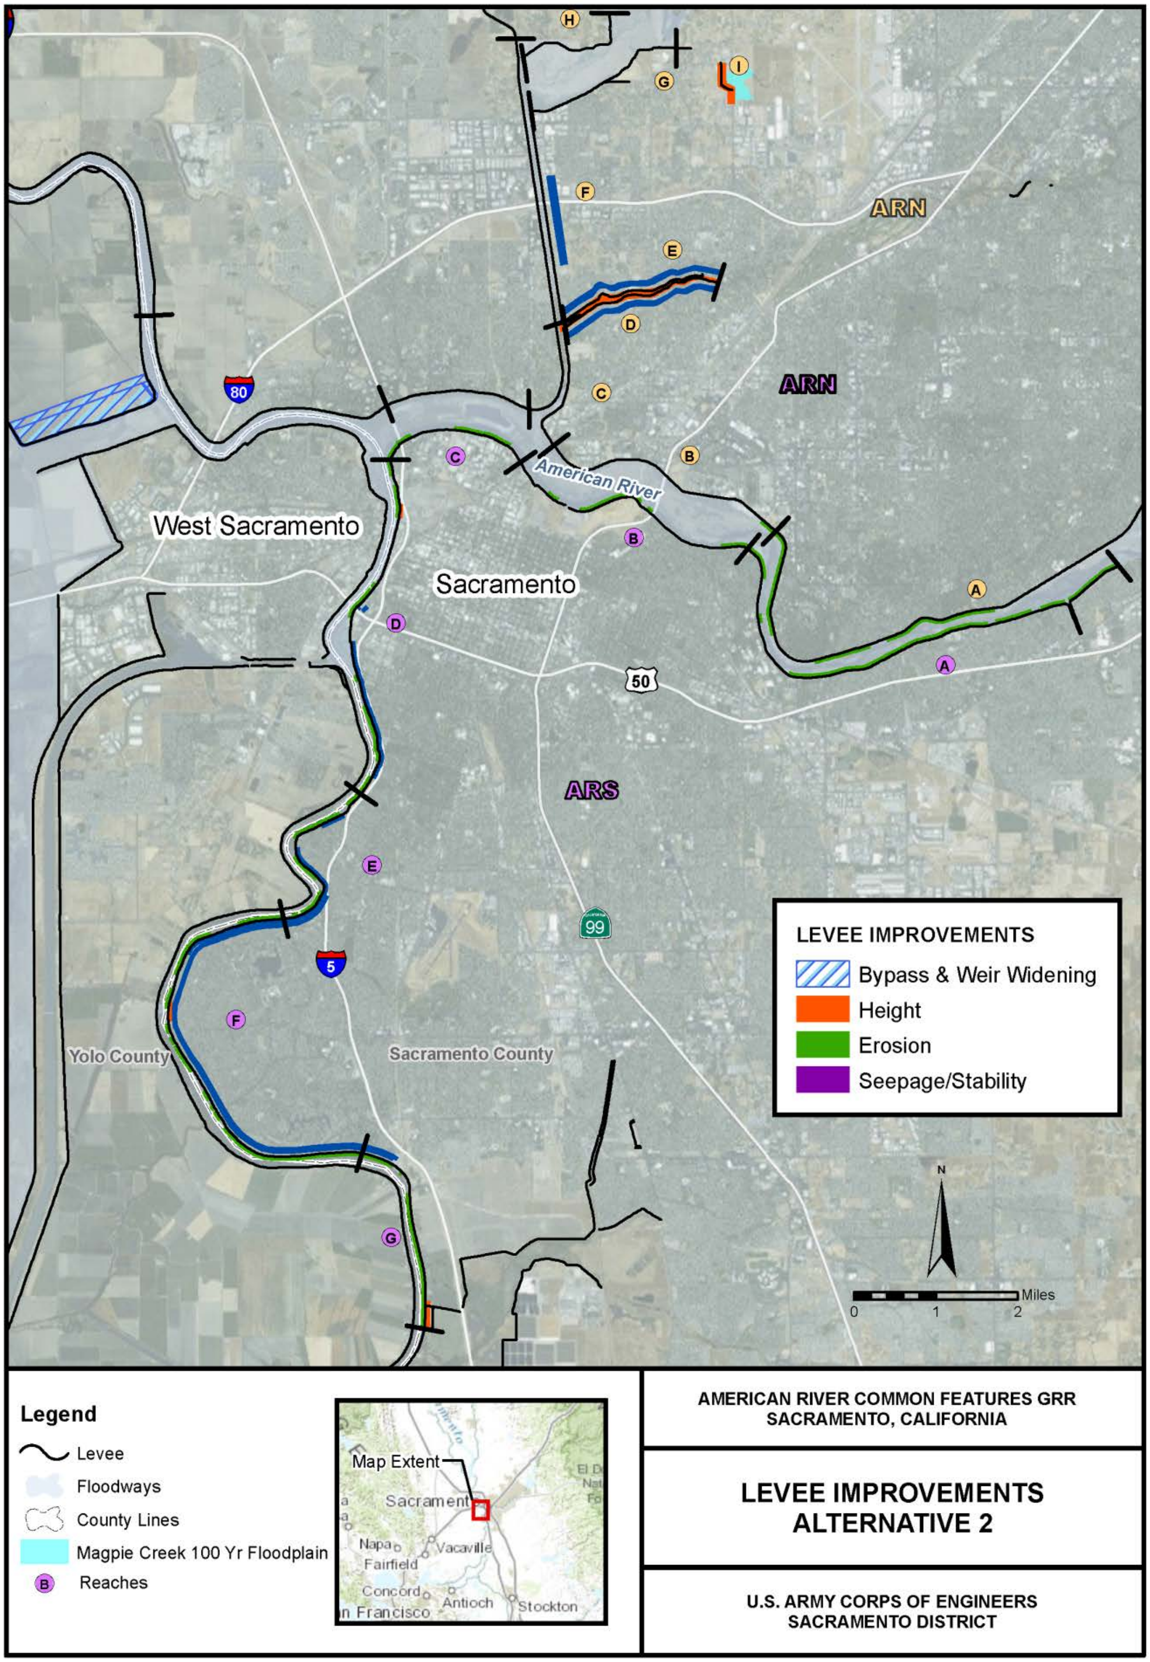

Figure 2. Alternative 2 Proposed Measures.

Sacramento Weir and Bypass Widening

The Sacramento Bypass and Weir currently allow excess flood waters to spill out of the system into the Yolo Bypass thereby reducing the loading on the levee system below. Alternative 2 leverages this existing structure by constructing a new weir structure, and relocating the levee 1,500 feet to the north. The existing weir would not be altered under this measure. The weir, combined with the increased bypass width and operations change, would allow more water to be released out of the system eliminating the need for most of the height improvements along the ARS sub-basin, Reaches D to G. However, this alternative does not reduce the need for seepage, stability and erosion improvements within those reaches. Relocation of the Sacramento Bypass levee would result in the placement of fill in waters of the U.S. Construction methods for this measure are described in Section h below.

<u>b. Location</u>

The proposed project is located in and around the city of Sacramento, California. The ARCF GRR study area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the NEMDC, Arcade Creek, and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento. Figure 1 shows the proposed study area for Alternative 1 and Figure 2 shows the Alternative 2 study area, which includes the additional measures to the Sacramento Weir and Bypass.

<u>c. Purpose and Need</u>

The purpose of this project is to reduce the flood risk and damage in the greater Sacramento area. The Sacramento Metropolitan area is one of the most at risk areas for flooding in the United States. There is a high probability that flows in either the American River or Sacramento River would stress the network of levees protecting the study area to the point that levees could fail. The consequences of such a levee failure would be catastrophic since the inundated area is highly urbanized and the flooding could be up to 20 feet deep. Providing flood damage reduction would reduce loss of life and damage to property in the project area.

The Sacramento metropolitan area has a high probability of flooding due to its location at the confluence and within the floodplain of two major rivers. Both of these rivers have large watersheds with very high potential runoff which has overwhelmed the existing flood management system in the past. The existing levee system was designed and built many years ago, before modern construction methods were employed. These levees were constructed close to the river, which increases velocities associated with flood flows. This results in increased erosion of levees, which are critical components of the flood management system needed to reduce the flood risk in the study area.

In addition to the high probability of flooding, the consequences of flooding in the study area would be catastrophic. The flooding would rapidly inundate a highly urbanized area with minimal warning or evacuation time. As the Capital of California, the Sacramento metropolitan area is the center of State government and many essential statewide services are located here. The study area is also at the crossroads of four major highway/interstate systems that would be impassable should a flood occur. The effects of flooding within the study area would be felt not only at the local level, but at the regional, State, and National level as well.

Because of the deposits of hydraulic mining debris that washed into the American River and Sacramento River valleys, early levee builders constructed the flood management features by dredging material from the river beds and placing it on the bank near the river. This served several purposes. First, the resulting levee provided a degree of protection from flooding. Second, it removed material from the river bed, allowing it to convey more water. And finally, by placing the levees close to the river's edge, the river flow was confined, speeding its flow, and causing it to erode away the material that had been deposited by hydraulic mining, further increasing the river's capacity.

The levees continue to confine the flow into a relatively narrow channel, still eroding and degrading the river channel. However, by now, most of the sediment deposited in the river channels has been removed. Both the Sacramento River and the American River are confined by levees and have very little sediment in the water. Additionally, on the American River, Folsom Dam blocks sedimentation from upstream sources. Therefore, the energy of the flow tends to erode riverbanks and levees. This channel erosion and degradation could have detrimental effects on the levees by undercutting the foundation materials beneath the levees, particularly if the riverbank consists of easily erodible materials. The erosion of the riverbank adjacent to levee embankments may increase the underseepage through the foundation soils. It can also reduce the stability of the levee slopes by undermining the levee embankment and eroding the levees themselves. Significant erosion can lead to the failure of the levee.

Empirical evidence and prototype experiments indicate that stream bank erosion in the area can be gradual or episodic. That is to say, some erosion occurs almost every year. This is primarily due to the fact that materials have been placed on the banks by landowners in an effort to halt erosion. These materials are generally random materials, placed without regard to engineering standards. The Sacramento District is currently evaluating erosion trends as part of the Sacramento River Bank Protection Project (SRBPP).

d. Authority

The authority for the Corps to study water resource related issues in the American and Sacramento Rivers is Section 209 of the Flood Control Act of 1962, Pu. L. No.87-875, § 209, 76 Stat. 1180, 1196-98 (1962). The EIS/EIR for the project was prepared as part of the interim general reevaluation study of the ARCF Project, which was authorized by Section 130 Section 130 of the Energy and Water Development and Related Agencies Appropriations Act of 2008, Pub. L. No. 110-161, § 130, 121 Stat. 1844, 1947 (2007). Additional authority was provided in Section 366 of WRDA of 1999. WRDA 1999, Pub. L. No. 106-53, § 366, 113 Stat. 269, 319-320 (1999). Significant changes to the project cost were recommended in the Second Addendum to the Supplemental Information Report of March 2002. This report was submitted to the Assistant Secretary of the Army for Civil Works, but before it could be forwarded to Congress, authorized total cost of the project was increased to $205,000,000 by Section 129 of the Energy and Water Development Appropriations Act of 2004, Pub. L. No. 108-137, § 129, 117 Stat. 269, 1839 (2003). The current estimated cost of the authorized project is $305,340,000. The allowable cost limit is $307,071,000.

e. Alternatives [40 CFR 230.10]

Unless otherwise noted, the information is from the September 2015 American River Common Features EIS/EIR.

(1) No action:

The No-Action Alternative is also the no fill alternative. The No Action Alternative assumes that no work would be completed by the Corps that would result in placement of fill in waters of the U.S. As a result, the identified erosion problem would not be addressed and the study area would continue to be at a very high risk of levee failure and subsequent flooding of the Sacramento Metropolitan area. Although the No Action Alternative would have no impacts on waters of the U.S., it does not meet the project purpose since it does not address the flood risk in the study area, and is, therefore, not considered to be one of the least environmentally damaging practicable alternatives (LEDPA).

(2) Other project alternatives:

Alternative 1 – Improve Levees

Alternative 1 involves the construction of fix-in-place levee remediation measures to address seepage, slope stability, erosion, and overtopping concerns identified for the American and Sacramento River, NEMDC, Arcade Creek, and Magpie Creek levees. A complete summary of the measures proposed under Alternative 1 can be found above in Table 1. The project area for Alternative 1 is shown above in Figure 1. This action is considered a practicable alternative and will be retained and evaluated in determining the LEDPA.

Alternative 2 – Improve Levees and Widen the Sacramento Weir and Bypass

Alternative 2 would include all of the levee improvements described for Alternative 1, except that instead of approximately 7 miles of levee raises along the Sacramento River there would be approximately 1 mile of levee raises. Instead of the full extent of levee raises, the Sacramento Weir and Bypass would be widened to divert more flows into the Yolo Bypass, as described above. A complete summary of the proposed measures can be found in Table 2 above. The project area for Alternative 2 is shown above in Figure 3. This action is considered a practicable alternative and will be retained and evaluated in determining the LEDPA.

f. General Description of Dredged or Fill Material

(1) General Characteristics of Material

Erosion Protection

Erosion protection measures would involve the discharge of fill material into waters of the U.S. Fill materials for erosion protection would consist of large stone riprap, ranging from 18 to 36 inches, to armor the waterside slope, or to construct a launchable rock trench, with a fine sand or silt fill over the top to allow for vegetation planting. The proposed sand or silt for the erosion protection measures would come from clean, imported fill material.

Overtopping Measures

The implementation of levee raises at Magpie Creek would involve the discharge of fill material into waters of the U.S. Fill materials for levee raises would be silty and clayey soils with a minimum content of 20% fine particles, a Liquid Limit less than 45, and a plasticity index between 7 and 15. No organic material or debris may be present in the soil. The proposed soil would be clean and would be imported from either a tested and approved borrow site, or from an commercial source.

Sacramento Bypass Widening

Relocation of the Sacramento Bypass north levee, as part of the Sacramento Bypass widening, would involve placement of fill into waters of the U.S. Fill materials associated with this action would consist of silty and clayey soils with a minimum content of 20% fine particles, a Liquid Limit less than 45, and a plasticity index between 7 and 15. No organic material or debris may be present in the soil. The proposed soil would be clean and would likely consist of the current Sacramento Bypass north levee soils, as the existing levee material is proposed for reuse to the maximum extent practicable. Any borrow material necessary would be clean and would be imported either from a tested and approved borrow site, or from a commercial source.

(2) Quantity of Material

Erosion Protection

Approximately 2.75 million tons of rock would be required to construct bank protection sites on the American River and Sacramento River. This would result in approximately 11 miles of bank protection fill on the American River and approximately 10 miles on the Sacramento River. Approximately 17 acres of fill would be placed in the American River. Approximately 15 acres of fill would be placed into the Sacramento River. Additionally, approximately 0.4 acre of wetland would be impacted by construction of a proposed launchable rock trench on the south bank of the American River.

Overtopping Measures

Approximately 0.25 acre of soil fill would be placed in waters of the U.S. to construct the levee raise at Magpie Creek.

Sacramento Weir and Bypass

There are approximately 14 acres of soil that would be placed in farm canals and drainage ditches in the widened Sacramento Weir and Bypass area. However, the widened Sacramento Bypass area of approximately 325 acres would become permanent waters of the U.S., therefore the effect from this measure could be offset by the new floodplain habitat created within the widened bypass, due to the potential for natural establishment of wetlands within this area.

(3) Source of Material

Erosion Protection

Riprap for bank protection, seepage berms, and adjacent levees would be imported from a licensed, permitted facility that meets all Federal and State standards and requirements. The material would be transported along either existing roadways and construction access roads, or for Sacramento River sites could be imported via river barge hauling.

Overtopping Measures

Potential locations for borrow material, soil maps and land use maps were obtained for a 25-mile radius surrounding the project area. Borrow sites would be lands that are the least environmentally damaging and would be obtained from willing sellers. Material would be excavated from upland areas and not waterways, wetlands, or water bodies. The criteria used to determine potential locations were based on current land use patterns, soil types from Natural Resources Conservation Service (NRCS), and Corps' criteria for material specifications. The data from land use maps and NRCS has not been field verified, therefore, to ensure that sufficient borrow material would be available for construction the Corps looked at all locations within the 25 miles radius for 20 times the needed material. This would allow for sites that do not meet specifications or are not available for extraction of material.

It is estimated that a maximum of 1 million cubic yards (CY) of borrow material (soil) could be needed to construct the project. Because this project is in the preliminary stages of design, detailed studies of borrow material needs for each alternative have not been completed. For the purposes of

NEPA/CEQA, the analysis evaluates the maximum foreseeable volume of borrow material that could be needed to construct the project. Actual volumes exported from any single borrow site would be adjusted to match demands for fill. The source of the material would come from inland areas (i.e. rock quarries).

The excavation limits on the borrow sites would provide a minimum buffer of 50 feet from the edge of the borrow site boundary. From this setback, the slope from existing grade down to the bottom of the excavation would be no steeper than 3H:1V. Excavation depths from the borrow sites would be determined based on available suitable material and local groundwater conditions. The borrow sites would be stripped of top material and excavated to appropriate depths. Once material is extracted, borrow sites would be returned to their existing use whenever possible, or these lands could be used to mitigate for project impacts, if appropriate. Waters of the U.S. would not be impacted by source material being used.

Sacramento Weir and Bypass

Soil necessary for the Sacramento Weir and Bypass levee relocation would be reused from the existing levee and the footprint of the new Sacramento Bypass. Any additional borrow soil needed would be acquired through the methods discussed above for Overtopping Measures.

g. Description of the Proposed Discharge Site

(1) Location

Erosion Protection

Erosion protection measures would be constructed along approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River. In addition, there would be construction along the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento. On the American River south levee, a short stretch of launchable rock trench is proposed for an area that includes wetlands adjacent to the levee.

Overtopping Measures

Overtopping measures are proposed along the west bank of the Magpie Creek Diversion Canal from just downstream from Raley Boulevard to about 100 feet south of Vinci Avenue Bridge.

Sacramento Weir and Bypass

The Sacramento Bypass is located in Yolo County approximately 4 miles west of Sacramento along the northern edge of the city of West Sacramento. The Sacramento Weir runs along the west bank of the Sacramento River and separates the river from the Bypass. The Sacramento Bypass is located in a rural area owned by the State of California and operated as the Sacramento Bypass Wildlife Area. The area proposed for the Sacramento Bypass widening is currently active farm fields which include row crops and newly planted nut orchards. A series of farm canals and drainage ditches separate the fields in this area.

(2) Size

Erosion Protection

Approximately 17 acres of fill would be placed in the American River. Approximately 15 acres of fill would be placed into the Sacramento River.

Overtopping Measures

Approximately 1 acre of fill would be placed in vernal pool habitat.

Sacramento Weir and Bypass

Approximately 14 acres of fill would be placed in canals and drainage ditches in the widened Sacramento Bypass.

(3) Type of Site

Erosion Protection

To construct the erosion protection measures, riprap would be placed in the American River and Sacramento River along the waterside slope of the levee. Additionally, on the south bank of the American River, a trench comprised of riprap would be buried adjacent to the levee.

Overtopping Measures

To construct the levee raise along the Magpie Creek levee, soil would be placed along the landside of the levee in vernal pool habitat.

Sacramento Weir and Bypass

To relocate the Sacramento Bypass levee and grade the bypass area, soil would be placed in canals and drainage ditches.

(4) Type of Habitat

Erosion Protection

Habitat types along the footprint of the bank protection measures include valley foothill riparian habitat and open water habitat. These habitat types are described below.

Valley Foothill Riparian Habitat. Valley foothill riparian habitat occurs along the Sacramento and American River levees. The overstory of the riparian habitat consists of mature, well-established trees: Fremont cottonwood (*Populus fremontii ssp. fremontii*), valley oak (*Quercus lobata*), black willow (*Salix gooddingii*), and box elder (*Acer negundo var. californicum*). During the reconnaissance-level field visits, Oregon ash (*Fraxinus latifolia*), western sycamore (*Platanus racemosa*), and white alder (*Alnus rhombifolia*) were also observed. The shrub layer consists of smaller trees and shrubs; representative species observed were poison oak (*Toxicodendron diversilobum*), sandbar willow (*Salix exigua*), and Himalayan blackberry (*Rubus discolor*). Elderberry shrubs (*Sambucus mexicana*), the host plant of the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), which is Federally listed as threatened, were observed in the riparian habitat along the Sacramento River north and south levees. Riparian habitat is listed as a sensitive natural community by the CNDDB (2009).

Open Water. The American River and Sacramento River are located within the study area and would both be impacted by placement of fill into waters of the U.S. Both of these rivers are navigable waterways that are jurisdictional under Section 404 of the Clean Water Act.

Wetlands. Wetlands are those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas (40 CFR 230.3[t]). Representative species observed in seasonal wetlands include Mediterranean barley (*Hordeum marinum* ssp. *gussoneanum*), Italian ryegrass (*Lolium multiflorum*), water pepper (*Persicaria hydropiperpoides*), and alkali mallow (*Malvella leprosa*). Wetlands in the study area are assumed to be jurisdictional waters of the United States subject to regulation under CWA Section 404. Within the study area, wetlands also include features such as drainage ditches and farm canals, vernal pools, and open water habitat such as rivers and creeks. Vernal pools are discussed further in Section 3.8. Wetlands and vernal pools are considered sensitive habitats under CEQA.

Overtopping Measures

Habitat types in the footprint of the levee raises at Magpie Creek include potential vernal pool habitat. Vernal pool habitat is described below.

Vernal Pools. Vernal pools are depressions in areas where a hard underground layer prevents rainwater from draining downward into the subsoils. When rain fills the pools in the winter and spring, the water collects and remains in the depressions. In the springtime the water gradually evaporates away, until the pools become completely dry in the summer and fall. Vernal pools support plants and animals that are specifically adapted to living with very wet winter and spring conditions followed by very dry summer and fall conditions. The pools are most beautiful in the spring, when many specially-adapted flowering plants are in full bloom following initial evaporation of surface water. Almost all plants that occur in vernal pools are annuals, meaning they germinate, flower, set seed, and die all within one year. Many vernal pool plant species have seeds that can remain dormant for many years, an adaptation that allows them to survive through periods of drought. Many specially-adapted crustaceans, amphibians, and insects also occur only in vernal pools.

Sacramento Weir and Bypass

Habitat types in the expanded Sacramento Weir and Bypass area include primarily agricultural habitats, such as irrigated grain, row, and field crops. The habitat impacted by placement of fill is primarily open water habitat, as described above for the bank protection sites, in the form of small canals and drainage ditches.

(5) Timing and Duration of Discharge

Erosion Protection

The construction schedule for the ARCF project was estimated based on a 3 month construction window per year due to logistical constraints. Construction would likely occur during the summer months due to special status species work windows and the flood season. Construction of erosion protection measures on the American River would take approximately 9 years. Construction of the overall work proposed for the Sacramento River, including the seepage, slope stability, and height improvements, would take approximately 8 years, with bank protection construction occurring intermittently throughout that time frame.

Overtopping Measures

Construction of the levee raises at Magpie Creek would occur in one construction year. Similar to the erosion protection schedule discussed above, this schedule assumes a 3 month construction window. Construction would likely occur during the summer months due to special status species work windows and the flood season.

Sacramento Weir and Bypass

Relocation of the Sacramento Bypass levee would occur in one construction year. Similar to the erosion protection schedule discussed above, this assumes a 3 month construction window. Construction would likely occur during the summer months due to special status species work windows and the flood season.

h. Description of Disposal Method

Erosion Protection

Erosion protection along the American River and Sacramento River would be addressed via either the launchable rock trench method or by standard bank protection. There are no erosion protection measures proposed for the East Side Tributaries. Construction methods for the bank protection and launchable rock trench measures are described below.

Bank Protection

This measure consists of placing riprap on the river's bank, and in some locations on the levee slope, to prevent erosion (Figure 3). Bank protection is proposed along the American River and Sacramento River and would result in the placement of fill in waters of the U.S. Construction methods are described below.

When necessary, the eroded portion of the bank would be filled and compacted prior to the rock placement. The sites would be prepared by clearing and stripping the site prior to construction. Small vegetation and loose materials would be removed. In most cases, large vegetation would be permitted to remain at these sites. Temporary access ramps would be constructed, if needed, using imported borrow material that would be trucked on site.

Riprap would be imported from an offsite location via haul trucks and temporarily stored at a staging area located in the immediate vicinity of the construction site. A loader would be used to move riprap from the staging area to an excavator that would be placing the material. The excavator would place a large rock berm in the water up to an elevation slightly above the mean summer water surface. A planting trench would be established on this rock surface for revegetation purposes. The excavator would either be working from the top of the bank placing riprap on the bank beneath it and in the water, or from on top of the rock berm that it established.

The placement of rock onto the levee slope would occur from atop the levee. Rock placement from atop the levee would require one excavator and one loader for each potential placement site. The loader would then bring the rock from a staging area to the excavator and the excavator then places it on the waterside of the levee slope

The riprap would be placed on the existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After riprap placement has been completed, a small planting berm would be constructed in the rock where feasible to allow for some revegetation of the site, outside of the vegetation free zone required by ETL 1110-2-583. This vegetation would be designed on a site specific basis to minimize the O&M responsibility of the LMA and in such a way to not impact the hydraulic conveyance of the channel.

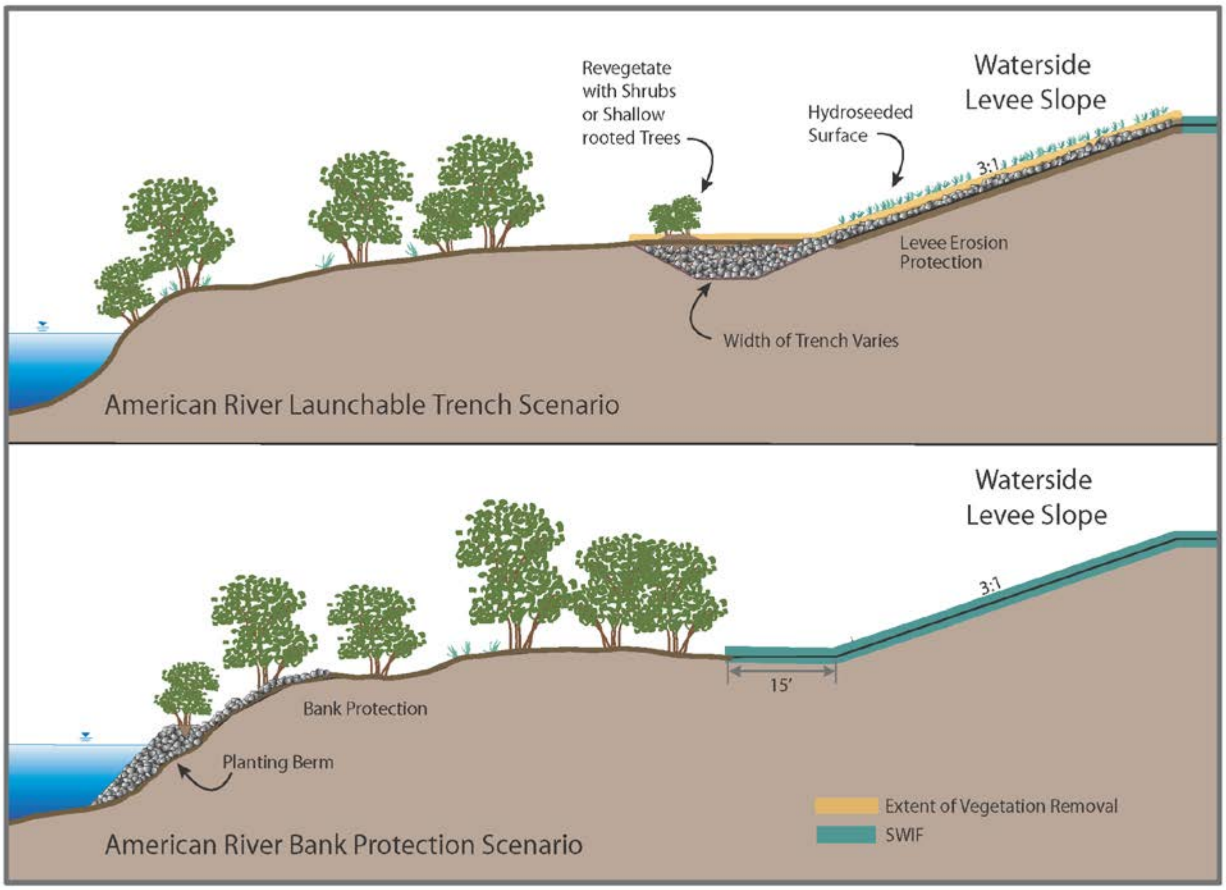

Figure 3. Erosion Protection Measures Typical Design.

Launchable Rock Trench

This measure includes construction of a launchable rock filled trench, designed to deploy once erosion has removed the bank material beneath it (Figure 3). All launchable rock trenches would be constructed outside of the natural river channel. As a result, launchable rock trenches would be above the ordinary high water mark and fill materials would not be placed into waters of the U.S. However, this measure is described in detail below because it is a practicable alternative to the bank protection measure.

The vegetation would be removed from the footprint of the trench and the levee slope prior to excavation of the trench. The trench configuration would include a 2:1 landside slope and 1:1 waterside slope and would be excavated at the toe of the existing levee. All soil removed during trench excavation would be stockpiled for reuse or disposal. The bottom of the trench would be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and amount of rock required.

After excavation, the trench would be filled with riprap that would be imported from an offsite location. After rock placement the trench would be covered with a minimum of 3 feet of the stockpiled soil to allow for planting over the trench. Rock placed on the levee slope would be covered with the stockpiled soil. All disturbed areas would be reseeded with native grasses and small shrubs where appropriate. Some vegetation could be permitted over the trench if planted outside the specified vegetation free zone required by ETL 1110-2-583. This vegetation would likely be limited to native grasses, shrubs, and trees with shallow root systems to ensure that they do not limit the functionality of the trench during a flood event.

Overtopping Measures

To begin levee raising, the area would be cleared, grubbed, stripped, and, where necessary, portions of the existing embankment would be excavated to allow for bench cuts and keyways to tie in additional embankment fill. Excavated and borrow material (from nearby borrow sites) would be stockpiled at staging areas. Haul trucks or scrapers would bring borrow materials to the site, which would then be spread evenly and compacted according to levee design plans. The existing levee centerline would be shifted landward, where necessary, in order to meet the Corps' standard levee footprint requirements. The levee crown patrol road would be re-established and a new toe access corridor would be added 10 feet landward of the levee toe in areas where levee raises are required.

Sacramento Weir Bypass

For this alternative, the existing north levee of the Sacramento Bypass would be degraded and a new levee constructed approximately 1,500 feet to the north. A new weir would be extended north of the existing Sacramento Weir without impacting the existing structure. The new weir would be extended approximately 1,500 feet and include a seepage cutoff wall below. The increase in Bypass flows through the new weir would occur during high water events only, when the flow released from Folsom Dam on the American River exceeds 115,000 cfs. The existing Sacramento Weir and Bypass would be operated consistent with current conditions based on the stage at the I Street gage.

The new north levee of the Sacramento Bypass would be constructed per new levee construction standards, including 3H:1V waterside and landside slopes and a minimum crest width of 20 feet. As both the existing north and south levees have experienced underseepage and slope stability related distress, the new north levee would include a 300-foot wide drained landside seepage berm (5 feet thick at the landside levee toe tapering to 3 feet thick at the berm toe and constructed of random fill with a 1.5-foot thick drainage and filter layer at the base) with a system of relief wells located at least 15 feet landward of the berm toe and spaced at 200-foot intervals. Existing infrastructure, including roads, railways, canals, and pump stations would be relocated to maintain current operation. Placement of fill into waters of the U.S. would occur as a result of the relocation of canals and drainage ditches associated with the Bypass widening.

II. Factual Determinations

a. Physical Substrate Determinations (Sections 230.11 (a) and 230.20)

(1) Comparison of Existing Substrate and Fill

The project area generally consists of deep soils derived from alluvial sources, which range from low to high permeability rates and low to high shrink-swell potential. Soils immediately adjacent to the Sacramento River are dominated by deep, nearly level, well-drained loamy and sandy soils. The natural drainage is good, and the soils have slow to moderate subsoil permeability. The river terraces consist of very deep, well drained alluvial soils. The porous nature of the soils underneath the existing levee system is an important consideration for the design of levee improvements within the ARCF GRR study area. The major source of sediments deposited in the ARCF GRR study area is from the erosion of the Sierra Nevada mountain range and foothills to the east of the Sacramento Valley. Naturally occurring asbestos (NOA) is known to occur in the foothill metamorphic belt. Therefore, NOA may be present; however, the likelihood of project area soils containing significant concentrations of NOA is low due to the long distance from the source rock.

As discussed in Section I.f(1) above, fill material for bank protection construction would consist of large stone riprap ranging from 18 to 36 inches, to armor the waterside slope, with a fine sand or silt fill over the top to allow for vegetation planting on the berms. Approximate size of the berms would be 5 feet thick at the berm toe and construction of random fill with a 1.5-foot thick drainage and filter layer at the base). The proposed sand or silt for the bank protection would come from clean, imported fill material. The fill material for the overtopping measures and the Sacramento Bypass levee relocation would consist of silty and clayey soils with a minimum content of 20% fine particles, a liquid limit less than 45, and a plasticity index between 7 and 15. No organic material or debris may be present in the soil. The proposed soil would be clean and would be imported from either a tested and approved borrow site, or from an commercial source.

(2) Changes to Disposal Area Elevation

Erosion Protection

Due to the placement of rock bank protection along the river banks, there would be an increase in elevation of approximately 1.5 feet in the locations where fill is placed in the waters of the U.S. Launchable rock trenches would be buried beneath the surface and would not result in a change in elevation.

Overtopping Measures

Raising the Magpie Creek levee would increase the ground elevation in the footprint of the fill placement by anyway from a few inches to a few feet, depending on the slope of the levee.

Sacramento Weir and Bypass

There would be a significant increase in elevation in the footprint of the new Sacramento Bypass levee, as the levee would be constructed above the existing ground surface elevation.

(3) Migration of Fill

Erosion Protection

The erosion repairs within the project area is likely to somewhat reduce the sediment supply for riverine reaches directly downstream because the riprap would hold the bank or levee in place. However, from a system sediment perspective, the bank material that would be protected in the project reaches is not a major source of sediment compared to the upstream reaches of the Sacramento, Feather, and, especially, the Yuba River systems.

A typical bank protection site has an approximate life span of 50 years. Over that time period, there would be a natural erosion and migration of fill occurring at the site; however it would occur at a slightly slower rate than natural conditions if no bank protection were to occur. Riprap established along the waterside levee toe is designed to stay in place and prevent further erosion. However, there is a possibility that there may be slight degradation or migration of riprap material over the years as well. The sites would be designed to avoid significant migration of newly placed fill through the use of geotextiles and the establishment of on-site vegetation.

Sediment associated with the launchable rock trench measure is not expected to migrate over time. The soil placed on the trench would be compacted and vegetation would be established to avoid long-term erosion impacts.

Overtopping Measures

Sediment associated with the levee raise at Magpie Creek is not expected to migrate over time. The soil placed would be compacted and would be seeded with natural grasses to avoid long-term erosion impacts.

Sacramento Weir and Bypass

Sediment placed to construct the relocated Sacramento Bypass levee is not expected to migrate over time. The Bypass is dry the majority of the time. During a flood event there would be some natural erosion associated with flood flows in the bypass, however, the levee would be constructed in a manner to ensure that it would not significantly degrade during a typical flood event.

(4) Duration and Extent of Substrate Change

Erosion Protection

There would be a permanent change of substrate on the riverbanks from alluvial soils to stone riprap. However the rock berms would be covered with a silty or sandy layer of soil in order to allow for the planting of vegetation along the river banks. This silty or sandy layer of soil would be of a similar substrate type to the existing condition. The launchable rock trench measure would result in a change in substrate of approximately 0.4-acre from undrained hydric soils to buried stone riprap with a silty or sandy layer of soil on the surface to allow for revegetation of the site.

Overtopping Measures

There would be a permanent change of substrate from vernal pool hardpan soils to the silty clayey soils described above for levee construction.

Sacramento Weir and Bypass

There would be a permanent change of substrate in the drainage canals to the silty clayey soils described above for levee construction. However, relocation of the Sacramento Bypass levee would not substantially alter the majority of the soil in the footprint of the new levee construction. Since the existing levee would be used to construct the new levee, and the borrow material used in the levees likely originated in the Bypass footprint, these soils would be consistent with the soil content of the overall area.

(5) Changes to Environmental Quality and Value

Alternative 1 would result in potential impacts to water quality, including increased turbidity during bank protection construction, runoff of exposed soils, and cement, slurry, or fuel spills during construction. Emissions from construction equipment, haul trucks, and barges also pose a potential impact to environmental quality and value during the duration of construction activities. BMPs would be implemented during construction to reduce these impacts to less than significant. There would be a permanent change in substrate in the footprint of the erosion protection areas; however these sites would be designed to be as consistent as feasible with natural riverbanks through the placement of silt over the rock layer and the planting of on-site shrubby vegetation and native grasses. To the extent feasible, large trees on the lower waterside slope would be left in place to maintain shaded riverine aquatic habitat for special-status fish species and new vegetation would be established to provide mitigation for vegetation that must be removed in order to construct the project.

Alternative 2 would reduce water surface elevation in the Sacramento River downstream of the confluence of the American River without significantly increasing water surface elevation in the Yolo Bypass downstream of the confluence of the Sacramento Bypass. Impacts associated with the placement of fill in waters of the U.S. to water quality, air quality, vegetation, and listed fish species are the same as discussed above for Alternative 1, with the addition of the 14 acres of canals and drainage ditches that would be permanently impacted as part of the Sacramento Bypass widening. However, Alternative 2 would also create approximately 300 acres of new floodplain habitat within the widened Sacramento Bypass. Impacts to existing soil and substrate conditions are the same as Alternative 1.

(6) Actions to Minimize Impacts

The following mitigation measures would be used during construction of Alternative 1 to reduce impacts to environmental quality:

- Prior to construction, the Corps or its contractor would be required to acquire all applicable permits for construction.
- Prior to construction, a Stormwater Pollution Protection Plan (SWPPP), Spill Prevention Control and Countermeasures Plan, and a bentonite slurry spill contingency plan would be prepared, and best management practices (BMPs) would be proposed to reduce potential erosion and runoff during rain events.
- Minimize ground and vegetation disturbance during project construction by establishing designated equipment staging areas, ingress and egress corridors, spoils disposal and soil stockpile areas, and equipment exclusion zones prior to the commencement of any grading operations.

- After construction of the flood risk management features is completed, the direct effects to habitat for special status species would be compensated in accordance with the Biological Opinions. Mitigation plantings would be monitored during the plant establishment period for success. Successful habitat mitigation would compensate for significant effects to vegetation, wildlife, special status species, and aesthetic resources.
- BMPs, including the Sacramento Metropolitan Air Quality Management District's Basic Construction Emission Control Practices, would be implemented to reduce emissions of criteria pollutants and greenhouse gases and to reduce potential effects to air quality and associated with climate change.
- During construction, noise-reducing measures would be employed in order to ensure that construction noise complies with local ordinances. Prior to the start of construction, a noise control plan would be prepared that would identify feasible measures to reduce construction noise, when necessary.
- Coordination with recreation user groups would occur prior to and during construction for input into mitigation measures that would reduce affects to the maximum extent practicable. Advance notice would be given to recreation users informing them of anticipated activities and detours to reduce the affects. To ensure public safety, flaggers, warning signs, and signs restricting access would be posted before and during construction, as necessary. In the event that bike trails would be disrupted, detours would be provided. Detour routes would be clearly marked, and fences would be erected in order to prevent access to the project area. In areas where recreational traffic intersects with construction vehicles, traffic control will be utilized in order to maintain public safety.

Additional mitigation associated with Alternative 2 includes:

- Planting riparian tree species within the widened Sacramento Bypass to compensate for 8 acres of permanent, direct impacts associated with construction of the new Sacramento Weir.
- Grading the new portion of the Sacramento Bypass to ensure positive drainage with the design of the existing Sacramento Bypass.
- Inclusion of fish passage features and ramp down of operation following flood events to reduce potentially adverse effects to listed fish species due to stranding within the Sacramento Bypass.

.

b. Water Circulation, Fluctuation, and Salinity Determinations

(1) Alternation of Current Patterns and Water Circulation

Since Alternative 1 consists of fix-in-place levee improvements, implementation of these measures would have no effect on current patterns and water circulation.

Alternative 2 would result in a diversion of flows from the Sacramento River to the Yolo Bypass that would slightly raise water surface elevations by approximately 0.10-foot in the Yolo Bypass during large flood events events (200 year) compared to both the existing and future without project conditions. To avoid potential effects to the Yolo Bypass, the widened portion of the Sacramento Weir would only be operated when the release from Folsom Dam is increased to above 115,000 cfs. With the Folsom Dam improvements in place, releases from Folsom Dam would be above 115,000 cfs for flood events greater than 1/100 ACE event. Operation of the existing segment of the Sacramento Weir would not change from current practices.

Therefore, for events up to and including the 1/100 ACE event, only the existing weir would be operated per the criteria previously established. For events greater than the 1/100 ACE event when the release from Folsom Dam would go above 115,000 cfs, the new weir would be opened. As a result of the increased flood storage space and anticipatory releases at Folsom Dam, this translates into a reduction of flows into the Yolo Bypass with Alternative 2 in place compared to the existing conditions. Table 3 compares the flows at various locations for the Existing, Future Without Project, and with Alternative 2 in place. For the 1/100 ACE event and greater, the benefits of the Folsom Dam improvements would be realized in the form of reduced flows compared to the Existing condition.

Table 3. Comparison of 10-, 100-, and 200-year Frequency Flows under Various Conditions.

10 year event	**Existing Condition**	**Future Without Project Condition (also Alternative 1)**	**Alternative 2**
American River	43,000 cfs	72,000 cfs	72,000 cfs
Sacramento Bypass	50,000 cfs	66,000 cfs	66,000 cfs
Yolo Bypass below Sac Bypass	270,000 cfs	296,000 cfs	296,000 cfs
100 year event	**Existing**	**Future Without Project and Alt. 1**	**Alt. 2 (TSP)**
American River	145,000 cfs	115,000 cfs	115,000 cfs
Sacramento Bypass	131,000 cfs	115,000 cfs	115,000 cfs
Yolo Bypass below Sac Bypass	555,000 cfs	535,000 cfs	535,000 cfs
200 year event	**Existing**	**Future Without Project and Alt. 1**	**Alt. 2 (TSP)**
American River	320,000 cfs	160,000 cfs	160,000 cfs
Sacramento Bypass	183,000 cfs	149,000 cfs	164,000 cfs
Yolo Bypass below Sac Bypass	656,000 cfs	631,000 cfs	643,000 cfs

Although Alternative 2 would result in the creation of a new drainage area within the Sacramento Bypass, the area would be contained within the levee system and would not result in substantial additional erosion, siltation, or runoff. The expanded bypass would not create or contribute flows in excess of the existing capacity of the system, as shown in Table 12 above.

(2) Interference with Water Level Fluctuation

Because the Sacramento River and American River systems are regulated by upstream dams which allow a specific amount of water to be released into systems, the Alternative 1 and the no action/no project alternative would not change water level fluctuation patterns. Alternative 2 would change the water level fluctuation patterns by reducing and stabilizing the maximum water surface elevations on the Sacramento River during flood events, as described in Table 3 above.

Potential implications of the simulated long-term changes in bed profiles can be increased stress along the toe of the project levees or overbank berms in the degradational reaches, which may result in increased scour along unrevetted channel sections. In the aggradational reaches, an increase in bed elevations may result in higher flood stages and reduced flood conveyance.

(3) Salinity Gradients Alteration

Salinity gradients would not be affected, as salinity normally only increases in the river system during low flow events when there is a higher than average tidal influx from the Delta. With-project conditions in the system would remain consistent with existing conditions during normal and low flow periods. Flows would be increased during high water events, however the flood flows during these events would be pushing any salinity intrusion back down into the Bay-Delta system and would not result in any salinity increases in the riverine system.

(4) Effects on Water Quality

The Basin Plan states that where ambient turbidity is between 5 and 50 nephelometric turbidity units (NTUs), projects would not increase turbidity on the Sacramento River by more than 20 percent above the ambient conditions. Furthermore, if the ambient diurnal variation in turbidity fluctuates in and out of the 5 and 50 NTUs threshold, the Basin Plan states that averaging periods can be applied to data to determine compliance. For example, during the summer months, the Sacramento River turbidity could be less than 50 NTUs, and during the winter months, the turbidity could be more than 50 NTUs because of the higher flow rate causing more river scouring. Thus, the monthly average was calculated using hourly CDEC data and is presented in Table 3-3 below. Specific construction activities that are part of the potential alternatives would need to comply with the above-stated thresholds for turbidity.

Water quality impacts that could result from project construction activities and project operations were evaluated based on the construction practices and materials that would be used, the location and duration of the activities, and the potential for degradation of water quality or beneficial uses of project area waterways.

Table 3-3. Monthly Average Total Suspended Sediment and Turbidity for the Sacramento River at Freeport from 1997 to 2007.

Month	Discharge (cfs)	TSS (mg/L)	TSS Load (tons)	Turbidity (NTU)
January	41,414	104	11,670	64
February	44,084	83	9,839	68
March	39,586	70	7,476	15
April	28,552	51	3,946	11
May	25,152	48	3,279	12
June	21,461	30	1,741	17
July	20,432	37	2,019	21
August	18,235	27	1,332	9
September	16,121	29	1,266	10
October	11,950	29	940	6
November	13,612	24	868	8
December	25,105	81	5,463	12

Note: Flow and TSS data are from the USGS and are presented as monthly average from 1997 to 2007. Turbidity data are from CDEC from March 2007 to January 2009 and also are presented as a monthly average. Turbidity data are from the Sacramento River at Hood, a few river miles downstream from the USGS station.
Source: USGS 2013; DWR 2012b.

Where bank protection construction is proposed, riprap would be placed along the river bank to prevent erosion. The placement of riprap along the river banks would temporarily generate increased turbidity in the immediate vicinity of the construction area. Additionally, placement of riprap in the water could result in a sediment plume, generated from the channel bottom and levee side, becoming suspended in the water and could generate turbidity levels above those identified as acceptable by the Basin Plan. Turbidity effects from landside construction (e.g., vehicle, staging, placement of construction equipment) would be limited to stormwater runoff carrying loose soil from staging areas and construction vehicle access areas. Best management practices would be implemented to reduce the effect of runoff into the stormwater system to less than significant. Best management practices include such things as coir mats or hay bales to prevent runoff, rock groins to retain sediment, sand bags to prevent erosion, and drain screens to prevent sediment from traveling outside the construction area footprint and into the storm drains system.

As rock riprap is placed in the open water, significant indirect effects would result as the sediment and turbidity plume would drift further downstream and later affect the water qualify in those areas further downstream of the project area. By implementing the BMPs contained within the SWPPP, impacts would be reduced to less than significant.

Effects to water quality for Alternative 2 would be the same as Alternative 1 with the additional effects associated with the widening of the Sacramento Weir and Bypass. Construction of the new north levee would occur when water is not flowing through the bypass, and therefore there would be not impacts to water quality during construction of the new north levee of the bypass. However, effects could occur during the construction of the expanded weir along the Sacramento River. There is a potential for water quality impacts to occur if the weir is constructed in a way that debris or other construction materials could enter the Sacramento River. However, it is likely that the weir could be constructed behind the existing levee, which would result in no impacts to water quality.

(a) Water Chemistry

The potential of hydrogen (pH) is a unit for measuring the concentration of hydrogen ion activity in water and is reported on a scale from 0 to 14. If a solution measures less than 7, it is considered acidic. If a solution measures more than 7, it is considered basic, or alkaline. If a solution measures 7, it is considered neutral. Many biological functions occur only within a narrow range of pH values. The Basin Plan objective for pH is between 6.5 and 8.5. Furthermore, discharges cannot result in changes of pH that exceed 0.5. The monthly average pH of the Sacramento River from 2003 to 2009 remained stable throughout the year (Table 3-4). Construction materials such as concrete or other chemicals could affect the pH of the Sacramento River if a discharge were to occur. The proposed materials and construction activities have the potential to affect water chemistry during the duration of construction. Construction contractors would be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity. The contractor would be required to obtain a permit from the CVRWQCB detailing a plan to control any spills that could occur during construction. The plan would describe the construction activities to be conducted, BMPs that would be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that would be conducted.

(b) Salinity

The proposed materials and construction activities are not expected to affect salinity.

(c) Clarity

Placement of fill materials would temporarily reduce clarity due to an increase in total suspended solids within the project area. Clarity is not expected to be substantially affected outside the immediate project area. However, the reduction of clarity caused by construction activities would be short in duration and would return to pre-construction levels upon project completion.

(d) Color

The proposed project is expected to affect color only during fill activities. Placement of fill materials would temporarily induce a color change due to an increase in turbidity. These effects would be consistent with those discussed above for clarity. The change in color caused by construction activities would be short in duration and would return to pre-construction levels upon project completion.

(e) Odor

The proposed project would not result in any major sources of odor, and the project would not involve operation of any of the common types of facilities that are known to produce odors (e.g., landfill, wastewater treatment facility). Odors associated with diesel exhaust emissions from the use of onsite construction equipment may be noticeable from time to time by adjacent receptors. However, the odors would be intermittent and temporary and would dissipate rapidly from the source with an increase in distance. Furthermore, as required by CARB regulation 13 CCR 2449(d)(3), no in-use off-road diesel vehicles may idle for more than 5 consecutive minutes. Therefore, this direct effect would be less than significant. In addition, implementation of mitigation measures, which are required under other air quality effects, would further reduce exhaust emissions and provide advanced notification of construction activity.

(f) Taste

The proposed materials and construction activities are not expected to affect taste.

(g) Dissolved Gas Levels

The proposed materials and construction activities are not expected to affect dissolved gases.

(h) Temperature

Construction activities have the potential to create substantial turbidity affecting water temperature. Implementing the BMPs established in the SWPPP, conducting work during low flow periods, and installing sediment barriers to reduce sediment from entering waterways would be required to control turbidity and the mobilization of pollutants that may be present in sediments. There is the potential for some increases in water temperature, due to the removal of waterside vegetation during construction. However, the vegetation that would be removed would primarily consist of shrubby vegetation and grasses, which do not significantly contribute to shade. The larger trees in the bank protection footprint, which are the primary contributors to shade, would be protected in place, which would help to maintain consistent long-term water temperatures after construction. Additionally, shrubs would be planted on the bank protection planting berms during construction to allow the vegetative cover near the banks to redevelop long-term.

(i) Nutrients

The proposed materials and construction activities have the potential to affect nutrient levels in the water. Release of suspended sediments during construction could potentially cause turbidity thresholds for metals and nutrients to be exceeded. Turbidity would be controlled outside the working area using a combination of BMPs as appropriate. Development and implementation of an approved SWPPP would also prevent release of excess nutrients. Long-term nutrient levels would not be significantly altered by project construction because existing vegetation on the waterside slopes of the levee would be protected in place, and the shaded riverine aquatic corridor would still remain a source of nutrients for the rivers. In addition, nutrients from the upstream watershed would remain in the system.

(j) Eutrophication

The project is not expected to contribute excess nutrients into the stream or promote excessive plant growth due to BMPs and the high content of rock in disposal material.

c. Suspended Particulate/Turbidity Determinations

(1) Alteration of Suspended Particulate Type and Concentration

Where bank protection construction is proposed, riprap would be placed along the river bank to prevent erosion. The placement of riprap along the river banks would temporarily generate increased turbidity in the immediate vicinity of the construction area. Additionally, placement of riprap in the water could result in a sediment plume, generated from the channel bottom and levee side, becoming suspended in the water and could generate turbidity levels above those identified as acceptable by the Basin Plan. Turbidity effects from landside construction (e.g., vehicle, staging, placement of construction equipment) would be limited to stormwater runoff carrying loose soil from staging areas and construction vehicle access areas. Best management practices would be implemented to reduce the effect of runoff into the stormwater system to less than significant. Best management practices include such things as coir mats or hay bales to prevent runoff, rock groins to retain sediment, sand bags to prevent erosion, and drain screens to prevent sediment from traveling outside the construction area footprint and into the storm drains system.

As rock riprap is placed in the open water, significant indirect effects would result as the sediment and turbidity plume would drift further downstream and later affect the water qualify in those areas found further downstream of the project area. By implementing avoidance and minimization measures, discussed in Section 3.5.6 of the ARCF GRR EIS/EIR, impacts could be reduced to less than significant.

(2) Particulate Plumes Associated with Discharge

Placement of riprap in the water could result in a sediment plume, generated from the channel bottom and levee side, becoming suspended in the water and could generate turbidity levels above those identified as acceptable by the Basin Plan. As rock riprap is placed in the open water, significant indirect effects would result as the sediment and turbidity plume would drift further downstream and later affect the water qualify in those areas found further downstream of the project area. By implementing avoidance and minimization measures, discussed in Section 3.5.6 of the ARCF GRR EIS/EIR, impacts could be reduced to less than significant.

(3) Changes to Environmental Quality and Value

There could be significant affects to water quality due to increased turbidity during construction, as discussed above. Additionally, on the Sacramento River, the use of barges to install the riprap could cause additional turbidity as the barge moves into the site and anchors. With the implementation of the BMPs that will be established in the SWPPP, these effects would be reduced to less than significant during construction. Once construction is complete there could be reduced turbidity in the direct vicinity of the site because there would be no exposed soil to erode and deposit into the river. Further, the bank protection sites would include the installation of riparian vegetation which could slow the flows down and reduce turbidity during high flows.

Construction contractors would be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity. The contractor would be required to obtain a permit from the Central Valley RWQCB detailing a plan to control any spills that could occur during construction. The plan would describe the construction activities to be conducted, BMPs that would be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that would be conducted.

(4) Actions to Minimize Impacts

Environmental commitments included in the project to reduce the potential for impacts to water quality include: preparation and implementation of the SWPPP, Spill Prevention Control and Countermeasures Plan (SPCCP), and a bentonite slurry spill contingency plan (BSSCP).

d. Contaminant Determinations

The proposed project is not expected to add contaminants to any body of water; however, if there were a release of contaminants into adjacent water bodies, that could result in significant effects. Therefore, BMPs are proposed during construction to ensure that no contaminants enter the waterways.

Under Alternative 1, construction activities would involve the use of potentially hazardous material, such as fuels, oils and lubricants, and cleaners, which are commonly used in construction projects. Construction contractors would be required to use, store, and transport hazardous materials in compliance with Federal, State, and local regulations during project construction and operation. Testing of borrow sites would occur prior to the use of material and sites which have contaminated soils would not be used for this project. Any hazardous substance encountered during construction would be removed and properly disposed of by a licensed contractor in accordance with Federal, State, and local regulations. Compliance with applicable regulations would reduce the potential for accidental release of hazardous materials during transport and construction activities. The risk of significant hazards associated with the transport, use, and disposal of these materials is low.

Project areas would be tested for HTRW contaminants prior to construction, and any materials found would be disposed of by the non-federal sponsor in accordance with all Federal, State, and local laws and regulations at an approved disposal site. Implementation of these mitigation measures would reduce the impacts from hazardous materials at project sites to less than significant. If significant time has elapsed between approval of this document and construction, additional investigations should be done to reduce the risk of encountering a site during construction. If construction activities would occur in close proximity to sites listed in the existing conditions section, a Phase II ESA should also be conducted. This would further reduce the risk of exposure to workers and the public during construction and assist in the remediation planning.

Alternative 2 would have the same impacts as Alternative 1, with the additional affects associated with the expansion of the Sacramento Weir and Bypass. A known HTRW site, the Old Bryte Landfill, is currently present within the area proposed for the expanded Sacramento Bypass. No construction activities would occur in proximity to this site until the site has been completely remediated and meets all Federal, State, and local regulatory requirements. Therefore, this alternative would have no impacts.

Compliance with applicable laws and regulations would reduce the potential for accidental release of hazardous materials during construction of both Alternatives 1 and 2. The contractor would also be required to prepare a SWPPP, which details the contractors plan to prevent discharge from the construction site into drainage systems, lakes, or rivers. This plan would include BMPs, as detailed in Section 3.5.6 of the ARCF GRR EIS/EIR, which would be implemented at each construction site.

In addition, a SPCCP would be prepared prior to project construction. An SPCCP is intended to prevent any discharge of oil into navigable water or adjoining shorelines. The contractor would develop and implement an SPCCP to minimize the potential for adverse effects from spills of hazardous, toxic, or petroleum substances during construction and operation activities. The SPCCP would be completed before any construction activities begin. Implementation of this measure would comply with state and Federal water quality regulations. The SPCCP would describe spill sources and spill pathways in addition to the actions that would be taken in the event of a spill (e.g., an oil spill from engine refueling would be immediately cleaned up with oil absorbents). The SPCCP would outline descriptions of containments facilities and practices such as doubled-walled tanks, containment berms, emergency shut-offs, drip pans, fueling procedures and spill response kits. It would also describe how and when employees are trained in proper handling procedure and spill prevention and response procedures.

e. Aquatic Ecosystem and Organism Determinations

(1) Effects on Plankton

Plankton are drifting organisms that inhabit the pelagic zone of oceans, seas, or bodies of fresh water. Project construction activities would be temporary and short-term. The only short-term effect would be a less abundant supply of plankton for the Delta smelt, and other fish and aquatic organisms. With implementation of mitigation measures and BMPS, this project would not introduce materials that would disrupt the nutrient supply for plankton, and as a result effects to plankton would be temporary and not significant.

(2) Effects on Benthos

Benthic organisms may be disturbed during construction, but following construction, the rock berm would be covered with a silty soil layer, and native benthic organisms would be expected to recolonize the area.

(3) Effects on Nekton

Nekton are actively swimming aquatic organisms that range in size and complexity from plankton to marine mammals. Native fish present in the project area can be separated into anadromous species and resident species. Native anadromous species include four runs of Chinook salmon, steelhead trout, Delta smelt, and green sturgeon. All of these anadromous species are expected to use habitat in parts of the study area.

Within the ARCF GRR study area, the Sacramento River and Sacramento Bypass are designated critical habitat for winter-run Chinook salmon. Critical habitat for spring-run Chinook salmon includes all river channels and sloughs within the ARCF study area on the Sacramento River and on the American River from the confluence to the Watt Avenue bridge (NMFS 2006b). Critical habitat for Central Valley steelhead includes the stream channels and the lateral extent as defined by the ordinary high-waterline or bank-full elevation in the designated stream reaches of the Sacramento and American River, NEMDC and Dry/Robla Creek portions of the ARCF project area. Critical habitat for delta smelt consists of all water and all submerged lands below ordinary high water and the entire water column bounded by and contained in Suisun Bay (including the contiguous Grizzly and Honker bays); the length of Goodyear, Suisun, Cutoff, First Mallard (Spring Branch), and Montezuma sloughs; and the contiguous waters in the Delta (USFWS 1994). Critical habitat for delta smelt is designated in the following California counties: Alameda, Contra Costa, Sacramento, San Joaquin, Solano, and Yolo (USFWS 2003). Designated critical habitat for the southern DPS of green sturgeon includes the Sacramento River downstream of Keswick

Dam, the Feather River downstream of Oroville Dam, and the Yuba River downstream of Daguerre Dam; portions of Sutter and Yolo Bypasses; the legal Delta, excluding Five Mile Slough, Seven Mile Slough, Snodgrass Slough, Tom Paine Slough and Trapper Slough; and San Francisco, San Pablo, and Suisun bays.

Under Alternative 1 and 2, rock placement on the Sacramento River and American River would most likely disturb the native resident fish by increasing vibration, water turbulence, and turbidity, causing them to move away from the area of placement. In some pelagic native juvenile species utilizing the near shore habitat for cover, moving away from that cover could put them at a slight risk of predation. Direct effects to resident native fish species are less than significant, with the implementation of mitigation. Proposed mitigation for salmonid species includes the creation of planting berms to provide shade and instream woody material elements of SRA habitat. The natural bank element of SRA would be lost with the placement of rock along the levee slope. Over time sediment would settle into the rock voids and provide similar substrate characteristics as a natural bank. The direct effects would also not result in a substantial reduction in population abundance, movement, and distribution for salmonid species.

Alternative 1 and 2 would result in permanent impacts to 14 acres of Delta smelt shallow water habitat, and a change in substrate to 32 acres of Delta smelt spawning habitat. Construction-related effects include disruption of spawning activities, disturbance or mortality of eggs and newly hatched larvae, and alteration of spawning and incubation habitat. With the implementation of compensation for the impacts to Delta smelt shallow water habitat and spawning habitat, these effects would be reduced to less than significant.

Alternative 1 and 2 would result in significant, direct effects to green sturgeon through the loss of benthic feeding habitat due to the change in substrate at the bank protection sites. If larvae or juveniles are present during construction, in-water activities could result in localized displacement and possible injury or mortality to individuals that do not readily move away from the channel or nearshore areas. Project actions associated with bank protection measures may increase sediment, silt, and pollutants, which could adversely affect rearing habitat or reduce food production, such as aquatic invertebrates, for larval and juvenile green sturgeon. Compensation would be implemented for the impacts to benthic substrate, and construction-related monitoring would occur to help to better identify additional measures to reduce significant effects to green sturgeon.

Effects associated with Alternative 2 would be the same as described for Alternative 1 above. Proposed construction in the Sacramento Bypass would take place during the dry season when no water would be flowing through the project area from the Sacramento River. There would be no significant direct effects to native fish populations because they would not be present in the construction footprint during the proposed construction. By widening the Sacramento Weir and Bypass, the project would create additional floodplain habitat, which could benefit native fish consistent with the results of the Knaggs Ranch Study. The increase of floodplain habitat could increase opportunities for successful rearing and feeding during seasonal flooding.

Widening of the weir and bypass will increase the entrainment and stranding exposure and rates of juvenile fish species. When the weir is overtopping and water is flowing down the bypass, adult fish are attracted to the flow and follow it upstream in an attempt to reach their holding and spawning habitat. Widening the weir and bypass would increase the amount of water going over the weir and increase the attraction rate of sturgeon, salmon and steelhead. Without fish passage in place, the stranding rates of these fish would increase. Given that green sturgeon are long-lived species that have the strongest upstream migration and cohort replacement rates during wet water years and especially after high river flow conditions, the effect of the stranding occurring only two to three times over a 50 year period could be significant to sturgeon. Implementation of fish passage features, operational considerations, and grading of the expanded bypass to reduce stranding pits and ensure positive drainage would reduce these impacts to less than significant.

(4) Effects on Aquatic Food Web

Effects on the aquatic food web, or the plankton, benthic, and nekton communities, would be temporary and less than significant. Indirect effects were not considered significant to resident native fish species because it was determined that existing conditions would not be worsened by project construction, and would not result in a substantial reduction in population abundance, movement, and distribution.

(5) Effects on Special Aquatic Sites

(a) Sanctuaries and Refuges

No sanctuaries and refuges are within the project area.

(b) Wetlands

Approximately 0.4-acre of wetland could be filled and permanently lost during construction of both Alternatives 1 and 2. The Corps has proposed to purchase one acre of credit from a mitigation bank in order to compensate for this loss of habitat.

Wetlands in the existing Sacramento Bypass would not be impacted by construction of Alternative 2. There is a potential for additional wetlands to develop in the additional 300 acres since this land would no longer be farmed. The conversion of this land back to its natural state would have benefits to other wildlife and could become an expansion of the Sacramento Bypass Wildlife Refuge in Alternative 2.

Reasonable effort would be taken in the detailed design of the project to avoid disturbance to existing wetlands and implementation of environmentally sustainable designs. Any destruction, loss, or degradation of wetlands would be compensated through creation of new wetland habitat.

(c) Mud Flats

No mud flats are within the project area.

(d) Vegetated Shallows

No vegetated shallows are within the project area.

(e) Coral Reefs

No coral reefs are within the project area.

(f) Riffle and Pool Complexes

No riffle pool and complexes are within the project area.

(6) Threatened and Endangered Species

Implementation of Alternative 1 or 2 would result in direct effects to giant garter snake, valley elderberry longhorn beetle, salmonids, green sturgeon, Delta smelt, Western yellow-billed cuckoo, vernal pool crustaceans, and Swainson's Hawks. Impacts to special status fish species were addressed above in Section e(3), nekton.

Construction activities under Alternative 2 have the potential to affect giant garter snake and their habitat, due to the removal and relocation of farm canals and drainage ditches during construction of the Sacramento Weir and Bypass Widening. Giant garter snake habitat would be restored on site to the maximum extent practicable. Permanent impacts to giant garter snake habitat would be compensated through the purchase of credits at a mitigation bank.

Direct effects would occur to valley elderberry longhorn beetle due to the removal and transplanting of shrubs from the construction footprint on the American River and Sacramento River. Additionally, elderberry shrubs could be incidentally damaged by construction personnel or equipment. Potential impacts due to damage or transplantation include direct mortality of beetles and/or disruption of their lifecycle. The Corps will compensate for lost habitat onsite to the maximum extent practicable, create new offsite mitigation areas in coordination with the Sacramento County Department of Parks and Recreation, or purchase credits at a mitigation bank.

Adverse effects could occur to Western yellow-billed cuckoo and Swainson's hawk due to the removal of riparian vegetation during construction of Alternative 1 and 2 on the Sacramento River and American River. Swainson's hawk is known to nest within the study area. Prior to construction, the Corps would survey the construction area per the CDFW survey protocols and determine if nesting hawks are present. If they are present, buffers would be set up and the nests would be monitored. Additional avoidance and minimization measures would be coordinated with CDFW, as needed. Western yellow-billed cuckoo is not currently known to nest in the project area, however the riparian habitat along the American River is suitable nesting habitat for the cuckoo. Additionally, both rivers lie within the cuckoo's migratory corridor and they are likely to be present during their migration period. As a result, the Corps proposes to compensate for the removal of riparian vegetation onsite to the maximum extent possible. If onsite mitigation is not possible, offsite mitigation would occur in coordination with the Sacramento County Department of Parks and Recreation, or credits would be purchased at a mitigation bank.

Vernal pool tadpole shrimp and vernal pool fairy shrimp could be adversely affected by the removal of 0.25 acre of vernal pool habitat due under both Alternatives 1 and 2. During the design phase of the project, a wetland delineation and survey would be conducted near Magpie Creek to verify this impact. The Corps will compensate for this impact by purchasing 1 acre of credit from a mitigation bank.

Because avoidance, minimization, and compensation measures would be implemented in accordance with the requirements of the Endangered Species Act (ESA), California Endangered Species Act (CESA) and other relevant regulatory requirements, and the protect would protect habitat in place and create habitat, potential adverse effects on special-status species and on sensitive habitats would be reduced to a less than significant level.

(7) Other Wildlife

Wildlife effects associated with the construction are expected to be temporary and no additional measures to minimize effects are needed for fill occurring in the area. Under Alternative 1, construction of levee improvements and vegetation removal would result in significant loss of vegetation and wildlife habitat on the landside of the Sacramento River Parkway, and along Arcade Creek. Alternative 2 would have the same impacts on the project area in addition to the construction of the Sacramento Weir extension. That would require the widening of the Sacramento Weir and Bypass which would result in a reduced affect to landside vegetation and wildlife.

Because this area is very urbanized under Alternative 1, the primary effects to wildlife would be to avian species. Surveys would be conducted to determine if any nesting birds are present prior to construction. If nesting birds are located adjacent to the project area, coordination with the resource agencies would occur. Trees where nesting birds are located would not be removed while they are actively nesting. However, once the young have fledged the trees may be removed to construct the project. The same impacts apply to Alternative 2 with the addition of construction activities causing any wildlife within the bypass and adjacent areas to relocate to nearby rural lands and away from human activities. Once construction is complete the wildlife is expected to return to the area. Therefore, the impacts to wildlife in the Sacramento Bypass would be less than significant. Both native and non-native fish species, along with some endangered species, use this area of the river and are discussed in Fisheries (Section 3.7) and Special Status Species (Section 3.8).

Mitigation measures would include, when possible, in-kind compensation would be planted on planting berms, on top of launchable rock trenches, or on other lands within the Parkway. A hydraulic evaluation would be conducted to determine whether mitigation could occur in the Sacramento Bypass. Additional mitigation sites are identified in Section 3.6.6 of the ARCF EIS/EIR.

To compensate for the removal of 134 acres of riparian habitat supporting Swainson's hawks and other migratory birds approximately 268 acres of replacement habitat would be created as a mitigation area. Some areas that may be considered for mitigation are Cal Expo and Woodlake. For those mitigation lands within the American River Parkway species selected to compensate for the riparian corridor removal would be consistent with the approved list of trees, shrubs, and herbaceous plants native to the Parkway. Mitigation within the Parkway would provide contiguous habitat connectivity with wildlife migratory corridors that supports the needs of important native wildlife species, without compromising the integrity of the flood control facilities, the flood conveyance capacity of the Parkway, and Parkway management goals in the Parkway Plan. To comply with the Parkway Plan, lands within the Parkway will be evaluated for compensation opportunities for any riparian habitat removed from Parkway. The exact location of the compensation lands in the Parkway would be coordinated in the design phase of the project with Sacramento County Parks Department and comply with the Parkway Plan objectives and goals. It is assumed that sufficient lands will be available within the Parkway, however, if there is not sufficient land, other locations within Sacramento County will be identified and pubic coordination will occur. Additional mitigation may be planted in the expanded Sacramento Bypass or on other lands within the Sacramento area that provide similar value to those removed.

(8) Actions to Minimize Impacts

The proposed project is not likely to result in take to these species for either Alternative as long as the applicable conservation and mitigation measures, as detailed in Section 3.8.6 of the ARCF GRR EIS/EIR are adhered to. Among other measures listed in the EIS/EIR, the conclusion of non-jeopardy is based on the Corps' commitments to: (1) avoid direct impacts by maintaining buffers around sensitive habitat (e.g. 100-foot buffer for elderberry shrubs) and/or conducting construction activities outside of sensitive timeframes (e.g. during the giant garter snake active window or fledging period of special-status birds); (2) minimize wetland losses through the purchase of credits from an approved mitigation bank; (3) implement a SWPPP and associated BMPs; including the designation of staging areas for stockpiling of construction materials, portable equipment, vehicles, and supplies and (4) appoint onsight biologists to provide worker environmental awareness training to contractors and to monitor, report, and remove and transport special-status species if necessary or suspend construction activities until special-status species leave the project on their own. Concurrent implementation of these conservation measures would adequately avoid, minimize, and mitigate adverse effects on the special-status fish, wildlife and plant species discussed in this document.

f. Proposed Disposal Site Determinations

(1) Mixing Zone Size Determination

Not applicable.

(2) Determination of Compliance with Applicable Water Quality Standards

Water quality could be affected within the actual construction area and upstream and downstream of the work area. Construction activities such as rock placement, clearing and grubbing, and slope flattening, have the potential to temporarily degrade water quality through the direct release of soil and construction materials into water bodies or the indirect release of contaminants into water bodies through runoff.

The ARCF study is located within the jurisdiction of the Central Valley RWQCB, within the greater Sacramento Valley watershed. The preparation and adoption of water quality control plans, or Basin Plans, and statewide plans, is the responsibility of the SWRCB. State law requires that Basin Plans conform to the policies set forth in the California Water Code beginning with Section 13000 and any State policy for water quality control. These plans are required by the California Water Code (Section 13240) and supported by the Federal CWA. Section 303 of the CWA requires states to adopt water quality standards which "consist of the designated uses of the navigable waters involved and the water quality criteria for such waters based upon such uses." According to Section 13050 of the California Water Code, Basin Plans consist of a designation or establishment for the waters within a specified area of beneficial uses to be protected and water quality objectives to protect those uses. Adherence to Basin Plan water quality objectives protects continued beneficial uses of water bodies. Because beneficial uses, together with their corresponding water quality objectives, can be defined per Federal regulations as water quality standards, the Basin Plans are regulatory references for meeting the State and Federal requirements for water quality control (40 CFR 131.20). The potential effects of the proposed project on water quality have been evaluated and are discussed in Section 3.5 of the ARCF EIS/EIR. Compliance with the California Water Code will be accomplished by obtaining certifications from the Central Valley RWQCB prior to construction. In addition a CWA Section 404 review has been conducted internally by the Corps.

(3) Potential Effects on Human Use Characteristics

a) Municipal and Private Water Supplies

The Sacramento River waterways historically were used as places to dispose of contaminants. In recent decades, treatment for municipal wastewater, industrial wastewater, and management of urban stormwater runoff have increased and improved greatly. Industries and municipalities now provide at least secondary treatment of wastewater. The American River originates in the high Sierra Nevada just west of Lake Tahoe, in the Tahoe and El Dorado National Forests. Its three main forks – the South, Middle, and North – flow through the Sierra foothills and converge east of Sacramento. The waters of the American River provide recreation, municipal power, and irrigation for the northern California area. The fill material would not violate Environmental Protection Agency or State water quality standards or violate the primary drinking water standards of the Safe Drinking Water Act (42 USC 300f-300j). Project design, compliance with State water quality thresholds and standard construction and erosion practices would preclude the introduction of substances into surrounding waters. The groundwater table is separated from the slurry wall by a non-permeable layer of soil, therefore there would be minimal risk to groundwater supply. Materials removed for disposal off-site would be disposed of in an appropriate landfill or other upland area.

b) Recreation and Commercial Fisheries

Under Alternative 1, there would be temporary closure of recreation facilities in the American River Parkway during construction, including the bike trails, walking trails, and boat launches. Alternative 2 would affect the same facilities as Alternative 1, but the possible closure of the Sacramento Bypass during hunting season. Notification and coordination with recreation users and bike groups would be arranged. Flaggers, signage, detours, and fencing would be present to notify and control recreation access and traffic around construction sites.

Alternative 1 would cause indirect effects to fish habitat from the removal of vegetation from the levee slopes. Direct effects from the placement of rock at a bank protection sites would cause an increase in turbidity. The same effects for Alternative 1 apply for Alternative 2, with the addition of widening the Sacramento Bypass, which would create a floodplain that could provide a benefit to fish species. For Alternatives 1 and 2, a vegetation variance would allow waterside vegetation, which would include native grasses, shrubs, and trees, to remain on the lower one-third of the waterside slope along the Sacramento River. Bank protection sites and launchable rock trenches would be revegetated with native grasses, shrubs and trees following construction. BMPs would be implemented to address turbidity.

c) Water-related recreation

Recreational boating is one of the primary uses of the American River. Boat access is located at Discovery Park on both the Sacramento and American River side of the park. Boat launches within the Parkway are located at Howe Avenue, Watt Avenue, and Gristmill Park. The river can become very shallow between Sunrise and Howe Avenue when releases from Folsom Dam are reduced, making motorized boating impracticable. Rafting on this stretch of the river is very common during summer months with the highest use on the weekends and holidays.

Under Alternative 1, recreational resources that could potentially be affected by construction of the erosion protection measures include Paradise Beach, the Campus Commons Golf Course, the Guy West Bridge, and the boat launches at Howe Avenue, Watt Avenue, and Gristmill Park. Construction will also occur during the summer months when the Parkway recreation activities are at the peak. There would be short-term term significant effects along the Sacramento River reach of the project, however, there would be no long-term effects because the area would be returned to the pre-construction conditions once completed. The timing of construction cannot be mitigated as it is unsafe to perform construction activities in the floodway during the flood season.

Effects to recreation from the construction of levee improvements under Alternative 2 would be consistent with those analyzed for Alternative 1 with the addition of effects resulting from construction of levee improvements associated with the Sacramento Weir and Bypass widening. Impacts to water-related recreation are the same for both Alternatives.

If any access point needs to be closed during construction, notices will be posted providing alternative access routes. Any recreation facilities affected by the project would be replaced in-kind within the existing area and no long-term impacts are anticipated.

d) Aesthetics

Alternatives 1 and 2 would result in vegetation loss and construction activities would disrupt the existing visual conditions in the Parkway and along the Sacramento River. Native trees would be planted after construction is completed on planting berms and on top of launchable rock trenches; however, there would still be a temporal loss of vegetation. Disturbed areas would be reseeded with native grasses.

e) Parks, National and Historic Monuments, National Seashores, Wilderness Areas, Research Sites, and Similar Preserves

Many parks are located within the American River Parkway portion of the study. Following is a description of the parks and their activities.

<u>Discovery Park</u>. Located just north of downtown Sacramento at the confluence of the American River and the Sacramento River, this 302-acre park is a popular site for rafters and waders. Discovery Park is the trailhead for the 32-mile long Jedediah Smith Memorial Trail. The park also features a boat launch. Discovery Park was designed to flood and take pressure off American River levees during high water events. For safety reasons, the park closes when water flows into the public areas and remains closed until the water subsides.

<u>Sutter's Landing Regional Park</u>. Nestled along the banks of the American River about a mile northeast of downtown Sacramento, this 172-acre park currently offers a wide variety of recreational opportunities including a covered skateboard park, a dog park, picnic areas, basketball and bocce ball courts, as well as access to trails along the American River and a boat launch for kayaks, canoes, and other non-motorized boats. Visitors can also see a diversity of wildlife at this site including river otters, beavers, jackrabbits, cottontails, coyotes, raccoons, gopher snakes, fence lizards, skunks, ground

squirrels, voles, and an occasional sea lion, as well as a wide variety of bird species ranging from shorebirds and waterfowl to raptors making it an ideal location for nature watching as well as birding. Other popular activities at this location include walking, jogging, and biking.

Paradise Beach. Just off of U.S. 50 at Howe Avenue, Paradise Beach offers a sandy beach area and is a popular spot for swimming.

Campus Commons Golf Course. Built in 1972, the 1,699 yard Campus Commons Golf Course is a public nine hole executive course located just north of California State University Sacramento, along the American River.

Guy West Bridge. The Guy West Bridge is a pedestrian-only suspension bridge crossing the historic Lower American River. It is modeled after the famed Golden Gate Bridge in San Francisco, but spans only 600 feet compared to the Golden Gate's 6,450 feet. The bridge was constructed to tie the California State University campus to a business and residential community on the north side of the American River.

Howe Avenue. Located down river from California State University, Sacramento, this car-top launch site allows small boats and rafts to be launched into the American River. Because of the swift rapids, this site is not conducive to swimming and wading.

Waterton and Save the American River Association. Just off of U.S. 50 at Watt Avenue, Waterton Access is a small site providing access along the river. The area is inhabited by deer and jackrabbits, so it is ideal for nature watching. The nearby Save the American River Association Access offers similar opportunity.

Watt Avenue. Just off Watt Avenue is an American River access point popular as a take-out spot for rafters, canoeists, and kayakers. Fishing is also popular here because of the range of shallow and deep water.

Gristmill Park. Located off Mira Del Rio Drive and Folsom Boulevard in Rancho Cordova, Gristmill Park is a popular place for fishing, bird watching, and nature watching/photography. The area also has some nice walking paths popular with the locals that wind through oak woodlands along the southern bank of the river in either direction from the parking area. In addition to the usual assortment of birds in these woodlands such as woodpeckers, Northern flickers, and red-shouldered hawks, it is not unusual to spot deer and coyote here as well. Due to the calmness of the river at this location, it is a popular launch spot for kayaking and canoeing.

William Pond Recreation Area. Located off Arden Way, the William Pond Recreation Area is one of the most well-established and popular parks along the river. Named in honor of the first director of County Parks, the park is handicap-friendly and offers a man-made fishing pond with a specialized fishing pier and ramp and paved walking trails that gently slope around the park.

River Bend Park (formerly Goethe Park). River Bend Park, formerly C.M. Goethe Park, is one of Sacramento's oldest county parks. It is located at U.S. 50 and Bradshaw Road and offers many recreation facilities. Horse and hiking trails wind through the park for plenty of wildlife viewing. This facility also has large group picnic sites often used for community events. River Bend Park is the endpoint for many recreational rafters on the American River.

Soil Born Farms. Located on the American River in Rancho Cordova (40 acres) and in Sacramento on Hurley Way (1.5 acres), Soil Born Farms organically grows a wide variety of fruits and vegetables linked to the seasons and temperament of the Sacramento region. All produce is harvested within a day of distribution to local restaurants, famers markets, and at their own farm stand at the American River ranch location from May to November. This nonprofit farm is actively involved in fostering organic farming through their farm apprentice program and youth education. All water used in irrigation comes from the American River and no synthetic pesticides or fertilizers are used.

Miller Park. Adjacent to the Sacramento Marina, off Harborview Drive from Front Street, this 57 acre city park is right on the Sacramento River. The park includes picnic areas, boat trailer parking, and a boat ramp and dock. There is also a store called Rat's Snack Shop.

Garcia Bend Park. Located between Pocket Road and the Sacramento River, this 19-acre community park is a popular place for recreation providing soccer fields, lighted tennis courts, play areas, picnic areas, restrooms, and a public boat ramp providing access to the Sacramento River.

The Riverfront Promenade. A new addition to Sacramento's riverfront, a couple blocks were opened in 2001. It is located just downstream of Old Sacramento and is still in the early stages of development. When complete, the promenade will be a mile long walking and cycling path that connects Old Sacramento to Miller Park.

For Alternative 1, construction of erosion protection measures is expected to take up to 10 years, with construction occurring in multiple locations within the Parkway at the same time. While this would not be a permanent long-term affect, 10 years of linear construction would be considered a significant effect to recreation activities because it would reduce the quality of existing recreation activities. Portions of the road on top of the levee would be closed to pedestrian access during the construction period. Additionally, construction of the launchable rock trench would temporarily disturb several miles of bike trails as well as access to public parks and boat launches within or adjacent to the Parkway. Such closures and disturbances would result in non-compliance with the American River Parkway Plan which states that flood control berms, levees and other facilities should be, to the extent consistent with proper operation and maintenance of these facilities, open to the public for approved uses, such as hiking, biking and other recreational activities. Once construction is complete the recreation facilities would be returned to the pre-construction conditions and long term effects would be less than significant.

These closures and disturbances would also result in direct and adverse effects to recreation, an outstandingly remarkable value under the Wild and Scenic Rivers Act. Recreational resources that could potentially be affected by construction of the erosion protection measures include Paradise Beach, the Campus Commons Golf Course, the Guy West Bridge, and the boat launches at Howe Avenue, Watt Avenue, and Gristmill Park.

Effects to recreation from the construction of levee improvements under Alternative 2 would be consistent with those analyzed for Alternative 1 with the addition of effects resulting from construction of levee improvements associated with the Sacramento Weir and Bypass widening. Construction of levee improvements associated with the Sacramento Weir and Bypass widening would have possible short-term effects on recreational use. During construction, certain areas would be closed to the public while other areas might be used as haul routes or borrow/disposal sites. Activities such as bird watching, walking, running, and jogging along the Sacramento Bypass levee crown and nearby roads would be restricted. Construction activities could potentially overlap with hunting season in the Sacramento Bypass Wildlife Area, which occurs from September 1 through January 31, restricting hunting activities for a limited period of time. In addition, there may be temporary effects to the Yolo Shortline Railroad. Construction activities would have a significant effect on the Yolo Shortline Railroad as portions of the railway may have to be shut down or relocated during construction activities.

To ensure public safety, flaggers, warning signs, and signs restricting access would be posted before and during construction, as necessary. In the event that bike trails would be disrupted, detours would be provided. Detour routes would be clearly marked, and fences would be erected in order to prevent access to the project area. In areas where recreational traffic intersects with construction vehicles, traffic control will be utilized in order to maintain public safety. The public will have continued access to the Parkway and recreation facilities during construction, but bike and running trail users would likely be required to detour onto public roads or alternative trails. If any access point needs to be closed during construction, notices will be posted providing alternative access routes.

These mitigation measures will reduce the effects on recreation; however, impacts would still be significant because of the duration of construction and the inability to provide similar quality recreation during construction. Any recreation facilities affected by the project would be replaced in-kind within the existing area and no long-term impacts are anticipated.

g. Determination of Cumulative Effects on the Aquatic Ecosystem

Effects of the proposed action include reductions in nearshore aquatic and riparian habitats that are used by aquatic and terrestrial species. Corps actions which could create a cumulative effect on waters of the U.S. in the Sacramento area include the West Sacramento Project, the Southport Early Implementation Project, the American River Common Features Project, the North Sacramento Streams Project, the Sacramento River East Levee Project, and the Sacramento River Bank Protection Project (SRBPP). The North Sacramento Streams Project and the Sacramento River East Levee Project are proposed by SAFCA to construct certain features that are also part of the ARCF GRR Alternative 2. The

North Sacramento Streams Project includes proposed measures on Arcade Creek and NEMDC, and the Sacramento River East Levee Project includes the seepage and stability measures on the Sacramento River that are also proposed by the Corps under the ARCF GRR project, but with limited erosion protection.

The purpose of the West Sacramento Project is to investigate and determine the extent of Federal interest in plans that reduce flood risk to the City of West Sacramento. The proposed alternative for this project consists of levee improvements to 50 miles of existing levees surrounding the city and extending down along the Sacramento Deep Water Ship Channel to address identified seepage, stability, and erosion concerns through the construction of slurry walls and bank protection. In addition, the project proposes to set back the Sacramento River levee in the Southport area of West Sacramento. The recommended West Sacramento Project includes the geographic area and project features that are also being considered in the Southport Early Implementation Project. The Southport Early Implementation Project is being proposed by the West Sacramento Area Flood Control Agency and the State of California to provide 200-year protection consistent with the State's goal for urbanized areas, as well as to provide opportunities for ecosystem restoration and public recreation. The Southport Early Implementation Project's proposed alternative includes the Sacramento River setback levee in the Southport area of West Sacramento. The Southport project is planned to begin construction in 2016. The West Sacramento and Southport projects propose to implement a combined 16,000 linear feet of rock protection on the west bank of the Sacramento River in the study area.

The SRBPP was authorized to protect the existing levees and flood control facilities of the SRFCP. The SRBPP is a long-range program of bank protection authorized by the Flood Control Act of 1960. The SRBPP directs the Corps to provide bank protection along the Sacramento River and its tributaries, including that portion of the lower American River bordered by Federal flood control project levees. Beginning in 1996, erosion control projects at five sites covering almost two miles of the south and north banks of the lower American River have been implemented. Additional sites at RM 149 and 56.7 on the Sacramento River totaling one-half mile have been constructed since 2001. During 2005 through 2007, 29 critical sites totaling approximately 16,000 linear feet were constructed under the Declaration of Flood Emergency by Governor Schwarzenegger. This is an ongoing project, and additional sites requiring maintenance will continue to be identified indefinitely until the remaining authority of approximately 24,000 linear feet is exhausted over the next 3 years. WRDA 2007 authorized an additional 80,000 linear feet of bank protection, however sites for implementation have not been selected at this time.

The construction periods and related effects from these projects could all occur simultaneously. For the ARCF and West Sacramento projects, to include the Sacramento River East Levee Project and the Southport Project, this means that similar construction-related effects such as rock placement or tree removal could be occurring at the same time for the stretch of the projects from the I Street Bridge to the Stone Locks. To avoid potentially significant construction-related cumulative effects, the two projects would coordinate to ensure that construction sites are offset from each other (i.e., sites directly across the Sacramento River from each other where there is bank protection being installed, specifically from the I-Street Bridge downstream to the Stone Locks, would not be constructed in the same construction season). These are also different types of bank protection. The West Sacramento side has some berm between the levee and the channel, and therefore it is really a "bank" fix, while the ARCF side has levee toe underwater and includes rock berm. Both of these projects propose to implement planting berms and new SRA habitat, and to protect lower waterside trees in place to preserve the existing habitat to the maximum extent possible.

Additionally, levee maintenance activities by state agencies and local reclamation districts are likely to continue, although any effects on waters of the U.S. will be addressed through the Section 404 permitting process with the Corps Regulatory Division. Potential cumulative effects on the aquatic ecosystem could include: wave action in the water channel caused by boats that may degrade riparian and wetland habitat and erode banks; dumping of domestic and industrial garbage; land uses that result in increased discharges of pesticides, herbicides, oil, and other contaminants; and conversion of riparian areas for urban development.

h. Determination of Secondary Effects on the Aquatic Ecosystem

The placement of rock would not only reduce the risk of erosion, but would also anchor remaining trees in place and reduce the potential for trees falling over during a high flow event. The understory, which provides habitat for small rodents, ground nesting birds and waterfowl, and various reptiles, would be removed in order to provide a clean surface to place the rock. Because the riprap is a hard surface it would not support the growth of large amounts of vegetation. In areas with a soil trench or soil placed over rock on the lower portion of the slope vegetation would be planted or allowed to establish naturally. The riprap would also provide basking areas for some small reptiles such as snakes and lizards. Because the riparian corridor and shaded river aquatic habitat left in place would still provide value to fish and wildlife species, and compensatory mitigation would be implemented for trees that were removed, impacts are consider less than significant.

Risk exists for the unintentional placement of dredge and/or fill material to be placedoutside of the proposed project area. Unintentional placement could result in additional adverse impacts to water quality, erosion and accretion patterns, aquatic and other wildlife habitat, recreation, aesthetics and air quality. In order to reduce the risk of such impacts, contract specifications would require the contractor to mark the project boundaries, and that the contractor install erosion control (i.e. silt fencing, silt curtains) where possible within any standing waters.

III. Findings of Compliance or Non-Compliance with the Restrictions on Discharge

a. Adaptation of the Section 404(b)(1) Guidelines to this Evaluation

No significant adaptations of the guidelines were made relative to this evaluation.

b. Evaluation of Availability of Practicable Alternatives to the Proposed Discharge Site

The only practicable alternative to the proposed bank protection sites along the American River is the launchable rock trench measure, which was described in Section I(h) above. This measure would involve digging a trench in the berm at the waterside toe of the levee and filling it with rock. The rock would be covered with soil, and as the berm slowly erodes away during a high water event, the rock would "launch" and cover the bank to form a barrier to prevent further erosion. While this measure would minimize impacts associated with the placement of fill in waters of the U.S., it would still result in the removal of 0.40-acre of wetlands on the south bank of the American River. Additionally, this measure would result in significant impacts to vegetation, wildlife, and recreation during construction due to the removal of 65 acres of riparian habitat during construction, and disruption or closure of trails within the American River Parkway during construction. It is anticipated that this measure will be used in some locations on the American and Sacramento Rivers, however, the least environmentally damaging alternative would be a combination of both this measure and bank protection, with onsite environmental and recreational conditions taken into account when selecting the appropriate measure. Implementation of the launchable rock trench would reduce the quantity of fill in the American River from what was analyzed in this 404(b)(1) analysis by reducing the quantity of in-river bank protection required, while implementation of the bank protection would reduce significant effects on riparian habitat, recreational resources, and could avoid impacts to 0.40-acre of wetlands..

Additionally, in some locations where the river flow velocity is low, it may be practicable to use a biotechnical measure rather than bank protection or launchable trenches to provide erosion protection. This measure would involve using biomaterials such as fallen trees to protect the banks from erosion. This would be the least environmentally damaging measure, however it is not practicable for the majority of the river because currents are too strong. As a result there are only minimal locations where this measure could be feasibly implemented.

Because of the significant effects associated with the launchable rock trench measure, the feasibility of the biotechnical measures, and the placement of fill associated with the bank protection measure, a combination of these measures would be the least environmentally damaging practicable alternative.

c. Compliance with Applicable State Water Quality Standards

The proposed project would implement BMPs to ensure that it does not violate State water quality standards identified in the Central Valley Basin Plan (CVRWQCB 1998).

d. Compliance with Applicable Toxic Effluent Standard or Prohibition Under Section 307 of the Clean Water Act

The discharges of fill materials will not cause or contribute to, after consideration of disposal site dilution and dispersion, violation of any applicable State water quality standards for waters. The discharge operations will not violate the Toxic Effluent Standards of Section 307 of the Clean Water Act.

e. Compliance with Endangered Species Act of 1973

The placement of fill materials in the project area(s) will not jeopardize the continued existence of any species listed as threatened or endangered or result in the likelihood of destruction or adverse modification of any critical habitat as specified by the Endangered Species Act of 1973.

f. Compliance with Specified Protection Measures for Marine Sanctuaries Designated by the Marine Protection, Research, and Sanctuaries Act of 1972

Not applicable.

g. Appropriate and Practicable Steps Taken to Minimize Potential Adverse Impacts of the Discharge on the Aquatic Ecosystem

Appropriate and practicable steps to minimize potential adverse effects of discharge and fill on the aquatic ecosystem include: placing fill material only where it is needed for the proposed project and confining it to the smallest practicable area. The areas disturbed by construction would be returned as close as possible to pre-project conditions when practicable.

On the basis of the guidelines, the proposed project is specified as complying with the inclusion of appropriate and practical conditions to minimize pollution or adverse effect on the aquatic ecosystem. Alternative 2 has been identified as the Least Environmentally Damaging Practicable Alternative, as it minimizes the footprint of the levee improvements through the removal of the majority of the levee raises along the Sacramento River, results in less impacts to aquatic resources, and also proposes to create approximately 300 acres of new floodplain habitat through the widening of the Sacramento Bypass.

INTRODUCTION

This appendix provides responses to public and agency comments on the American River Common Features (ARCF) Draft Environmental Impact Statement/ Environmental Impact Report (EIS/EIR) and General Reevaluation Report (GRR), as received during the public comment period.

PUBLIC COMMENT SUMMARY

The draft GRR and EIS/EIR were circulated for public review beginning on March 13, 2015. The notice of availability (NOA) was published in the Federal Register on March 13, 2015. The draft GRR and EIS/EIR were made available both on the Sacramento District, Corps of Engineers website as well as the website for the Central Valley Flood Protection Board. Hard copies of the draft GRR and EIS/EIR were provided to area libraries. Letters and/or DVD copies of the GRR and EIS/EIR were sent to interested parties, local residents, and to the agencies and elected officials listed in Section 6.4 of the EIS/EIR. Public workshops were held during the review period to provide additional opportunities for comments on the draft documents. All comments received during the public review period were considered and incorporated into the final GRR and EIS/EIR as appropriate. The meeting locations, dates and times were as follows:

- April 8, Hagginwood Community Center—3270 Marysville Blvd, Sacramento (5-7 p.m.).
- April 9, Elk's Lodge— 6446 Riverside Boulevard, Sacramento (5-7 p.m.).
- April 15, Library Galleria—828 I Street, Sacramento (3-5 p.m.).
- April 17, Arden-Dimick Library— 891 Watt Ave., Sacramento (5-7 p.m.).

A total of 137 people attended the four meetings. Comments were solicited through the use of court reporters at the meetings. Additionally, comments could be submitted through mail or electronic mail. Oral and written comments were made throughout the series of meetings by local, State, and Federal agencies, community organizations, and individuals.

During the Draft EIS public review period, a total of 471 comments were received from the public in the following manner:

- 39 different parties commented, including 2 Federal agencies, 7 State of California agency, 9 local agencies and organizations, 1 Native American Tribe, and 20 private citizens.
- 9 people presented verbal comments to the court reporter at the public meetings.
- 4 people left hand-written comment cards at the public meetings.

A summary of the major issues from the public comments are included below. Original letters, e-mails, and the transcripts of the public hearings follow. Responses to the public comments are included in the table that follows.

RESPONSES TO PRIMARY COMMENTS

Public comments on the draft documents focused in part on: 1) access to recreational features during and after construction; 2) design, placement and justification for rock erosion protection along the American and Sacramento Rivers; 3) effects to vegetation as a result of the recommendations; 4) clear presentation of the anticipated level of the performance of the project; and 5) coordination with stakeholders in future phases of the project.

MATRIX OF COMMENTS AND RESPONSES

The following pages include the posters from the public scoping meeting. Following the posters are all public comments received and a matrix of the Corps' responses to those comments. The responses are annotated to refer back to the corresponding letters and comments that precede them. Each letter and comment has been annotated with a designation such as "C-5". The letter, "C" refers to the comment letter, and the number, "5" refers to the comment number within the letter.

Welcome

Introduction

Sacramento Area Levee Improvements

- Together, the State of California, Sacramento Area Flood Control Agency and the U.S. Army Corps of Engineers have made tremendous progress in reducing flood risk for Sacramento – perhaps America's most at-risk city for severe flooding.

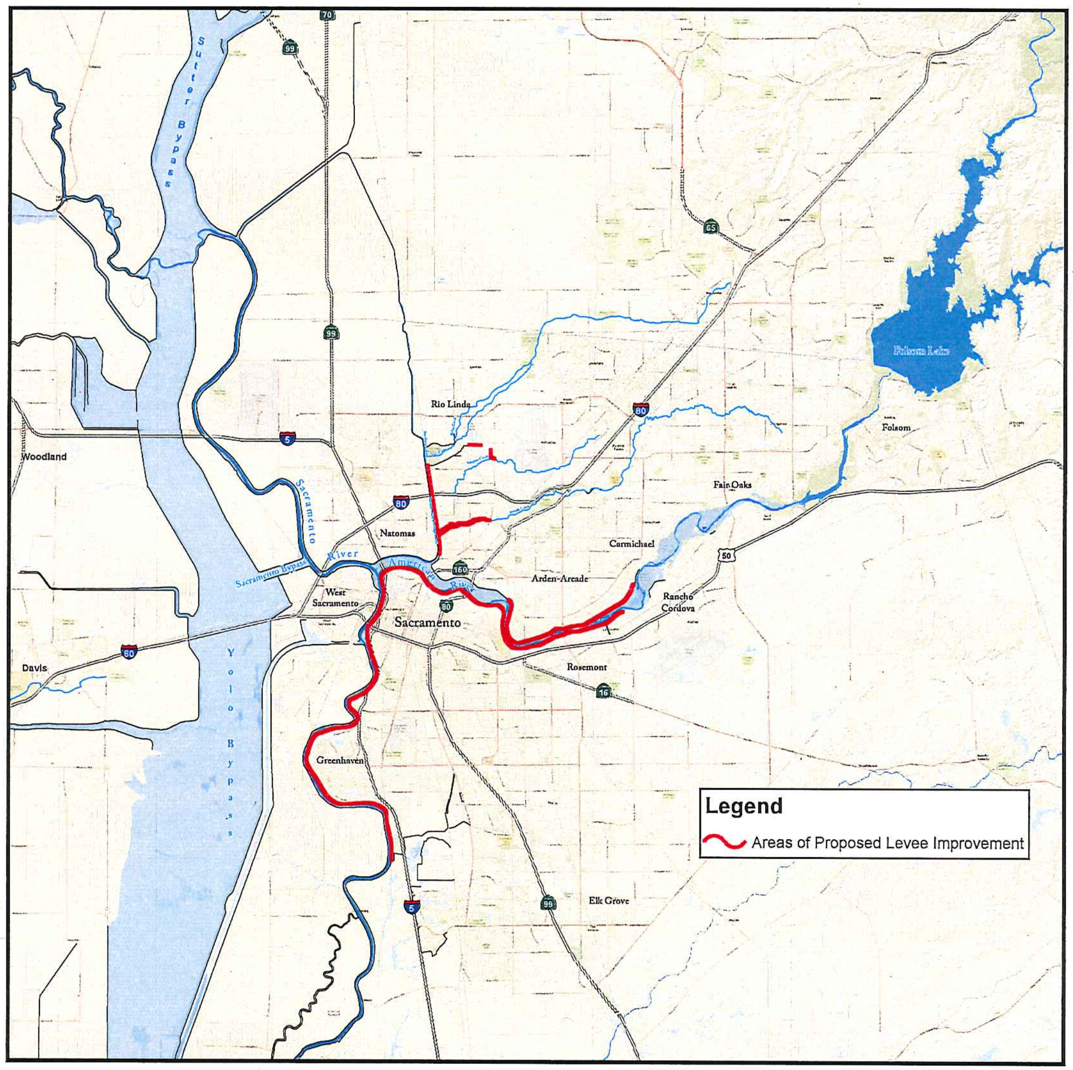
- Modernizing Sacramento's aging flood infrastructure still requires a lot of work. These proposed plans recommend $1.46 billion in further improvements to modernize Sacramento's flood infrastructure so it reliably and sustainably reduces Sacramento's flood risk for decades to come.

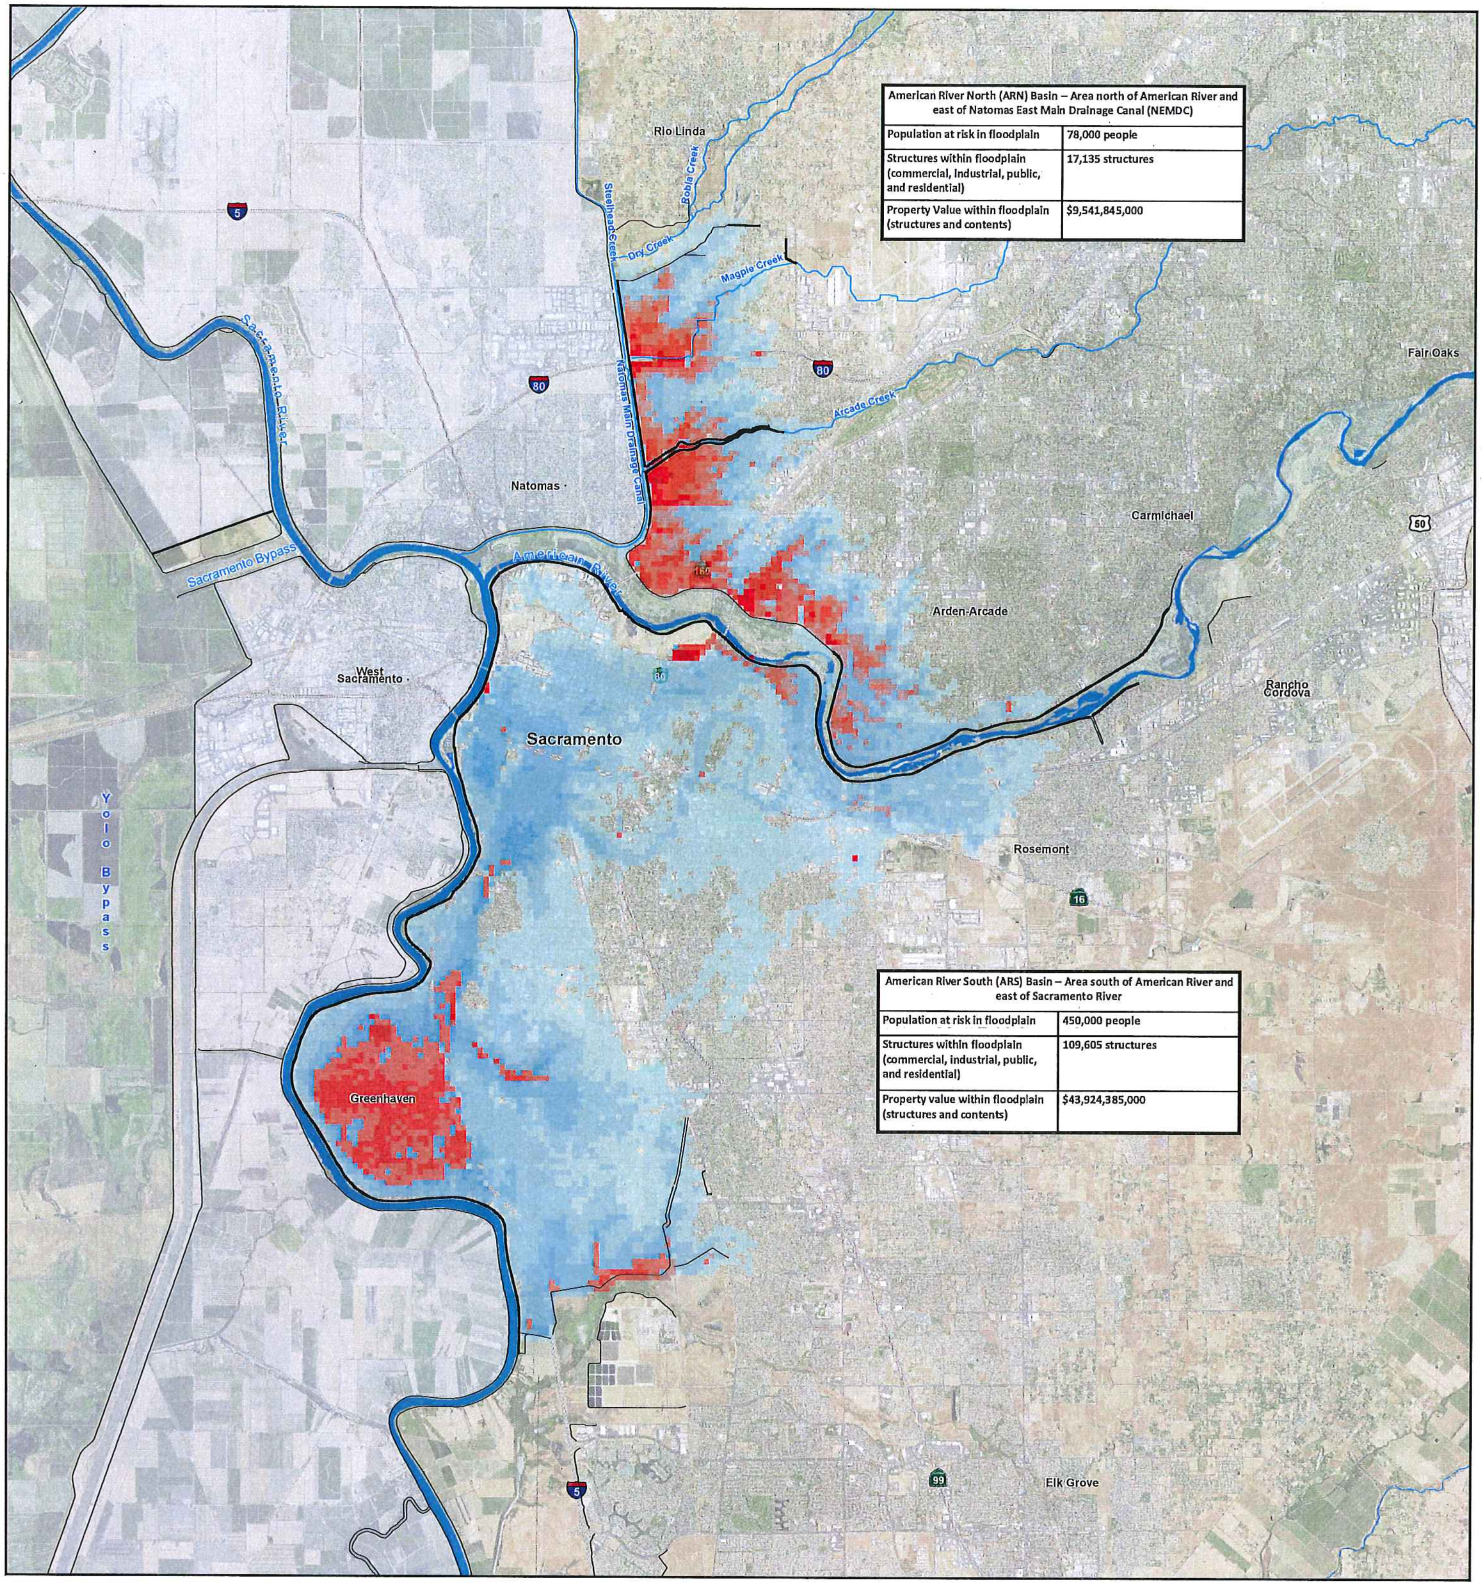
- SAFCA's plan and the Corps' are well coordinated and work together to achieve the same goals.

- We need your feedback. These proposals are drafts, and this is your chance to have a say in the development of the project.

US Army Corps of Engineers

SAFCA





American River North (ARN) Basin – Area north of American River and east of Natomas East Main Drainage Canal (NEMDC)	
Population at risk in floodplain	78,000 people
Structures within floodplain (commercial, industrial, public, and residential)	17,135 structures
Property Value within floodplain (structures and contents)	$9,541,845,000

American River South (ARS) Basin – Area south of American River and east of Sacramento River	
Population at risk in floodplain	450,000 people
Structures within floodplain (commercial, industrial, public, and residential)	109,605 structures
Property value within floodplain (structures and contents)	$43,924,385,000

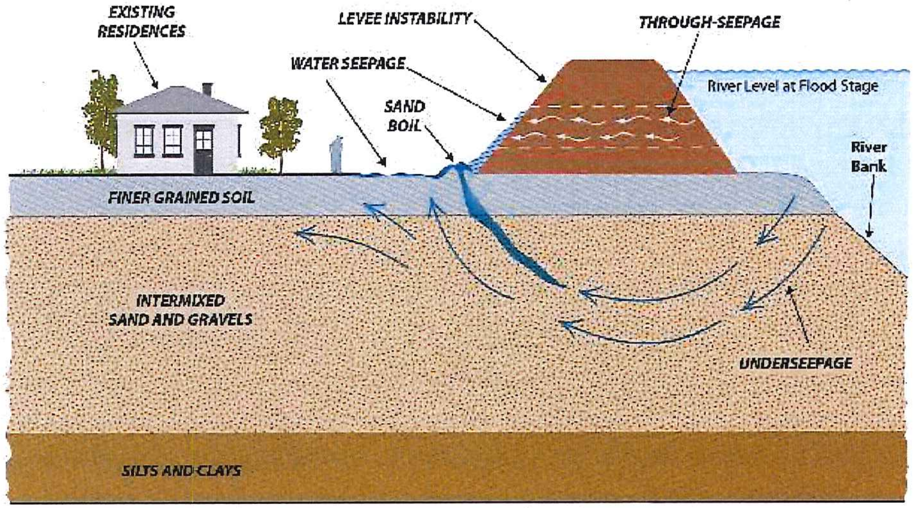
Seepage & Stability Issues



Seepage and stability problems

Levee Instability:

Saturated soil and sand layers may cause levee slopes to slump, or levee foundation to settle risking levee failure at flood stage.

Levee Through-Seepage:

When the river is approaching flood stage, high water pressure at some locations causes seepage through the levee.

Levee Underseepage:

High river levels lead to seepage through sandy and gravelly soils. High water pressure beneath the surface can emerge at the landside levee toe, causing sand boils, and can also appear at the surface up to several hundred feet landside of the levee. Sand boils could cause loss of levee foundation, and eventual collapse of levee.

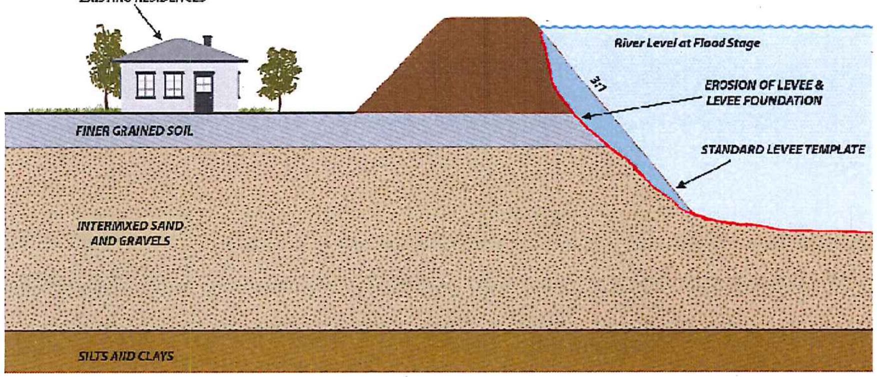
Seepage problem

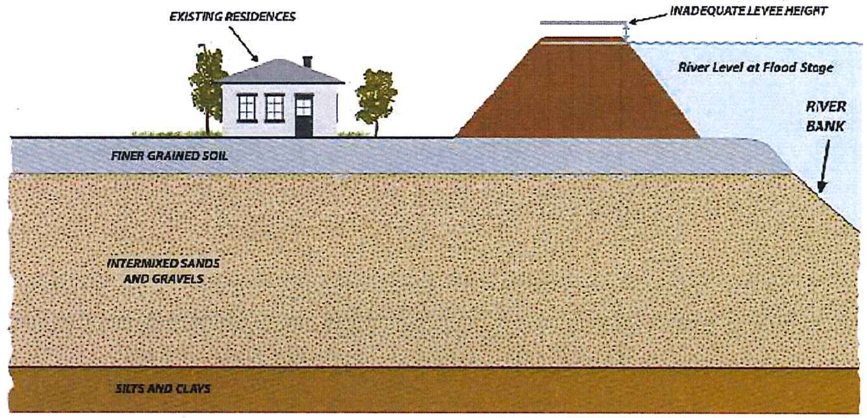
Levee instabiity problem

US Army Corps of Engineers

SAFCA

Erosion & Height Issues





Levee Erosion Problems:

River currents remove soil material from channel bank. Eventually, or sometimes suddenly, a portion of the levee and/or levee foundation erodes away which greatly reduces the stability of the levee.

Levee Height Problems:

Levee height may be too low to contain high river flows, account for uncertainty in the design water level, and/or contain wind-wave run-up.

Erosion problems

Erosion problems

Levee overtopping problem

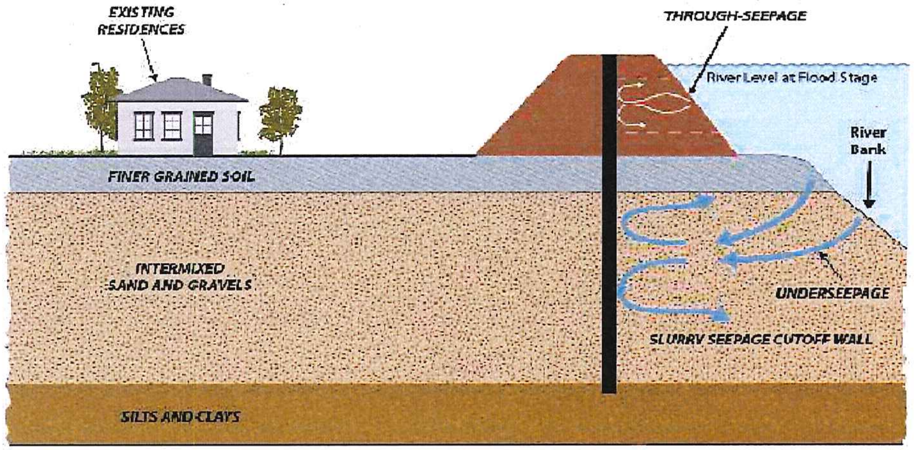
What We've Accomplished

N
0 1 2 4 6 8
Miles

SAFCA
Sacramento Area Flood Control Agency

Seepage & Stability Addressed



Levee Seepage:

Primarily addressed by constructing a seepage cutoff wall. Water pressure is greatly reduced as it passes through the wall so that seepage and boils on the landside toe are either eliminated or greatly reduced.

Levee Instability:

Stability problems are typically addressed by construction of a seepage cutoff wall, with either soil reinforcement or levee slope flattening improvements constructed. In areas needing soil reinforcement, geotextiles will be placed within the levee in layers. In areas needing slope flattening, new soil material will be added to the levee slope and compacted.

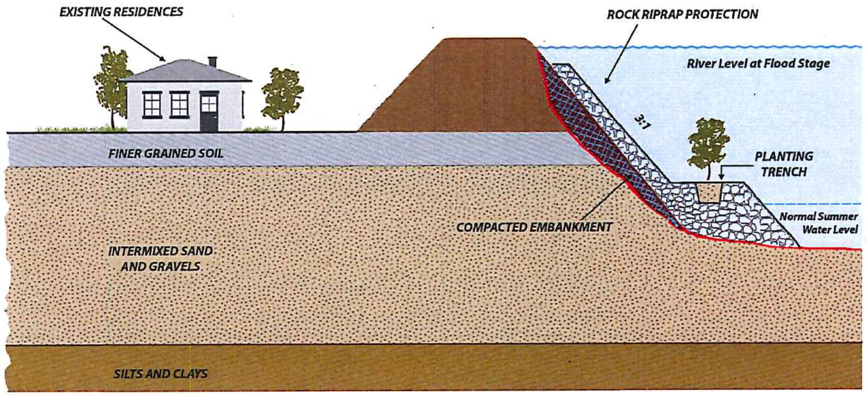
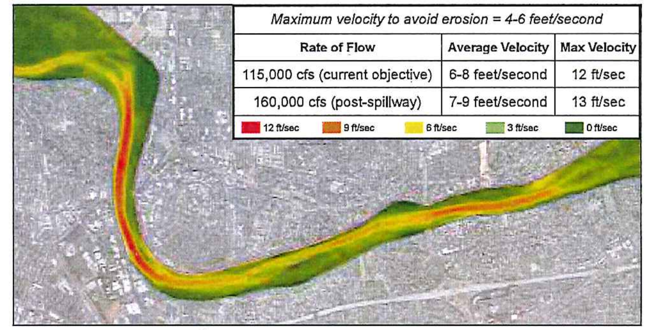
Erosion Addressed



Levee Erosion:

Primarily addressed by placing rock riprap revetment either on channel bank or at toe of levee. Construction from barge preferred, where practical.

Velocity:

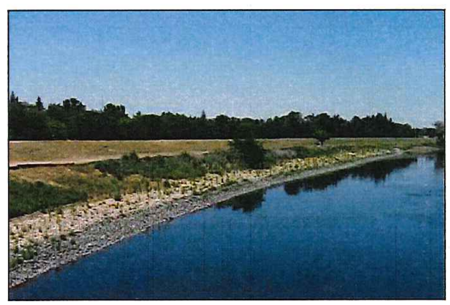


Maximum velocity to avoid erosion = 4-6 feet/second

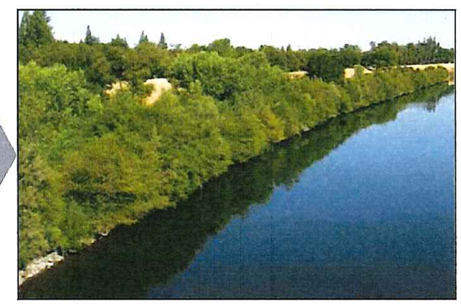
Rate of Flow	Average Velocity	Max Velocity
115,000 cfs (current objective)	6-8 feet/second	12 ft/sec
160,000 cfs (post-spillway)	7-9 feet/second	13 ft/sec

Levees were historically constructed from highly erodible mining deposits and sands, close to the main channel so more land was available for urban development. The American River downstream of Folsom Dam is very steep, creating faster, stronger stream flows confined between levees that could promote erosion. History shows that a levee can fail because of erosion on American River, and Sacramento will experience significant flood risk reduction when the issue is addressed.

Typical bank protection placing rock riprap revetment from barge



Typical bank protection as constructed at Lower American River Site 4 between Guy West bridge and H Street Bridge in 2001



Lower American River Site 4 in 2010

US Army Corps of Engineers

SAFCA

Height Addressed: Bypass vs. Levee Raise

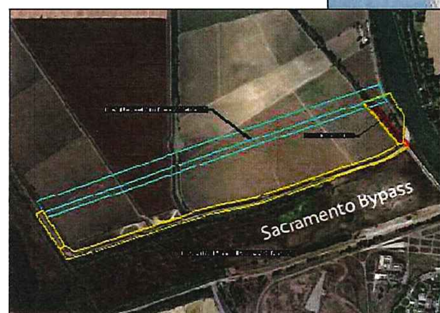
Sacramento Area Levee Improvements

In order to convey a flood event with an annual chance of exceedance of 1 in 200, the Sacramento River downstream of the American River requires either eight miles of levee to be raised or a combination of conveyance improvements with less than one mile of levee raising.

Alternative 1 (NED plan) shows approximately 8 miles of levee raises.

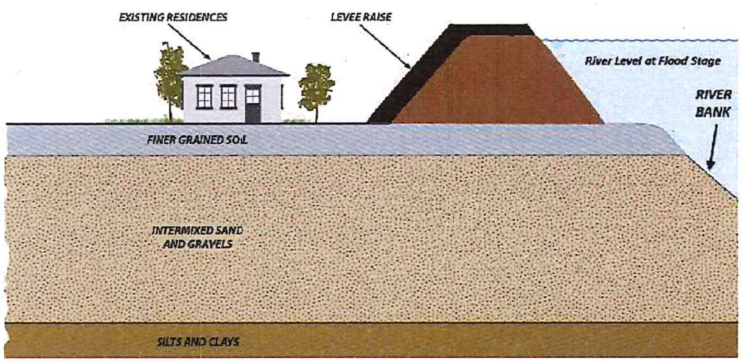
Alternative 2 (recommended plan) relies upon widening the Sacramento Weir and Bypass, reducing the need to raise the levees identified in the NED plan. Less than one mile of levee raising would still be necessary.

Alternative 2 is recommended because it requires less raise construction and improves the operational flexibility provided by widening the Sacramento Weir and Bypass.



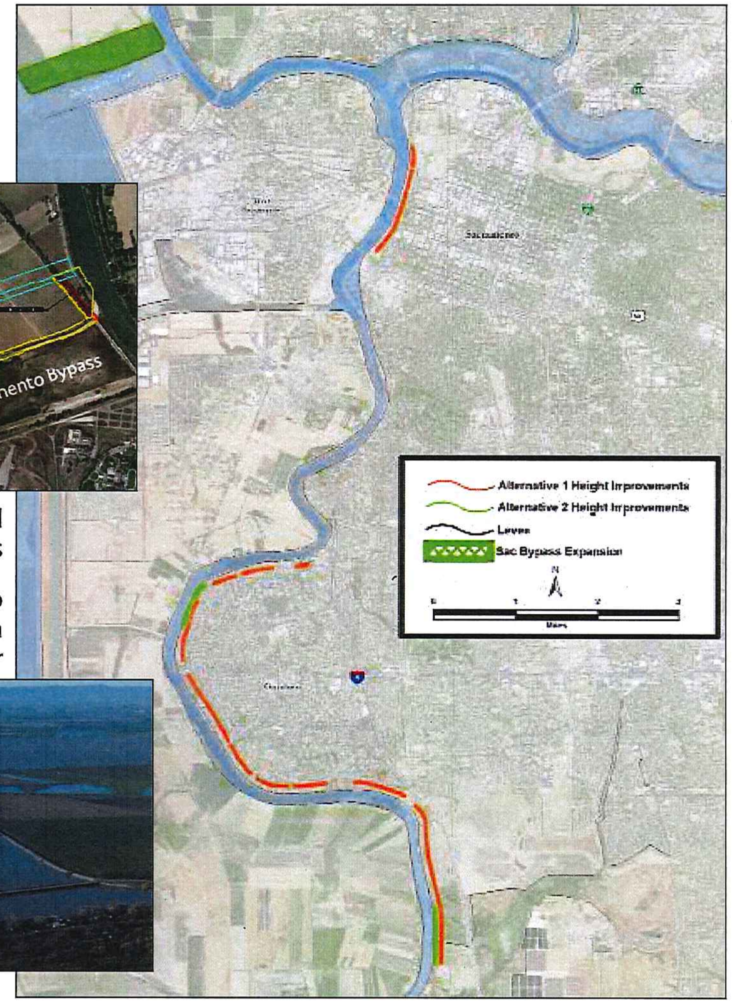
ABOVE: Drawing of widened Sacramento Weir & Bypass

BELOW: Aerial of Sacramento Weir and bypass from Sacramento River



Levee Height:

Primarily addressed by raising levee with soil or constructing a floodwall on top of levee. In some cases, the need to increase levee height can be reduced by diverting flow away from the river such as by widening Sacramento Weir & Bypass.

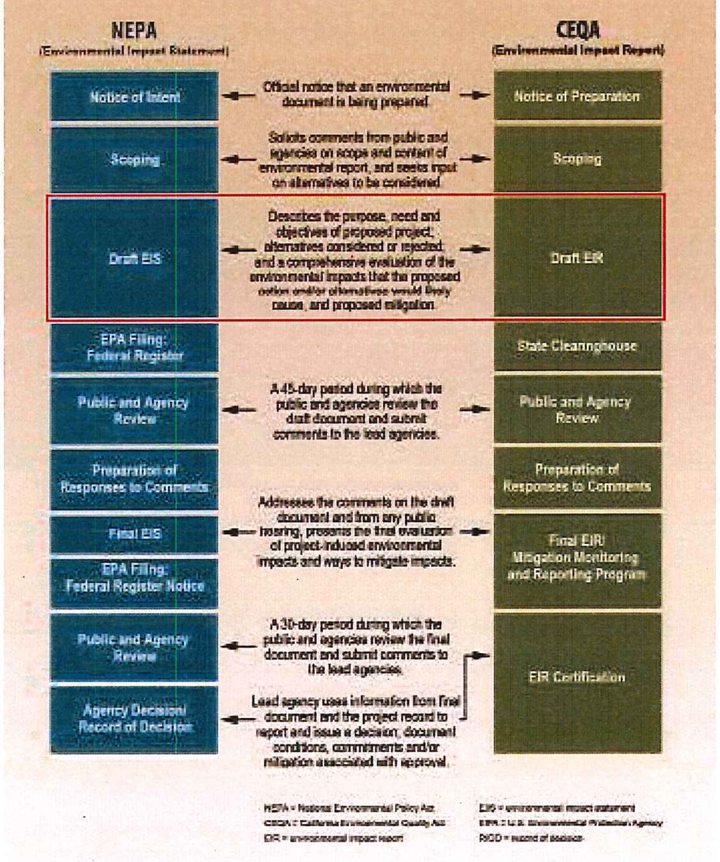


US Army Corps of Engineers

SAFCA

NEPA/CEQA

Understanding the environmental review processes



Environmental Topics Addressed:

Air Quality, Noise, Traffic and Water Quality

- Temporary effects during construction.
- Best management practices and environmental commitments for construction will reduce localized construction effects.

Biological Resources

- Compliance with Corps Levee Safety policy requires vegetation to be removed from the levees, however:
    - Acquisition of a variance from the policy would allow vegetation to remain on the lower waterside slopes to protect habitat for listed species.
    - Locals will implement a Systemwide Improvement Framework (SWIF), to allow vegetation to be addressed on a "worst-first" basis.
    - Vegetation will only be impacted in the construction footprint; approximately the upper half of the levee slope.
- Vegetation removal could adversely impact listed species, such as the valley elderberry longhorn beetle and Swainson's hawk.
- Other construction activities could adversely impact giant garter snake, vernal pool crustaceans, and listed fish species such as salmon, steelhead, sturgeon, and Delta smelt.

Cultural Resources

- Potential effects on archaeological resources. A Programmatic Agreement between the Corps, the CVFPB, and State Historic Preservation Officer will govern the phased approach to comply with Section 106 of the National Historic Preservation Act.
- Ongoing coordination with tribal representatives will continue throughout implementation of the Programmatic Agreement.

US Army Corps of Engineers.

A-1

MS. MAXWELL: My name is Sandra Maxwell, S-A-N-D-R-A, M-A-X-W-E-L-L. I am a resident. I live on Verano Street. V, as in Victor, E-R-A-N-O, Street. It's --

How do I explain this?

Periodically we get high water. In '95 because of a tree falling down along -- further on down the creek, and then it rained like crazy, the house flooded, and I was out of my house for five months.

Luckily, my mother -- I mean, it was her house. I was living with her because she had Alzheimer's. Luckily she had flood insurance, so we were okay, except financially -- except we were out of the house for five months, and if you've ever dealt with an Alzheimer's patient, it's traumatic.

So all these years I've carried flood insurance. Now, I have been notified by the flood insurance people, FEMA, that I'm losing my discount, but there's no -- there's no explanation as to what happens after that loss.

So we came over tonight when Arcade Creek was mentioned. Runs along the back of the property. Was that going to effect us in any rate? Didn't really get that answered.

But I have a phone number and a name, and I'm going to give him a call and see if they have any information.

The levy work that they're talking about does not appear to affect my house. It's not going to be in that area. It's to the west of us, which solves the problem of them cutting down trees, which I read that in the paper. That's not a worry.

I still don't know whether I'm considered in the flood plain or not, that the flood insurance people are concerned about.

A-1 (Cont.)

Is the work that they're going to be doing going to make the bank and the flood insurance people happier?

Is the City going to come in and clean all the silt out that has built up over the years?

I mean, it didn't rain very much in February, but the creek almost went over into my backyard because it's so shallow back there because of the crude buildup of silt.

So I solved the problem by being the squeaky wheel every year. I start in the spring, come clean the creek out, and in October they usually show up. They didn't this last year.

So that's where I'm at.

The City fenced off years ago, years ago fenced

A-1
(Cont.)

off the creek, so the homeowners can't get back there, and cut down weeds and clean up trash and do anything.

We can't get back there and get -- the City doesn't adequately take care of what they fenced off.

Okay.

THE REPORTER: Is there a number that they can reach you at?

MS. MAXWELL: Area code 916-922-3176. And they can --

I rarely answer the phone. If I don't recognize the phone number, I don't answer, but I will call back when they leave a message.

Okay. Thank you very much. Thank you.

(Conclusion at 7:00 p.m.)

REPORTER'S CERTIFICATE

I, CATHERINE D. LAPLANTE, a Certified Shorthand Reporter for the State of California, do hereby certify:

That I am a disinterested person herein; that the foregoing was reported in shorthand by me, CATHERINE D. LAPLANTE, a Certified Shorthand Reporter of the State of California, and thereafter transcribed into typewriting; that the foregoing is a true and correct record given.

IN WITNESS WHEREOF, I hereby certify this transcript at my office in the County of Placer, State of California, this 15th day of April, 2015.

PUBLIC COMMENTS

Reported by: CATHERINE D. LAPLANTE
CSR License No. 10140

COURT REPORTER DEPOT
Phone (877) 808-3376 Fax (973) 353-9445
www.courtreporterdepot.com

B-1

MS. NASON: My name is Beverly, B-E-V-E-R-L-Y. Last name is Nason, N-A-S-O-N. And I live at 6728 Benham, Way, B-E-N-H-A-M, Way, and that's 95831.

And my e-mail address is [redacted], [redacted].

And my comment is we have been at our house like 30, 35, 36 years, so we've gone through a lot of -- two times digging down the slurry.

Our house backs up to the levy, and so they've done two times with the -- down the middle of the levy, and if it rains a foot, which I'm grateful of.

I don't know how many years ago that was, the last incident, which quite made me come to this, is they put, I guess, erosion, the cement, the big barges came, and then they would dump the -- the big cement. I guess they were for erosion, which I was glad they were doing but didn't realize it was cracking our house, which it did.

We have a stucco house, and it got cracked.

I didn't know anything about it. I was just glad they were doing the work that I wouldn't get flooded again.

And my friend lived about half a mile in the new section, and they're three houses from the levy. Our house backs up to the levy. Hers, the new units, are the levy, and they're three houses in. All three houses from the levy had cracked damage, and they were all fixed. They put in a complaint, and they were all fixed.

I did not know to do that, so that's why I'm here today, so in case that was going to happen again, I would know who to call.

So I appreciate the meeting tonight so that I'm a more-informed consumer. Yeah.

So that's what it's all about because I didn't get it done, and I should have because I was a victim of, but I'm glad to see it raised, glad to see it was not going to flood again.

B-1
(Cont.)

Glad everyone did it, but I wished I would have put in for the damage. I did have damage.

So now I have a card, and I will be able to -- if they do do that.

I didn't think it was going to be done again because they've done it, erosion correction, that's where the big cement, that's where the vibration cracked the houses, damage was done from the -- I guess the soil is such that --

So now I'm glad that we had this meeting.

Thank you.

* * * * * * * * * * *

B-2

MS. BIGELOW: Pamela Bigelow. B-I-G-E-L-O-W. Address [redacted], Sacramento, just the number [redacted]

The first thing I want to say is I have a walnut tree within 15 feet of the levy that I would like removed. It has the family of squirrels that live in it. You can replace it with another tree, that's just fine.

It is, however, on City property, but there are quite a few squirrels that have lived there for many, many years, so I'm sure there are a lot of burrows there.

Right behind it is a large oak tree, which they live in. The squirrels live in the oak tree because they eat the acorns, and they eat the walnuts.

Second thing is I'd like consideration for not having -- for not having a staging area on the big lot next to Marlton Court.

We had one there in the early '90s, and we think we've done our duty, so if you could please find another place for a staging area, we would very much appreciate it.

Third thing, which goes to the City of Sacramento, the cul-de-sac and levy need to have the grass cut on a monthly basis rather than an annual

B-2 (Cont.)

basis. The group of neighbors in our cul-de-sac is paying a gardener to cut the levy grass because it's a fire hazard, and it's dangerous, and people fall down the levy all the time because they can't see where they're going because the grass is so tall.

So we would like to request the grass be cut much more often.

That's it.

* * * * * * * * * * *

B-3

MS. SHORT: My name is Shirley. Last name Short, S-H-O-R-T, and I live along the river and brick yard, and I don't want to be contacted. There's no reason to.

I was just disappointed, that my impression was this was going to be a meeting tonight, and that there was going to be a presentation by the agencies involved, and we would have an opportunity to ask questions, and we have had an opportunity to ask questions, and they've provided a lot of really good information.

But I think a meeting where they gave us a presentation would have been more helpful to us, and some -- you know, some things to take away, some handouts would have also been more helpful.

I was disappointed. I thought this was going to be a meeting. That's what they told us it was going

B-3
(Cont.)

to be, so why didn't they have a meeting?

That's my comment.

* * * * * * * * * * *

MR. CARROLL: Craig, C-R-A-I-G, Carroll, C-A-R-R-O-L-L. [redacted].

B-4

My first concern is the vegetation, the existing vegetation that is on the water side of the levy behind my property.

Prior to any removal of the vegetation, will there be a report or a document available on which trees or which -- what vegetation will be removed prior to the removal in the event that I can challenge, legally challenge whether or not it meets the criteria of a hazardous tree or the question -- the reason for the removal.

I know the trees are tagged, and I would like to see in the proposal that these tag numbers be included on which trees will be removed and which trees won't be removed.

My piece of property is actually between Reach 15 and 16. That's the first concern.

And the second will be the privacy issue. Right now we're not allowed to have privacy fences because of the regulations on the fence sizes, heights, has to be see-through.

Whether or not there's going to be any screens or any sort of privacy protection, so while we're enjoying our pool or backyard during the construction phase of it, whether or not we just have to live with one or two, three months, however long the project is, of people in our backyard with little or -- giving us little or no privacy are my two biggest concerns.

So vegetation removal and the privacy issue are my two issues with this particular project.

Also, the existing permits, the use permits that we have on our piece of property, if they encroach -- for the encroachment permits, if they encroach into the area of the levy that will be constructed or affected by the construction, and it's required to be removed.

B-4
(Cont.)

A, who's going to pay for the cost of removal, and, B, whether or not it will be replaced after the construction's over, and the cost to that, and whether or not I'll have to reapply for a new permit, or if I can use the existing permit and reconstruct what was in there.

So the three issues are cost of removal, the cost of replacing it after the construction is over, and whether or not I will be able to get a permit, or if I can use -- if I'll have to apply for a permit all over

B-4
(Cont.)

again, or if I can just use the existing permit to
repair what was removed.

(Conclusion at 7:00 p.m.)

COURT REPORTER DEPOT
Phone (877) 808-3376 Fax (973) 353-9445
www.courtreporterdepot.com

C-1

JOHN LUNDGREN: On behalf of the county's regional parks director, Jeff Leatherman, I'm just a little bit concerned about a lack of specificity for the improvements along the American River because it makes it hard for us to evaluate the impacts to American River Parkway. We're specifically concerned about a loss of revenue from parkway fees and sales of annual passes, and we're concerned about a loss of use, meaning that that park won't be available for the regular users.

We agree with the draft document that the impacts to recreation will be significant and unavoidable, but we would like to see more specific mitigation with performance criteria. We're also concerned that the Campus Commons Golf Course will be impacted, and we're not sure we saw that in the document to date, and with past Corps projects in the parkway, we've experienced some confusing information from the contractor when directing parkway users around closed areas and would like extra effect and coordination in the future to work on a more consistent, unified public information system.

C-2

Okay. Now the comments are from me, so I'm representing the county's mining program. And the SAFCA portion of the project has several borrow sites identified. For those sites within unincorporated

C-2
(Cont.)

Sacramento County, they will need to obtain a borrow site permit pursuant to county code and the State Surface Mining and Reclamation Act, SMARA, S-M-A-R-A. Please leave enough time in the process to coordinate permitting with the county. We're available to assist with early consultation to streamline the process.

Some of the areas may not require a borrow permit, but still will require a grading permit. If the specific impacts of that grading are not analyzed in this document, you will need to leave time in the process for analyzing them under a future CEQA document. There's a potential borrow site identified in the Dry Creek Parkway. Please be aware that the area is particularly sensitive for cultural resources and may be regulated by the Dry Creek Parkway Plan.

COURT REPORTER'S CERTIFICATE

www.courtreporterdepot.com

BE IT REMEMBERED, that on Friday, April 17th, 2015, commencing at the hour of 5:00 p.m., at the Dimick Library, 891 Watt Avenue, Sacramento, California before me, JILLIAN M. SUMNER, a Certified Shorthand Reporter in and for the county of Sacramento, state of California, was present and recorded verbatim the following proceedings:

COMMENTS BY THE PUBLIC:

(Comments made by Pat Hara and Jack Burrows, collectively:)

PAT HARA:

D-1

Basically, we live in -- what is it -- Walnut View Estates. That's off of Sierra Boulevard. And my flood insurance goes up 100 bucks a year, $1,700. And I'm going, that's just -- what can we do?

So we talked to Pete about the issues of the flooding in that area and the drainage issues, and I need to find a way to get my flood insurance down, if at all possible.

D-1
(Cont.)

JACK BURROWS:

What Pete was telling us was that what was really required is a larger pump capacity. But the cross-benefit analysis is not there. So he's recommending that we get something from the County, meet with a man by the name of George Booth to evaluate her elevation.

Because I'm not paying any flood insurance in my home. I have another home a few houses down that I'm paying 400 and something. Jane is paying -- across the street from me -- paying 400 and something.

PAT HARA:

And the kids are right next to the canal. So, yeah, that's the issue.

We originally wanted to have to put up another Cal Expo to pump water out of the slough when the water backs up. But obviously that's not going to work. We have too many issues working against us there.

JACK BURROWS:

So Pete said to bring the comment to your attention, and he'll bring it to the County's --

D-1
(Cont.)

George Booth and the County to see if there's anything we can do. And we'll bring it to his attention also.

Thank you.

(Next commenter:)

D-2

JUDITH SCOTT:

I just wanted to say everybody was very helpful and friendly, and I love the charts. And several people answered a lot of questions that we've had.

And another neighbor came in, and we picked Pete's brain, and heard we're supposed to talk to George -- somebody.

It was all very well done and everybody was very helpful. We got our questions answered. But we're not as affected as the other people here are.

(Whereupon, the meeting concluded at 7:00 p.m.)

REPORTER'S CERTIFICATE

STATE OF CALIFORNIA)

COMMENT/QUESTION:

Very concerned about vegetation removal - trees, shrubs + habitat for threatened/endangered species. Hopeful ACE will rethink philosophy & allow majority/most of veg to remain. Prefer SAFCA approach. ACE needs to update its printed materials (poster boards) to reflect more enlightened reality, not "slash & burn" mentality that all veg in footprint will be removed. Hope SAFCA gets there first & gets the job done.

Subject: RE: [EXTERNAL] American river Common Features Project (UNCLASSIFIED)

I

Hi Anne,

I already sent the following question/comment to a DWR contact several days ago; I made it a bit less caustic at the end for you:

My home abuts the levee on the south side of the American River Parkway bewteen Howe and Watt Ave., and I noticed trees were tagged several years ago, I believe 30 feet away from the toe on the river side and 20 feet or so on the residential side; does this project intend to remove trees? If so, how many and why? I-1

If there is a tree removal component to this project, have measures been put in place to manipulate vegetation outside the breeding season for birds (starting in January for Great-horned Owls and Anna's Hummingbirds; beginning late February/early March for songbirds and continuing through August)? I can see an active Swainson's Hawk nest from my living room, and there are noise buffers that are usually put in place for this listed California Threatened species. I-2

Also, I noticed at the bottom of page 13 of the Environmental Site Assemssment, under Sacramento East Maps, the last bullet states:

I-3

The Sacramento East map of 1975 was a photo revision of the 1967 edition and added a crossing at Howe Road.

I am a firm believer in getting the small details correct, especially in a project like this, so when I see that Howe Avenue was mis-named as Howe Road, even though it was correct in the bullet right above, it makes me wonder if any other details were mixed-up in the analysis.

Anyway, those are my main concerns: unnecessary tree removal (from my perspective) and limbing/tree removal during the avian nesting season.

The comment reflects my duties as an editorial board member for the Central Valley Bird Club Bulletin, where I read every word to help ensure everything is as grammaticaly and factually correct as possible. It is not meant as a personal attack; just an observational extrapolation.

Thanks,

Dan Kopp

Subject: [EXTERNAL] Sac. River Levee Work

J

Hi,
Thank you for providing an opportunity to comment on the proposed levee upgrades. I have a few thoughts on this.

The public should be able to see what we're getting for the millions & millions being spent. I propose some "viewing areas" along the levee during the work, to see what's being done. These should be accessible to the public. Maybe a sign or 2 explaining what is being done. J-1

Get rid of all the gates & fences that criss/cross the levees in South Sacramento. They are an "attractive nuisance" to kids, who have been seen climbing on them. Some fences have barbed wire, another has 'concertina wire' at the top. This could be a huge liability. Most all of the fences can be bypassed by walking down to the water's edge and going around them, so they don't really accomplish anything. Most of the fences do not have legally valid permits anyway. Removal of all the gates & fences will certainly make the repair work easier and more efficient. J-2

There are a number of dead & sick trees along the Pocket and Little Pocket areas of the levee. Also a number of trees infested with mistletoe that need attention. Were any of these dead trees to topple over in a storm, they might take out a huge rootball of dirt and rock, and leave a large gaping hole in the side of the levee. This work should receive a high priority. J-3

I live 3 blocks from the Sacramento River, and enjoy walking and bike riding on the levee, and kayaking on the Sacramento River. We are very much in favor of stronger levees! I'd be happy to provide additional information to you if requested.
Best Regards,

Stan Jones

Subject: [EXTERNAL] public comment - levee reinforcement

Hello there - I would like to submit the following public comments regarding levee improvements in the Pocket Area. Would you please forward to Tyler Stalker, who is evidently the person collecting them? That's who the hand-out forms on the table at the Elk's Club last night were addressed to. But email is much more efficient than filling out a form by hand and mailing by snail mail......

Name: Janet Fullwood
Address: 6470 Surfside Way 95831
Phone: 916.718.5666
Email: jfullwood@me.com

Comment No. 1:

The last round of levee reinforcement, in 2007, stopped at my house on the downstream end (My property is at the intersection of Surfside and Cruise Way). Only one time since has the river come up high enough for the effectiveness of the repairs to be tested, that being during the high-water winter of 2010-2011. Before the reinforcement, water seeped and weeped from the sidewalks in front of every river-side house on my block. This last time: every sidewalk on the street was dry except mine, which wept just as badly as before. I also had water pooled under my house that had to be pumped out via the sump installed after the 1997 floods that brought eight inches of water under my house (neither federal or homeowners flood insurance would pay for repairs by the way; hydrostatic seepage is not covered, only breaches in the levee). Evidently the water is creeping in through angled sediments. Please make note of this and get in touch if you need more detail. K-1

Comment No. 2:

During the 2007 repairs, new sod was planted on the river side of the levee. Unfortunately, what came up was two species of spear grass, colloquially known as foxtails, that are lethal to animals. Every farmer and rancher in the state is trying to get rid of this invasive, unwanted stuff, and we get stuck with a sea of it. The explanation I've gotten is that the seeds were embedded in "imported" soil. Imported from where, I don't know, but these invasive species are an unwelcome hazard. Last year, the levee was not mowed until after the awns had set and it was bad news for a number of pets that were infected and incurred huge vet bills.Who knows how many wild animals were hurt, too?. When the next round of repairs is made, can we please kill that stuff off and replant with certified weed-free native grasses? Something needs to be done; it's s shameful situation. K-2

That's all for now. My thanks to all the Corps and SAFCA and city representatives who turned out last night at the Elk's Lodge and for all the great graphics and explanations.

Sincerely,

Janet

To: Baker, Anne E SPK
Subject: [EXTERNAL] Public Workshop with SAFCA & the Army Corp of Engineers at Elk's Lodge #6, 4/14/15

As part of these projects, neither SAFCA or the Army Corps should replace any of the nine fences that presently cross the levees in the Pocket areas. None of the fences are in compliance with their permits and most of the permits are not held by the present homeowners. No government agency should be engaged in replacement of obstructions on the levee that are illegal and add to the danger of the flooding in the Pocket area.

To: Baker, Anne E SPK
Subject: [EXTERNAL] SAFCA public comment feedback

M

Hello Ms. Baker,

I am writing to provide SAFCA public comment on the upcoming levee project. As a resident of Sacramento and the Pocket community, I would like to strongly urge that the fences across the levee NOT not be replaced during this levee improvement as each one of those fences are illegal and/or are not properly permitted by SAFCA. Replacing the illegal fences will only further exacerbate community concerns about levee access, impartiality, and objectivity. With this new levee project, SAFCA has a perfect opportunity to not only save taxpayer dollars, but to also disengage in any activity that replaces illegal fences with more illegal fences.

Thank you for your consideration.

Respectfully submitted,

Dr. Maggie Beddow, Pocket resident

Subject: [EXTERNAL] DEIR/DEIS ARCF General Reevaluation Report, CVFPB

Hello All, please see UAICs comments to the DEIR ARCF General Reevaluation Report, CVFPB, Sacramento County, Ca.

After an internal review of the project documentation the DEIR/DEIS for the Project has some significant deficiencies beyond those already noted.

1. DEIR/DEIS does not appear to contact an Environmentally Preferred Alterative that is required under CEQA Guidelines 15126.6(e)(2) and NEPA. The tribe would like to be allowed to microsite or get other design features incorporated to reduce the potential for direct cultural impacts. N-1 N-2

2. UAIC left out of DEIR/DEIS analysis as Tribe, government or partner. There is no discussion of the Tribe/tribal values in areas of controversy, construction timing, project and alternatives screening criteria (i.e., a tribal burial mound avoidance alternative), environmental commitments for cultural resources, social effects, environmental justice or identified as a viewer group for visual impacts. The UAIC requests to be allowed to participate in the EIR analysis. N-3 N-4 N-5

4. On Alternatives, it appears that very little consideration was given to any others. The rationale for rejecting other design features and preservation in place falls short of what the Tribe considers a minimum level of effort. The Tribe requests a complete and full analysis of such preservation in place and avoidance alternatives as setback levees, and seepages and stability berms. N-6

5. If the USACE/CVFPB materially revises any section of the DEIR/DEIS then the document should be recirculated. USACE/CVFPB shall evaluate, determine effects, and develop treatment before the project construction activities begin. The tribe does not consider data recovery appropriate which is in fact a negative effect and direct impact to the cultural resources. The DEIR/DEIS addresses solely scientific archeology, there is zero discussion regarding tribal cultural values, sanctified cemeteries, or cultural landscapes. Include a section on why preservation in place is a feasible alternative. DEIR/DEIS does not admit that human remains could be impacted and that state law would be followed. N-7 N-8 N-9 N-10

6. The DEIR/DEIS also will any new sections on PG&E utility relocation be in the DEIR/DEIS? Especially of this work includes use of cranes, land leveling, poll removal and relocation, tree replanting and vegetation removal - all activities that could have significant impacts on cultural resources. N-11

7. The cumulative impact section is wholly deficient and also contains improper analysis such as cultural resources are typically not subject to cumulative effects which is unsupported in CEQA/NEPA. Yet DEIR/DEIS then admits impacts are cumulatively significant but then offers no mitigation for that impact. Again, there is no mention of tribes or cultural landscapes, the latter is especially relevant when dealing with cumulative effects or effects across several phases or projects over wide geography. N-12

8. Specific borrow and staging sites were not identified in the DEIR/DEIS. N-13

9. Will there be a section on Wetland delineation. N-14

10. will the project be avoiding FEMA land use restrictions and are barges included in the project - use of barges could help to reduce impacts on cultural resources? N-15

11. Other interesting points, we would like to discuss are:

· Admits no further federal action assumed, raises question of whether feds could assume the project without reopening the environmental review; N-16

· No analysis of vibration or compression effects on project on cultural resources; N-17

· No analysis of vegetation impacts that relate to native or cultural plants including those that might have been part of the burial mounds or part of the tribal cultural landscape; N-18

· Will there be conservation bank purchased for giant garter snake - why not for cultural landscape; N-19

· Please note that post approval technical studies are not okay; N-20

· No section in climate change discussing whether it makes sense to raise structure instead of hardening levees. N-21

· No text references to NPS Bulletin 38 (TCPs) or ACHP guidance on cultural landscapes, document takes a very stilted view of what Section 106 means. We understand this may be in the DEIS, yet to be developed, but it would be good to include the important of place, setting, landscape, to the Tribe. N-22

· NAHC not listed as a trustee agency. N-23

We will also be submitting additional comments and would like to schedule a government to government meeting to discuss this project.

Marcos Guerrero, RPA

Cultural Resources Manager

American River Water Shed Common Features, General Reevaluation Report - Draft Environmental Impact Statement, Environmental Impact Report (DEIR/EIS)

Dear Mr. Johnson:

Thank you for including the California Department of Transportation (Caltrans) in the environmental review process for the project referenced above. Alternative 1 of the project involves the construction of fix-in-place levee remediation measures to address seepage, slope stability, erosion, and overtopping concerns. Alternative 2 of the project seeks to improve levees and widen the Sacramento Weir and Bypass. The study area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry, Robla, and Arcade Creeks and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento.

Caltrans new mission, vision, and goals signal a modernization of our approach to California's transportation system. We review this local development project for impacts to the State Highway System (SHS) in keeping with our mission, vision, and goals for sustainability/livability/economy, and safety/health. We provide these comments consistent with the State's smart mobility goals that support a vibrant economy, and build communities, not sprawl. The following comments are based on the DEIR/EIS.

Levee Stability

Caltrans recognizes the importance of levee improvements to the mobility of travelers using the SHS. The continued stability of the levee is necessary to prevent a complete levee failure, which would result in the harm, and perhaps total destruction of a highway segment. Additionally, levee work is necessary to prevent seepage, which could undermine a substantial section of the adjoining highway.

Bridge Structures and Maintenance

Below is the list of bridges in Sacramento County in which Caltrans has identified as scour critical. A complete modeling of any affected bridge may be required for Alternatives 2 and 3.

O-1

Bridge No.	Feature Intersected	Dist	Cnty	Route		Mile Post	Insp Date	Structure Name
240001L	**AMERICAN RIVER**	**03**	**SAC**	**00160**	**R**	**44.47**	**05/28/2013**	**AMERICAN RIVER (160 SB)**
24 0020L	COSUMNES RIVER	03	SAC	00099		8.40	01/29/2014	COSUMNES RIVER
24 0020R	COSUMNES RIVER	03	SAC	00099		8.40	01/29/2014	COSUMNES RIVER
24 0021R	COSUMNES RIVER OVERFLOW	03	SAC	00099		7.92	01/29/2014	COSUMNES RIVER OVERFLOW
24 0045L	LAGOON CREEK	03	SAC	00099		4.98	01/24/2014	LAGOON CREEK
24C0004	COSUMNES RIVER	03	SAC	00000		.00	04/09/2013	COSUMNES RIVER
24C0080	ARCADE CREEK	03	SAC	00000		.00	01/16/2014	ARCADE CREEK
24C0293	ELDER CREEK	03	SAC	00000		.00	11/18/2014	ELDER CREEK
24C0328	CHICAGO CREEK	03	SAC	00000		.00	04/15/2014	CHICAGO CREEK

Caltrans routinely inspects bridges for the purposes of bridge maintenance. Therefore, bridge
O-2 engineers and other authorized workers require access to the underside of the bridges. In the path of
levees or flood wall height increases, a Caltrans-approved method of bridge access needs to be
designed and installed.

A bridge embankment seepage analysis, including any mitigation, needs to be submitted to Caltrans
O-3 for review.

Any new bridge or existing bridge modification needs to be designed based on the current Caltrans
O-4 Bridge design codes.

O-5 Flood walls or levees cannot exceed the bridge embankment in height proportionally.

Construction Traffic

As identified by this project's traffic study, this project plans to transport 1 million yards of borrow material and 2.8 million tons of rock for construction. The construction period is estimated to take approximately 10 years. As the result, there will be substantial increases in traffic on local roadways associated with truck haul trips during construction activities. In addition, traffic controls would cause, or contribute to, temporary substantial increases in traffic levels and speed differentials on several roadways, as traffic is detoured or slowed. Traffic controls could cause delays particularly during the morning and evening peak commute hours.

O-6 The project sponsor would require the contractor to prepare a Traffic Control and Road Maintenance Plan to address its construction traffic impacts. Caltrans requests the project sponsor to haul its building materials by barges as much as possible to reduce truck trips. If the building materials could be hauled by barges, this would reduce the project's traffic impacts significantly. Caltrans would like to review the Traffic Control and Road Maintenance Plan.

Bicycle and Pedestrian Travel on Levees

O-7 The Pocket levees are a well-used recreational and commute bicycle route. Please consider providing convenient alternate means of travel for bicyclists and pedestrians during construction of the levees. Also, please consider providing for connected bicycle and pedestrian access along the levees following construction. The levee paths provide important parallel alternatives for non-motorized travel and help reduce demand on the SHS.

O-8 Please provide our office with copies of any further actions regarding this project. We would appreciate the opportunity to review and comment on any changes related to this development.

If you have any questions regarding these comments or require additional information, please contact Larry Brohman, Intergovernmental Review Coordinator, at (916) 274-0627 or by email at: larry.brohman@dot.ca.gov.

Sincerely,

Eric Fredericks

April 27, 2015

Erin Brehmer
Department of Water Resources
3464 El Camino Avenue Room 200
Sacramento, CA 95864

Subject: DRAFT ENVIRONMENTAL IMPACT ASSESSMENT/ENVIRONMENTAL IMPACT REPORT FOR THE AMERICAN RIVER COMMON FEATURES PROJECT, SCH # 2005072046.

Dear Ms. Brehmer:

The California Department of Fish and Wildlife (Department) has reviewed the draft environmental impact statement/draft environmental impact report (DEIS/DEIR) from the Army Corps of Engineers (ACOE) and the Central Valley Flood Protection Board regarding the American River Common Features Project (Project).

As a trustee for California's fish and wildlife resources, the Department has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species (Fish & G. Code, § 1802). The Department may also act as a Responsible Agency (Cal. Code Regs., § 21069) for a project where it has discretionary approval power under the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.) and the Lake and Streambed Alteration (LSA) Program (Fish & G. Code, § 1600 et seq.). The Department also administers the Native Plant Protection Act (NPPA), Natural Community Conservation Program (NCCP), and other provisions of the Fish and Game Code that afford protection to California's fish and wildlife resources.

The Department offers the following comments and recommendations for this Project in our role as a trustee and responsible agency pursuant to the California Environmental Quality Act (CEQA).

PROJECT DESCRIPTION AND ALTERNATIVE ANALYSIS

The Project intends to reduce the overall flood risk within the city of Sacramento and surrounding areas. The DEIS\DEIR identifies three alternatives, the No Action Alternative, Alternative 1 Improve Levees, and Alternative 2 Improve Levees and Widen the Sacramento Weir and Bypass (Tentatively Selected Plan).

Alternative 1 involves the construction of fix-in-place levee remediation measures to address seepage, slope stability, erosion, and overtopping concerns identified for the

American and Sacramento River, Natomas East Main Drainage Canal, Arcade, Dry/Robla, and Magpie Creek levees. A vegetation variance would be sought to allow for vegetation to remain on the lower portion of the waterside levee slope.

Alternative 2 would include all of the levee improvements discussed in Alternative 1, except levee raises along the Sacramento River would be included to a lesser extent. Instead of the full extent of levee raises, the Sacramento Weir and Bypass would be widened to divert more flows into the Yolo Bypass. The levees along the American River, NEMDC, Arcade, Dry/Robla, and Magpie Creek, would be improved to address identified seepage, stability, erosion, and height concerns. The levees along the Sacramento River would be improved to address identified seepage, stability, and erosion concerns. A small amount of levee raising would be required on the Sacramento River. Due to environmental, real estate, and hydraulic constraints within the study area, the majority of the levees would be fixed in place.

ENVIRONMENTAL SETTING

The final environmental document should include a complete assessment of the existing biological conditions within the Project area including but not limited to the type, quantity and locations of the habitats, flora and fauna. Adequate mapping and information regarding the survey efforts should be included within the document. The DEIS\DEIR only identifies impacts to riparian habitat. The environmental document needs to clarify what type of riparian habitats will be impacted by the proposed Project. The Department recommends the use of A Manual of California Vegetation 2nd Edition (Sawyer and Keeler-Wolf 1995, and Sawyer, Keeler-Wolf and Evens 2009).

P-1

To identify a correct environmental baseline, the final EIS/EIR should include a complete and current assessment of the habitats, flora, and fauna within the Project area. The DEIS\DEIR lacks analysis of other sensitive species, and locally unique species such as but not limited to white-tailed kite (*Elanus leucurus*), burrowing owl (*Athene cunicularia*), Cooper's hawk (*Accipiter cooperii*), purple martin (*Progne subis*), Sanford's arrowhead (*Sagittaria sanfordii*), woolly rose-mallow (*Hibiscus lasiocarpos*).

CEQA guidelines Section 15125, subdivision (c) requires lead agencies to provide special emphasis to sensitive habitats and any biological resources that are rare or unique to the area.

IMPACT ANALYSIS AND MITIGATION MEASURES

<u>Sensitive Species and Habitats</u>

The final EIS/EIR should include an impact analysis to other sensitive species as identified in the Environmental Setting Section that could be present within the Project
P-2 limits and could be impacted by the proposed Project. Avoidance, minimization, and/or mitigation measures should be proposed if any potential significant impacts to other sensitive species and/or their habitats are identified. The Department recommends that

P-2 (Cont.) maps showing the different habitats and the Project impacts are included in the final environmental document.

Fisheries

P-3 The Department is concerned that Project impacts caused by widening the Sacramento Weir and Bypass are not fully analyzed in the DEIS/DEIR. An impact analysis with respect to the potential entrainment of adult and juvenile listed fish species should be included in the environmental document. The DEIS/DEIR should analyze how listed fish species are able to egress out of the Sacramento Bypass to continue their migration once entrained. This is especially important since the document does not include any activities that could reduce the entrainment potential within the Sacramento Bypass.

The operation of the weir directly alters juvenile salmonid emigration routes. Juvenile salmonids have access to the Sutter bypass when the Sacramento bypass is active, increasing the length of the Sacramento Bypass weir will provide a greater chance of juvenile entrainment in both bypasses. While it is shown that some salmonids may use the bypasses to rear when given access (wet years), some juvenile salmon become trapped in swales within the bypasses when flows recede. The Department frequently performs fish rescue activities within the Project area where sturgeon and salmon species are relocated from swales and depressions present within the Project vicinity. The Department recommends that the proposed Project include activities to eliminate swales and depressions that could strand and isolate fish species within the Sacramento Bypass. Any areas that may be flooded as a result of this Project should be designed in a way that the area will drain completely to avoid the creation of predatory fish habitat.

P-4 The Department is concerned about placing rock boulders at erosion sites along the Sacramento and American Rivers. Rock boulders constitute good habitat for predatory fish species that prey on juvenile listed species. The EIS/EIR should analyze potential impacts caused by the installation of rock boulders within the wetted portions of the levees. Additional avoidance, minimization and/or mitigation measures should be proposed if these impacts are deemed significant.

P-5 The DEIS/DEIR states that the ACOE will request a vegetation variance so the waterside vegetation on the lower one-third of the waterside of the levee will be protected along American and Sacramento Rivers. The Department recommends that the EIS/EIR describe what would occur if the variances are not obtained.

P-6 The Department recommends that the EIS/EIR includes specific mitigation measures to offset the proposed Project long term effects to listed fish species. The Department recommends that filling existing swales within the Sacramento Bypass is included in the DEIS/DEIR as a potential mitigation measure to offset long term effects to listed fish species.

Sacramento Weir and Bypass

P-7 The DEIS/DEIR states that the expansion of the Sacramento Weir will impact rice fields and canals. There is no rice grown in the 1,550 feet footprint north of the bypass levee only dryland annual row crops in this area. Please revise the document accordingly. The Department recommends that the new area that will be added to the Sacramento P-8 Bypass is incorporated to the existing wildlife area to enhance recreational activities and to provide a consistent land management of the Sacramento Bypass.

The Sacramento Bypass Wildlife area is a great asset to the public and gets over 1,500 user days per year. It is very important that the recreation opportunities are not affected by the Project. If impacts to recreational wildlife viewing, hunting, and fishing aspects are determined significant additional mitigation is required. Please contact the P-9 Department to develop specific measures to ensure that recreation activities are not impacted by the Project. If the main parking lot located at the north levee of the Sacramento Bypass will be impacted by the Project, alternative public parking should be proposed on the new north levee to enhance parking and public access to the area.

Major hunting seasons and high use days expand from September 1st until January 31st. The Department recommends that construction around the Sacramento Bypass should P-10 avoid this timeframe as much as possible. In addition to this, turkey hunting season starts in mid-March and extends until May.

The final environmental document should include specific information regarding what activities will occur within the over 300 acres that will be impacted by the widening of the P-11 weir. The canals constitute a valuable habitat for species like giant garter snake (GGS) (*Thamnophis gigas*) and potential Project related impacts should be disclosed in the final environmental document. The Department is concerned that leaving land that will only be flooded sporadically will promote the introduction of invasive species in the P-12 area. The EIS\EIR should include specific impact analysis and proposed additional avoidance, minimization, and/or mitigation measures to offset these impacts.

The Department recommends that any depressions created by the Project within the P-13 land that will be added to the Sacramento bypass should be filled to avoid listed fish entrainment. The new area that will be added to the bypass should be sloped to the south to allow fish to find the toe drain when flows subside in the bypass.

P-14 The DEIR should include additional information about the future north levee within the Sacramento Bypass to better analyze any impacts to listed species from the Project action. The Biological Assessment (BA) also identifies a hazardous, toxic, and radiological waste site near the existing north levee. The environmental document P-15 should include an impact analysis of the remediation activities that will be conducted as part of the Project.

Borrow sites

P-16 Figure 2 of the BA shows potential for borrow sites in the Yolo Bypass. There is a potential for environmental damage to the Yolo Bypass Wildlife Area (YBWA) as a borrow site. The EIS\EIR should include information about the borrow sites and analyze the potential impacts caused by the borrow sites. Additional avoidance, minimization, and/or mitigation measures may be required to offset borrow sites impacts. These borrow sites could be in conflict with requirements for the 2009 National Marine Fisheries Service Operational Criteria and Plan Biological Opinion for the Yolo Bypass.

P-17 The BA also states that the "borrow sites would be returned to their existing use whenever possible, or these lands could be used to mitigate for Project impacts, if appropriate." The EIS/EIR needs to include information of the existing condition in the proposed borrow sites and proposed specific mitigation measures. Restored borrow site habitat should not count as mitigation for riparian habitat removed during Project operations.

P-18 Borrow sites should not occur along side of levees, in river channels, flood plains or bypass areas. As water recedes after flood events, all fish species are subject to becoming entrained in borrow pits.

The Department also has the following specific comments:

DEIS/DEIR

P-19
1. Page, 61, Section 3.3.1: The DEIS\DEIR should include that the Sacramento Bypass is operated by the Department as a Wildlife Area and provides access to the public.

P-20
2. Page 102, Section 3.6.1: Please replace "Refuge" with "Area". Please change the word throughout the document. If the additional land incorporated to the Sacramento Bypass becomes open space it could potentially create difficulties managing the properties cohesively with the Sacramento bypass since similar habitats would get different land designation.

P-21
3. Page 109, Section 3.7.1: It is unknown if most juvenile fish emigrate from the Sacramento Bypass after it spills. Please clarify what analysis or studies have been conducted to confirm that most fish move out of the Sacramento Bypass prior to drying up. Additionally, in spring of 2011, a total of 25 adult green sturgeons and 20 adult white sturgeons were rescued from Fremont Weir and several swales within the Yolo Bypass. The DEIS/DEIR should include and /or reference the assurances and analysis that was conducted to show that survival of both juvenile and adult listed species will not be jeopardized with the Project.

P-22
4. Page 114, Section 3.7.5: The Knaggs Ranch study utilized hatchery origin fish in a controlled setting. Though they experienced considerable growth, there is no

P-22 (Cont.) mention as to what the mortality rate was for the fish. Furthermore, there is no assurance as to how the fish can egress from the Yolo Bypass to reach the Delta. Widening the Sacramento Bypass will only create additional floodplain during periods when high flow conditions exist; however, the DEIS/DEIR does not indicate how these fish can leave the floodplain during these high flow conditions. It is very important that the Project is designed in a way that will allow listed fish to migrate from floodplains to the Delta. These activities should be identified and analyzed in the environmental document.

P-23

5. Page 115, Section 3.7.6: Avoidance, Minimization, and Mitigation Measures. Section 3.3.6 should be Section 3.7.6. The proposed construction window is incorrect. Adult Chinook salmon spawning in the lower American River spans from October through December with peak spawning occurring mid-November. The Department recommends that the construction period avoid peak spawning.

Appendix G Draft Biological Assessment

P-24

6. Page 20, Section 2.2.3: The planting berm should be constructed in a way to prevent any stranding of juvenile listed species as the water recedes.

P-25

7. Page 33, Section 2.5.1: The BA should include the citations for the compensation time periods included in this section.

P-26

8. Page 47, Section 3.3.1: The life history subsection includes information about juvenile Chinook salmon outmigration past Red Bluff Diversion Dam. The construction site is located up to 200 miles from the diversion dam. The document needs to identify when juvenile outmigration occurs at the construction sites near Sacramento in order to identify any impacts to listed species. Data collected by the Department in the Sacramento River near Knights Landing suggests that juvenile salmonids (federally listed endangered winter-run Chinook salmon) are present in October in the Sacramento River. The study cited in this section, Sommer et al. (2001), found high growth and survival rates for fall-run Chinook salmon and not winter-run. Please note that juveniles may rear on inundated floodplains during high flow events when they occur although survival is not fully understood due to isolation and stranding in swales and from farm road crossings.

P-27

9. Page 66, Section 4.2.2: It should be noted that although all four runs of Chinook salmon may enter the Yolo Bypass during intermittent high winter and spring floods, survival is not fully understood due to stranding and isolation in swales and between farm road crossings within the bypass.

P-28

10. Page 66, section 4.2.3: It should be noted that although green sturgeon can inhabit the Sacramento Bypass, when flooded, survival is not fully understood due to isolation and stranding in swales and at farm road crossings.

P-29

11. Page 79, Section 5.2.1: The Juvenile Rearing and Migration section states that juvenile winter run Chinook salmon moving downstream peaks at Red Bluff in September and October and continues until mid-March in drier years. This section should include what the peak observation of winter-run are at the construction site. Because downstream migration may be triggered by storm events, winter-run Chinook salmon may be in the vicinity of the proposed construction site in greater numbers than foreseen and could negatively impact the winter-run. This is similar for juvenile spring-run Chinook salmon, specifically for those that migrate as yearlings (October through March).

P-30

12. Page 79, Section 5.2.1: Figures 11-14: This Section of the environmental document states that riparian vegetation within a levee can be restored to a level that could benefit Chinook salmon within 5 years. Please clarify if sampling occurred at these sites to verify if juvenile Chinook salmon were utilizing these areas for rearing. The Department recommends that monitoring be done at these sites to verify their utility in providing a positive effect.

P-31

Please note that when acting as a responsible agency, CEQA guidelines Section 15096, subdivision (f) requires the Department to consider the CEQA environmental document prepared by the lead agency prior to reaching a decision on the Project. Addressing the Department's comments and disclosing potential Project impacts on CESA-listed species in any river, lake, or stream, and provide adequate avoidance, minimization, mitigation, monitoring and reporting measures; will assist the Department with the consideration of the DEIR and reduce potential delays when issuing an Incidental Take Permit under CESA and/or an LSA Agreement.

Thank you for the opportunity to comment on the DEIS/DEIR for the Project. If you have any questions regarding these comments please contact please contact Juan Lopez Torres at (916) 358-2951 or Juan.Torres@wildlife.ca.gov.

Subject: Review of Draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR) for the American River Watershed Common Features General Reevaluation Report.

Dear Ms. Baker:

Thank you for the opportunity to comment on the Draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR) for the American River Watershed Common Features General Reevaluation Report.

We have the following comments to assist your preparation of the Final EIS.

The National Park Service's (NPS)'s primary interest in the proposed project relates to its potential impact on the Lower American River. The Lower American River is a designated National Wild and Scenic River (WSR) and is also included in the California State Wild and Scenic River program.

NPS is the federal river administering agency for the Lower American River and, as such, is the reviewing authority for "water resource projects" proposed within the WSR boundary. This boundary extends ¼ mile from the ordinary high water mark on either side of the river. The proposed projects, irrespective of the final selected alternative, clearly meet this standard.

In its role to oversee the protection and enhancement of the Lower American River, NPS considers the impacts of water resource projects on free flow, water quality, and outstanding remarkable values (ORV). The ORVs for the Lower American River are fish (anadromous species) and recreation.

The American River Common Features (ARCF) Project impacts both banks of the Lower American River for some 12 miles upstream from the river's confluence with the Sacramento

River. Erosion of the Lower American River levees has been a problem for decades and NPS has reviewed previous levee expansion and improvement projects on the Lower American River where similar vegetation removal has taken place. We have weighed in on the impacts of various levee stabilization and improvement projects through the years.

Generally, we support the selection of Alternative 2, which decreases erosion while improving the levees' stability with the construction of bank protection and launchable rock trench. We should note that, as affects the Lower American River, the protections afforded under Alternative 1 are generally the same as those under Alternative 2 (which includes the Sacramento Weir and Bypass widening), so either alternative may have been acceptable.

We note that riparian vegetation along the Lower American River is classified as "valuable shaded riverine aquatic habitat" for the federally listed (anadromous) fish species which form the basis for one of the River's outstandingly remarkable values and its original designation as a National WSR. We further note that Alternative 2 limits negative impacts to the shaded riverine aquatic habitat with the riparian zone to a "single construction season", while acknowledging indirect effects to the habitat due to vegetation removal and more direct effects due to placement of rock at bank protection sites.

Q-1

However we are aware of the protracted nature of the construction period common in this region, and recommend that the duration of time that constitutes a "season" be specified.

We are pleased to note that the ARCF project is receiving consultation with the National Marine Fisheries Service (NMFS) per Section 7 of the Endangered Species Act. We generally defer to NMFS for biological determinations on projects' effect on anadromous fish. We assume that NMFS's assessment will address our concerns for impact on fish, regardless of which alternative is ultimately adopted.

We note that there has been a history of controversy and considerable concern regarding this, and past, projects' effect on recreation, another ORV for which the Lower American River was designated as a WSR. One important component of this ORV, the Jedediah Smith Recreation Trail which lies within the American River Parkway, extends throughout the 12 mile affected area of the ARCF project.

Recreational activities take place throughout the Parkway, including the bulk of actual access to the river which occurs between the levees and the bed and banks of the River. According to the Report, Alternative 2 will result in temporary closure of the Parkway during construction including the bike and hiking trails, boat launches, and other river access sites. This is deemed to be significant effect. Notification and coordination with users and user groups and traffic control around construction areas are noted as mitigations.

Q-2

NPS strongly urges that these mitigation steps (which include signage, detours, flaggers, and fencing) be strictly adhered to in view of the large population that uses the Parkway. While no cumulative effect to recreation is cited, we are again concerned about the length of the construction "season", accordingly public notice should be provided throughout the entire recreational use period.

A large part of the recreational experience includes the aesthetic quality of visual resources along the American River Parkway and from the vantage of the river itself. We note that, here again, the effect is substantial in that vegetation loss or construction along the Parkway will disrupt the Q-3 existing riverside visual conditions. We recommend that all contractors associated with the project adhere to best management practices (including replanting of displaced trees and reseeding with native grasses) in the course of construction to limit this disruption.

Q-4 §3.14.1 Recreation, Environmental Setting - The National Wild and Scenic Rivers Act (Public Law 90-542; 16 U.S.C. 1271 et seq.) should be specifically cited.

§6.3 Coordination With Other Federal, State, and Local Agencies - This section should also Q-5 emphasize consultation and coordination with NPS. Again, as the federal administering agency for the Lower American River, NPS should be consulted regarding consistency of the ARCF projects with the WSR Act.

Almost the entire project lies within the ¼ mile boundary of the Lower American WSR and, based on the specific location of areas affected by construction on the levees, many elements of the project will have at least an indirect effect on the ORVs and water quality. As an example, activities associated with bank stabilization may cause excessive turbidity which, however temporary, has a negative effect on water quality.

Ultimately, NPS is obligated to assess the potential effects of any proposed project on the Lower American River as they pertain to consistency with the WSR Act. Therefore, we appreciate the opportunity to review the Draft EIS for the American River Watershed Common Features General Reevaluation Report and provide these comments.

Sincerely,

Patricia Sanderson Port

SUBJECT: COMMENTS ON NOTICE OF AVALIABLITY (NOA) OF DRAFT ENVIRONMENTAL IMPACT REPORT (DEIR) AND GENERAL REEVALAUTION REPORT (GRR) FOR AMERICAN RIVER COMMONS.

Dear Ms. Baker and Ms. Brehmer:

The Sacramento County Department of Transportation (SACDOT) has reviewed the NOA of the DEIR and GRR for American River Commons, dated March 2015. We appreciate the opportunity to review this document. We have following comments to offer:

R-1

1. **General.** The proposed levee improvements require the transport of approximately one million yards of soil and nearly three million tons of rock over Sacramento County roads to various levee sites within Sacramento County. The high volume of trucks and heavy weight associated with these trucks will significantly degrade affected County roadways and shorten the life of these haul roads. Due to the roadway impacts site specific studies should be done for each levee improvement area. The study should contain detailed truck traffic information including haul routes, haul volumes per truck (soil and rock), associated haul truck types, number and frequency of trucks, proposed hauling hours, and associated roadway traffic volumes. Based on the results of the project specific reports, the project applicant should provide to Sacramento County a summary of the roadway impacts and proposed remediation efforts that will be undertaken by the project sponsor to account for County roadway degradation and damage.

R-2

2. **General.** Please coordinate with the SACDOT staff in implementing the Traffic Safety and Control Plan for construction related truck traffic and any bike trail and/or roadway closures.

If you have any questions please call me at (916) 875-2844.

Sincerely,

Kamal Atwal

American River Common Features General Reevaluation Report Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR) (SAC201301442)

Dear Ms. Baker and Ms. Brehmer:

Thank you for providing the draft EIS/EIR for the American River Common Features (ARCF) General Reevaluation Report to the Sacramento Metropolitan Air Quality Management District (SMAQMD) for review. SMAQMD staff comments on the air quality and climate change sections of the draft EIS/EIR follow.

S-1
1. Clarify which model year on-road haul trucks will be used for the project, 2007 and newer or 2010 and newer (pages 188, 190, 196, 199 and Appendix D).

S-2
2. The emissions discussion for Alternative 2 refers to Tables 30 and 31, the emissions estimates for Alternative 1 (page 198). Since the two alternatives would result in different emissions due to expansion of the Sacramento Weir in Yolo County and reduction of levee work in Sacramento County, separate emissions tables should be provided for Alternative 2.

S-3
3. Requiring contractors to do particulate matter "dispersion" modeling prior to starting construction is not generally recommended (page 201). Emissions modeling conducted for the project assumes construction would disturb approximately 7 acres/day, which is below the 15 acres/day level that triggers dispersion modeling (Appendix D). SMAQMD's recommended fugitive dust control mitigation measures (basic and enhanced) are included in the project, therefore additional dispersion modeling is not necessary.

S-4
4. Clarify which mitigation measure is being required for off-road equipment, Tier 4 standards or SMAQMD's enhanced exhaust controls (20% NOx and 45% PM reduction) (pages 188 and 202). Is the mitigation for Alternative 1 different from Alternative 2?

S-5
5. Clarify that SMAQMD adopted GHG significance thresholds in October 2014 that can be used in subsequent environmental analyses for ARCF projects (page 212).

S-6
6. Although greenhouse gas emissions were analyzed and determined to be less than significant, a list of measures were included that "may be considered to lower GHG" emissions during construction including the purchase of offsets for GHG emissions that exceed future significance thresholds (page 215). Since the SMAQMD has an adopted construction threshold for GHG emissions and this document already referenced the 10,000 metric ton Bay Area threshold, all reference to a 7,000 metric ton presumptive threshold should be removed from the measure.

S-7
7. Appendix D references Tables 1a and 1b, which don't appear to be included in the document.

S-8
8. All projects are subject to applicable SMAQMD rules in affect at the time of construction. A list of the most common rules that apply to construction projects is attached for your convenience. SMAQMD rules can be obtained on the SMAQMD's webpage: www.airquality.org.

If you have any questions regarding these comments please contact me at (916) 874-4881 or khuss@airquality.org. I look forwarding to receiving the final EIS/EIR.

Sincerely,

Karen Huss

ATTACHMENT - SMAQMD Rules & Regulations Statement (revised 3/12)

*The following statement is recommended as standard condition of approval or construction document language for **all** development projects within the Sacramento Metropolitan Air Quality Management District (SMAQMD):*

All projects are subject to SMAQMD rules in effect at the time of construction. A complete listing of current rules is available at www.airquality.org or by calling 916.874.4800. Specific rules that may relate to construction activities or building design may include, but are not limited to:

Rule 201: General Permit Requirements. Any project that includes the use of equipment capable of releasing emissions to the atmosphere may require permit(s) from SMAQMD prior to equipment operation. The applicant, developer, or operator of a project that includes an emergency generator, boiler, or heater should contact the SMAQMD early to determine if a permit is required, and to begin the permit application process. Portable construction equipment (e.g. generators, compressors, pile drivers, lighting equipment, etc.) with an internal combustion engine over 50 horsepower are required to have a SMAQMD permit or a California Air Resources Board portable equipment registration. Other general types of uses that require a permit include, but are not limited to dry cleaners, gasoline stations, spray booths, and operations that generate airborne particulate emissions.

Rule 403: Fugitive Dust. The developer or contractor is required to control dust emissions from earth moving activities, storage or any other construction activity to prevent airborne dust from leaving the project site.

Rule 414: Water Heaters, Boilers and Process Heaters Rated Less Than 1,000,000 BTU PER Hour. The developer or contractor is required to install water heaters (including residence water heaters), boilers or process heaters that comply with the emission limits specified in the rule.

Rule 417: Wood Burning Appliances. This rule prohibits the installation of any new, permanently installed, indoor or outdoor, uncontrolled fireplaces in new or existing developments.

Rule 442: Architectural Coatings. The developer or contractor is required to use coatings that comply with the volatile organic compound content limits specified in the rule.

Rule 460: Adhesives and Sealants. The developer or contractor is required to use adhesives and sealants that comply with the volatile organic compound content limits specified in the rule.

Rule 902: Asbestos. The developer or contractor is required to notify SMAQMD of any regulated renovation or demolition activity. Rule 902 contains specific requirements for surveying, notification, removal, and disposal of asbestos containing material.

Naturally Occurring Asbestos: The developer or contractor is required to notify SMAQMD of earth moving projects, greater than 1 acre in size in areas "Moderately Likely to Contain Asbestos" within eastern Sacramento County. Asbestos Airborne Toxic Control Measures, Section 93105 & 93106 contain specific requirements for surveying, notification, and handling soil that contains naturally occurring asbestos.

Subject: Draft Environmental Impact Statement/Report (Draft EIS/EIR) for the American River Common Features General Re-evaluation Report, Sacramento County

Dear Ms. Brehmer:

The California State Lands Commission (CSLC) staff has reviewed the subject Draft EIS/EIR for the American River Common Features General Re-evaluation Report (Project), which is being prepared by the Central Valley Flood Protection Board (CVFPB), as the lead agency under the California Environmental Quality Act (CEQA) (Pub. Resources Code, § 21000 et seq.), and the U.S. Army Corps of Engineers (Corps) as the lead agency under the National Environmental Policy Act (NEPA) (42 U.S.C. § 4321 et seq.). The CSLC is a trustee agency for projects that could directly or indirectly affect sovereign lands and their accompanying Public Trust resources or uses. Additionally, because the Project involves work on sovereign lands, the CSLC will act as a responsible agency. Comments on the Notice of Preparation were provided on March 28, 2008 (attached).

<u>CSLC Jurisdiction and Public Trust Lands</u>

The CSLC has jurisdiction and management authority over all ungranted tidelands, submerged lands, and the beds of navigable lakes and waterways. The CSLC also has certain residual and review authority for tidelands and submerged lands legislatively granted in trust to local jurisdictions (Pub. Resources Code, §§ 6301, 6306). All tidelands and submerged lands, granted or ungranted, as well as navigable lakes and waterways, are subject to the protections of the Common Law Public Trust.

As general background, the State of California acquired sovereign ownership of all tidelands and submerged lands and beds of navigable lakes and waterways upon its admission to the United States in 1850. The State holds these lands for the benefit of all people of the State for statewide Public Trust purposes, which include but are not limited to waterborne commerce, navigation, fisheries, water-related recreation, habitat preservation, and open space. On navigable non-tidal waterways, including lakes, the State holds fee ownership of the bed of the waterway landward to the ordinary low water mark and a Public Trust easement landward to the ordinary high water mark, except where the boundary has been fixed by agreement or a court. Such boundaries may not be readily apparent from present day site inspections.

Based on the information submitted in the Draft EIS/EIR, portions of the Project are or may be located on State-owned sovereign land in the Sacramento River and the American River. Portions of the Project that are located in the American River may also be on sovereign land granted to the city of Sacramento pursuant to Chapter 519, Statutes of 1868. To the extent the proposed levee improvement project involves State-owned sovereign lands in the Sacramento River and the American River, a lease will be required. Staff of the Commission will need to review each of the specific proposed project sites prior to determining whether the project site involves land under the granted or ungranted jurisdiction of the CSLC, and whether a lease is required.

T-1

Portions of the Project located in Natomas East Main Drainage Canal are not under CSLC jurisdiction and therefore do not require a lease. Portions of the proposed Project including Arcade Creek, Dry Creek, Robla Creek, Magpie Creek and the Sacramento Weir and Bypass may involve sovereign land under the jurisdiction of the Commission, however, we are currently unable to determine the extent or location of any sovereign ownership interests of the State in these project areas, so no lease will be required for these areas of the Project. If you have any questions, please contact Wendy Hall, Public Land Management Specialist (see contact information below) to discuss the Commission's leasing requirements.

T-2

Please also be advised that the waterways involved in the Project are subject to a public navigational easement. This easement provides that the public has the right to navigate and exercise the incidences of navigation in a lawful manner on State waters that are capable of being physically navigated by oar or motor-propelled small craft. Such uses may include, but are not limited to, boating, rafting, sailing, rowing, fishing, fowling, bathing, skiing, and other water-related public uses. The activities completed under the Project must not restrict or impede the easement right of the public.

T-3

Project Description

The Project area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry, Robla, and Arcade Creeks and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento.

The purpose of the Project is to reduce the overall flood risk within the study area. The study area includes the city of Sacramento and surrounding areas. An unacceptably high risk of flooding from levee failure threatens the public safety of approximately 530,000 people, as well as property and critical infrastructures throughout the study area. Additionally, the State Capitol and many State agencies reside within the study area. Historic flooding events have caused loss of life and extensive economic damages. Approximately 83,000 structures throughout the study area are at risk of flooding in a 100-year event (1% annual change of flooding). This Draft EIS/EIR evaluates the potential significant environmental impacts of the alternatives discussed in the American River Common Features (ARCF) General Re-evaluation Report (GRR) (ARCF GRR). If the ARCF GRR is authorized by Congress, the Corps would begin construction to implement the Project. Alternative 2, Improve Levees and Widen the Sacramento Weir and Bypass has been identified as the Tentatively Selected Plan (TSP) and as the least environmentally damaging alternative as it results in less riparian habitat removal along the Sacramento River.

Environmental Review

CSLC staff requests that the lead agencies consider the following comments on the Project's Draft EIS/EIR.

General Comments

T-4

1. On page ES-1, the Draft EIS/EIR makes a statement in regards to purposes and intended uses of the EIS/EIR. CSLC staff requests that this paragraph be revised as shown below, to provide a clearer understanding of the Commission's role in the proposed Project.

   This ~~D~~EIS/~~D~~EIR will also be used by CEQA lead agencies, such as the CVFPB and Central Valley Regional Water Quality Control Board (RWQCB), Sacramento Area Flood Control Agency (SAFCA), and trustee and responsible *agencies, such as the California Department of Fish and Wildlife (CDFW)* and the California State Lands Commission (CSLC)*, to ensure that they have met the requirements of CEQA before deciding whether to issue discretionary permits* or leases *over which they have authority.*

Water Quality

T-5

2. Mercury/Methylmercury: Section 3.5 of the Draft EIS/EIR study area discusses mercury and methylmercury in the Sacramento and American Rivers. As noted on page 90, the placement of revetment along the river banks would temporarily generate increased turbidity in the immediate vicinity. Although section 3.5.6 (Avoidance, Minimization, and Mitigation Measures) does state that the Project would not exceed the Basin Plan turbidity objectives, and does provide for water quality testing, CSLC staff requests that the Draft EIS/EIR also include specific measures to control sediment release (and the subsequent release of mercury/methyl mercury) into waterways and onto State lands underlying those waterways, to further prevent exceedance of the turbidity objectives.

On April 22, 2010, the Central Valley Regional Water Quality Control Board (CVRWQCB) identified the CSLC as both a State agency that manages open water areas in the Sacramento-San Joaquin Delta Estuary and a nonpoint source discharger of methylmercury (Resolution No. R5-2010-0043), because subsurface lands under the CSLC's jurisdiction are impacted by mercury from legacy mining activities dating back to California's Gold Rush. Pursuant to a CVRWQCB Total Maximum Daily Load (TMDL), the CVRWQCB is requiring the CSLC to fund studies to identify potential methylmercury control methods in the Delta and to participate in
T-6 an Exposure Reduction Program. The goal of the studies is to evaluate existing control methods and evaluate options to reduce methylmercury in open waters under jurisdiction of the CSLC. Any action taken that may result in mercury or methylmercury suspension within the Sacramento-San Joaquin Delta Estuary may affect the CSLC's efforts to comply with the CVRWQCB TMDL.

Cultural Resources

3. Title to Resources: CSLC staff requests that Page 172 of the Draft EIS/EIR (under Avoidance, Minimization, and Mitigation Measures), and the programmatic
T-7 agreement that has been developed by the Corps in consultation with the State Historic Preservation Officer and the Advisory Council on Historic Preservation, include a statement that the title to all archaeological sites, and historic or cultural resources on or in the tide and submerged lands of California is vested in the State and under the jurisdiction of the CSLC (Pub. Resources Code, § 6313). CSLC staff also requests that the following statement be included in EIR's Mitigation and Monitoring Plan: "The final disposition of archaeological, historical, and
T-8 paleontological resources recovered on State lands under the jurisdiction of the CSLC must be approved by the Commission." Finally, CSLC staff requests that the lead agencies consult with Assistant Chief Counsel Pam Griggs (see contact
T-9 information below) should any cultural resources on State lands be discovered during construction of the proposed Project.

Climate Change

4. Sea Level Rise: Although sea level rise is mentioned in section 3.12 of the Draft EIS/EIR, there is no discussion of how the Project would address this potential issue. A tremendous amount of State-owned lands and resources under the Commission's jurisdiction will be impacted by rising sea levels. With this in mind, the lead agencies should consider discussing the effects of sea level rise on all resource
T-10 categories potentially affected by the proposed Project in the Draft EIS/EIR. Because of their nature and location, these lands and resources are already vulnerable to a range of natural events. Note that the State of California released the final "Safeguarding California: Reducing Climate Risk, an Update to the 2009 California Climate Adaptation Strategy" (Safeguarding Plan) on July 31, 2014, to provide policy guidance for state decision-makers as part of continuing efforts to prepare for climate risks. The Safeguarding Plan sets forth "actions needed" to safeguard ecosystems and resources as part of its policy recommendations for State decision-makers.

In addition, at its meeting on December 17, 2009, the CSLC approved the recommendations made in a previously requested staff report, "A Report on Sea Level Rise Preparedness" (Report), which assessed the degree to which the CSLC's grantees and lessees have considered the eventual effects of sea level rise on facilities located within the CSLC's jurisdiction. (The Report can be found on the CSLC's website, www.slc.ca.gov.) One of the Report's recommendations directs CSLC staff to consider the effects of sea level rise on hydrology, soils, geology, transportation, recreation, and other resource categories in all environmental determinations associated with CSLC leases. When considering lease applications, CSLC staff will (1) request information from applicants concerning the potential
T-11 effects of sea level rise on their proposed projects, (2) if applicable, require applicants to indicate how they plan to address sea level rise and what adaptation strategies are planned during the projected life of their projects, and (3) where appropriate, recommend project modifications that would eliminate or reduce potentially adverse impacts from sea level rise, including adverse impacts on public access.

Thank you for the opportunity to comment on the Draft EIS/EIR for the Project. As a responsible and trustee agency, the CSLC will need to rely on the Final EIR for the issuance of any lease as specified above and, therefore, we request that you consider our comments prior to certification of the EIR. Please send copies of future Project-related documents, including electronic copies of the Final EIS/EIR, Mitigation
T-12 Monitoring and Reporting Program (MMRP), Notice of Determination (NOD), CEQA Findings and, if applicable, Statement of Overriding Considerations when they become available, and refer questions concerning environmental review to Cynthia Herzog, Senior Environmental Scientist, at (916) 574-1310 or via e-mail at Cynthia.Herzog@slc.ca.gov. For questions concerning archaeological or historic resources under CSLC jurisdiction, please contact Assistant Chief Counsel Pam Griggs at (916) 574-1854 or via email at Pamela.Griggs@slc.ca.gov. For questions concerning CSLC leasing jurisdiction, please contact Wendy Hall, Public Land Management Specialist, at (916) 574-0994, or via email at Wendy.Hall@slc.ca.gov.

Sincerely,

Cy R. Oggins, Chief
Division of Environmental Planning
and Management

Subject: American River Common Features General Re-evaluation Report

Dear Ms. Bronson:

The State acquired sovereign ownership of all tidelands and submerged lands and beds of navigable waterways upon its admission to the United States in 1850. The State holds these lands for the benefit of all the people of the State for statewide Public Trust purposes which include waterborne commerce, navigation, fisheries, water-related recreation, habitat preservation, and open space. The landward boundaries of the State's sovereign interests in areas that are subject to tidal action are generally based upon the ordinary high water marks of these waterways as they last naturally existed. In non-tidal navigable waterways, the State holds a fee ownership in the bed of the waterway between the two ordinary low water marks as they last naturally existed. The entire non-tidal navigable waterway between the ordinary high water marks is subject to the Public Trust Easement. Both the easement and fee-owned lands are under the jurisdiction of the State Lands Commission. The locations of the ordinary high and low water marks are often related to the last natural conditions of the river, and may not be apparent from a present day site inspection.

To the extent the proposed levee improvement project involves State-owned sovereign lands in the Sacramento River, American River or the Natomas Basin, a lease will be required. Staff of the Commission will need to review each of the proposed sites prior to making the determination that a lease is required. If you have any questions, please contact Diane Jones, Public Land Manager, at 916-574-1843, to discuss the Commission's leasing requirements.

<u>Environmental Planning and Management Comments:</u>

The State Lands Commission recommends any of the proposed mitigation and project construction activities consider timing of the proposed work to account for state and federally listed endangered species. All arrangements with pertinent regulatory agencies should coincide with specific protection policies regarding incidental take and avoidance measures. Consideration should include, but not be limited to, seasonality of migratory or nesting species within the footprint of the project (i.e. Swainson's Hawks, Salmonids, etc.). Any construction activities along the water-side bank of restoration or flood protection improvements shall consider water quality issues affecting clarity and chemical reactions within the waters and make all the necessary arrangements to reduce or mitigate for these concerns.

In addition, greenhouse gas emissions information consistent with the California Global Warming Solutions Act (AB 32) should be included. This would include a determination of the greenhouse gases that will be emitted as a result of construction and ongoing operations and maintenance, a determination of the significance of the impact, and mitigation measures to reduce that impact.

If you have any questions with the environmental review, please contact Christopher Huitt, Staff Environmental Scientist, at 916-574-1938, to discuss these comments or questions.

Sincerely,

Marina R. Brand

Re: ARCF Draft EIR/EIS Comments

Dear Ms. Baker,

I reviewed the Cultural Resources Section in light of recent discoveries along the Feather River levees during degrading operations in preparation for improvements to address levee deficiencies. It is my understanding that the Sutter Buttes Flood Control Agency encountered nine buried American Indian midden sites within a nine-mile stretch in Butte County alone, some including human burials. Cultural deposits ranged anywhere from 9 to 18 feet below levee grade.

Historically, sites along the river were situated on high ground (the natural levees) in the form of mounds. As such, it stands to reason that when Euro-Americans began raising these embankments to combat floods, archaeological sites were incorporated, if possible, to save on the cost of construction efforts. Such early improvements to natural levees were then subsequently raised, enlarged, and bolstered with slope stability berms, essentially covering over any evidence pointing to the existence of cultural resource today.

U-1 My concern is that *some* sites within the ARCF study area are likely to have remained unidentified during this initial stage of the Section 106 process, given that investigations were restricted to surface observations. Mitigation Measure CR-3, Archaeological Monitoring, while addressing the possibility for undiscovered resources, essentially serves to defer the identification effort. Unfortunately, post-review discoveries occur during critical construction operations when it is too late to treat them properly and delays can be ill-afforded. I am not suggesting this mitigation measure be removed… only that, in addition, subsurface investigations be required to ensure that sites are found prior to construction when it is still possible to avoid or limit impacts. This proactive approach can be achieved through geophysical survey and ground-truthing.

Sincerely,

Kim Tremaine

Re: ARCF Draft GRR Comments

Dear Ms. Baker,

V-1 I have reviewed portions of the Draft GRR related to Geotechnical Risk Analysis. It focused on three failure modes taking into account existing base conditions revealed through a methodology heavily dependent upon limited bore log data. From this, strengths and weaknesses of various reaches were calculated and prioritized. As one of the Independent External Peer reviewers in 2009 commented, the methods used faithfully followed USACE guidance in ETL 1110-2-547 and ETL-1110-2-556. It was, at that time, a sufficient level of analysis. In the interim, however, the National Levee Safety Program has been reevaluating their guidance and is now advocating Total Conditional Performance Analysis (i.e., the combined probability of *all* failure modes). Does the USACE plan to require the analysis be updated accordingly?

V-2 DWR, in a state-led effort to improve levee safety through new urban levee design criteria, now recognizes that urban areas are more likely to contain numerous associated embedded deteriorating features related to infrastructure and flood defenses that are potentially 100 years or older. As such, they recommend civil engineers use or conduct land-based continuous levee crown geophysical methods to assess the levee material and the upper 20 feet of foundation materials to identify unknown penetrations in an effort to meet the urban level of flood protection (Section 7.13 of their 2012 guidance). This is because aging penetrations, under certain load conditions, can result in transient and progressive interior damages, leading to localized instabilities and piping (recognized as the prime failure mechanism for almost all levee systems). Does the USACE plan to require an update of existing conditions to included fine-grained geophysical data to reduce uncertainty in performance risk assessments?

Sincerely,

Kim Tremaine

RE: Draft American River Watershed Common Features General Reevaluation Report

Dear Ms. Baker:

Thank you for the opportunity to comment on Draft American River Watershed Common Features General Reevaluation Report (GRR). As you may be aware, the Delta Stewardship Council (Council) is an independent state agency and the Council's primary mission is to further the achievement of the coequal goals of water supply reliability for California and protecting and restoring the Delta ecosystem while protecting and enhancing the Delta as an evolving place (Water Code section 85054).

The Council has a legally enforceable management framework for the Delta and Suisun Marsh called the Delta Plan. The Delta Plan applies a common sense approach based on the best available science to restore habitat, increase the diversity and efficiency of California's water supplies, enhance floodplains, improve the Delta's levee system, and preserve the Delta's agricultural values. In many cases, the Delta Plan calls for balancing competing needs in the Delta, e.g., protecting habitat while reducing flood risk. In addition, the Delta Reform Act requires the Council to develop an investment strategy for project and non-project levees in the Delta to protect people, property and the State's interests (Water Code sections 85305(a) and 85306).

The Delta Plan contains an interim set of priorities for levee investments in the Delta. These priorities, in combination with the Council's authority to assure that State agencies act consistently with the Delta Plan, ensure that levee spending by the California Department of Water Resources and the Central Valley Flood Protection Board reflects the Delta Plan's priorities. The Council is currently updating this investment strategy to better define the State's interests. The updated strategy will incorporate information on proposed projects based on system-wide risk evaluations such as the one described in this draft document. Since some of the proposed GRR project activities lie within the Delta and play an important role in maintaining the integrity of the Delta levee system, it is essential that our agencies continue to coordinate closely on these types of efforts.

Comments on the Draft General Reevaluation Report

Comments in this letter are focused primarily on our concerns with the overly narrow definition of federal interest in the project area, uncertainty regarding achieving the urban level of flood protection for the Sacramento Metropolitan area, and mitigation of impacts to biological resources. In a separate letter to the California Central Valley Flood Protection Board (CVFPB) on the companion draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for this draft document, we provide comments specifically on the consistency of this project with the Delta Plan's 14 regulatory policies. A copy of this letter will be provided to your agency as well.

Overly Narrow Definition of Federal Interest

We are concerned about policy constraints and planning processes that have resulted in the definition of an overly narrow federal interest in the Delta. As stated in the draft GRR, the U.S. Army Corps of Engineers (USACE) is working on the Central Valley Integrated Flood Management Study (CVFIMS), which is a federal companion document to the Central Valley Flood Protection Plan of 2012 (CVFPP), Regional Flood Management Plans, and Integrated Regional Watershed Management Plans. The CVIFMS shares the CVFPP's vision of a multi-objective watershed study focused on integrated water resource management for flood risk management, ecosystem restoration, and other water resource purposes. In addition, the federal Energy and Water Development Appropriations Act of 2012 (Title II of the Consolidated Appropriations Act of 2012 [PL 112-074]) contains, in pertinent part, the following:

> *The Federal policy for addressing California's water supply and environmental issues related to the Bay-Delta shall be consistent with State law, including the coequal goals of providing a more reliable water supply for the State of California and protecting, restoring, and enhancing the Delta ecosystem....(Section 205).*

The multi-objective approach of these planning activities are also aligned with the State's two coequal goals as part of the Delta Reform Act of 2009 – providing a more reliable water supply for the Delta and protecting, restoring and enhancing the Delta ecosystem (Public Resources Code section 29702). The objectives inherent in these goals include restoring the Delta ecosystem and reducing risks to people, property and state interests in the Delta (Water Code section 85020).

The Tentatively Selected Plan (TSP), however, was developed based on the USACE's single objective of regional flood risk reduction while the GRR evaluates the flood risk management system for the American River, Sacramento River and additional five (5) adjacent small channels. We believe this is also inconsistent with USACE's *Civil Works Strategic Plan 2014-*

2018, which calls for the use of Integrated Water Resources Management, a holistic approach that considers economic benefits, ecosystem quality, and health and public safety in project formulation. Failure to include multiple objectives in the planning process results in a lost opportunity to implement projects that provide multiple benefits.

W-1 We understand that the conclusions of the GRR, along with other recently completed feasibility studies such as the West Sacramento General Reevaluation Study, Sacramento River Bank Protection Project, and the Delta Islands and Levees Feasibility Study, will support the development of the CVFIMS. Therefore, for this GRR, USACE should include a system-wide evaluation with a multi-benefit approach for the alternatives screening process to support a broader definition of the federal interest.

Clarification of Urban Level of Flood Protection

The objective of the non-federal sponsors, the State of California and Sacramento Area Flood Control Agency (SAFCA), is to meet the requirements of California Senate Bill (SB) 5 and the Central Valley Flood Protection Act to achieve an urban level of 200-year flood protection, including the Urban Levee Design Criteria (ULDC). One purpose of the ULDC requirement is to increase the likelihood that the levee will hold water until it overtops without a catastrophic breach, providing additional levee reliability and time for evacuation. It is unclear in the draft GRR whether this urban level of protection will be achieved by the TSP. According to the risk analyses from the GRR, with the TSP in place, the flood protection assurance (i.e. non-exceedance probability) for the Pocket Area of Sacramento, given a 200-year flood event, is 94%. In addition, given the project conditions, the risk analyses also show that a levee segment along the America River South Reach (index point A) around River Mile (RM) 8.9 can only provide 65% assurance, given a 200-year flood event. The results of the risk analyses from the GRR for the America River South Reach concluded that the Annual Exceedance Probability (AEP) for the America River South Reach as a whole is 1 in 147. Even with a 94% flood protection assurance, given the elevations of the natural terrain and the indicated weak link of the levee system at the RM 8.9 along the America River, we are concerned that the W-2 Pocket Area in the Delta may not attain the state-required 200-year level of flood protection. However, the GRR states that the TSP meets the goal of attaining FEMA level accreditation and meets the SB 5 criteria for urban level of protection. In the final GRR, please clarify the current annual chance of flooding, the resulting annual chance of flooding under each alternative, and whether the TSP can provide 200-year protection according to the USACE risk evaluation guidelines and state requirements. This analysis should be agreed upon by USACE and local communities.

Sacramento Weir and Bypass Widening

As the draft GRR states, widening the Sacramento Weir and Bypass as a part of the TSP will
W-3 reduce the regional flood risk by lowering the flood stage during a flood event greater than a 1/100 Annual Chance Exceedance (ACE) event. It is unclear whether there is coordination

W-3 (Cont.) between the GRR work and the Department of Water Resources (DWR) Sacramento River Basin-Wide Feasibility Study effort (including the scales and configurations for the Sacramento Weir and Bypass improvements and the analyses of potential impacts and benefits on a system-wide scale), and the draft 2017 Central Valley Flood Protection Plan Conservation Strategy. In the final GRR, please address this concern by providing additional information on current coordination between these efforts. Coordination among the USACE, CVFPB, and DWR is critical in evaluating possible measures to protect existing developed areas along the Sacramento and the American River.

Biological Resources

Our primary concerns related to this section of the draft GRR are the impacts to riparian vegetation and associated impacts on special status species as a result of the TSP and the USACE's levee vegetation policy. Dynamic complexes of riparian woody and scrub habitat along river channels and associated floodplains, particularly in areas where there is connectivity between such habitats, provide a suite of ecosystem benefits to on-site and downstream environments. Riparian vegetation provides habitat for terrestrial species, such as Swainson's hawk, white-tailed kite, yellow breasted chat, yellow-billed cuckoo, and valley elderberry longhorn beetle. For aquatic species, including various life stages of Chinook salmon, Central Valley steelhead, splittail, and sturgeon, established woody riparian vegetation provides refuge from currents and predators, and serves as a source of organic carbon in support of the aquatic food web. Riparian areas can reduce non-point source pollution from pesticides, herbicides, and nutrients from fertilizers by serving as transition zones between upland urban/agricultural areas and adjacent waterways. Additional water quality benefits include improved levels of dissolved oxygen and moderation of water temperature. Riparian areas also provide the public with opportunities for active and passive recreation, such as hiking, boating and bird watching. According to the draft GRR, the proposed project would need to remove levee vegetation in consideration of the criteria of the SAFCA Vegetation Management Decision Key, the variance for the USACE Engineer Technical Letter (ETL) 1110-2-583 Vegetation Free Zone requirements, and the USACE System-Wide Improvement Framework (SWIF) agreement. Along the main stem of the Sacramento River, the proposed vegetation removal under the TSP could result in the loss of 750 riparian trees, as well as extensive removal of shaded riverine aquatic habitat associated with placement of rock fill along nine miles of river channel. The impacts to these habitats are expected to adversely affect the special status species that depend upon them, including Chinook salmon and Swainson's hawk. W-4 If a USACE vegetation variance is approved, it would allow vegetation to remain on the lower waterside levee slope and prevent additional impacts on riparian trees and shaded riverine aquatic habitat. In the final GRR, USACE should provide assurance of granting the vegetation variance or include the status of the USACE vegetation variance application process.

Given the tremendous investment by state, federal, and local agencies, as well as nonprofit organizations and individuals, to promote recovery of salmonids and other threatened and endangered species that use the Sacramento and American Rivers as migratory corridors, it is essential to make every effort to avoid or minimize these impacts. The benefits to special status species provided by the proposed mitigation measures in the draft GRR are unclear. We recommend that, to the maximum feasible extent, any impacts to the channel margin habitat along important salmonid migratory corridors should be mitigated on-site. In the event that off-site mitigation is necessary, we also suggest that any off-site mitigation occurs in close proximity and along the same waterway as where the impacts would occur to demonstrate that the mitigation is restoring equivalent, in-kind habitat. In the final GRR or the associated EIS/EIR, please identify and include the details of the mitigation measures with or without the USACE vegetation variance and/or the SWIF in place, and describe how they would address impacts to special status species, such as salmonids and Swainson's hawk.

W-5

Other recent USACE flood-risk reduction feasibility studies/plan, including the Sacramento River Bank Protection Project and the Lower San Joaquin River Project Integrated Interim Feasibility Report, also involve substantial removal or degradation of riparian and shaded riverine aquatic habitat within the Delta. We recommend that, as the USACE develops the CVIFMS, the cumulative impacts of levee improvement and maintenance projects on riparian and shaded riverine aquatic habitat be assessed. The study should analyze whether the collective loss of those habitat types will adversely affect the achievement of the coequal goal of ecosystem restoration of the Delta. Additionally, we recommend that the CVIFMS assess the cumulative impacts that proposed placement of miles of rock revetment along salmonid migration corridors for levee bank erosion control measures will have on juvenile salmonid rearing and outmigration success.

W-6

According to the draft GRR, the Benefit-Cost (B/C) ratio of the TSP is 4.3 and the TSP is also the Local Preferred Plan (LPP). If additional funding is available, the project team should reconsider including additional alternatives or objectives with lower but acceptable B/C ratios, given the planning constraints. These alternatives could include additional project features that may restore and improve shaded riverine aquatic habitat for the study area, since the riparian habitat along the Sacramento River and the American River is important for native terrestrial and aquatic wildlife. For example, the project can evaluate the use of setback levees as a part of the alternatives, where feasible, to increase floodplains and riparian habitats. The Delta Plan recommends areas of the Delta for evaluating the feasibility of using setback levees for levee projects within the Sacramento River watershed, including urban levee improvement projects in Sacramento.

W-7

Next Steps

We look forward to continuing to work with your agency on this project. I encourage you to contact You Chen (Tim) Chao (916-445-0143) at YouChen.Chao@deltacouncil.ca.gov or Daniel Huang at Daniel.Huang@deltacouncil.ca.gov with your questions, comments, or concerns. We look forward to working with you to ensure consistency of the American River Watershed Common Features General Reevaluation Report Project with the Delta Plan while also avoiding, minimizing, or mitigating potential environmental impacts. We also look forward to continued discussions with the USACE and the CVFPB regarding this proposed project as well as the development of the CVFIMS and how these activities can be incorporated into the updated Delta levees investment strategy.

Sincerely,

Cindy Messer

RE: Draft American River Watershed Common Features General Reevaluation Report Project Environmental Impact Statement/Environmental Impact Report, SCH #2005072046

Dear Ms. Brehmer:

Thank you for the opportunity to comment on the draft American River Watershed Common Features General Reevaluation Report (GRR) Project Environmental Impact Statement/Environmental Impact Report (EIS/EIR), prepared by the U.S. Army Corps of Engineers (USACE). The Delta Stewardship Council (Council) staff is pleased to see that this project is being proposed to improve the regional levee system and its existing conditions to reduce flood risk in the Sacramento area.

The Council has a legally enforceable management framework for the Delta and Suisun Marsh called the Delta Plan. The Delta Plan applies a common sense approach based on the best available science to restore habitat, increase the diversity and efficiency of California's water supplies, enhance floodplains, improve the Delta's levee system, and preserve the Delta's agricultural values. In many cases, the Delta Plan calls for balancing competing needs in the Delta, e.g., protecting and restoring habitat while reducing flood risk. Since part of the proposed GRR project activities lie within the Legal Delta and play an important role in maintaining the integrity of the Delta levee system, it is essential that our agencies continue to coordinate closely on these types of efforts.

Delta Plan Covered Actions and Certification of Consistency

Through the Delta Reform Act, the Council was granted specific regulatory and appellate authority over certain actions that take place in whole or in part in the Delta and Suisun Marsh. The Council exercises that authority through development and implementation of the Delta

Plan. State and local agencies are required to comply with the set of 14 regulatory policies contained within the Delta Plan.
According to the Delta Reform Act, it is the state or local agency approving, funding, or carrying out the project that must determine if a project is a "covered action" subject to regulations of the Delta Plan, and if so, certify consistency of the project with Delta Plan policies (Water Code Section 85225). Generally, the California Environmental Quality Act (CEQA) lead agency makes the determination if a project is a covered action, which in the case of this project is the Central Valley Flood Protection Board (CVFPB). If it is determined that the project is a covered action, CVFPB will need to complete a certification of consistency that demonstrates that the project is consistent with the regulatory policies of the Delta Plan. (Please refer to our website at http://deltacouncil.ca.gov/covered-actions for more information about the covered action process.) Information and analysis needed to support a consistency certification could be taken directly from the EIS/EIR.

X-1

Council staff has reviewed the draft EIS/EIR and has found that several of the proposed risk reduction measures are within the legal Delta and this proposed project may be a "covered action" and, therefore, subject to Delta Plan regulations, although that determination ultimately resides with CVFPB. Consequently, we have identified the issues below that we believe you should consider, for the purposes of compliance with both the Delta Reform Act and CEQA.

Comments on the Draft EIS/EIR

For this letter, our comments are organized by subject area. Within each subject area we have included information on the Delta Plan policy (or policies) possibly implicated by this project and the requirements of these policies, as well as specific comments on the draft EIS/EIR. Where appropriate, we have also provided information on mitigation measures from the Delta Plan's EIR that should be considered for this project if it is deemed a covered action. In a separate but related letter to the USACE on the draft GRR, we provide comments specifically on the process of identifying the federal interest in the project. A copy of this letter will be provided to your agency as well.

Delta Plan EIR Mitigation Measures

Delta Plan Policy **G P1** (23 CCR Section 5002) requires that actions not exempt from CEQA and subject to Delta Plan regulations must include applicable feasible mitigation measures consistent with or more effective than those identified in the Delta Plan Environmental Impact Report (EIR). The Delta Plan's Program EIR provides a list of mitigation measures to address, including those to address impacts to biological resources and agricultural resources. (Mitigation measures can be found in the Delta Plan Mitigation and Monitoring Reporting Program document, http://deltacouncil.ca.gov/sites/default/files/documents/files/Agenda%20Item%206a_attach%202.pdf.) The Delta Plan mitigation measures most relevant to this project are discussed under the relevant subject area headings below.

Risk Reduction

Delta Plan Policy **RR P1** (23 CCR Section 5012) calls for the prioritization of State investments in Delta flood risk management, including levee operation, maintenance and improvements. This policy includes interim priorities categorized as specific goals to guide budget and funding allocation for levee improvements and to assist California Department of Water Resources (DWR) and the CVFPB in achieving a balance in funding the various goals. In consultation with DWR, CVFPB, Delta Protection Commission, and other state and local agencies, the Council is currently updating this investment strategy to better define the State's interests. The updated strategy should incorporate information on proposed projects such as the one described in this draft document.

The draft EIS/EIR states that the purpose of the proposed action under CEQA is to reduce flood risk to the Sacramento area by improving the levees that surround the study area. The draft GRR further states that the objective of the non-federal sponsors, the State of California and Sacramento Area Flood Control Agency (SAFCA), is to meet the requirements of California Senate Bill (SB) 5 and the Central Valley Flood Protection Act to achieve an urban level of protection. The non-federal sponsors' goal is consistent with one of the goals contained in Delta Plan Policy RR P1: to "Protect existing urban and adjacent urbanizing areas by providing 200-year level flood protection."

The Sacramento area, according to the draft EIS/EIR, is one of the most at risk areas for flooding in the United States, and there is a high probability of levee failure when flood waters flow in either the American or Sacramento Rivers, which stress the network of levees protecting the study area. Based on our review of the draft GRR, it is unclear if the proposed project can effectively reduce the flood risk for the region and assist local communities in achieving the urban level of flood protection as required by the State. According to USACE's risk analyses from the draft GRR, the results of the risk analyses for the American River South Reach concluded that the Annual Exceedance Probability (AEP) for the American River South (ARS) Reach as a whole is 1 in 147. These results demonstrate that the flood risk for the ARS region would be reduced with the Tentatively Selected Plan (TSP) in place, but this information is insufficient for concluding that the proposed project can achieve the non-federal sponsors' goal.

X-2

In the final EIS/EIR, the results of risk analyses of multiple alternatives should be included and clearly presented according to the USACE standards and State's urban level of flood protection criteria. This information will be essential for assessing consistency with Delta Plan Policy RR P1. Also, the final EIS/EIR should include the potential effects on existing conditions or adjacent upstream and downstream flood control systems. These additional analyses will not only enhance the environmental impact assessments for the proposed alternatives but may also be beneficial to USACE's ongoing Central Valley Integrated Flood Management Study, DWR's 2017 Central Valley Flood Protection Plan update, and the Council's development of the Delta Levees Investment Strategy.

The draft EIS/EIR states that the operation and maintenance (O&M) of the improved levee segments and the modified Sacramento Weir/Bypass are the responsibility of the local maintaining agencies, including the American River Flood Control District, DWR's Maintenance Area 9, and the City of Sacramento. The final EIS/EIR, or subsequent environmental evaluation documents, should include the details of the O&M plan, along with mitigation

X-3 measures, for each levee improvement site and the modified Sacramento Weir/Bypass with well-defined measurable performance standards. This should be included in addition to the Standard Operation and Maintenance Manual for the Sacramento River Flood Control Project.

Habitat Restoration

The comments regarding habitat restoration pertain to the Sacramento River East Levee work and proposed associated off-site mitigation sites, since these areas are located within the legal Delta. There are two regulatory policies in the Delta Plan related to ecosystem restoration actions. Delta Plan Policy **ER P2** (23 CCR Section 5006) states that habitat restoration must be consistent with Appendix 3 of the Delta Plan regulations, which is an excerpt from the 2011 Draft Ecosystem Restoration Program Conservation Strategy. Delta Plan Policy **ER P4** (23 CCR Section 5008) calls for levee projects to evaluate and where feasible incorporate alternatives, including the use of setback levees, to increase floodplains and riparian habitats. The policy also calls for the evaluation of setback levees of certain areas of the Delta, including the urban levees addressed in this EIS/EIR.

The proposed project will involve extensive levee improvement work along the east bank of the Sacramento River and the American River. The TSP includes a suite of erosion protection measures for identified levee segments which include placement of rock fill above and below the low summer/fall waterline, placement of a launchable rock trench, and substantial removal of levee vegetation.

According to the draft EIS/EIR, the Local Maintaining Agency would address vegetation issues under the System Wide Improvement Framework (SWIF) agreement, with the assumption that the USACE would approve a variance for USACE Engineer Technical Letter (ETL) 1110-2-583 Vegetation Free Zone requirements. Even with a USACE approved vegetation variance, the proposed vegetation removal under the TSP could result in the loss of 750 riparian trees along the main stem of the Sacramento River, as well as extensive removal of shaded riverine aquatic habitat associated with placement of rock fill along nine miles of river channel. The impacts to these habitats are expected to have adverse effects on the special status species that depend upon them, including Chinook salmon and Swainson's hawk. CVFPB should work

X-4 with USACE to obtain a vegetation variance and include the status of the variance application process in the final GRR and associated final EIS/EIR.

As acknowledged in the draft EIR under Impact AG-2, the project proposed in the GRR is expected to have potentially significant impacts on riparian habitat. This would be due to removing established riparian vegetation and shaded riverine aquatic habitat through placement of rock fill and its vegetation management plan to remove trees and shrubs it considers detrimental to maintaining levee integrity. The Delta Plan's EIR Biological Resources Mitigation Measure 4-3 calls for proponents to design projects that avoid impacts that would lead to substantial loss of fish and wildlife habitat. If there will be a loss of habitat for fish and wildlife species from a project, Mitigation Measure 4-3 calls for proponents to replace, restore, or enhance habitats for those species and preserve in-kind habitat.

Given the tremendous investment by State, federal, and local agencies, as well as nonprofits, to promote recovery of salmonids and other threatened and endangered species that use the Sacramento and American Rivers as migratory corridors, it is essential to make every effort to avoid or minimize impacts to these riparian and channel margin habitat. The benefits to special status species provided by the proposed mitigation measures in the draft EIS/EIR are unclear. X-5 We recommend that, to the maximum extent feasible, any impacts to the channel margin habitat along important salmonid migratory corridors should be mitigated on-site. In the event that off-site mitigation is necessary, we also suggest that any off-site mitigation occurs in close proximity and along the same waterway as where the impacts would occur to demonstrate that the mitigation is restoring equivalent, in-kind habitat.

X-6 In the final draft EIS/EIR or additional environmental evaluations, please identify and include the details of the mitigation measures with or without the USACE vegetation variance and/or the SWIF in place, and describe how they would address impacts to special status species, such as salmonids and Swainson's hawk. X-7 If additional funding is available, and a lower benefit-cost ratio of the project is acceptable to USACE and non-federal sponsors, additional alternatives that offer opportunities to restore and improve shaded riverine aquatic habitat important for native terrestrial and aquatic wildlife should be considered.

Invasive Species

Delta Plan Policy **ER P5** (23 CCR Section 5009) calls for avoiding introductions and habitat improvements for invasive nonnative species. This policy states, "The potential for new introductions of or improved habitat conditions for nonnative invasive species, striped bass, or bass must be fully considered and avoided or mitigated in a way that appropriately protects the ecosystem." Analysis on this matter should address both nonnative wildlife species (e.g., introduced sport fish species), as well as nonnative vegetation, including both aquatic and terrestrial weeds. X-8 In-water rock fill often provides cover for nonnative predators like striped bass, but is often negatively associated with native fish species like Chinook salmon. In the final EIR, please describe how the project will avoid or mitigate permanent impacts associated with in-water rock fill, including the creation of habitat conducive to invasive fish predators which could impact listed native fish.

X-9 Delta Plan Biological Resources Mitigation Measure 4-1 includes a requirement that an invasive species management plan shall be developed and implemented for any projects where construction or operation could lead to introduction or facilitation of invasive species establishment. Based on the concerns raised above regarding invasive species, we believe that such a plan is necessary and should be developed soon to help guide site-specific levee

X-9 (Cont.) improvement designs. This plan is to be developed in consultation with Department of Fish and Wildlife (DFW), U.S. Fish and Wildlife Service, National Marine Fisheries Service, and local experts. The invasive species management plan is to include the following elements: nonnative species eradication methods, nonnative species management methods, early detection methods, notification requirements, best management practices for preconstruction, construction, and post construction periods, monitoring, remedial actions and report requirements; and provisions for updating the target species list over the lifetime of the project as new invasive species become potential threats to the integrity of the local ecosystems.

Best Available Science and Adaptive Management

X-10 Delta Plan Policy **G P1** (23 CCR Section 5002) also states that actions subject to Delta Plan regulations must document use of best available science, as defined by Appendix 1A of the Delta Plan (refer to http://deltacouncil.ca.gov/sites/default/files/documents/files/AppB_Combined_2013.pdf). Additionally, this policy calls for water management and ecosystem restoration projects to include adequate provisions for continued implementation of adaptive management, appropriate to the scope of the action. This requirement can be satisfied through the development of an adaptive management plan that is consistent with the framework described in Appendix 1B of the Delta Plan (refer to http://deltacouncil.ca.gov/sites/default/files/documents/files/AppB_Combined_2013.pdf), along with documentation of adequate resources to implement the proposed adaptive management process. This policy is most applicable to the habitat restoration planned as mitigation for the environmental impacts of the levee projects.

Based on the draft GRR and the draft EIS/EIR, we understand that no monitoring or adaptive management plans have been developed related to the proposed habitat mitigation and enhancement activities. Prior to implementation of these habitat related actions, USACE, CVFPB, and potential local levee maintaining partners should develop adaptive management plans consistent with the Delta Plan; particularly the Plan's Appendix C. The uncertainty of whether the proposed habitat mitigation and enhancement measures are able to offset the impacts of the project and provide net benefits for native fish and wildlife species highlights the need for an effective adaptive management strategy and associated monitoring framework. Council staff is available to assist you in developing an adaptive management plan as part of early consultation to promote consistency with the Delta Plan. We suggest including documentation of best available science and an adaptive management plan as an appendix to the final EIS/EIR in order to have it available for use in a consistency certification.

Inconsistencies with the Delta Plan

X-11 The final EIS/EIR should discuss any inconsistencies between the proposed plan and the Delta Plan, as required by 15125(d) of the CEQA Guidelines. Please note that the CEQA guidelines' Appendix G states that a project that is inconsistent with any applicable land use plan, policy, or regulations may result in a finding of significant impact on biological resources.

X-11 (Cont.) Based on our initial review of the project, we have found potential inconsistencies with Delta Plan Policies **RR P1, ER P5**, and **G P1,** as described above.

Early Consultation

The Council strongly encourages all agencies who propose to approve, fund, or carry out an action in the Delta, as early in the project's development as possible, to consult with the Council and ensure the project (whether it is a covered action or not) is consistent with the Delta Plan. If CVFPB staff chooses to engage in early consultation, the Council staff will meet with you and offer guidance on determining whether the project meets the definition of a covered action, provided that the ultimate determination in this regard must be made by your agency. Council staff will also work with you to ensure consistency between the project and the Delta Plan's policies and recommendations. We also can help guide you through the certification process.

As mentioned above, Delta Plan Policy **G P1** requires that water management projects document use of best available science and include an adaptive management plan when filing a certification of consistency with the Delta Plan. We recommend that adaptive management for this project incorporate a monitoring, evaluation and reporting program that evaluates whether the project is successfully achieving the goals and objectives for the project. Delta Stewardship Council staff, including staff from the Delta Science Program, can provide early consultation to help in your preparation of documentation of use of best available science and adaptive management.

Next Steps

We look forward to continuing to work with your agency and other local, state, and federal agencies on this project. I encourage you to contact You Chen (Tim) Chao (916-445-0143) at YouChen.Chao@deltacouncil.ca.gov or Daniel Huang at Daniel.Huang@deltacouncil.ca.gov with your questions, comments, or concerns. We look forward to working with you to ensure consistency of the GRR Project with the Delta Plan while also avoiding, minimizing, or mitigating potential environmental impacts.

Sincerely,

Cindy Messer

Re: American River Common Features General Reevaluation Report Draft Environmental Impact Statement/Environmental Impact Report (SCH # 2005072046)

Dear Ms. Baker and Ms. Brehmer:

Thank you for providing the Delta Protection Commission (Commission) the opportunity to review the Draft Environmental Impact Statement/Environmental Impact Report for the American River Common Features General Reevaluation Report Project (Project).

The Commission is charged with ensuring orderly, balanced conservation and development of Delta land resources and improved flood protection. Proposed local government projects within the Primary Zone of the Legal Delta must be consistent with the Commission's Land Use and Resource Management Plan (LURMP). The Commission also provides comments on proposed projects in the Secondary Zone that have the potential to affect the resources of the Primary Zone. Portions of the Project are located within the Primary and Secondary Zones of the Legal Delta.

Proposed USACE and CVFPB actions are not subject to consistency requirements with the LURMP since the Project is sponsored by a federal and state agency. However, the Commission reviewed the EIS/EIR for possible impacts on the resources of the Primary Zone. We find that the Project provides necessary improvements to the Delta's levees and flood management system that promote the protection of life and property. We urge the U.S. Army Corps of

Y-1

Engineers (USACE), Central Valley Flood Protection Board (CVFPB), and Sacramento Area Flood Control Agency to minimize potential impacts to aesthetic, biological, cultural, and recreational resources where feasible.

In addition, the Great California Delta Trail Act (Chapter 839, statutes of 2006) directed the Commission to develop and adopt a plan and implementation program for a continuous regional recreational corridor extending throughout the five Delta Counties linking to the San Francisco Bay Trail and Sacramento

River Trail. In support of this objective, the Commission approved a resolution that encourages the incorporation of improved bicycle lanes as Delta levees are designed, engineered, and upgraded, taking
Y-2 into account the concerns of local residents and the viability of the Delta economy. Please consider incorporating improvements to accommodate bike lanes along the Sacramento River.

Thank you for the opportunity to provide input. Please contact Blake Roberts, Associate Environmental Planner, at 916-375-4237 for any questions regarding the comments provided.

Sincerely,

Erik Vink
Executive Director

Anne.E.Baker@usace.army.mil

Dear Ms. Baker:

Comments on the Draft Environmental Impact Statement/Environmental Impact Report: American River Watershed Common Features Project-General Reevaluation Report (SCH No. 2005072046)

The Metropolitan Water District of Southern California (Metropolitan) has reviewed the Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR) prepared by the two lead agencies, U.S. Army Corps of Engineers and Central Valley Flood Protection Board, to comply with the National Environmental Policy Act and the California Environmental Quality Act, respectively. As proposed, the subject project would provide flood risk management to the city of Sacramento by improving the levees that surround the city. This letter contains Metropolitan's comments on the EIS/EIR as a stakeholder in the State Water Project (SWP) and the Sacramento-San Joaquin Delta (Delta).

Southern California has an important stake in the Delta region and its existing infrastructure. As a SWP contractor, Metropolitan has invested and will continue to invest significantly in the SWP, efforts to restore sensitive fish populations in the Delta watershed, and scientific research into the causes of decline in fish native to the Delta. Even with the diversification of its supply sources and water use efficiency and conservation efforts, the SWP will remain a critical source of water supply for Metropolitan's service area. Hence, strategic levee protection measures are vital in protecting lives, infrastructure, and water quality in the Delta. However, should Alternative 2 of the subject project become the preferred alternative, then additional analyses should be conducted in support of the Folsom Dam Water Control Manual Update.
Z-1 These evaluations should consider flow frequency, duration, rate, and stage of American River Common Feature Project and Folsom Dam operations as they effect the Sacramento River, Yolo Bypass and related Delta water operations. Such analyses would ensure that habitat restoration opportunities in the Yolo Bypass, including the Cache Slough area, are not potentially compromised.

We appreciate the opportunity to provide input to your planning process and we look forward to receiving future information concerning this proposed project. If we can be of further assistance, or if you would like to discuss Metropolitan's comments, please contact me at sarakawa@mwdh2o.com or Mr. Randall Neudeck at rneudeck@mwdh2o.com.

Very truly yours,

Stephen N. Arakawa

Subject: American River Watershed Common Features General Reevaluation Report Draft Environmental Impact Statement/Environmental Impact Report, Sacramento and Yolo Counties, California [CEQ #20150071]

Dear Ms. Baker:

The U.S. Environmental Protection Agency has reviewed the above referenced document. Our review and comments are provided pursuant to the National Environmental Policy Act, the Council on Environmental Quality's NEPA Implementation Regulations at 40 CFR 1500 - 1508, and our review authority under Section 309 of the Clean Air Act.

The Draft Environmental Impact Statement evaluates alternatives to provide flood risk management to the city of Sacramento by improving the levees that surround the city. The Tentatively Selected Plan -- Alternative 2-Sacramento Bypass and Improve Levees -- appears to be the least environmentally damaging alternative as it results in less riparian habitat removal along the Sacramento River and creates additional floodplain acreage. EPA has rated the Tentatively Selected Plan and the Draft EIS as EC-2 -- Environmental Concerns-Insufficient Information" (see Enclosure 1: "Summary of EPA Rating Definitions").

Our concerns are based on the need for remediation of the Old Bryte Landfill in the proposed Sacramento Bypass expansion area, as well as the potential for construction emissions to contribute to violations of the National Ambient Air Quality Standard for oxides of nitrogen (NOx). We recommend that the Final EIS include additional information on cleanup plans for the landfill. We also recommend that, if NOx emissions would exceed the *de minimis* threshold under the Tentatively Selected Plan, the Final EIS demonstrate that the project would conform to the State Implementation Plan and include a draft conformity determination. Furthermore, we recommend that the Final EIS include additional information regarding wetlands and riparian habitat, climate change, mitigation measures, and the project's ability to meet flood protection levels required by California Senate Bill 5. Please see the enclosed detailed comments (Enclosure 2) for additional concerns and recommendations.

We appreciate the opportunity to review this Draft EIS. Please send one hard copy and one CD of the Final EIS to this office (mailcode ENF-4-2) when it is officially filed with EPA's *e-NEPA*. If you have any questions, please call me at (415) 972-3521 or contact Jeanne Geselbracht, our lead NEPA reviewer for this project, at geselbracht.jeanne@epa.gov or (415) 972-3853.

Sincerely,

Kathleen Martyn Goforth

Kathleen Martyn Goforth, Manager
Environmental Review Section

Enclosures:
(1) Summary of EPA Rating Definitions
(2) EPA's detailed comments on the American River Watershed Common Features Draft EIS

cc: Erin Brehmer, Central Valley Flood Protection Board
Peter Buck, Sacramento Area Flood Control Agency
Howard Hold, Central Valley Regional Water Quality Control Board

SUMMARY OF EPA RATING DEFINITIONS

This rating system was developed as a means to summarize EPA's level of concern with a proposed action. The ratings are a combination of alphabetical categories for evaluation of the environmental impacts of the proposal and numerical categories for evaluation of the adequacy of the EIS.

ENVIRONMENTAL IMPACT OF THE ACTION

"LO" (Lack of Objections)
The EPA review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

"EC" (Environmental Concerns)
The EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact. EPA would like to work with the lead agency to reduce these impacts.

"EO" (Environmental Objections)
The EPA review has identified significant environmental impacts that must be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

"EU" (Environmentally Unsatisfactory)
The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potentially unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the CEQ.

ADEQUACY OF THE IMPACT STATEMENT

Category 1" (Adequate)
EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

"Category 2" (Insufficient Information)
The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analysed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses, or discussion should be included in the final EIS.

"Category 3" (Inadequate)
EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analysed in the draft EIS, which should be analysed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

*From EPA Manual 1640, "Policy and Procedures for the Review of Federal Actions Impacting the Environment

Hazardous Materials

The Old Bryte Landfill is located immediately adjacent to the land side of the northern levee of the Sacramento Bypass and the eastern levee of the Yolo Bypass Flood Channel. This landfill area would become part of the expanded Sacramento Bypass floodway when the existing northern Sacramento Bypass levee is removed and relocated 1,200 feet farther north. The Draft Environmental Impact Statement (p. 272) states that the landfill would be completely remediated in accordance with Federal, State, and local laws by the non-federal partner prior to construction.

The Old Bryte Landfill is the subject of a Preliminary Assessment Report prepared for the EPA in February 2012. According to the Preliminary Assessment Report (p. 8), sampling results showed the presence of elevated levels of lead, zinc, dioxins, and polychlorinated biphenyls (PCB). Lead was detected in all samples at concentrations ranging from 13 milligrams per kilogram (mg/kg) to 22,000 mg/kg. The average lead concentration of 4,285 mg/kg exceeded the Total Threshold Limit Concentration (TTLC) of 1,000 mg/kg. The average Waste Extraction Test (WET) concentration for lead of 64 milligrams per liter (mg/L) exceeded the Soluble Threshold Limit Concentration (STLC) of 5.0 mg/L. Zinc was detected in one soil sample at 17,000 mg/kg, exceeding the TTLC of 5,000 mg/kg. PCBs were detected in five soil samples ranging from 0.50 to 0.98 mg/kg. Dioxins were detected in one soil sample at 0.14 mg/kg. TTLC and STLC are used for hazardous waste characterization under California State regulations. Trench logs indicate an overall waste depth from ground surface to 13 feet with an average waste depth ranging from 5.9 to 7.2 feet, and the estimated volume of the waste is approximately 127,107 cubic yards. In 2001, the California Integrated Waste Management Board concluded that the burn ash material would likely be classified as a California hazardous waste if it were to be excavated for disposal.

AA-1 The Draft EIS neither describes how the landfill would be remediated and the materials disposed, nor identifies applicable cleanup standards, confirmation testing, or agencies responsible for overseeing the remediation before the weir construction and bypass expansion can be completed.

Recommendation: Include the above information in the Final EIS.

Air Quality

EPA's guidance on General Conformity applicability analyses states, "the Federal agency can take measures to reduce its emissions from the proposed action to in fact below *de minimis* levels and, thus, the rule would not apply. The changes must be State or Federally enforceable to guarantee that emissions would be below *de minimis* in the future."[1] The Draft EIS is unclear regarding the assumptions, including the enforceability of emissions controls, that were factored into the emissions estimates for the truck delivery scenario and the barge delivery scenario under the project alternatives.

Table 31 of the Draft EIS indicates that Year 2 total oxides of nitrogen (NOx) emissions would exceed the *de minimis* General Conformity threshold for the Sacramento Area under the barge delivery scenario. In addition, Table 30 indicates that, under the truck delivery scenario, NOx emissions would

[1] General Conformity Guidance: Questions and Answers (Response to Question 29), July 13, 1994 http://www.epa.gov/air/genconform/documents/gcgqa_940713.pdf

be less than, but quite close to, the *de minimis* threshold. The Draft EIS (pp. 196 and 199) states that, with the implementation of the Sacramento Metropolitan Air Quality Management District's Enhanced Exhaust Control Practices for off-road equipment and using only on-road heavy-duty diesel trucks or equipment that comply with EPA 2007 on-road emission standards, annual construction emissions would be reduced to below *de minimis* thresholds. It appears, however, that the emissions estimates in tables 30 and 31 already account for emission reductions from these measures, since the methodology section (Draft EIS, p. 188) indicates that the air quality emissions analysis was based, in part, on an assumption that "all project plans and specifications will require that construction contractors use only off-road equipment that implements the SMAQMD Enhanced Exhaust Control Practices and only use on-road hauling equipment that was manufactured in 2010, or later."

In addition, the Draft EIS implies that a 20 percent reduction in NOx from off-road equipment, relative to the emissions provided in tables 30 and 31, would be applied to the project. The SMAQMD Enhanced Exhaust Control Practices for off-road equipment require demonstrating that the heavy-duty off-road vehicles will achieve a project wide fleet-average 20 percent NOx reduction and 45 percent particulate reduction *compared to the most recent California Air Resources Board fleet average*. It is unclear what assumptions for fleet averages were used in the emissions analyses, and whether the 20 percent NOx reduction mentioned on pp. 194 and 198 is in reference to, or in addition to, this Enhanced Exhaust Control Practice.

The Draft EIS (p. 202) states that the use of Tier 3 and Tier 4 standards for newly built marine engines would be encouraged under the barge delivery scenario. The Draft EIS (p. 202) also states that, under the barge delivery scenario, off-road diesel-powered construction equipment greater than 50 horsepower shall meet Tier 4 off-road emission standards at a minimum, and on-road heavy-duty diesel trucks or equipment with a GVWR of 19,500 pounds or greater shall comply with EPA 2007 on-road emission standards for PM and NOx.

Recommendations:

AA-2
- In preparing the Final EIS, please consult with Tom Kelly, EPA Region 9 Air Division, on the requirements of EPA's General Conformity Rule. He can be reached at (415) 972-3856 or kelly.thomasp@epa.gov.

AA-3
- Clarify in the Final EIS the measures and assumptions that were factored into the emissions estimates in tables 30 and 31, and provide any recalculations if needed.

AA-4
- Clarify the mechanisms that would be used to ensure that emissions reductions are enforceable (e.g., included in contract specifications?) and achievable.

AA-5
- Estimate in the Final EIS the additional emission reductions that would accrue to each scenario with application of all enforceable mitigation measures. If NOx emissions would exceed the *de minimis* threshold under the Tentatively Selected Plan, we recommend that the Final EIS include a draft conformity determination and demonstrate that the project would conform to the State Implementation Plan.

AA-6
- We encourage the use of marine engines meeting EPA's Tier 4 emissions standards for the barge delivery scenario, on-road trucks meeting EPA's 2007 emission standards for the truck delivery scenario, and off-road construction equipment meeting EPA's 2014 emissions standards, to the extent possible for both of these scenarios.

AA-7
- In the Final EIS, correct the following informational errors that appear in the Air Quality sections of the Draft EIS:

AA-7 (Cont.)

- Table 25 identifies a 24-hour sulfur dioxide National Ambient Air Quality Standard. On August 23, 2010, EPA revoked the 24-hour sulfur dioxide standard.
- Table 26 and p. 185, bullet 2: On October 28, 2013, the Sacramento PM10 nonattainment area was redesignated as an attainment area with an EPA-approved maintenance plan.
- Tables 28 and 31: The *de minimis* threshold for volatile organic compounds in the Bay Area Air Basin is 100 tons per year rather than 50 tons per year.

Flood Protection Level

The General Reevaluation Report (GRR, p. 2-3) identifies the California Senate Bill 5 requirement for urban areas to achieve a 200-year level of flood protection, and notes concern that improvements under the Federal plan might not achieve this standard. Table 3-19 of the GRR indicates that the American River South portion of the project would not meet this standard under the Tentatively Selected Alternative. We were unable to find a discussion in the Draft EIS of the requirements of SB 5 or of whether and how each alternative would meet its requirements. We also note that the list of significance thresholds for hydrology and hydraulics impacts (Draft EIS, p. 78), which is based on the environmental checklist in the California Environmental Quality Act Guidelines, does not include the project's ability to meet SB 5. The Council on Environmental Quality's regulations for implementing the National Environmental Policy Act require that EISs address possible conflicts between the proposed action and the objectives of Federal, regional, State, and local land use plans, policies and controls for the area concerned.

AA-8

Recommendation: We recommend that the Final EIS discuss whether and how each alternative would meet SB 5, including a description of any additional measures that would be needed to meet the standard and identification of the parties responsible for implementing and funding them.

According to the Draft EIS (p. 102), operation of the new weir and Sacramento Bypass will be determined after construction is complete. It is unclear what this information would entail and why it is not described in the EIS.

AA-9

Recommendation: We recommend that the Final EIS describe operation of the new weir and expanded Sacramento Bypass, and any potential additional impacts associated with operations not already discussed in the Draft EIS.

Vegetation

The Draft EIS (p. 49) states that lands within the extended Sacramento Bypass could be used to compensate for some of the trees being removed from the levees, and that a hydraulic analysis would need to be done to determine to what extent planting could occur. Elsewhere (p. 97), the Draft EIS states that detailed wetland surveys in the bypass will be done prior to construction. These analyses are also needed for determination and disclosure of the anticipated effectiveness of mitigation opportunities in the bypass and whether additional offsite mitigation sites may be necessary to compensate for project-

AA-10

related losses of riparian and wetland habitat.

Recommendation: We recommend that the Final EIS discuss the results of the hydraulic evaluation and wetland survey in the expanded Sacramento Bypass area, including available

AA-10 (Cont.)

resources and opportunities to compensate for riparian and wetland habitat losses there, and the effectiveness of such compensation. If additional compensation areas would be needed, the Final EIS should identify those areas and the acreages needed.

Climate Change

The Draft EIS (p. 213) states, "project-wide GHG emissions would be well below the BAAQMD's GHG threshold of 10,000 MT CO2e per year, indicating that project-generated GHG emissions would not contribute to climate change." While the project-generated greenhouse gas emissions of approximately 3,400 metric tons of carbon dioxide equivalent emissions per year (Draft EIS, Table 34) are well below the Bay Area Air Quality Management District's GHG threshold, it is not accurate to indicate that the project-generated GHG emissions would not contribute to climate change, as all GHG emissions do contribute to climate change. Please note that, on December 18, 2014, the Council on Environmental Quality (CEQ) released revised draft guidance for public comment, which describes how Federal departments and agencies should consider the effects of greenhouse gas emissions and climate change in their NEPA reviews, and specifically addresses incremental contributions to climate change. As noted in the draft guidance,

AA-11

> "CEQ recognizes that many agency NEPA analyses to date have concluded that GHG emissions from an individual agency action will have small, if any, potential climate change effects. Government action occurs incrementally, program-by-program and step-by-step, and climate impacts are not attributable to any single action, but are exacerbated by a series of smaller decisions, including decisions made by the government."

Recommendation: We recommend that the conclusion regarding the project's contribution to climate change be revised to indicate that all GHG emissions contribute to climate change.

COMMENTS TO REQUEST FOR REVIEW FOR THE DRAFT ENVIRONMENTAL IMPACT REPORT, AMERICAN RIVER COMMON FEATURES GENERAL REEVALUATION REPORT PROJECT, SCH# 2005072046, SACRAMENTO AND YOLO COUNTIES

Pursuant to the State Clearinghouse's 20 March 2015 request, the Central Valley Regional Water Quality Control Board (Central Valley Water Board) has reviewed the *Request for Review for the Draft Environment Impact Report* for the American River Common Features General Reevaluation Report Project, located in Sacramento and Yolo Counties.

Our agency is delegated with the responsibility of protecting the quality of surface and groundwaters of the state; therefore our comments will address concerns surrounding those issues.

Construction Storm Water General Permit

BB-1 Dischargers whose project disturb one or more acres of soil or where projects disturb less than one acre but are part of a larger common plan of development that in total disturbs one or more acres, are required to obtain coverage under the General Permit for Storm Water Discharges Associated with Construction Activities (Construction General Permit), Construction General Permit Order No. 2009-009-DWQ. Construction activity subject to this permit includes clearing, grading, grubbing, disturbances to the ground, such as stockpiling, or excavation, but does not include regular maintenance activities performed to restore the original line, grade, or capacity of the facility. The Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP).

For more information on the Construction General Permit, visit the State Water Resources Control Board website at:
http://www.waterboards.ca.gov/water_issues/programs/stormwater/constpermits.shtml.

Phase I and II Municipal Separate Storm Sewer System (MS4) Permits[1]

BB-2 The Phase I and II MS4 permits require the Permittees reduce pollutants and runoff flows from new development and redevelopment using Best Management Practices (BMPs) to the maximum extent practicable (MEP). MS4 Permittees have their own development standards, also known as Low Impact Development (LID)/post-construction standards that include a hydromodification component. The MS4 permits also require specific design concepts for LID/post-construction BMPs in the early stages of a project during the entitlement and CEQA process and the development plan review process.

For more information on which Phase I MS4 Permit this project applies to, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/water_issues/storm_water/municipal_permits/.

For more information on the Phase II MS4 permit and who it applies to, visit the State Water Resources Control Board at:
http://www.waterboards.ca.gov/water_issues/programs/stormwater/phase_ii_municipal.shtml

Industrial Storm Water General Permit

BB-3 Storm water discharges associated with industrial sites must comply with the regulations contained in the Industrial Storm Water General Permit Order No. 97-03-DWQ.

For more information on the Industrial Storm Water General Permit, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/water_issues/storm_water/industrial_general_permits/index.shtml.

Clean Water Act Section 404 Permit

BB-4 If the project will involve the discharge of dredged or fill material in navigable waters or wetlands, a permit pursuant to Section 404 of the Clean Water Act may be needed from the United States Army Corps of Engineers (USACOE). If a Section 404 permit is required by the USACOE, the Central Valley Water Board will review the permit application to ensure that discharge will not violate water quality standards. If the project requires surface water drainage realignment, the applicant is advised to contact the Department of Fish and Game for information on Streambed Alteration Permit requirements.

If you have any questions regarding the Clean Water Act Section 404 permits, please contact the Regulatory Division of the Sacramento District of USACOE at (916) 557-5250.

---

[1] Municipal Permits = The Phase I Municipal Separate Storm Water System (MS4) Permit covers medium sized Municipalities (serving between 100,000 and 250,000 people) and large sized municipalities (serving over 250,000 people). The Phase II MS4 provides coverage for small municipalities, including non-traditional Small MS4s, which include military bases, public campuses, prisons and hospitals.

Clean Water Act Section 401 Permit – Water Quality Certification

BB-6 If an USACOE permit (e.g., Non-Reporting Nationwide Permit, Nationwide Permit, Letter of Permission, Individual Permit, Regional General Permit, Programmatic General Permit), or any other federal permit (e.g., Section 9 from the United States Coast Guard), is required for this project due to the disturbance of waters of the United States (such as streams and wetlands), then a Water Quality Certification must be obtained from the Central Valley Water Board prior to initiation of project activities. There are no waivers for 401 Water Quality Certifications.

Waste Discharge Requirements

BB-7 If USACOE determines that only non-jurisdictional waters of the State (i.e., "non-federal" waters of the State) are present in the proposed project area, the proposed project will require a Waste Discharge Requirement (WDR) permit to be issued by Central Valley Water Board. Under the California Porter-Cologne Water Quality Control Act, discharges to all waters of the State, including all wetlands and other waters of the State including, but not limited to, isolated wetlands, are subject to State regulation.

For more information on the Water Quality Certification and WDR processes, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/help/business_help/permit2.shtml.

Regulatory Compliance for Commercially Irrigated Agriculture

If the property will be used for commercial irrigated agricultural, the discharger will be required to obtain regulatory coverage under the Irrigated Lands Regulatory Program.
There are two options to comply:

BB-8

1. **Obtain Coverage Under a Coalition Group.** Join the local Coalition Group that supports land owners with the implementation of the Irrigated Lands Regulatory Program. The Coalition Group conducts water quality monitoring and reporting to the Central Valley Water Board on behalf of its growers. The Coalition Groups charge an annual membership fee, which varies by Coalition Group. To find the Coalition Group in your area, visit the Central Valley Water Board's website at: http://www.waterboards.ca.gov/centralvalley/water_issues/irrigated_lands/app_approval/index.shtml; or contact water board staff at (916) 464-4611 or via email at IrrLands@waterboards.ca.gov.

2. **Obtain Coverage Under the General Waste Discharge Requirements for Individual Growers, General Order R5-2013-0100**. Dischargers not participating in a third-party group (Coalition) are regulated individually. Depending on the specific site conditions, growers may be required to monitor runoff from their property, install monitoring wells, and submit a notice of intent, farm plan, and other action plans regarding their actions to comply with their General Order. Yearly costs would include State administrative fees (for example, annual fees for farm sizes from 10-100 acres are currently $1,084 + $6.70/Acre); the cost to prepare annual monitoring reports; and water quality monitoring costs. To enroll as an Individual Discharger under the Irrigated Lands Regulatory

Program, call the Central Valley Water Board phone line at (916) 464-4611 or e-mail board staff at IrrLands@waterboards.ca.gov.

BB-9

Low or Limited Threat General NPDES Permit

If the proposed project includes construction dewatering and it is necessary to discharge the groundwater to waters of the United States, the proposed project will require coverage under a National Pollutant Discharge Elimination System (NPDES) permit. Dewatering discharges are typically considered a low or limited threat to water quality and may be covered under the General Order for *Dewatering and Other Low Threat Discharges to Surface Waters* (Low Threat General Order) or the General Order for *Limited Threat Discharges of Treated/Untreated Groundwater from Cleanup Sites, Wastewater from Superchlorination Projects, and Other Limited Threat Wastewaters to Surface Water* (Limited Threat General Order). A complete application must be submitted to the Central Valley Water Board to obtain coverage under these General NPDES permits.

For more information regarding the Low Threat General Order and the application process, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/general_orders/r5-2013-0074.pdf

For more information regarding the Limited Threat General Order and the application process, visit the Central Valley Water Board website at:
http://www.waterboards.ca.gov/centralvalley/board_decisions/adopted_orders/general_orders/r5-2013-0073.pdf

If you have questions regarding these comments, please contact me at (916) 464-4684 or tcleak@waterboards.ca.gov.

Subject: **American River Common Features General Reevaluation Report – Draft Environmental Impact Report**

Dear Ms. Baker:

Sacramento Regional County Sanitation District (Regional San) has reviewed the subject report and has the following comments.

Regional San has numerous pipeline crossings of the American River that could potentially be impacted by the proposed erosion control work referenced within the subject report. The launchable rock trench, which is described as up to 10' in depth, may be in conflict with some of these facilities.

CC-1 Regional San requests that all design submittals for the proposed erosion control effort be reviewed and approved by Regional San for any reach of work that may potentially impact Regional San facilities.

If you have any questions or concerns regarding this letter, please feel free to contact me at (916) 876-6104.

Sincerely,

Robb Armstrong

Subject: Draft Report, American River Watershed, Common Features, General Reevaluation Report, March 2015

I am submitting a response to the subject Draft Report for consideration regarding overtopping concerns at the east end of the south-side of the American River levee. More specifically, it’s the east end of the levee section known as the Mayhew Levee. When the entire Mayhew levee section was raised and upgraded it was noted that it did not tie into high ground at the east end, but instead left nearly a two-foot gap between the high levee top and lower adjacent ground to the rear where rising river water could prematurely pass. Members of our community, including myself, reported this to the Sacramento Area Flood Control Agency and the Corps of Engineers and requested a repair.

DD-1

This past November, the Corps of Engineers completed what they considered a repair; however, this minor repair, while reducing some of the shortfall, still falls short of tying the east end into high ground equal to the levee top. To address the shortfall in an emergency, the Corps of Engineers has introduced a plan involving adding a wall of sandbags to fill the low area around the rear of the levee’s east end. This would involve removing homeowner fences and building the sandbag wall across back yards. In such a dire emergency, flood control officials shouldn’t be concerning themselves with something that’s so easy to fix long before hand. The east end of the Mayhew Levee should tie into high ground equal to the top of the levee. A project to do this should be added to this General Reevaluation Report.

Sincerely,

Joseph E. O’Connor Jr.

May 18, 2015

Re: American River Watershed, Common Features, General Reevaluation Report, Draft Report, March 2015.

This was an important document to read, with the key new element to the traditional Common Features Project, the expansion of the Sacramento River bypass, apparently well supported in the tentatively selected alternative. The other new elements, additional work on tributaries to the Natomas East Main Drain, was somewhat surprising, but this should have been expected since private-citizen forums for reviewing the detailed work of this lengthy draft General Reevaluation Report (GRR or Report) before the release of the draft GRR have been somewhat limited.

Regrettably, the short comment period for this GRR limits the scope of these comments. But before going to the meat of our comments on the Report, we'd like to highlight an important issue:

The GRR does and should recognize that bank protection and other land and river-edge and riparian-forest disturbing projects within the American River Parkway are of significant concern to the public. The GRR suggests that the project sponsors will work to address these concerns. However, the new Corps feasibility review process for submitting to Congress for authorization does not develop enough site-specific project detail for the public to engage effectively at this level of project characterization. The public and the authorizing bodies (including the Congress) are being asked to trust project sponsors that the final as-constructed projects will be good ones for the Parkway as well as community safety. An argument can be made that this trust has been earned. Perhaps this is correct. Perhaps not.

In these circumstances, assurances that the project sponsors can make that they will abide by relevant laws protecting the American River Parkway and wild & scenic river are important. We hope that you take our specific suggestions seriously. Accepting them may or may not require recirculation, but the Final GRR needs to successfully address the deficiencies of the draft.

EE-1

Our comments here address a few themes: (1) Let's get the history of the Sacramento River Basin and area floodwater-management projects right. These documents live on, so it's important to write carefully and communicate accurately at all the important levels. To do so, let's meet to discuss our offered comments. We want to avoid misunderstandings so that your responses to comments are on target. Don't bury any needed corrections to the GRR in the Response to Comments appendixes. We want to make sure if you don't get the words right in the draft Report, get them right in the final Report that people actually will read in the future (2) Make sure that you don't ignore or downplay your environmental responsibilities. Make it clear what they are, and tell us that you will abide by them.

EE-2

These comments cannot contain sufficient expert subject matter comments on the reach-by-reach vulnerability of river and creek levees affected by the project, or the project designs to avoid or robustly mitigate adverse impacts, as much as we would like to have delivered these comments. The GRR is not detailed enough and the comment period too short to review these critical project assumptions. The consequence may have to be that preconstruction engineering and design will need to be the robust "formal and informal" processes that the GRR commits to engage in. As you know, previous bank-protection projects on the Lower American River had and have been thoroughly vetted in the Lower American River Task Force formed in 1993. The setting of the GRR is now a wider one, but the Task Force is certainly a good place to start. In fact, starting this review early is a good idea. Failing a quick authorization by the Congress (their record does not inspire confidence), one or more than one of the project sponsors may wish to or should find the resources to engage in a collaborative advanced site design process.

EE-3

With that admonition, let's move on to the page-by-page comments on the Report.

EE-4

GRR p. PAC-18: The description of the purpose of the 1986 release from Folsom Dam above the objective release is misleading. It is true that "rapid inflow" was part of the decision to make the 134,000 cfs release, but the status of the reservoir and antecedant operational decisions were the real reasons for the departure from the objective release. As noted in the National Research Council (NRC) report referenced below, there would have been no reason to surcharge the reservoir and make a release in excess of the objective release if the Reservoir Water Control Manual had been followed. Of course the nerves of the dam operators were also tested by the failure to revise the Manual to account for the likely failure of the Auburn Coffer Dam at the halted construction site (suddenly releasing enough water to fill more than a quarter of Folsom's flood reservation) in an already significant high-water event. We excerpt some of the conclusions from the NRC here:

> On February 13 and 14 the California Department of Water Resources (CDWR) began preparations for a full flood fight, given computer projections of a[n] extraordinary storm

EE-4
(Cont.)

approaching the state from across the Pacific (CDWR, 1986). The American River flood flows began in earnest on February 15, with inflows rising to over 60,000 cfs early the next day, but Figure 2.1 shows that Folsom operators did not begin to evacuate the flood control storage volume, nor did releases from Folsom match the inflows to the lake. Operators expressed a major concern for the effect of large Folsom releases on recreational facilities in the lower American River floodway; releases were held to 20,000 cfs for 36 hours. This is inconsistent with the 1977 USACE flood control diagram in force at the time; the diagram states that when Folsom storage is in the flood control reservation the water "shall be released as rapidly as possible" subject to ramping limits. Even after increased releases from Folsom began on February 16, and before they reached the 115,000-cfs limit, Folsom releases continued to lag behind inflows into Folsom Lake by 30,000 cfs or more. USACE-prescribed ramping limits of "15,000 cfs during any 2-hour period" do not appear to have limited the rate of increase of Folsom releases during the 1986 flood, nor were physical release rate limits at Folsom Dam a constraint given the initial elevation of the reservoir.

Lesson: Procedures need to be adopted to ensure that flood releases are made as required by operating regulations if intended flood risk reduction is to be achieved.

Folsom operations were primarily based on the actual inflow to Folsom Reservoir calculated from lake level changes (Figure 2.1). This calculation ignored the accumulation of water in the cofferdam near the Auburn dam site above Folsom. Written operating procedures do not mention this accumulation of water. Because this cofferdam was designed to breach with the 30-year flood flow, its accumulation distorted the effective inflow to the Folsom-cofferdam system and the accumulated storage in the two reservoirs, which ended up in Folsom Reservoir when the cofferdam finally breached.

Lesson: Plans need to be updated to reflect changes in facilities in basins and "temporary" structures.

If the Bureau of Reclamation had been able to more closely match outflow to inflows while inflows were less than 115,000 cfs, then releases into the American River would not have exceeded 115,000 cfs during the 1986 flood using the nominal storage capacity of the reservoir, even without anticipation of the Auburn cofferdam failure. Fortunately, disaster was averted by the use of extra surcharge storage in Folsom and by the ability of the downstream channel and levee system to handle releases of 130,000 cfs. Lessons drawn from the 1986 experience should not be forgotten. (See National Research Council Committee on *Flood Control Alternatives in the American River Basin,* National Academy Press, Washington, D.C., 1995, pp. 44–48. We'd be happy to make these pages available if the planning team does not have them.)

Resuming our thoughts, the History of Project (PAC-18) implies that "rapid inflow"[1] was responsible for the 1986 release in excess of Folsom Reservoir's objective release. To the extent that readers draw the conclusion that the 1986 high water exceeded Folsom Dam's reservoir design flood, the project sponsors are rewriting the history of the 1986

---

[1] The instantaneous peak inflow in 1986 was reported to be 900,000 cfs when 120,000 acre feet were released with the failure of the Auburn coffer dam. *Corps of Engineers. Sacramento District, Folsom Dam and Lake, American River, California, Water Control Manual*, Appendix VIII to Master Water Control Manual, Sacramento River Basin, California, 1987, pp. iv, IV-7–8.

EE-4 (Cont.)

American River flood event and failing to abide by the admonition of the NRC not to forget these lessons.[2]

GRR p. 1-18: The history of Folsom Dam's design is slightly over-simplified when it is reported that it was designed to meet the Standard Project Flood in existence at that time: instead, it was designed to handle the predecessor method to the Standard Project Flood. Here's the more detailed history as told by the U.S. Bureau of Reclamation (Reclamation):

EE-5

> "In the design of Folsom Reservoir, the Corps of Engineers recognized the need to provide protection against a very large winter rain flood. The flood of January 1862 was thought to be the largest experienced flood for which estimates could be made, and those estimates[3] were initially considered by the local Corps of Engineers' staff for the Folsom flood control design operation plan. Objections raised by higher echelons of the Corps of Engineers, based on flood control experience throughout the United States resulted in discarding the estimated 1862 flood hydrograph and preparing a revision of the design flood to assure that a higher or "project design" degree of protection would be provided by the flood control operation under consideration, when allowance for unforseen contingencies was included." (Corps of Engineers Comments on Draft of USBR 'Amendment to the Final Environmental Statement and Supplement on Auburn-Folsom South Unit,' " July 11, 1974, *Amendment to the Final Environmental Statement and Supplement on Auburn-Folsom South Unit, American River*

---

[2] Reservoir design floods are the volume of water in a reservoir-specific hydrograph that can be safely stored and released downstream under a given set of initial-state conditions. Flood hydrographs with routings that, for example, cause a reservoir to surcharge or cause releases above a dam's objective release or downstream conveyance capacity would exceed the reservoir design flood. In practice, no American River flood has caused surcharge or release of more than the objective release with the exception of 1986, and this was because of operational irregularities described by the NRC. Folsom Dam's reservoir design-flood hydrograph is represented in a number of Corps documents, including *Corps of Engineers. Sacramento District, Folsom Dam and Lake, American River, California, Water Control Manual*, Appendix VIII to Master Water Control Manual, Sacramento River Basin, California, 1987, sheet 2 of 8, Plate 19. The hydrograph is a partially reregulated inflow into Folsom Reservoir. The peak of the design hydrograph is 340,000 cfs, which no unregulated (unimpaired) historic flood has approached. In recent decades, three-day unregulated inflow volumes have been the customary way to describe actual flood magnitudes experienced by section-7 reservoirs in this region. Three-day design floods have never been developed for the existing Folsom Dam and the various reservoir-regulation manuals that described its operations from 1955 to 1986 (a six-day volume and a peak inflow were developed), a period where the SMUD UARP and PCWA Middle Fork Projects were constructed. If a three-day volume (regulated or not) has been developed for Folsom's design flood for this period, the following period 1987–95, and the current variable storage period, we would appreciate it if this data and supporting assumptions could be shared with us. The estimate of the peak of the variable-storage Folsom Dam design hydrograph, 360,000 cfs, is from MBK, personal communication, 2006.

[3] We have the Corps of Engineers 1941 and 1943 Leslie E. Bossen American River 1862 flood-estimate memos. They are an interesting and valuable read, and a written review is under preparation, but the Bossen memos suffer from a lack of a hydrograph and documentation of the stage-discharge routings. We can share the Bossen memos with the GRR team if they have passed from collective memory of the Sacramento District. If the Corps or the Central Valley Flood Protection Board has additional library documentation of the 1862 flood or the detailed history of the design of Folsom Dam's reservoir design flood, please contact us. They belong in our library as well and would be of interest to academic researchers as well.

Division, Central Valley Project-California, Volume 2, Department of the Interior, USBR, p. 248)

A complementary take on the design flood comes from the California Department of Water Resources (DWR): the reservoir design flood for Folsom Dam was developed from statistically centering the 1937 large regional flood over the American River Basin and computing its outflow—developing a peak inflow of 340,000 cfs at the design hydrograph used at the time. (*A Preliminary Study of Flood Control Alternatives on the Lower American River*, California Department of Water Resources, Central District, September 1982, p. 7). The GRR should note that Folsom Dam's reservoir design flood peak flow or the crucial three-day volume has not been exceeded by recorded flows.

EE-5 (Cont.)

GRR p. 1-18's characterization of the SPF event frequency ("between the 250- and 500-year event") is perhaps a simplification of the annual flood frequency often found in (but not assigned to) modern SPFs, although the SPF is now a fairly unused concept.[4] Regardless as noted above, this frequency was not the statistical characterization of the "project design" flood hydrograph at the time that Folsom Dam was designed. In fact, as the authors of the GRR must know, probability characterizations of the SPF are not relevant to the creation of SPFs. Instead, particularly in the early years, SPFs were based on transposition of the historic regional flood hydrology over the basin of interest. In recent years, SPFs have tended to be scaled PMFs. Neither methodology bases its determinations on a statistical probability range for a hydrologic event.

For example, statistical analysis to characterize the Folsom Dam's design flood (the pre-SPF, but similar "project design" flood) at the time of initial design suggested that the dam and levee system could contain the modeled 1000-year flood (*A Preliminary Study of Flood Control Alternatives on the Lower American River*, California Dept. of Water Resources 1982, p. 7). When Folsom Dam was built, it was expected to provide 250-year protection (*ARWI Feasibility Report, Main Report*, Corps of Engineers, Sacramento District, 1992, p. III-5). But soon after the dam was constructed, a 120-year level of protection was modeled, an annual flooding risk of 0.7%.[5] Of course, as new statistical treatments resulting from high water in 1986 and 1997, along with new deterministic engineering criteria for levee competence, became incorporated, the modeled frequency of Folsom Dam's design flood has bounced around, something that continued as more

---

[4] The standard project flood methodology was the subject of a Corps engineering manual: *USACE, ER 1105-2-101, 1952 revised 1965*. It has been updated subsequently.

[5] *A Preliminary Study of Flood Control Alternatives on the Lower American River*, California Dept. of Water Resources 1982, p. 7. The reports of this post-construction-era assessment varied. In the 1962 Letter From the Secretary of the Interior Transmitting a Report on the Auburn-Folsom South Unit Proposing Expansion of the Central Valley project in California, Pursuant to Section 9(a) of the Reclamation Act of 1939 (53 Stat. 1187), and Section 2 of the American River Basin Development Act of October 14, 1949 (63 Stat. 852), House Document #305, 87th Congress, 2nd Session, p. 16, the Department estimated the modeled level of protection at that time to be 200 years. (January 18, 1962)

annual flood records affected the statistical analysis and Common Features and reoperation projects came on line.

EE-5 (Cont.)

This should be expected. Unlike design floods (which are expressed in relevant volumes or peak discharges of the design hydrograph—and only change when topography or the flood-control facilities change), statistical characterizations of the "level of protection" or "return frequencies" or "annual exceedances" of this and other project design floods vary widely, depending on statistical methodologies and the underlying hydrology data set and engineering assumptions, which evolve with time. This should be particularly true for statistical estimates for the probability distribution of hypothetical flood magnitudes—which, after all, have never been experienced and the "true" probability distribution of which is speculative—but in practice is driven by the chosen statistical methodology, adopted skew, and even the low flow record events.

EE-6

Again on page 1-18, there is another error: that the emergency release for Folsom Dam is 152,000 cfs. It is not. It is most simply characterized as 160,000 cfs (See Corps of Engineers. Sacramento District, *Folsom Dam and Lake, American River, California, Water Control Manual, Appendix VIII to Master Water Control Manual, Sacramento River Basin, California,* 1987, chart A-9, Emergency Spillway Release Diagram, Operating Instructions). The 152,000 cfs number comes from the flows assigned to the original design minimum freeboard of the levees along the lower American River: 3 feet for 152,000 cfs or 5 feet at 115,000cfs.[6]

EE-7

P-1-19. It's an exaggeration to suggest that the 1986 134,000 cfs release was made "to manage the risk of dam failure" (the release was made to avoid higher regulated releases that might cause greater strain on the American River levees and banks) and that conditions "came dangerously close to requiring operation of the [three] emergency flood gates at flows in excess of 152,000 [sic] cfs." With a full or nearly full reservoir, the five operational gates can make a release considerably in excess of the 152,000 cfs, nor does the diagram contemplate making releases higher than the emergency release target of 160,000 cfs until circumstances become noticeably more dire than what occurred in 1986 (inflows were declining sharply during most of the 134,000 cfs release according to Figure 2.1 on page 48 of the NRC report and sheet 8 of 8, plate 19 of the Folsom Dam Water Control Manual).[7]

---

[6] For a simple but informative discussion of American River design levee height and flow relationships, see pages 3-17–18 of the *Folsom Dam Raise & Auxilliary Spillway Alternative Project Alternative Solutions Study (Pass) II, Final Report*, June 2006, ACE, Rec Board, DWR, USBR, SAFCA.

[7] The U.S.A.C.E. Sacramento District, *Folsom Dam and Lake, American River, California, Water Control Manual, Appendix VIII to Master Water Control Manual, Sacramento River Basin, California,* 1987. Chart A-9, "Indicated Release for the Next Hour" diagram, displays the maintaining-no-more-than-160,000 cfs "rule" until there is four feet of surcharge (in 1986, Folsom Reservoir surcharged 1.56 feet according to the *Sacramento and San Joaquin River Basins, California, Post-Flood Assessment*, March 1999, U.S. Army Corps of Engineers p. 5-18), and chart A-5, Spillway Total Capacity Curve [without emergency gates], displays a gross-pool discharge capacity as approximately 280,000–300,000 cfs. Note

EE-8 GRR p. 1-29: The Central Valley Flood Protection Plan (CVFPP) 200-year standard for reduced floodplain management and proposed improvements for urban levees need not be based on Corps of Engineers statistical and engineering methodologies. The statute provides that DWR, not the Corps, determines the statistical and engineering-criteria methodologies to assess performance against a state 200-year standard for floodplain management restrictions under California state law, SB-5, state legislation passed in 2007 (Cal GC 65300.2(a)). The CVFPP echoes this.

EE-9 GRR p. 2-4: It's true to say that in 1986 the Sacramento River flood-control system was near or somewhat above capacity, which perhaps could be translated to the "Sacramento River flood control system was overloaded" statement contained in the report. But with the exception of the left-bank Yuba River levees, the project levees along the major rivers held[8], and the Yuba River levee on the descending limb of the flood hydrograph at 60% of design flow. We have not previously seen estimates that 1986 actual flows were meaningfully larger than design floodway capacities in this area until this report (650,000 cfs combined in the Yolo Bypass and Sacramento River in the GRR, against 600,000 cfs nominal and the 1991 Corps bypass-near-Lisbon and Sacramento-River-near-Freeport estimate of 605,000–614,000 cfs[9]). We are not aware of any releases in excess of tributary floodway capacity for any of the section-7 reservoir[10] tributaries to the Sacramento River, although the objective release was exceeded at Folsom Dam because of the previously mentioned operational irregularities.

It's barely correct to say that reservoirs in the Sacramento system "were filled beyond their design capacity" in 1986. Only one large reservoir was: Folsom Dam because of departures from operations prescribed in the Reservoir Regulation Manual. In fact, there were no exceedances of normal pools in the San Joaquin Valley section-7 reservoirs either.[11] It may be misleading and certainly vague to talk of "reservoirs

---

that the emergency (auxiliary) spillway with its flip-bucket energy dissipater instead of a large stilling basin is "intended for use only during extreme flood periods." (*Folsom Water Control Manual, 1987*, II-2)

[8] *Sacramento and San Joaquin River Basins, California, Post-Flood Assessment*, March 1999, U.S. Army Corps of Engineers, table 5-15.

[9] *Draft Feasibility Report, American River Watershed Investigation, California, Documentation Report,* Volume 2 - Appendix K, p. K-8. Table 8 here is a comparison of design flows and stages and peak flows and stages during February 1986 flood event. It would be interesting to see if, how, and why these figures would differ from estimates in 2015.

[10] Section-7 of the Flood Control Act of 1947. Flood control operations of these reservoirs are regulated by the Army Corps of Engineers' Water Control Manuals.

[11] In 1986, the small Sacramento Valley coast-range reservoir, Black Butte Reservoir, exceeded its gross pool of 144,000 acre feet by 24,000 acre-feet. It made a spillway release of 3,900 cfs (presumably augmenting its 15,000 cfs objective release by that amount) *Black Butte Dam and Lake, Stony Creek, California Water Control Manual*, U.S. Army Corps of Engineers, Sacramento District, May 1987, p. III-6 and *Post-Flood Assessment*, March 1999, U.S. Army Corps of Engineers, p. 5-18, table 5-14. Comanche

produc[ing] river flows that exceeded the design capacity of downstream levees: water came within inches of overtopping levees protecting Sacramento" if Common Features riverside levees are being referred to, although the new Common Features flow estimate in the Yolo Bypass/Sacramento River would put the 1986 combined flow at more than eight percent above the design flow.

Turning back to the American River, post-flood descriptions of design freeboard for these levees and the 1986 freeboard/flow relationships were published in the January 1995 *Proceedings of Phase Two, The Lower American River Task Force*. The Proceedings assessed then-existing Project levee freeboard conditions at various flows along the American river and concluded the following:

EE-9
(Cont.)

> For a release of 115,000 cfs, the existing minimum [freeboard] is the same for both left and right bank [project] levees (about 6 feet). The 130,000 cfs release condition also has about the same freeboard at the lowest point (interpolated to about 5.5 feet). (p. L-2, L-3)

This is not inches. It seems difficult to see how the current Common Features GRR could differ so significantly from the *Proceedings*. We suspect that the *Proceedings*' more detailed and documented descriptions are more accurate than these undocumented assertions in the draft GRR, but look forward to reviewing these conclusions with the GRR team.

The "inches" description could refer to a different problem involving what are now Common Features levees but not the river levees. The 1986 flood did show a freeboard/discharge/backwater problem with the Natomas East Main Drainage Canal (NEMDC) levee, which failed to have the freeboard envisioned by their designers in 1986 (remaining freeboard on the NEMDC near Main Avenue and the Natomas Cross Canal was 0.5 foot to 2 feet[12]). The drainage canal also had a problem with its upstream-levee creek collectors system, which failed to extend far enough upstream. It was this condition that caused localized severe flooding behind the outflanked NEMDC (Steelhead Creek) levee (Strawberry Manor). These deficiencies were largely remedied by the Sacramento Area Flood Control Agency (SAFCA) North Area Project of the early 1990s, which had a design philosophy to achieve sufficient freeboard for a stage associated with a 180,000 cfs flow in the American River and the design flow in the Sacramento River. The SAFCA North Area Project Feasibility studies characterize the problem and their solution. Although SAFCA's projects were largely completed, the

---

Reservoir (not included in either the Sacramento or San Joaquin Valleys) exceeded its gross pool of 430,000 acre-feet by 9,000 acre-feet. We have not seen documentation that Comanche Reservoir released more than its objective release as a result of this small surcharge. *Post-Flood Assessment*, March 1999, U.S. Army Corps of Engineers, p. 5-18, table 5-14.

[12] *Draft Feasibility Report, American River Watershed Investigation, California, Documentation Report,* Corps of Engineers, Part 1, April, 1991, p. III-14.

EE-9 (Cont.) Common Elements GRR recommends additional levee work in these upstream tributaries to the drain.

GRR p. 2-8: The Sacramento River Flood Control Project may have been "designed to pass the known flood of record," 1909, but since that time some major section-7 reservoirs have been constructed, allowing the 1909 Sacramento River flood system footprint to accommodate later high-flow events. It could be misleading to not mention these later additions to the floodwater-management system. It can also be misleading to state that "[t]he floods of 1986 and 1997 delivered much more water to the leveed
EE-10 reaches than they were designed to carry, resulting in levee failures." The connotations of the word "much" and perhaps "leveed reaches" are the issues here. Floodway design flows and design stages along major Project rivers and bypasses were not materially exceeded[13], however some tributary creek levees were overtopped or outflanked.[14] River levee failures here did occur, but at stages below design, such as the 1986 Peach Tree Mall Yuba River levee break, or estimated to be at the design stage, such as the 1997 Country Club Road Feather River levee break. We think it is undisputed that the 1986 and 1997 Sacramento Valley levee failures along major rivers or bypasses were because of engineering deficiencies associated with their original construction, foundation problems, or because of the consequences of nearby levee failures, not because their design stages were dangerously exceeded by flood-corridor river stages.

GRR p. 2-9: Far more than "the 200-year event design storm can be safely conveyed past the dam" once the Joint Federal Project (JFP) is completed; after all, Reclamation's
EE-11 goal is for Folsom Dam to pass the PMF without major damage to the Dam. A PMF is a highly improbable flood event that is the traditional standard for sizing spillways to avoid dam failure. A little more careful writing is warranted here since we suspect that the sought-for objective is to pass the GRR design storm without downstream levee failure or outflanking of tributary streams, not whether the flows can be conveyed safely past the dam.

GRR p. 2-13: Again we have the misleading at best and undocumented "inches from
EE-12 overtopping" statement for Sacramento area levees. It makes for dramatic reading, but engineers should strive for precision in language and avoid inaccurate or misleading statements. See above our comments on GRR p. 2-4 above.

---

[13] *Draft Feasibility Report, American River Watershed Investigation, California,* Corps of Engineers, Volume 2 - Appendix K, April 1991, p. K-8. Table 8 here is a comparison of design flows and stages and peak flows and stages during February 1986 flood event. Design stages in parts of the project area river and bypass system were exceeded to some degree in half the table locations, but none of these representative locations, nor the locations they were surrogates for, experienced failure or risk of overtopping.

[14] Levees along two Sacramento Valley creeks were overtopped in 1997, and one was outflanked/ "overtopped" in 1986. The west levee of the Sutter Bypass failed in 1997. See tables 5-15 and 5-34 of the *Post Flood Assessment,* March 1999, U.S. Army Corps of Engineers.

EE-13

GRR p. 2-18–19: Modeling the Campus-Commons/Sacramento State University "raceway" section of the Lower American River does show high velocities in this, the most narrow reach of the Lower American River. We have not yet been able to review the velocity contour analysis for the more typical reaches. Since additional erosion protection is being advocated for more than just the "raceway" reach, it would be appropriate for the GRR to characterize the wider and presumably lower-velocity reaches of river that it is seeking bank-protection authority for. We understand that bank vulnerability analysis and the resulting project recommendation would be to have the subject of discussions during post-authorization preconstruction engineering and design (PED) but remain uneasy about the potential scope of the authorization.

GRR p. 2-30: The Report identifies a single planning constraint: not violating FAA restrictions on providing additional bird habitat around the Sacramento International Airport, which we believe in the past has been used to argue (whether meritoriously or unmeritoriously) against levee setbacks and more extensive riparian forests along the Sacramento and American Rivers. The Report appears to be silent on the Corps of Engineer's responsibility to comply with the National Wild & Scenic Rivers Act (WSRA), which states that federal agencies shall not undertake any of a wide range of water-resources-project actions that would have "a direct and adverse effect on the values for which the river was established" (§7a, WSRA).

EE-14

The Lower American River is a state and federal wild & scenic river. According to the introduction on §7 of the federal act in the *Wild & Scenic Rivers Reference Guide* of the Interagency Wild & Scenic Rivers Coordinating Council, "[T]his key provision directs federal agencies to protect the free-flowing condition and other values of designated rivers and congressionally authorized study rivers." According to §16b of WSRA, "Free-flowing, as applied to any river or section of a river, means existing or flowing in natural condition without impoundment, diversion, straightening, rip-rapping, or other modification of the waterway." The *Reference Guide* adopts the definition of water resources project published in regulations developed by the Secretary of Agriculture (36 CFR 297) as "construction of developments which would affect the free-flowing characteristics of a wild and scenic or congressionally authorized study river."[15]

Because the bank protection projects that are envisioned in the Common Features draft GRR are water resources projects as defined by statute, regulation, and federal agency guidance, the project should be expected to comply with the National Wild & Scenic Rivers Act. Specifically, it should meet the §7 standards as determined by the federal wild & scenic river manager, the National Park Service. These "no direct and adverse impact on the values for which the river was established" as measured in §7 are again defined in the *Guide* consistent with 36 CFR 297 and §1b of the Act: "as the river's free-flowing condition, water quality, and outstandingly remarkable values (ORVs)." The outstandingly remarkable values on the Lower American River are anadromous

[15] *The Reference Guide* has now been broken up into a series of sub-publications from the Council that continue to be found at http://www.rivers.gov/publications.php.

fisheries and recreation (*American River Parkway Plan* 2008, Sacramento County, p. 90).

Section 2(a)(ii) national wild and scenic rivers such as the Lower American River are, in general, to be managed by the state or its political subdivisions. The most recent state plan is the *Lower American River Parkway Plan* adopted by the legislature in 2009 (AB-889). Although the federal manager has an independent duty to determine whether specific projects comply with federal WSRA law, the adopted state plan is intended to provide guidance to the federal manager, as well as the state manager, Sacramento County, (*American River Parkway Plan* 2008, Sacramento County, pp. 89–92). This plan contemplates additional floodwater-management works and contains detailed flood-control policies (pp. 82–83), later discussed and displayed in the GRR draft EIS, to avoid or mitigate adverse impacts to wild & scenic river values and Parkway resources. It should also be noted that State agencies such as the Central Valley Flood Protection Board (the non-federal sponsor) and political subdivisions of the state such as Sacramento County or the Sacramento Flood Control Agency, have a duty to comply with the provisions of the California Wild & Scenic Rivers Act (See California Public Resources Code §5093.56, §5093.61, and see §5093.50 for some relevant provisions).

EE-14
(Cont.)

We do not argue here that the 2015 Common Elements Project cannot comply with these statutes, only that the state and federal agency sponsors must shape the projects to comply with their obligations under their respective statutes. It is important the GRR acknowledge those responsibilities, and since the GRR does not contain specific site designs, the GRR should acknowledge that specific site designs will be subject to compliance with state and federal WSRAs. Projects along the lower American River have done so in the past; they can do so in the future. But their design must reflect the obligations of the GRR sponsors, both state and federal.

EE-15

GRR p. 2-32: This could be a subtle point, but it's not apparent to us that the JFP is aimed at having the ability to pass an *objective* release of 160,000 cfs. That certainly is currently the traditional emergency release, and it's fair to say that the Long-Term Study (see references below) envisioned that releases above 115,000 cfs would be included in measures of project performance, but we would characterize the releases above 115,000 cfs as contingency releases to be made when conditions require them. The Long Term Study envisioned that a new Emergency Spillway Release Diagram (ESRD) (figure 4, p. B-20) would determine operations in this range, proposed a new diagram, and stated the following:

> "Before adoption of a new ESRD, the proposed ESRD will undergo refinement and thorough analysis to ensure that the procedures are well defined to assist in the precise operational decisions necessary to make the selected plan function effectively for a range of events near design magnitude through extreme floods." *Volume III: Appendix C, Engineering, American River Watershed, California, Long-Term Study, Final Supplemental Plan Formulation Report/EIS/EIR*, Corps of Engineers, SAFCA, California Reclamation Board, Feb 2002, p. B-6."

EE-15 (Cont.)

The revision to Folsom Dam's Water Control Manual is underway. We assume that it will be the mechanism to tackle how these releases are characterized and will, therefore, contain the definitive terms and accompanying definitions needed to describe Folsom Dam's future operations. We offer up our characterization here for use by the Corps reservoir regulation manual update team.

EE-16

GRR p. 3-2: The yield of Reclamation's Auburn Dam is characterized in the Report as 270,000 acre-feet per year. The latest update from Reclamation, in 2006, estimated average yield at 208,000 acre feet per year.[16] The Report characterizes the energy production at the authorized Auburn Dam as 600 megawatt hours per year. This is confirmed by DWR and Reclamation sources. DWR characterized the annual energy production of the original Auburn dam as 600 GWhs (*Auburn Dam, Reconnaissance Appraisal of Construction Under State Sponsorship*, DWR Division of Planning, 1987 p. 8). This was echoed by Reclamation in a report published the same year with a 607.8 GWh estimate, arguably an estimate with too many significant figures (*Auburn Dam Report, Auburn Dam Alternative Study*, Bureau of Reclamation, Mid-Pacific Region, 1987, table 11).[17]

EE-17

GRR p. 3-5: The Report states that the section-7 reservoirs in the Sacramento River Basin "were completed prior to the largest flood in Sacramento; therefore, their designs are based on hydrology that does not take these large floods into account." In addition to being somewhat off the mark[18], this statement can mislead: as discussed earlier, the

---

[16] Reclamation made some sub-estimates as well: (1) American River deliveries, an increase of 21,000 acre feet or a 3% change, (2) CVP total deliveries, an increase of 138,000 acre feet or a 3% change, (3) SWP total deliveries, 70,000 acre feet or a 2% change, (4) CVP dry and critical year deliveries, 229,000 acre feet or a 5% change, and SWP dry and critical year deliveries, 114,000 acre feet or an increase in 4%. (*Auburn-Folsom South Unit Special Report, Benefits and Cost Update*, Central Valley Project California, U.S. Department of Interior, Bureau of Reclamation, Mid Pacific Region, December 2006, pp. TS-3, Table III-2).

[17] We do note parenthetically that Reclamation's 2006 report appears to upsize the generation plants and develop a range of estimates for a number of re-envisioned hypothetical unit number and configurations, making comparisons with the authorized project difficult. Moreover, Reclamation's 2006 Special Report was unable to firmly identify average annual energy production saying the following:

> [t]he power generation potential at a hydropower plant is unique to each facility. Extensive analysis is required to develop power generation equations for a specific facility. This type of analysis has not been completed for the proposed Auburn Reservoir power plant.

The 2006 Reclamation report demonstrated a re-envisioned annual power generation potential ranging from 1,667 to 3,618 GWhs but fails to explain this considerable departure from earlier estimates. (*Auburn-Folsom South Unit Special Report, Benefits and Cost Update, Central Valley Project California,* U.S. Department of Interior, Bureau of Reclamation, Mid Pacific Region, December 2006, pp. III-15–17).

[18] A review of the Sacramento Valley reservoir water control manuals suggests that neither the early twentieth century storms magnitudes nor the latter twentieth century storms were the controlling factors in the design of most of their reservoir design floods. As noted earlier, Folsom Dam's design flood was initially based on 1862-flood estimates, then upsized. Review of the other respective reservoir regulation

EE-17 (Cont.)

record does not show any inflow events to these section-7 reservoirs that would have required releases in excess of dam objective releases or surcharged these reservoirs.[19] Of course, the original reservoir design floods, spillway design floods, SPFs, & PMFs would now be assigned a more probable "return frequency," which is probably what the GRR authors intended to say. The Report then states that "reoperation of these upstream reservoirs would not substantially reduce the flood risk to the Sacramento area," implying that this is because "flood storage is a small component of these dams' storage, since they are water supply reservoirs." Again, in spite of the "*small* component" of reservoir storage dedicated to a flood-control reservation, since their construction, these dams have been able, or should have been able, to maintain regulated releases to within their objective releases, which are usually keyed to leveed river-corridor capacity, indicating the dams' importance to the current floodwater-management system.

The real reasons why reoperation of upstream section-7 dams does not materially affect the performance of the Common Features floodwater-management systems are more varied. (1) Folsom Dam is already being "reoperated," reserving in some conditions more than two thirds of the reservoir for flood space, (2) the effectiveness of Common

---

manuals is instructive. New Bullards Bar Dam's flood reservation was designed, in concert with the authorized but still unconstructed Marysville Dam, to provide SPF protection to Marysville-Yuba City (p. 24, ¶27, 1972). Oroville Dam's flood space was designed to provide SPF protection to the Feather River basin (p. 15, ¶14, 1970). "Shasta Reservoir does not have a reservoir design flood," although the 1977 manual does note, in this case, that the dam could contain a 100-year flood within its flood space and not exceed nearby downstream flow objectives. The 1940s-era hydrologic basis for its design was to be a multipurpose reservoir and meet its authorized purposes and priorities (p. 9, ¶18 & p. 25, ¶24). The smaller Black Butte Project was authorized because "the required flood protection could be provided more effectively and economically" than downstream levee or channel improvement projects or small upstream reservoirs (p. III-1). Project objectives include protecting "the city of Orland from all reasonably probable rain floods," protecting downstream agricultural areas "during all but very large floods," and restricting releases from the dam to 15,000 cfs "insofar as possible" (p. VII-1, 1987). The 1970s-era Indian Valley Reservoir on the NF Cache Creek seems to be the only Sacramento Valley section-7 reservoir with a hydrologic basis for design based on a probability frequency that could be affected by more recent flood experience. Its small flood-space reservation of 40,000 acre-feet was based on "adequately contain[ing] all Indian Valley inflow for floods up to the 50-year flood until flows at Rumsey have returned to existing channel capacity of 20 cfs" (p. 9 ¶17, 1977).

[19] In the 1997 event, Oroville Dam operators made a release of 160,000 cfs, 10,000 cfs above the dam's objective release out of concern that pass-through operations were imminent. However, 1997 reservoir operations peaked with 206,000 acre feet of the standard 750,000 acre-feet flood control reservation and 150,000 acre-feet of objective-release-requiring surcharge operational space defined in the Water Control Manual still untouched. That's a 350,000 acre-feet cushion. Oroville Dam did not experience a reservoir design flood, and pass-through operations were not imminent. For a careful analysis of the Oroville Dam operations, see Motion to Intervene of Friends of the River, South Yuba Citizens League, and Sierra Club, Federal Energy Regulatory Commission, Project No 2100-52, October 17, 2005. Of course, two San Joaquin River Basin section-7 reservoirs filled and spilled in 1997, but given floodway constraints, this should not have been unexpected. Sacramento River Basin floodway capacities are an order of magnitude greater their southern neighbors. For a handy record of 1997 major section-7 reservoir operations, see the *Final Report, Governor's Flood Emergency Action Team*, The Resources Agency, May 10, 1997, Appendix B.

EE-17 (Cont.)

Features facilities is buffered from potential exceedances from dams upstream of the American River because these exceedances may be temporarily stored in upstream flood-deposition basins due to levee breaks or Butte Basin upstream weir operations, or mostly diverted into the Fremont and even Sacramento Weir and into the Yolo Bypass. (3) Shasta Dam and Oroville Dam have large flood reservations and substantial early-release capabilities now. The most deficient dam is New Bullards Bar Dam. It has the smallest flood-space reservation, even in percentage terms of any of these dams. It's early-release capabilities are limited enough that Yuba County Water Agency, the dam's owner, has undertaken preliminary design investigations to enlarge its low-level release capabilities to better enable the dam to conduct floodwater-management operations and benefit from a forecast-based reoperation. Physical modification to this dam and a modified Water Control Manual is a foreseeable circumstance, but their major benefits would mostly be improving regulation of flood stages along the Yuba and Feather Rivers for some floods and produce only attenuated benefits downstream, in part because most of these flows are diverted into the Yolo Bypass.

EE-18

GRR p. 3-6: As we recall the Corps 1991 ARWI alternative analysis, another reason the Corps did not carry forward the proposed Deer Creek offstream storage project was simple: the downstream channels needed to evacuate Deer Creek dam storage of antecedant flood events were too small. As a result, the Corps could not be confident that flood space there could be considered reliable during flood seasons like 1862 when large flows were experienced in multiple very large flood waves throughout the months of December and January. Sacramento River Basin flood corridors are a lot larger than more southerly corridors. That makes a huge difference in flood-space recovery times.

EE-19

GRR p. 3-7: The report notes "that some [study area] flood events were larger than those for which the flood control system was sized (1955, 1964, 1986, and 1997)." As noted earlier, Folsom Dam has never experienced a flood larger than its reservoir design flood (see attachments).[20] The JFP is designed to increase the Folsom Dam reservoir design flood in case flows larger than record or greater than reservoir-design-flood inflows occur. Common Features projects are designed to increase levee reliability at objective releases up to the emergency release target flow of 160,000 cfs (which may become a conditional release as well). Of course if the focus is on the Common Elements collector streams, these projects did not perform well during the 1986 flood and have been the focus of non-federal sponsor activity and this GRR to prevent the leveed corridors of upstream creeks from being outflanked or overtopped or failing during high-flow events, especially when high backwater conditions prevail. Nevertheless, these general

[20] We suspect that the metrics used to establish this assertion are six-day volumes. As noted earlier, the actual hydrograph may be best representation of a reservoir design flood. Failing that, three-day volumes have become the *lingua franca* of contemporary measures of reservoir flood-operations performance in this region. Design hydrographs that are challenged by three-day numbers are typically not very challenged by six-day flows given the large floodway capacities of Sacramento Valley reservoirs and typical runnoff patterns of the areas's great floods. In effect, the center-of-storm runnoff (3-day) metrics challenge flood space and timely reservoir operations, while long storm-sequence (6- or 14-day) metrics challenge downstream release and floodway capacities.

EE-19 (Cont.) statements should be made with more precision. Otherwise, they are subject to misinterpretation.

EE-20 GRR p. 3-20: Vegetation on or near levees can also reduce the probability of system failure by reducing water velocities at the bank or levee interface and by increasing levee or bank/berm cohesion. As noted in other areas of the Report, levee and near-levee vegetation-removal policies are a significant issue of public concern. That concern has resulted in a stand-down of enforcement of some of the Corps policies as a result of Congressional Action (WRRDA §3013) with a conforming court order (*Friends of the River v. U.S. Army Corps of Engineers,* Case 2:11-cv-01650-JAM-AC (E.D.Cal. Sept. 12, 2014). It would be helpful if the Project sponsor GRR presentations on this subject area were more balanced given the obvious local, state agency, and federal natural resources agency sensitivities to this issue while the Corps is reformulating its vegetation policies as discussed in WRRDA and the conforming court order.

EE-21 GRR p. 3-23: We concur with Table 3-6's assessment that the later not-carried-forward Upstream Storage on American River (Auburn Dam) alternative has demonstrated a lack of Congressional and public support. It's probably also true that there is no non-federal sponsor for this alternative. We are, therefore, curious why the same poor acceptability rating does not occur with the also not-carried-forward Maximum Plan alternative. It, too, also features the same upstream storage element as the previous (above) alternative and lacks any realistic potential non-federal sponsors.

EE-22 GRR p. 3-28: Regarding your Focused Alternative 5: Maximum Plan (later not carried forward) it would be helpful if the GRR discussion could include a caveat or two regarding the statistical meaningfulness of assigning apparently precise and therefore accurate probabilities to hypothetical never-before-experienced, particularly events considerably larger than recorded events. For example, the American River rain flood frequency analysis by the Corps of Engineers prepared with the advice of the National Research Council's Committee on American River Flood Frequencies does not extrapolate the frequency curve beyond 1 in 200.[21] While the Committee and we understand that assigning these rare probabilities to some hypothetical flows for some purposes is necessary, it would be appropriate to include the NRC's caution when discussing analyses concerning events modeled to be less probable than 1 in 200 in this watershed.

EE-23 GRR p. 3-38: The Vegetation and Access discussion of vegetation on and near levees begun here and carried through much of the rest of the Report seems curiously uninformed by WRRDA §3013 and the conforming court order. There are two relevant provisions neatly summarized by the order:

[21] U.S.A.C.E. Sacramento District, *American River, California, Adopted Rain Flood Flow Frequency Analysis*, April 1999, plate 1 and presumably subsequent successor analyses.

> The Corps will proceed to conduct the review of the guidelines and take the actions required by WRRDA § 3013. In accordance with § 3013(g) until the date on which revisions to the guidelines are adopted, the Corps will not require the removal of existing vegetation as a condition or requirement for any approval or funding of a project, or any other action, unless the specific vegetation has been demonstrated to present an unacceptable safety risk (*Friends of the River v. U.S. Army Corps of Engineers,* Case 2:11-cv-01650-JAM-AC (E.D.Cal. Sept. 12, 2014) ¶6).

EE-23
(Cont.)

To date, the review has not been concluded, nor have any revisions to the guidelines contemplated in the court order been adopted. Instead, the representations of how vegetation on and near levees will be treated by the Common Elements projects appear to be consistent with the current Corps Vegetation Engineering Technical Letter (ETL), SWIF, and variance policies, apparently prejudging the results of the review and release from the court order. It is therefore troubling that the Report fails to note that some vegetation-removal actions are not consistent with current federal law or the court order. Nor does the Report note that it has been required by the Congress to review the ETL with the expectation that a revised ETL will then be issued. We appreciate that the project sponsors need to be able to describe the environmental impacts of the successor ETL as the projects in the Common Elements GRR are constructed, but the range of potential of future Corps (and state) levee- and near-levee vegetation policy alternatives are not included in your descriptions.

In fact, it is impossible not to note that the Report and draft EIS/EIR fail to develop any alternatives to implementation of the meat and substance of the current ETL and related vegetation policies. Instead, the GRR apparently assumes that variances will be given. We appreciated that the Sacramento District will seek a variance to the ETL (*Appendix C, Engineering,* 2.4.2) and hope that they receive a variance. However, there could be severe consequences if the existing ETL or similar successor ETL (apparently assumed here) is required to be implemented because variances are not granted. Given the proximity to wild & scenic rivers and the potential to take actions that may violate federal laws meant to protect the environment, this is a deficiency in the project formulation and assurances that needs to be addressed in the Final Report and environmental documents or challenges could arise.[22]

The Central Valley Flood Control Board's adoption resolution for its levee vegetation policy in the Central Valley Flood Protection Plan (CVFPP) also contemplated a state review of the adopted levee-vegetation elements of the CVFPP, which were not consistent with the ETL. Again the possibility of revisions to the state plan elements, particularly the Life Cycle Management Policy (which would gradually result in absence of woody vegetation from most of the levee profile and all of the landside near-levee area) or of the DWR Urban Levee Design Criteria vegetation requirements, are not contemplated in the Report. DWR is also reviewing how their vegetation policy squares

---

[22] See NEPA Regulations: 1508.27(b) ("severity" "intensity"); 1508.27(b)(3) ("proximity to. . .wild and scenic rivers"); and 1508.27(b)(10) ("Whether the action threatens a violation of Federal, State, or local law or requirements imposed for the protection of the environment.").

with the Draft Conservation Strategy being prepared for adoption before or at the 2017 update to the CVFPP.

EE-23 (Cont.)

A little humility is necessary here. It's O.K. to recognize and report that the federal and state policies are under review but this is how it would work with the existing, but in the federal circumstance, stood-down policy and the state policy that is supposed to be under review. But you have to make it abundantly clear that these policies may change or be refined as a result of future review and discuss the implications of various alternatives.

And speaking of humility, consider the lowly California Poppy *(Eschscholzia californica, E. caespitosa, or E. lobbi)*. The Report assumes that hydroseeding perennial grass seeds on the otherwise barren or mowed or burnt levees envisioned in the Report will be successful in keeping wildflowers and annual grasses of the Sacramento Valley from invading the slopes of the levees in violation of the ETL. It is probably worth some real inquiry on the track record of this technique to achieving mowable perennial grasses that can successfully exclude vegetation inconsistent with the ETL such as forbs and annual grasses. And if the Corps intends to revise the ETL, don't declare war again on California's native wildflowers. They aren't the enemy.

EE-24

GRR p. 4-8: We were pleased to read the following commitment:

> An initial assessment with regards to the method of bank stabilization has been made for this document. During detailed design, the Corps will coordinate closely with the county, state, and federal agencies responsible for managing the resources of the parkway in selecting which method of bank stabilization should be deployed. In carrying out this effort, the Corps will coordinate through the formal and informal processes that have been created to facilitate management of the parkway in application of the above criteria. Where erosion protection is needed to meet established flood risk reduction objectives, the selection of the method of protection will be based on a determination of which method would do the most to protect valuable parkway land, fish and wildlife resources, and recreational facilities considering both the short term impacts of construction and the long term effects of any mitigation measures included in the design of the project.

As you know, one of these groups is the now twenty-two-year-old Lower American River Task Force. This is so important that if necessary the Corps may be well-advised to seek specific authorization to do this if and when an authorization proposal is submitted to the Congress.

EE-25

GRR p. 4-36: It is perhaps premature to specify that the expanded portion of the Sacramento Weir will never be operated "for events up to and including the 1/100 ACE event." By implication, this is either an inflow-into-Folsom Dam or a Folsom Dam outflow statistic (the text is not clear). It should be noted that the current 1/100 ACE inflow into Folsom Reservoir has never been experienced in the period of hydrological record. And no Water Control Manual operation would have required outflows greater than 115,000 cfs in the same period routed through the existing system of dams. It is, thus, not out of the question that the expanded Sacramento Weir would never be used under this policy.

EE-25 (Cont.) The California Department of Water Resources, along with local governments, is also developing a project to expand the Sacramento Weir, which it probably intends to marry with the Corps Common Features tentatively selected alternative. It is premature to judge what project operational criteria they will develop for weir operations. It is certainly possible that DWR et. al. would conclude that opening the weir could be important in circumstances not within the criteria put forward in GRR p. 4-36.

EE-26 GRR p. 4-37–40: Again, the State and National Wild & Scenic Rivers Act §7 standards are not mentioned as avoidance or mitigation objectives. They belong here.

EE-27 GRR p. 7-1–4: In the list of recommendations a number of project-related relevant statutes are referenced for the purposes of a pledge of compliance. There are at least two relevant ones that we do not see: (1) WRRDA §3013 and the conforming District Court order (*Friends of the River v. U.S. Army Corps of Engineers*, Case 2:11-cv-01650-JAM-AC (E.D.Cal. Sept. 12, 2014) as applicable, and (2) the National Wild and Scenic Rivers Act (16 U.S.C. 1271-1287) as set forth herein consists of Public Law 90-542 (October 2, 1968) and amendments thereto.

EE-28 dEIS/EIR p. 56: We suspect that the conclusion, "[i]f a large regional earthquake occurred during a major flood event, these potential [structural degredation] effects would be magnified, and potential for levee breach would be increased," is true, especially for the American River and upstream levees, which rarely experience high stages. But the Sacramento River does experience high stages for weeks and longer during relatively routine rainy periods even in the absence of "a major flood event." Since the GRR project area includes the Sacramento River, the conclusion there that "the potential for failure or significant damage of project structures is low" because, in part, of the "small likelihood of coincidence [of a] flood event and a major earthquake." Given the large populations and ongoing land-use and floodplain-management decisions within the protected reaches of the GRR, more detailed discussion of this issue is in the public interest, even if the project may not change the relative risk of this failure mode in comparison to the without-project condition. Some discussion is also warranted of how sensitive the liquefaction risk is to stage since deeper foundation wetness conditions may not be as sensitive to stage as shallow foundation wetness may be.

EE-29 dEIS/EIR p. 59: The lower American River is not classified as a "Recreation" river within the state and federal wild & scenic river systems. It is classified as a "Recreational" river. "Recreation" is one of two identified extraordinary values of the lower American River wild and scenic river, the other being anadromous fishery.

EE-30 dEIS/EIR p. 60: Thank you for quoting the American River Parkway Plan flood-control policies. As you note on page 59, the parkway plan acts as the management plan for the

EE-30 (Cont.) state and federal wild and scenic rivers acts. It also should be noted that the parkway managers and state and federal agencies need to comply with the statutes in their exercise of discretion when implementing the policies of the management plan.

EE-31 dEIS/EIR p. 63: Although the likely erosion of waterside berms is a basic assumption of the GRR, this hypothesis on a reach-by-reach basis will and should be demonstrated (preferably pre-authorization but failing that, during preconstruction engineering and design). We'll all have to spend more time with GRR Appendix C, Attachments C & E.

EE-32 dEIS/EIR p. 64: The following statement is so important, that we repeat it full:

> The American River Parkway Plan policies address flood risk reduction and levee protection activities with the overall aim of facilitating these activities as necessary to achieve established flood risk reduction objectives in a manner which provides optimum protection to the open space, recreation, and fish and wildlife resources of the Parkway. Consistent with these policies, bank protection improvements and to a lesser extent launchable rock trench improvements have been constructed at various locations in the Parkway over the past 20 years. In selecting which of these methods of protection should be deployed, the Corps will coordinate closely with the Sacramento County Department of Parks and Recreation, the National Park Service, the other Federal and State agencies responsible for managing the resources of the Parkway, and non-governmental stakeholders. In carrying out this effort, the Corps will coordinate through the formal and informal processes that have been created to facilitate management of the Parkway. Where erosion protection is needed to meet established flood risk reduction objectives, the selection of the method of protection will be based on a determination of which method would do the most to protect valuable Parkway land, fish and wildlife resources, and recreational facilities considering both the short term impacts of construction and the long term effects of any mitigation measures included in the design of the project.

We would add that the vegetation and aesthetic resources of the parkway should not be unnecessarily sacrificed, that they contribute to the parkway's extraordinary and outstandingly remarkable values, and that we believe that the above coordination commitment applies here as well.[23] Moreover, we expect that project decisions along the Sacramento River and tributary creeks to the American River will be well coordinated as

---

[23] See §10(a) of the National Wild & Scenic Rivers Act. "Each component of the national wild and scenic rivers system shall be administered in such manner as to <u>protect and enhance the values which caused it to be included in said system</u> without, insofar as is consistent therewith, limiting other uses that do not substantially interfere with public use and enjoyment of these values. In such administration primary emphasis shall be given to protecting its <u>esthetic</u>, scenic, historic, archaeologic, and scientific features." *(emphasis added)*

EE-32 (Cont.) well, recognizing, of course, that authorities and responsibilities along these waterways may differ.

EE-33 dEIS/EIR p. 69: The "Regulatory Setting" bullet points here and in other portions of the dEIS/EIR should give more careful consideration of whether to include the state and federal wild and scenic river acts. Water resources projects including bank protection projects need to get WSRA §7 sign offs from the National Park Service. Under the California WSRA, each agency makes its own determination of consistency (PRC 5093.61), although the Resources Agency is responsible for coordinating state agency actions and decisions (PRC 5093.60).

EE-34 dEIS/EIR p. 70: The document notes that "[t]he project area is divided into two basins—American River North and American River South." These may be congruent with the pre-leveed natural flood-deposition basins on either side of the American River: the American Basin to the north, and the Sacramento Basin to the south. Since professional and academic use will be made of the GRR, it may be helpful to explain their equivalence or how the terms differ. For example, the portion of the American Basin surrounded by levees in Natomas is often called the Natomas Basin. These three basins are nicely displayed in GRR Appendix E, but the relationships between geomorphic forms could use better discussion.

EE-35 dEIS/EIR p. 75: Table 8 compares pre and post Joint Federal Project (JFP) outflows for modeled year frequency events. We were unaware that the operational rules for the JFP had been completed, presumably a prerequisite for making these predictions. We would be interesting in learning what rule assumptions were made to construct Table 8 and Figure 7 on the following page.

EE-36 dEIS/EIR p. 81: Will the trigger for the use of the expanded Sacramento Weir and Bypass be when a Folsom Release of greater than 115,000 cfs is made or will it be tied to a hydrology analysis of higher inflow into or outflow from Folsom Reservoir than the modeled 1/100 ACE event (as it exists now or in the future)? See our remarks above about the wisdom of making this commitment at this time.

EE-37 dEIS/EIR p. 102, 2nd ¶, 1st sentence: Substitute "effect" for "affect."

EE-38 dEIS/EIR p. 103: Vegetation, both temporary and long-term, are clearly one of the big potential adverse impacts of the Project and revegetation, whether natural or artificial, is a major potential mitigation for the GRR. It is critical, as noted at this page, that [d]uring the design refinement phase, plans will be evaluated to reduce the impacts on vegetation and wildlife to the extent practicable." This is a high-visibility parkway. This commitment needs to be serious and meaningful and that the words "extent practicable" are not misused.

EE-39 dEIS/EIR p. 111: The hypothesis that "high flows in the American River would have a large impact on the American River Parkway as the berms disappear from continued

EE-39 (Cont.)

high flows against erodible material" has yet to be thoroughly and in detail reviewed outside of the GRR team and consultants. As noted earlier, a wider, more public technical reach-by-reach discussion is warranted. We'll all have to spend more time with GRR Appendix C, Attachments C & E.

EE-40

dEIS/EIR p. 116: As noted earlier, there needs to be a review of the Regulatory Setting sections in the dEIS/EIR on whether the state and federal wild and scenic river acts belong in the bulleted list of regulatory statutes. They certainly do here. Anadromous fisheries are listed outstandingly remarkable or extraordinary values.

EE-41

dEIS/EIR p. 148: Please see our earlier remarks regarding the status of the levee ACE vegetation policy. This policy is supposed to be under review.

If the existing ETL is not changed and is still enforced, in addition to the infeasible forb and annual grass prohibition, a variance of more than the lower waterside vegetation would be required. Corps policy is also to prohibit plantings of woody plants that may throw roots into levee critical features, regardless of distance from the levee.

The premise of a SWIF is to eventually comply with the Corps' vegetation policy. This slow deforestation of the landside woody, forb, and annual vegetation (and some levee vegetation?) and the planting prohibition where roots may reach the levee or levee foundation is controversial and not fully accepted by state and federal natural resources agencies. We certainly agree that "collaborative intergovernmental framework[s]" in "complex situations" "will take time," particularly as the Corps and the State of California and federal resource agencies review existing vegetation management policies.

EE-42

dEIS/EIR p. 149: Please list the NPS among the agencies from which to obtain "necessary permits and authorizations." We are pleased that "[t]he Corps would adhere to all applicable…laws…during implementation."

EE-43

dEIS/EIR p. 149: The Bay Delta Conservation Plan with its focus of an HCP and NCCP to recover listed species and co-equal goals appears to have been abandoned, replaced by an effort to construct tunnels under the Delta to deliver Sacramento River water to the export pumps and to mitigate their impact.

EE-44

dEIS/EIR p. 291: We hope that the project, as implemented, will not have significant environmental impacts from loss of vegetation and wildlife habitat and loss of aesthetic and visual resources. In other words, we note that Project proponents have described the environmental documents supporting the potential Corps and Assistant Secretary for Civil Works recommendations for this GRR reauthorization as describing the maximum project adverse impacts. Project proponents hope to avoid some of the described project impacts during preconstruction engineering and design. That is our hope and expectation as well.

Comment Attachments

EE-45 The first two one-page attachments (appended to this PDF) document historic American River floods as measured by flood peaks of hydrographs by estimation method. If you have different estimates and more detailed references, let's discuss this. The second attachment (also appended to this PDF) compares estimated flood peaks and compares them with current and contemplated reservoir design floods. Your assistance in better referencing this document would also be appreciated. EE-46 The last attachment is an outline of the GRR and dEIS/EIR with questions and comments in italics prepared by a consultant with considerable experience on the American River based on a preliminary initial review. It is in an accompanying docx file. Hopefully, these questions can be addressed in the Response to Comments and the "formal and informal processes that have been created to facilitate management of the Parkway" that project sponsors have committed to engage in.

Sincerely,

Ronald Stork

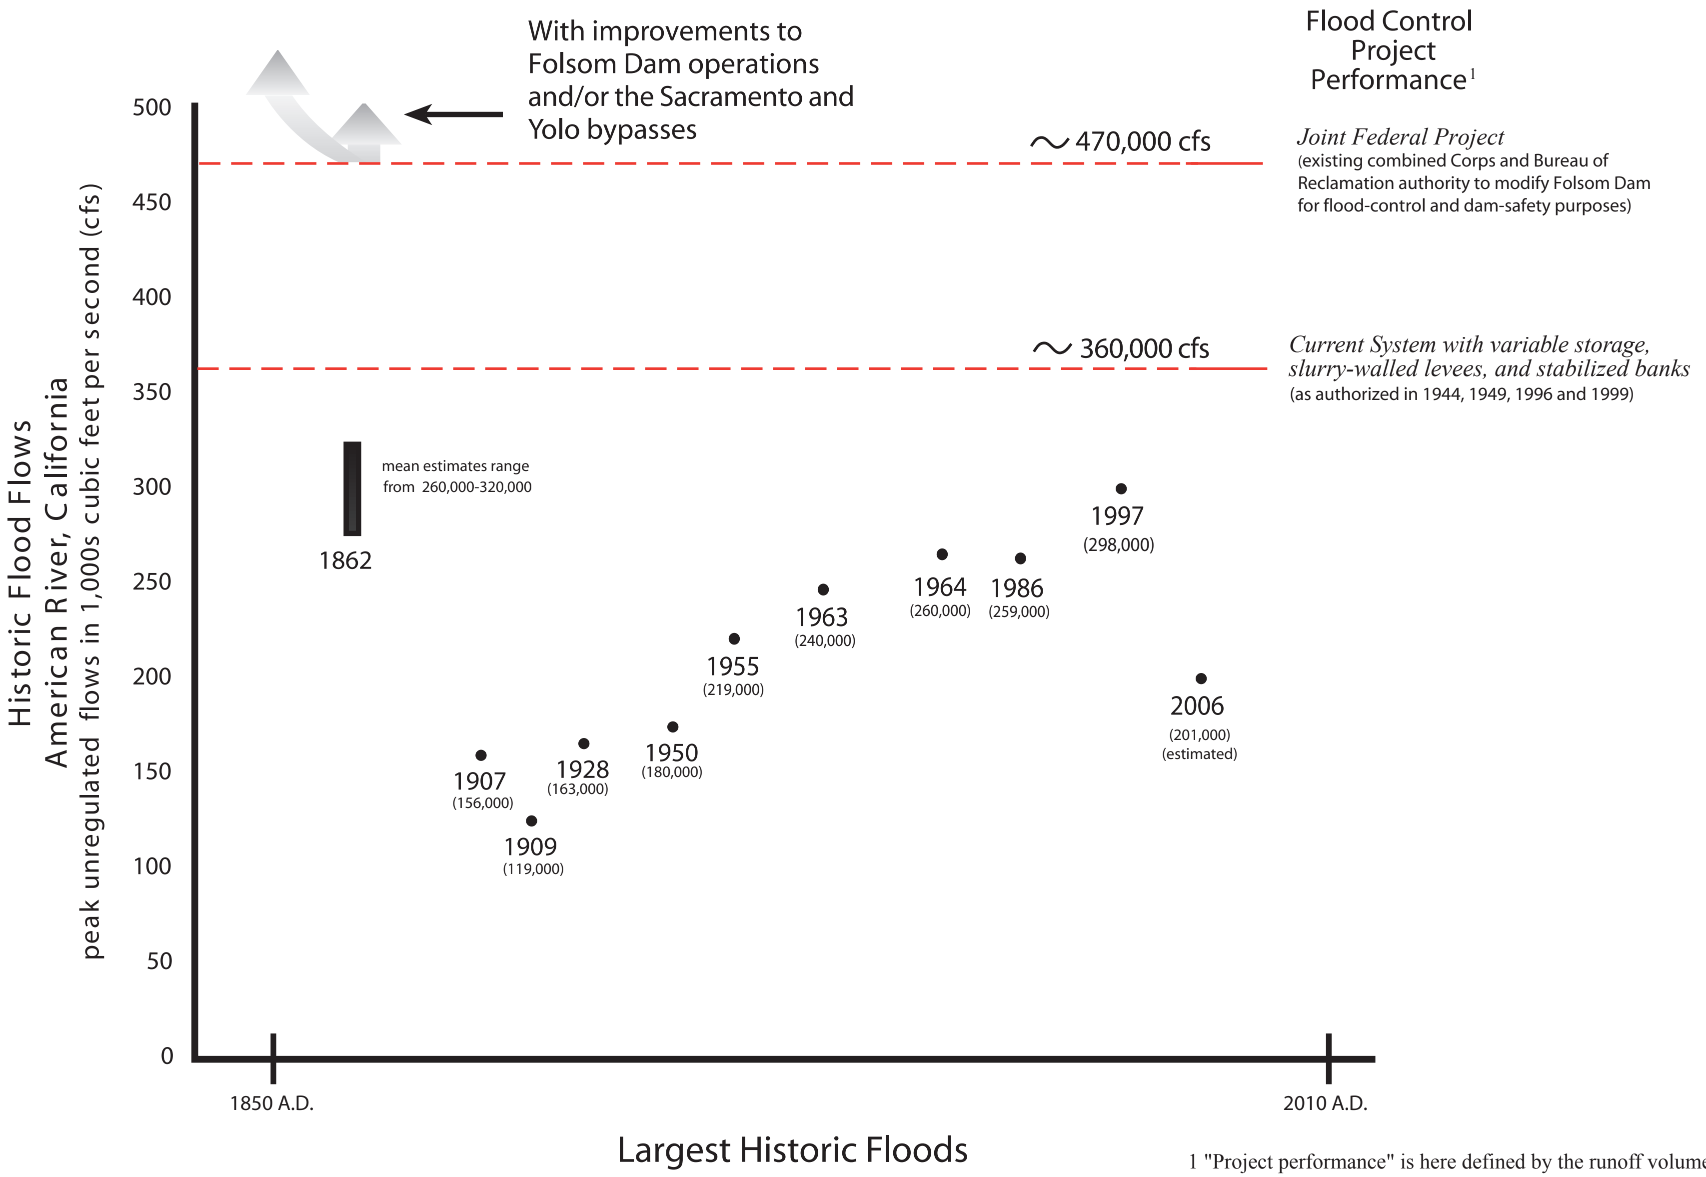
Record American River Floods, Existing and Authorized Flood Control Project Performance



1 "Project performance" is here defined by the runoff volume (as measured by the flood peak of the unregulated "design flood" hydrograph) that a particular flood-control system can reliably accommodate. In dam-controlled watersheds, use of unregulated (total flow into rivers and storage) runoff-volume hydrographs allows planners to easily compare the performance of past, existing, and planned flood-control projects against historic, modern, and hypothetical storm-runoff events.

June 12, 2006

Draft 5/8/15

DRAFT General Reevaluation Report - EIS/EIR (March 2015).

- **Executive summary:**
  - Introduction (1):
  - Purpose and intended uses of this EIS/EIR (1):
  - Study area (2):
  - Project background (2-4):
  - Need of action (4-5):
  - Alternatives (5-7):
    - No action alternative (5):
    - Alternative 1 – improve levees (5):
    - Alternative 2 – improve levees and widen Sacto. weir and bypass (TSP) (6-7):
  - Environmental effects and mitigation measures (7-8):
    - TABLE ES.2: Environmental impacts and proposed mitigation/compensation for the ARCF GRR: (8)
    - TABLE ES.3: Summary of environmental effects and mitigation measures: (10-16)
  - Cumulative impacts (8):
  - Areas of controversy and unresolved issues (8):
  - Public involvement (9):
  - Tentatively selected plan (TSP) (9

- **1.0 Introduction (1-19):**
  - 1.1 Scope of the environmental analysis (1-3):
  - 1.2 Project location and study area (2):
    - 1.2.1 Location (2):
    - 1.2.2 Study area (2-3):
  - 1.3 Background an history of the Amer. R. Common Features Project (3-7):
  - 1.4 Project purpose and need for action (8-14):
    - 1.4.1 Seepage and underseepage (9):
    - 1.4.2 Levee erosion (910):
    - 1.4.3 Levee stability (10):
    - 1.4.4 Levee overtopping (10-11):
    - 1.4.5 Vegetation and encroachment compliance (11-13):
      - System Wide Improvements Framework (SWIF) (12):
        - An agreement between the Corps and the non-federal sponsor that
          - Allows the local maintenance agency (LMA) to defer compliance with ETL 1110-2-583.
          - Provides that the LMA would address **<u>landside</u>** vegetation and encroachment issues through
            - Implementation of their standard O&M actions over time.
          - Vegetation not impacted by construction would be addressed
            - By the LMA in accordance with
              - State's Levee Vegetation Management Strategy in the CVFPP
                - Over the next 20-40 years.
        - Will be planned and implemented by the non-federal sponsor
          - Will include the flowing criteria.
            - List and short discussion.
      - Vegetation variance (13):
        - Will be sought by the Sacto District to comply with
          - ETL 1110-2-583
            - On the **<u>waterside</u>** of levees.
        - The request required the Corps to show that the
            - Safety
            - Structural integrity
            - Functionality
          - Of the levees would be retained
            - If vegetation were to remain in place.
        - An evaluation of
              - Underseepage
              - Waterside embankment slope stability
            - Was completed by Corps geotechnical engineers.
          - For a Sacto River location (Levee Mile 5.92)
            - As representative of the most critical
                - Channel and levee geometry
                - Underseepage
                - Slope stability
                - Vegetation

- Conditions.
- Results showed that
  - Tree fall and scour did not significantly affect levee performance
  - The levee meets Corps seepage and slope stability criteria
    - Considering that
      - Seepage
      - Slope stability
    - “With-project” improvement measures are in place.
  - It is reasonable to conclude that by
    - Allowing vegetation to remain
      - Safety
      - Structural; integrity
      - Functionality
    - Of Sacto. River levees would be retained.

EE-47

    - *What about American River issues?*
- Vegetation variance request would be developed
  - During design phase
    - To allow for vegetation to remain on the lower portion of waterside levees.
    - Vegetation on the upper waterside slope would be removed as part of project construction.
- If a variance is not approved
  - Recommendations for this portion of the project
    - Will be reformulated
      - Further environmental compliance efforts would be required.

EE-48

      - *If this variance is to apply to the American River, and if it is not approved; what additional vegetation impacts will occur on the LAR?*
- 1.4.6 Releases from Folsom Dam (13-14):
- 1.4.7 Flood management system (14):
- 1.5 Environmental regulatory framework and authority (14-16):
  - 1.5.1 NEPA (14):
  - 1.5.2 CEQA (14-15):
  - 1.5.3 State and local planning (15):
  - 1.5.4 Study authority (15-16):
- 1.6 Intended use of this document (16):
- 1.7 Related documents and resources relied on in preparation of this DEIS/DEIR (16- 17):
- 1.8 Application of NEPA and CEQA principle and terminology (17-18):
- 1.9 Organization of the DEIS/DEIR (18-19):

- **2.0 Alternatives (20-53):**
  - 2.1 Introduction (20-25):
    - 2.2.1 Alternative formulation and screening (20-22):
      - Future without Project condition (21-22):
    - 2.2.2 Measures and alternative considered, but eliminated from future consideration (22-25):
      - Upstream storage on the American River (Auburn Dam) (22):
      - Transitory storage in upstream basins (23):
      - Yolo bypass improvements (23):
      - Reoperation of upstream reservoirs (24):
      - Sacramento River I St. bridge diversion structure (24-25:
      - Non-structural measures (25):
  - 2.2 Non action alternative (25-26):
  - 2.3 Alternative 1 – improved levees (26-42):
    - 2.3.1 American River (30- 31):
        - Levees would require improvements to address erosion.
          - Consisting of waterside armoring to prevent erosion
            - Of banks and levees
              - If unaddressed <u>could potentially</u> undermine levee foundations.

EE-49
              - *What level of uncertainty/certainty does this "could potentially" imply?*
      - Bank protection (30):
        - Consists in placing rock on
          - Banks and in some cases levees
        - <u>When necessary</u> eroded portion of banks would be filled and compacted prior to rock placement.

EE-50
              - *What conditions make this "necessary"?*
        - Sites would be prepared by
            - Clearing and stripping prior to construction
              - <u>Small vegetation</u> and loose material would be removed
          - In most cases
            - <u>Large vegetation</u> would be left in place.

EE-51
              - *What size criteria are to be used for small/large?*

EE-52
              - *If large trees are left in place will the amount be specified by hydraulic modeling of conveyance?*

EE-53
              - *If large trees are left in place, when they die will they be replaced; will natural revegetation be allowed or even possible with the rocked surface?*

EE-54
              - *If these trees are expected to die and not be replaced how should these trees be counted for impact/mitigation purposes?*

EE-55
- *Because of these questions/issues, should the recreation and visual impact assessment be based on no trees at all on these banks?*

- Temporary access ramps would be developed
  - If needed

EE-56
- *In what conditions would access ramps not be needed?*

- Hauled revetment rock will be stored on-site immediately near the construction site.
  - A loader will move rock to the staging area.
- An excavator will place a large rock berm
  - In the water to an elevation slightly above mean summer flow elevation

EE-57
- *A berm using large rock or a large berm using rock?*

EE-58
- *This berm is not indicated on Figure 1.*

  - A planting trench would be established on this rock surface
    - For revegetation.
- The excavator would work to place rock either
  - From the top of bank
  - From the constructed berm
- On levees
  - Rock placement will be from the top of levees.
- On banks
  - The revetment would be placed at slopes of
    - 2V:1H to 3V:1H
      - Depending on site conditions.

EE-59
- *This must be a typo – 2:1 and 3:1 slopes (2H:1V and 3H:1V).*

  - After placing revetment
    - A small planting berm would be constructed in the rock
      - Where feasible
      - To allow some revegetation of the site
      - Outside the vegetation free zone as required by ETL 1110-2-583

EE-60
- *This planting berm is not indicated on Figure 1.*

    - This vegetation will be designed on a site specific basis to
      - Minimize O&M
      - Not impact the channel conveyance.
- Launchable rock trench (31):
  - Designed to deploy revetment once erosion has removed the bank material beneath it.
    - Will be placed outside the channel.
  - Vegetation would be removed from the trench footprint and levee slopes

        - Prior to trench excavation.
    - Trench will be located at the toe of existing levees
        - Will have a
            - River-side slope of 1:1
            - Levee-side slope of 2:1
        - The bottom of the trench would be constructed to an elevation near the summer mean water surface.
            - In order to reduce the;
                - Rock launching distance
                - Amount of rock required
                - *With the design depth and slopes, this configuration seems to maximize the amount of rock required?*

EE-61

    - Trench rock will be covered with a minimum of 3 ft. of stockpiled soil.
    - Rock placed on levee surfaces would be covered with stockpiled soil.
                - *Will soil be placed with the launchable rock in the trench to prevent progressive infiltration of surface soil into rock voids and prevent surface subsidence?*

EE-62

                - *Could the excess excavated soils be used to in-fill mine tailings at restoration sites? This would require the restoration sites to have working plans and to have the cobbles pre-graded.*

EE-63

    - All disturbed areas would be reseeded with
                - Native grasses
                - Small shrubs
                    - Where appropriate.
                - *What conditions make it inappropriate?*

EE-64

        - Some vegetation could be permitted over the trench
                - If planted outside the specified vegetation free zone required by ETL 1110-2-581.
            - This vegetation would likely be limited to
                - Native grasses
                - Shrubs
                - Trees with shallow root systems
                    - To ensure the functionality of the launchable rock trench.
            - This vegetation would only be permitted;
                - If it does not put undue burden on maintaining agencies
                - If it is in locations that do not interfere with channel conveyance capacity.
                - *These limitations seem to prohibit the use of the trench sites for riparian restoration.*

        - SAFCA Join Powers Agreement
      - Existing conditions (59-61):
        - General discussion of region
        - ARN (59-61):
          - Includes the ARP
          - ARPP;
            - Defines the ARP land uses
            - Acts as the management plan for the federal and state W&SR Acts.
            - Goal is to
              - Provide
              - Protect
              - Enhance
            - The ARP
              - For public uses.
            - Human developments and facilities
              - Are prohibited in "Open Space Preserve Areas"
                - Except as necessary to protect
                - Public health
                - Safety
                - Welfare
                - Habitat restoration.
            - Flood control-related polices include;
              - Flood control agencies should continue to maintain, and improve, where required, the reliability of the existing public flood control system along the LAR to meet the need to provide a high level of flood protection to the heavily urbanized

floodplain along the LAR consistent with other major urban areas. This effort is expected to include raising and strengthening the levees as necessary to safely contain very high flows (up to 160,000 cfs) for a sustained period.

- Flood control projects, including levee protection projects and vegetation removal for flood control purposes, shall be designed to avoid or minimize adverse impacts on he ARP, including impacts to wildlife and wildlife corridors. To the extent that adverse impacts are unavoidable, appropriate feasible compensatory mitigation shall be part of the project. Such mitigation should be close to the site of the adverse impact, unless such mitigation creates other undesirable impacts.
- Where feasible, multi-use buffers should be created on the landside of levees, including additional access points from public streets that enhance levee O&M activities, improve flood fight capabilities, provide opportunities to relocate or expand levees or supporting stability berms, if required, and support recreational opportunities.
- Vegetation in the ARP should be appropriately managed to maintain the structural integrity and conveyance capacity of the flood control system, consistent with the need to provide a high level of flood protection to the heavily urbanized floodplain along the LAR and in a manner that preserves the environmental, aesthetic, and recreation quality of the ARP.
- Flood control berms, leeves and other facilities should be, to the extent consistent with proper O&M of these facilities, open to the public for approved uses, such as hiking biking and other recreational activities.
- Public facilities and private encroachments that inappropriately constrain the operation and maintenance of the flood-control system should be redesigned or relocated.
- The flood control system should be maintained in a condition that ensures adequate flood fighting capability, consistent with demands of protecting a heavily developed floodplain.

        - Bank scour and erosion shall be proactively managed to protect public levees and infrastructure, such as bridges, piers, power lines, habitat and recreational resources. These erosion control projects, which may include efforts to anchor berms and banks with rock revetment, shall be designed to minimize damage to riparian vegetation and wildlife habitat, and should include a revegetation program that screens the project from public view, provides for a naturalistic appearance to the site, and restores affected wildlife habitat values.
        - Project to address bank stabilization and erosion that are threatening privately-owned structures shall; secure appropriate permits. The engineering of these projects should give preference to biotechnical or non-structural alternative, where feasible, over alternatives involving revetments, bank re-grading, or installation of river training structures. Use of rubble, gunnite, bulkheads, or similar material in these projects is prohibited.
        - It is recognized that flood control agencies have the authority to take actions(s) to prevent or respond to flood emergencies occurring in or adjacent to the ARP. In the event that these actions(s) have an adverse impact on biological resources in excess of the estimated impacts of the projected flood damage to such resources, the agency(ies) undertaking the emergency work will implement feasible compensatory mitigation measures pursuant to Policies. Nothing in the Policy shall be construed to interfere with the existing authority of flood control agencies to prevent or respond to an emergency situation occurring in or adjacent to the ARP.
    - ARS (61):
    - Sacramento bypass (61):
- 3.3.2 Methodology and basis of significance (62):
    - Methodology (62):
        - Determine the effects of the project on land use plans
            - Including;
                - ARPP
                - Sacto. Co. General Plan and zoning code
                - Sacto. City General Plan and zoning code

- Yolo Co, General Plan and zoning code
- Basis of significance (62):
  - Effect are considered significant if any one of the following results;
    - Conflict with any land use plan, policy, regulation.
    - Conflict with approved Habitat Conservation Plans or Natural Community Conservation Plan.
    - Physically divide an established community
    - Displace substantial numbers of people,
      - Necessitating the construction or replacement housing elsewhere.
- 3.3.3 No action alternative (62-63):
  - The waterside berm in the ARP would erode overtime
    - Resulting in the loss of ARP lands.
    - Timing is unknown
      - *Is there a Corps' estimate of potential land, habitat, and recreational facility losses that will be due to the No Action Alt.?*

EE-66

  - The ARPP designated most of the lands within the project area for
    - Natural
    - Recreational
    - Habitat enhanced
    - Uses.
  - Alt. is inconsistent with the ARPP
    - Would be considered a significant effect.
- 3.3.4. Alternative 1 – improved levees (63-67):
  - Barrow sites (63-64):
  - American River (64):
    - Approximately 11 mi of erosion protection needs has been identified.
      - Erosion protection approaches could be
        - Luanchable rock trench
        - Bank protection
  - ARPP policies address flood risk reduction
    - Overall aim of facilitating flood risk reduction activities in a manner that
      - Provide optimum protection to ARP resources;
        - Open space
        - Recreation
        - Fish and wildlife
    - Consistent with these policies
      - Bank protection improvements
      - Some launchable rock trench improvements
      - Have been constructed over the past 20 years
        - At various locations.
  - To select improvement methods (bank protection//launchable rock trench) to be used
    - The Corps will coordinate closely with

- SCRP
- NPS
- Other state and federal agencies
  - Responsible for resource management
- NGO stakeholders

- Will coordinate through
  - Formal processes
  - Informal processes
- That have been created to facilitate ARP management.

- Where erosion protection is needed
  - To meet established flood risk reduction objectives
  - Selection of improvement methods to be used
    - Will be based on
      - Which most protects ARP resource values
        - ARP lands
        - Fish and wildlife
        - Recreational facilities
      - Considering
        - Short-term construction impacts
        - Long-term effects of mitigation measures.
- Launchable rock trench (65):
  - Would minimize land use changes
    - For the 11 mi of erosion protection proposed.
  - Construction activities;
    - Could cause temporary LU changes
        - Within the levee structure
        - Adjacent waterside berm
        - Channel bank
      - Changes include lands for
        - Staging areas
        - Construction footprint
    - As construction progresses along the levee
      - Completed areas will be returned to their prior use.
      - Except;
        - A 15 ft. vegetation free zone on the waterside of the levee.
  - With a maximum trench <u>width of 70 ft</u>.
    - <u>65 ac will be disturbed</u>.
      - *At design trench slopes (2:1 and 1:1) (p31), a 70 ft. wide trench would be 23 ft. deep (70/3=23.3), if it has no bottom width. Design specifications (Figure 1) indicate varying trench bottom widths so*

EE-67

EE-67
(Cont.)

independently estimating trench top-widths is not possible here. However I'm thinking that most of the levee toe elevations are about 20 ft above with lowflow water surface which indicates that, if there is to be any bottom-trench width at all, maximum trench surfaces may be in excess of 70 ft. It is possible that 70 ft. could be the average trench surface width.

EE-68

- *Does this exclude staging areas, temporary ramps and access/construction roads?*

- These areas are presently
  - A 15 ft. wide maintenance road
  - Additional lands containing
    - Riparian habitat
      - Intermixed with
      - Recreation facilities
      - Open space
- Post-construction
  - The maintenance road at the toe of the levee will be replace to original condition
  - Some construction ramps may remain for maintenance access
    - In coordination with
      - SCRP
      - ARFCD
  - Construction roads not needed for maintenance
    - Would be returned to original condition
  - The <u>riparian areas would be replanted with vegetation</u>.
  - Re-establishing <u>riparian habitat would take many years</u>

EE-69

    - *Replanting requirements and limitation (p 31) seem to severely limit the types and amount of revegetation.*

EE-70

    - *Riparian re-establishment on or off-site? If on-site, planting requirements/limitations imply that no deep-rooted trees would be involved so why would on-site re-establishment take so long?*
  - Recreation facilities will be replaced to original condition
    - In coordination with SCRP
- <u>No LU changes</u>,
  - Except;
    - 15 ft. maintenance road
    - Vegetation free zone
- Alt 1. is in compliance with ARPP

        - LU impacts are considered less than significant
            - No mitigation is required.
            - ***In the No Action Alt. the Corps attribute land and resource losses due to ongoing erosion as a significant LU impact that is not consistent with ARPP. The proper functioning of the launchable rock trenches anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of habitat and recreation values. Why are these impacts, which are implicit to the expected proper functioning of the project as designed, not counted as project impacts?***

EE-71

    - Bank protection (65-66):
        - Bank protection may be used
            - Instead of launchable rock trenches
                - To reduce riparian habitat impacts.
        - Construction stage;
            - Access would be
                - From existing maintenance roads and ramps
                - Additional roads and ramps could be required
                    - To the bank for rock placement.
            - Staging areas required to store rock.
            - Construction site locations are presently unknown
                - However new access roads will be designed to
                    - Minimize natural resource impacts.
        - Design would not change existing LU designations
            - Therefore effects to LU are considered less than significant
                - No mitigation would be required.
            - (Riparian habitat loss mitigation is discussed in Veg & Wildlife Section)
  - Sacramento River (66):
  - East side tributaries (66-67):
- 3.3.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (67-68):
- 3.3.6. Avoidance, maintenance, and mitigation measures (68-69):
  - American River (68-69):
    - ARPP Flood Control Polices include;
        - Mitigation is defined as any project-related action taken to minimize or avoid an impact to the physical environment, or

any action designed to replace, repair, or restore a resource that was physically affected by a project.

- Construction projects on the ARP should be designed to first, avoid adverse environmental impacts; second, minimize adverse environmental impacts; and, third replace, repair, or restore adversely impacts resource as close as feasibly in time and place to the impact.
- Impacts are defined as any physical change to the environment, including but not limited to aesthetics, recreational facilities, and access points, water quality, soils, and all biological resources, such as native and non-native vegetation, aquatic habitat, fisheries, and special-status species. Noise, air quality (including fugitive dust), artificial lighting, and other impacts associated with construction activities are also considered to be impacts to avoid, minimize, and mitigate.

- ARPP states in the Flood Control Policy section;
  - Flood control project, including levee protection projects and vegetation removed for flood control purposes, shall be designed to avoids or minimize adverse ARP impacts, including impacts to wildlife and wildlife corridors. To the extent that adverse impacts are unavoidable, appropriate feasible compensatory mitigation shall be part of the project. Such mitigation should be close to the site of the adverse impact, unless such mitigation creates other undesirable impacts.
- Mitigation for lands converted from Parkway lands
  - To flood control uses
    - Will be mitigated
      - With fees to the Sacto. Co. under the Habitat Restoration Program Fees'
        - To be used for natural resource protection or enhancement and for land acquisition.
      - EE-72 *Under either Alternative and for either the bank protection of the launchable rock trench approach, how are these land areas to be computed? Is the Corps talking about land as land area, or land under changing uses and LU designations?*

- Sacramento River (69):
- East site tributaries (69):

- **3.4 Hydrology and hydraulics (69-82):**
  - 3.4.1 Environmental setting (69-76):
    - Regulatory setting (69):
      - Federal:
        - Clean water act 1972
        - Safe drinking act 1974
        - National flood insurance program

- State:
  - Porter-Cologne water quality control act 1970.
- Existing conditions (70-76):
  - Geomorphic conditions (70-71):
    - A short and somewhat strange discussion w/o importance.
  - Sedimentation (71-73):
    - As a result of SN hydraulic mining in the late 1800's
      - The Sacto R. and major tributaries aggraded 10-15 ft.
      - Since then they have gradually incised into residual mining debris.
    - Transport of SN mining debris into and through the Delta
      - probably continued into the mid 1900's
    - Many researchers believe
      - The present sediment loading of the Sacto. R. is approaching pre-gold rush levels.
    - A sediment analysis was not completed for this study
    - A Sacto. basin wide sediment study was conducted under the
      - Sacramento River Bank Protection Project (NHC, 2012).
        - Objectives were to
          - Investigate sediment transport processes in the Sacrto R. and major tributaries/distributaries.
        - HEC-6T sediment transport 1-D model
          - For the Sacto, American, Feather Rivers.
          - Computes streambed profile aggradation and degradation
          - Over the course of a hydrologic event.
    - Long-term simulation of the LAR
      - Most of the 22 mile LAR is actively degrading.
      - RM 22-12
        - 9-10 ft. of degradation
          - For both the 50 and 100 year periods
      - RM 11-12
        - 3-4 ft. of aggradation
        - (Timeframe not specified)
      - RM 0-11
        - Max of 15-16 ft. of degradation
          - 50 year period
        - Max of 19-20 ft. of degradation
          - 100 year period
      - <u>Average LAR degradation</u>
        - 50 year period
          - Thalweg – 5.39 ft.
          - Average channel bed- 4.83 ft.

- 100 year period;
  - Thalweg - 6.42 ft.
  - Average channel bed- 5.84 ft.
- *These modelling results are non-sensible – at least w/o further discussion and explanation.*

EE-73

  - *Were the cemented/indurated clay channel bed nick points considered and what influence would they have on channel degradation upstream of their locations over these timelines? Can very deep channel sections be expected to develop and survive upstream of the several clay-channel bed nick points?*

EE-74

  - *What is the volume of sediment predicted by this modelling to be lost in the LAR over these timelines?*

EE-75

  - *Where does this sediment go?*

EE-76

  - *Have they overlooked that the LAR channel is drowned downstream of RM 5 (due to geologic timescale sea level rise) and that now and in the future (increasing rates of sea level rise), out-fluxing of coarse sediment past this point is not likely. What are the implications of this sea-level rise process on long-term degradation/aggradation in the RM 5-7 reach?*

EE-77

  - *Does the 15-20 ft. of degradation in RM 0-11 reach imply that over these timelines (50-100 yrs.) the SN mining debris sand in the LAR system has become exhausted?*

EE-78

- Irregular channel reaches may not be adequately represented by this model
  - Especially in braided reaches above RM 8.
- *There are no really braided channel plan forms on the LAR upstream of RM 8 except possibly a 0.5 mi section at about RM 14/15 (this is really just a short reach recently experiencing over-loaded sediment influx in conjunction with erodible banks – local widening and the development of multiple channels. This "braided" feature is in the process of change and could develop into a*

EE-79

EE-79
(cont.)

single thread channel with time). The complex channel in the RM 11-12 reach is the result of the breaching of off-channel gravel pits – not channel braiding. The complex channel configuration at RM 9 downstream of the Watt bridge is due to a natural process of sediment deposition and channel re-configuring resulting from late-date gravel bar mining and the resulting over-widened channel – this is not channel braiding. The source of the sediment that is being deposited downstream of the Watt bridge is most likely due to ongoing scour in the 0.5 mi of channel upstream of the Watt bridge. At about RM 6 there is a 0.5 mi braided reach that is due to coarse sediment deposition at the head of the drowned LAR channel reach (RM 0-5) (due to geologic time-scale sea level rise). This is the expected final location of all coarse sediment transported through the LAR.

- Application of generalized results in irregular reaches may be subject to errors.
- Further site-specific analysis could potentially reduce the error.
- In general the mode results conform to records of channel degradation at the Fair Oaks Gage.

- Potential implications of model results;
  - Degraded bed can
    - Increase stress on
    - Levee toes
    - Berm toes
    - Can increase scour in unrevetted reaches.
  - Aggraded bed can
    - Increase floodflow water surface elevations
    - Reduce flood conveyance

- American River channel stability (73-74):
  - "LAR – Erosion Susceptibility Analysis for Infrequent Events (Ayers 2012)
    - 2-D hydraulic model
      - 115.000 cfs
      - 140,000 cfs
      - 160,000 cfs
  - Analyses have been completed;
    - Many more are still underway

        - To understand overall channel stability.
- Additional information in Civil Design and Geotechnical appendices.
- Pending result will not affect the following conclusions:
    - The LAR is degrading under present operational conditions
    - LAR is sediment starved.
        - Bedrock has been reached as far downstream as Guy West Bridge which is slowing further degradation.
        - Without significant bed slope reduction, it will now tend to erode laterally to satisfy need for sediment.

EE-80

    - *This conclusion seems to contradict the predictions of significant channel degradation noted above.*
    - Hydraulic modeling shows areas of bank and levees where allowable velocities for vegetation cover are exceeded
        - These site need to be evaluated in more detail to determine is a levee failure is likely to occur.
    - Field review verified that erosion of the bank is occurring at RM 9.0 RR, even at lowflow of 7,000 cfs.
        - Erosion of the LAR is continually occurring.
        - Leaving the banks sacred and susceptible to future erosion, especially at high flow events.
        - Further reducing the amount of berm separating the channel from the levees
        - Loss of vegetation is leaving the bare soil, which is susceptible to erosion at a lower velocity

EE-81

    - *All of these statements about "erosion" appear to be true when applied only to the field-verified erosion at "RM 9.0 RR."*

EE-82

        - *However this site of erosion is not characteristic of the LAR: It is due to local-scale natural channel adjustments underway in response to channel over-widening that occurred in the 1960-70's when the*

EE-82

(Cont.)

RL attached longitudinal gravel bar was removed for gravel mining purposes. With reduced stream power at this location a medial bar developed which is now morphing into a diagonal bar attached to the RL bank at the bridge. The process has progressively forced more flow and power to the RR bank causing the Corps' "field-verified" erosion. At the location of the original attached bar, the channel is aggrading to a significant degree making the existing boat ramp dysfunctional.

EE-83

- *This condition in not representative of the LAR in general, nor of the critical RM 6-11 reach but is a local phenomenon, with local symptoms and local causal factors.*

EE-84

- *Which could be corrected with proper channel restoration actions.*

EE-85

- *The real long-term erosion issue in this critical reach is the sewer main undercrossing at about RM 7. The line was installed as an inverted syphon with one limb at the edge of the RR active channel bank, with revetment armoring on this bank slope. This constitutes a critical channel impingement and constraint which resulted in severe RR bank erosion upstream of the line due to progressive erosive eddy development during the 1986 flood event. Without that armored nick point on the RR bank (and with the inverted syphon limb set back from the channel bank edge), it is most likely that bank erosion along the RR bank at that location during the 1986 event would have been very modest. The presence of this sewer undercrossing in its present configuration limits intelligent channel reconfigure alternatives for dealing with this critical flood conveyance reach.*

EE-86

- *The Corps' flood conveyance actions in this critical reach should be focused on the modification of the existing inverted syphon such that stream channel, channel bank, and riparian setting reconfiguration and restoration options are maximized not minimized.*

- o Climate (74):
  - Short unimportant discussion.
- o Surface water storage (74-75):
  - Short discussion.
  - For details on hydrologic inputs and storm centering see,
    - Hydrology appendix
- o Existing and future without project condition assumptions (75-76):
  - <u>Existing</u> condition assumptions include;
    - Existing releases from Folsom Dam
    - USBR/SAFCA reservoir operations agreement
      - o Allowing greater flood storage compared to the original operations manual.
  - Future <u>without project</u> condition assumptions include;
    - Construction and operation of all previously authorized on the LAR
      - o WRDA 1996, 1999 Common Features authorizations
      - o Levee repairs as described in the Natoma PACR authorized in WRRDA 1014

      - o Future planned raise of Folsom Dam
  - Future <u>with project</u> condition assumptions include;
    - The work proposed as part of the GRR.
  - Implications of the <u>future with project</u> conditions
    - Were developed on the basis of
      - o <u>Future without project</u> conditions
  - TABLE 8: comparison of existing and future w/o project releases from Folsom Dam (75)

Freq (yr).	Existing	Future w/o project (Alt 1)
10	43,000	72,000
25	100,000	115,000
50	115,000	115,000
100	145,000	115,000
200	320,000	160,000
500	520,000	530,000

  - FIGURE 7: Comparison of existing and future w/o project (Alt 1) Folsom Dam releases.

- 3.4.2 Methodology and basis of significance (77-78):

- Methodology (77-78):
- Basis of significance (78):
    - Alternatives were determined to have significant impacts if they result in any of the following;
        - Substantially alter the existing drainage pattern of the site or area, including through the alteration of a stream course in a manner that would result in;
            - Substantial erosion of siltation on- or off-site
            - Substantial increase in the rate or amount of surface runoff in a manner that would result in flooding on- or off-site.
        - Create if contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional source of polluted runoff.
        - Place housing within a 100-year flood hazard area.
        - Place within a 100-year flood hazard area structures which would impede or redirect flood flows.
        - Expose people or structures to a significant risk of loss, injury, or death involving flooding.

- 3.4.3 No action alternative (79):
    - Continued risk of levee failures
        - Continued flood flight regime.
            - Possibly placement of rocks at levee failure site
                - Emergency repair activities
                    - Could result in
                        - <u>Loss of channel capacity</u>
                        - <u>Alteration of present geomorphic processes</u>.

EE-87

                    - *Not sure why these either of these conditions should occur*.

- 3.4.4. Alternative 1 – improved levees (79-80):
    - Levee remediation measures to address deficiencies such as;
        - Seepage
        - Slope instability
        - Overtopping
        - Erosion
        - Lack of vegetation compliance
        - Lack of O&M access
    - Along;
        - American R.
        - Sacto. R.
        - NEMDC
        - Arcade C.
        - Dry C.
        - Robla C.
        - Magpie C.
    - Combines
        - Construction of improvement

- While maintaining present levee alignments.
- Purpose is to,
  - Improve the flood risk management system to
    - Safely convey flows up to a level that
      - Maximizes net benefits.
- Project work primarily includes landside levee fixes,
    - That do not change in-channel geometry or characteristics.
  - Therefore would not:
    - Substantially alter erosion or siltation in the system
    - Increase surface RO in a manner that would result in any flooding.
    - Impact stormwater drainage systems or create additional RO.

EE-88
        - *Can this be said of the proposed 11-12 miles of bank protection and launchable rock trench work in the LAR/ARP?*
- Water surface elevations for
      - Baseline,
      - Alt 1 (which is the "future without-project")
      - Alt 2
    - For the
      - 2-yr event
      - 100-yrevent
  - Is in the Engineering appendix
  - TABLE 12: Comparison or 10, 100 and 200 year events under various conditions (LAR only) (81):

Freq.	Existing (Baseline?)	Future w/o project (Alt 1)	Future w/ project (Alt 2)
10	43,000	72,000	72,000
100	145,000	115,000	115,000
200	320,000	115,000	115,000

  - The 200-yr flows in the LAR
    - Are tied to the changes on Folsom Dam operations
      - Which will be analyzed as part of the ongoing
        - Folsom Dam Water Control Manual Update.
    - Effects of these flows including cumulative effects
      - Will be addressed by
        - The Manual Update EIS/EIR.

EE-89
        - *Does this mean that the 200-yr LAR flows may not be 115,000?*

EE-90
        - *Does this mean that the impacts of changing the floodflow regime on the LAR will be assessed at a later time? That the possible channel implications of the GRR w/o or w/ project conditions do not consider the change in floodflow regime? And that they have not yet been assessed?*

EE-91

- *When will the Manual Update EIS/EIR be undertaken?*

- Alt 1 would not alter flows
  - There would be no significant change or effect on hydrology and hydraulics
    - With the project in place
    - No mitigation would be required.

EE-92

- *If the launchable rock trench method is used, the expected project functionality depends on progress bank erosion/retreat to launch the rocks. Under this post-launched condition, what would be the impacts on the hydraulic conditions of the channel?*

- 3.4.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (80-82):
- 3.4.6. Avoidance, maintenance, and mitigation measures (82):
  - Flows are not increased
    - Effect to hydrology/hydraulics are less than significant
      - No mitigation is required.

EE-93

- *If the launchable rock trench method is used, the expected project functionality depends on progress bank erosion/retreat to launch the rocks. Under this post-launched condition, what would be the impacts on the hydraulic conditions of the channel?*

  - 3.6.1 Environmental setting (94-97):
    - Regulatory setting (94):
      - Sacramento County Ordinance, Chapter 19.12, Tree Preservation and Protection (Tree Preservation Ordinance).

        - City of Sacramento Protection of Trees Ordinance (City of Sacramento Municipal Code 12.56.060).
        - City of Sacramento Heritage Tree Ordinance (Code 12.64.020)
- Existing conditions (94-97):
        - Addresses areas within potential construction footprint.
            - These are the areas where potential impacts to vegetation and wildlife could occur.
        - Conducted a survey (2011) of levee trees
                - Within 30 ft. of waterside
                - Within 15 ft. of landside
            - Included;
                - Species
                - Diameter
                - Location
    - American River (94-95):
        - Along the channel vegetation is primarily SRA habitat.
                - *Were the USFS criteria used in this survey/result?*
                - *Is this survey information available?*

EE-94

        - Trees adjacent to the channel are mainly
            - Oaks
            - Cottonwoods
                - With a thick understory of vines, berry bushes, willows.
        - The ARPP details
                - How vegetation should be managed and expanded
                    - Where appropriate
            - Recognizes the primary purpose of the system is for flood control
                - Attempts to manage the natural setting of vegetation and wildlife
                - While meeting the goals of the flood control system.
        - Protected areas contain tracts of naturally occurring vegetation and wildlife
            - Although capable of sustaining <u>light to moderate use</u>
                - With minimal alteration to the natural landscape
            - Would be easily disturbed by <u>heavy use</u>.
                - *Where does this judgment come from?*

EE-95

        - <u>Emphasis is on</u> protection an restoration of large portion of relatively natural areas
            - Which stands a better chance of preservation
                - And provide better sup[port for wildlife
                    - Than smaller pieces.

EE-96
- *Where does this statement/judgement come from?*
- Several areas have been used as
  - Mitigation sites for Corps and other agencies for endangered species
  - Compensation for loss of riparian habitat or oak woodlands from other projects.

EE-97
- *What is the difference between sites used as "mitigation" and "compensation?"*
- Example list of wildlife species in the ARP.
  - Sacramento River (95-96);
  - East side tributaries (96-97):
  - Sacramento weir and bypass (97):
- 3.6.2 Methodology and basis of significance (97-98):
  - Methodology (97-98):
    - Impacts are evaluated based on data collected from
      - Tree surveys
      - Site visits
      - Google Earth
      - ARPP
      - Which provide a comprehensive overview of vegetation conditions
      - Were used to evaluate impacts.
    - ARPP goals and objectives were considered for
      - The impact analysis
      - How construction would impact those goals and objectives.
    - Impacts to wildlife were evaluated based on
      - Construction activities
      - Changes in habitat types after construction.
    - Assumed the Corps would receive a variance to address waterside vegetation
      - Under the requirements of ETL 1110-2-583
    - A System Wide Improvement Framework (SWIF) agreement is being sought by the non-federal sponsor
      - Which would allow the local maintenance agency (LMA) to defer ETL 1110-2-582 compliance of landside vegetation encroachments
        - To be addresses by the LMA at a later time.
        - Details on the SWIF are **presented in 1.4.5**.
    - Effects to vegetation and encroachments are assumed to occur
      - In the footprint of all proposed construction activities.
  - Basis of significance (98):
    - Effect are considered significant if any one of the following results;
      - Substantial loss, degradation, or fragmentation of any natural communities or wildlife habitat.

- <u>Substantial</u> effects of a sensitive natural community, including;
  - Federal protected wetlands
  - Other wetlands of the US
    - As defined in Section 404.
- <u>Substantial</u> reduction in quality or quantity of important habitat
  - Or access to such habitat for wildlife species
- <u>Conflict</u> with
  - ARPP
  - Sacto. Co. Tree Preservation Ordinance
  - City of Sacto. Protection of Trees Ordinance.
- <u>Substantial</u> adverse effects of native wood habitats in the ARP
  - Resulting in the loss of vegetation and wildlife.
    - *What parameters were used to assess "substantial" and "conflict?"*

EE-98

- 3.6.3 No action alternative (98-99):
  - Over time the berms would erode
    - Vegetation would be lost
      - Wildlife would relocate
    - Trails would be lost that provide to access for
      - Wildlife observation
      - Fishing
      - Other recreational activities
  - Does not comply with the ARRP
    - Which states;
      - "Bank scour and erosion shall be proactively managed to protect public levees and infrastructure, such as bridged, piers, power lines, habitat and recreation resource."
        - ***Where is this statement – what context?***

EE-99

  - The loss of
    - Vegetation and wildlife habitat
      - Would be considered a significant impact.
        - *The Corps does not specify or estimate the amount of vegetation and wildlife habitat that would be lost in the ARP.*

EE-100

- 3.6.4. Alternative 1 – improved levees (99-101):
  - A vegetation variance would be obtained to
    - Reduce the impacts to vegetation and wildlife.
    - Allowing most trees on the lower ½ of the waterside slope to remain in place
      - Details on the vegetation variance **<u>are in 1.4.5</u>**.
      - *The discussion of the vegetation variance (p 13) specifies the Sacramento River levees. Will the variance include American River levees?*

EE-101

EE-102

- *What would be the ARP vegetation and wildlife habitat impact implications should the vegetation variance not be approved and/ot not really apply to the LAR?*
- A System Wide Improvement Framework agreement would allow vegetation and encroachment compliance on the landside of the levees to be deferred.
  - Details on SWIF **are in 1.4.5**.
- American River (99-100):
  - Construction of launchable rock trench;
    - Removal of 65 ac of riparian habitat in the ARP
    - Calculated by
      - Overlaying the largest possible footprint onto aerial photos

EE-103

        - *Will this overly be available during the NRMP process?*
      - Calculating the riparian habitat within the footprint.

EE-104

        - ***In Section ____ (p__) the Corps states that 65 ac of land would be disturbed; not 65 ac of riparian habitat. Which is correct?***
    - Is located in areas designated in the ARPP as
      - Protected Areas
      - Nature Study Areas
      - However, the ARPP allows for flood control activities to be conducted
        - In order to pass 160,000 cfs
      - ARPP Section 4.10 states;
        - "Flood control projects, including levee protection projects and vegetation removal for flood control purposes, shall be designed to avoid or minimize adverse impacts on the ARP, including impacts to wildlife and wildlife corridors. To the extent that adverse impacts are unavoidable, appropriate feasible compensatory mitigation shall be part of the project. Such mitigation should be close to the site of adverse impacts, unless such mitigation creates other undesirable impacts."
    - This impact is considered as significant because
      - The temporal loss of trees between the time of removal and their growth to a condition that provides original values.
      - Cannot be mitigated to less than significant.

EE-105

        - *Impacts and determination of significance seems to be based on construction and time delays for construction impacts. This seems to ignore the impacts of properly functions*

EE-105
(Cont.)

designed approach should the launchable rock trench approach be used. The proper functioning of this approach depends of the progressive loss of banks and berms that provide the locations of vegetation and wildlife habitat and the launchable rocks can only be launched once these ARP values are lost. Why shouldn't these proper operational impacts of the launchable rock trench approach be addressed in the same light as the No Action Alternative, that entail the same resource values loses, and over the same timeframe, as the launchable rock trench approach?

- Construction would likely by May-October
  - When birds are likely to be nesting.
- **Once the project is authorized and funded**
  - **Surveys would occur to determine**
    - If nesting birds are present which may be impacted during construction.
  - If nesting birds are located adjacent to the project area
    - Coordination with resource agencies would occur.

- Other additional construction;
  - Would occur on another 135 ac of the ARP
    - Primarily
      - Levees
      - Patrol roads
      - Open lands with no trees.
- 11 miles of intermittent erosion repair
      - Bank protection
      - Launchable rock trench
    - Would occur over a 7 year period.
  - Trees would be removed as the trench is constructed
    - Over multiple years
  - Trees outside the construction footprint
    - Would be covered by the <u>vegetation variance</u>
      - Would therefore remain in place.
      - *Unless the variance is not approved!*
      - *Section 1.4.5 (p 13) specifies that the vegetation variance was for Sacramento River levees. Is this an incorrect interpretation of the text? Would it also apply to LAR levees?*
      - ***Impacts addressed for this alternative are exclusively construction related. What would be the impacts of expected and***

EE-106

EE-107

EE-107

(Cont.)

proper functioning of the launchable rock trench approach?

- Sacramento River (100-101):
- East side tributaries (101):

- 3.6.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (102-103):
  - Sacramento River (102):
  - Sacramento weir and bypass (102-103):
- 3.6.6. Avoidance, maintenance, and mitigation measures (103-106):
  - Estimates of compensation measures are based on
    - The largest potential footprint
    - Worst case scenario
      - For the purposes of NEPA compliance
        - *Does this include the possibility that the vegetation variance will not apply to the LAR or that it will not be approved??*

EE-108

  - If design refinements result in reduced impacts to vegetation
    - Compensation would be coordinated with the appropriate resource agencies and adjust accordingly.
      - *As well as increased impacts??*

EE-109

  - American River (103-104):
    - Design-refinement plans will evaluate reductions to vegetation and wildlife impacts including;
      - Reduced footprint
      - Constructing bank protection rather than launchable rock trench
        - Whenever feasible
          - *This implies that bank protection is the preferred approach unless not feasible.*

EE-110

      - Designing planting berms in areas where significant riparian habitat exists adjacent to the levee toe
        - When no hydraulic impacts would occur.
          - *Could the NRMP be used to assess overall-ARP impacts and implications of mitigation to include greater (short-term) impacts in the construction area with greater long-term mitigation values with restoration/mitigation projects in the Arden/Sacto Bar/Sailor Bar areas??*

EE-111

      - Trees would remain in locations where
        - Bank protection
        - Planting berms
      - Can be constructed
        - Since this area is 15 ft. from levee toes
        - Complies with Corps vegetation policy.
        - *In Section 2.3.1, the Corps said that for bank protection work, large trees may be left in place. However, if these trees live for a while they will die and will leave a bare*

EE-112

EE-112
(Cont.)

rock slope because revegetation success on revetments is very poor. Shouldn't this mean that long-term impacts should count these slopes as unvegetated?

- <u>Trees would be protected</u> in place along the natural channel bank
  - During placement of rock
    - Would anchor trees to reduce risk of falling during high flow events.
    - *In Section 2.3.1, the Corps said that for bank protection work, large trees may be left in place. However, if these trees live for a while they will die and will leave a bare rock slope because revegetation success on revetments is very poor. Shouldn't this mean that long-term impacts should count these slopes as unvegetated?* EE-113
- Additional plantings would be installed on
  - <u>Newly constructed berms</u>
    - To provide habitat for
      - Fish species
      - Avian species
  - Planting berms would be used to <u>minimize impacts</u> to fish and wildlife species,
    - However impact to riparian habitat would still be significant.
    - EE-114 *These planting berms are not discussed specifically in Section 2.3.1 nor are indicated on Figure 1.*
    - EE-115 *Were these "minimized impacts" used to reduce the amount of mitigation obligation?*
    - EE-116 *Would these "newly constructed berms" extend into the channel from the present bank, reducing active channel widths?*

- Compensation for 65 ac of riparian habitat
  - 130 ac of replacement habitat would be created.
- Species selected to compensate for riparian corridor removal
  - Would be consistent with approved native plant species list for the ARP.
- The 130 ac would
  - <u>Create</u>
    - Habitat connectivity
    - Wildlife migratory corridors
      - That provide for the habitat needs of important wildlife species
    - EE-117 *How is this to be assured without a mitigation plan?*
  - <u>Without compromising</u>

- Integrity of the of the flood control facilities
- Flood conveyance capacity
- ARPP management goals
- EE-118 *Where is it demonstrated that this can be done? Has there been an assessment of this possibility?*

- 130 ac of riparian would be planted
  - On top of rock trenches.
- Corps vegetation policy allows
  - Trees to be planted >15 ft. from levee toes.
- To comply with
  - This policy
  - And to reduce maintenance on compensation lands
  - Trees could be planted on top of rock trenches starting 30 ft. from the waterside levee toe.
    - If the rock trench is 70 ft wide, trees plantings for riparian habitat could occur on the outer 40 ft.
  - EE-119 *Will the launchable rock trench surfaces be within the elevation and distance for natural riparian zone sub-irrigation required by trees?*
  - EE-120 *Section 2.3.1 indicates:1) that the trench rock will be covered with a minimum of 3 ft. of stockpiled soil, 2) some vegetation could be permitted over the trench if planted outside the specified vegetation free zone required by ETL 1110-2-581, 3) disturbed areas would be reseeded with native grasses, small shrubs, and trees with shallow root systems (to ensure rock trench functionality) but 4) would only be permitted if it does not burden floodway maintenance agencies and does not interfere with floodway capacity. It sound very much that the "riparian" revegetation in Section 3.3.6 is not compatible with Section 2.3.1. which prohibits deep rooted trees.*
  - EE-121 *This says that there will be at least 130 ac of rock trench surface outside the vegetation free zone (surface areas >30 ft. from the waterside levee toe). What does this say about the total area of (and length of) rock trench surface area on the LAR/ARP?*
  - EE-122 *How was the 130 ac of riparian replanting on rock trenches counted for impact/ mitigation?*

EE-123

- *When and if the launchable rock trenches actually launch the rocks due to erosive bank retreat (that is when the project functions as designed), how will the losses of real riparian vegetation along the banks, and the Corps' "riparian plants" on the rock trench surfaces, be counted as impacts resulting from proper project functioning?*

- The exact location of compensation lands
  - Would be coordinated in the design phase with
    - SCRP
  - And would comply with the ARPP objectives and goals.
- It is assumed that sufficient compensation lands are available in the ARP.
  - If not
    - Other location within Sacto Co. would be identified
    - And public coordination would occur.

- Prior to construction;
  - For several years
    - Survey will be conducted to determine if nesting birds are within 0.5 mi of construction sites.
  - If nests are located in any given year
    - Coordination with appropriate resource agencies would occur
      - To determine what actions should be taken.
    - Trees with active nests would not be removed
      - Until young have fledged.
  - If no nests are found in the vicinity of construction sites for that year
    - Construction may commence without further coordination.
- Sacramento River (104):
- East side tributaries (105)
- Sacramento weir and bypass (105-106):

- **3.7 Fisheries (106-115):**
  - 3.7.1 Environmental setting (106-110):
    - Regulatory setting (106):
    - Existing conditions (106-110):
      - Sacramento River and American River (106-109):
      - East side tributaries (109):
      - Sacramento bypass (109-110):
  - 3.7.2 Methodology and basis of significance (110-111):
    - Methodology (110-111):

    - Basis of significance (111):
  - 3.7.3 No action alternative (111):
  - 3.7.4. Alternative 1 – improved levees (112-114):
    - American River (112):
    - Sacramento River (113):
    - East side tributaries (113-114):
  - 3.7.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (114-115):
    - Sacramento weir and bypass (114-115):
  - 3.7.6. Avoidance, maintenance, and mitigation measures (115):
- **3.8 Special status species (115-150):**
  - 3.8.1 Environmental setting Regulatory setting (116-126):
    - Regulatory setting (116):
      - Federal:
        - ESA
        - Migratory Bird Treaty Act
        - Bald and Golden Eagle Protection Act
      - State:
        - Calif. ESA
        - Calif. Fish and Game Code
        - Calif. Native Plant protection Act
    - Existing conditions (116-110):
        - A list of species status species was compiled from
          - USFWS website
          - CNDDB
        - Those expected to be found in the study area are addressed below.
        - They may occur in any of the project areas so are not broken out to specific areas.
      - <u>VELB (116-117):</u>
        - Federally listed as threatened.
        - Documented along the LAR.
        - Corps conducted a survey of elderberry shrubs along levees in 2012 including
          - Levee structure
          - 15 ft. on either side
            - Where access was available.
        - Survey found the south side of the American River had the greatest amount of clusters.
        - All shrubs are considered to be in <u>the riparian zone</u>
          - Except if located on the landside of levees.
            - EE-124 *How was this "consideration" made? Simply assumed? Or used established criteria?*
            - EE-125 *Just because a particular shrub was "considered" to be in a "riparian zone," for impact/mitigation assessment are these particular plants considered riparian?*
      - <u>Giant garter snake (117)</u>:

        - Federal and state listed as threatened.
        - Inhabits; rice fields, irrigation supply and drainage canals, freshwater marshes, sloughs, ponds, other aquatic habitats
        - Primary cause of decline;
            - Loss or degradation of aquatic habitat caused by agricultural development
            - Compounded by loss of;
                - Upland refugia
                - Bankside vegetation cover
        - Large waterways such as the American River do not provide habitat.
    - <u>Swainson's hawk (120)</u>:
        - Federal listed as species of concern
            - Protected under the Migratory Bird Treaty Act
        - State listed as threatened
        - Occur March-September for breeding
            - Nesting territories established by April
            - Incubation and rearing occurring through June.
        - Found most often in;
            - Grasslands
            - Low shrublands
            - Agricultural areas
        - Nests are found in
            - Riparian woodlands
            - Roadside trees
            - Trees along field borders
            - Isolated trees
        - Majority of nesting sites are in remnant riparian forest corridors along drainages
        - Mostly forage within 1 mile of nest
        - Prey abundance and accessibility are the most important suitability parameters
            - Subject to land use operations (mowing, flood irrigation)
        - American River area is less likely to support nests
            - Urban development
            - Food less abundant than in agricultural areas.
    - <u>Sacramento River winter-run chinook salmon (120-121)</u>:
        - Federally listed as endangered.
        - Sacramento River is considered to be critical habitat.
        - All reaches within the ARCF GRR area are considered EFH.
    - <u>Central Valley spring-run chinook salmon (121-122)</u>:
        - Federally listed as threatened.
        - Critical habitat has been designated
                - Including the American River
            - Includes channel widths to the;
                - Bank-full elevation
                - Or ordinary high-water line elevation

      - All reaches within the ARCF GRR area are considered EFH.
    - Central Valley fall-/late fall-run chinook salmon (122-123):
      - Listed as a species of concern by NMFS
      - Critical habitat is not designated
      - Essential Fish Habitat is designated
        - EFH is defines as those
          - Waters and substrate necessary for
            - Spawning
            - Breeding
            - Feeding
            - Growth to maturity
          - Whether current or historical
        - All reaches within the ARCF GRR area are considered EFH.
    - Central Valley steelhead (123):
      - Federally listed as threatened
      - Critical habitat has been designated
          - For designated reaches
        - Includes channel widths to the;
          - Bank-full elevation
          - Or ordinary high-water line elevation
      - There is no EFH designated.
    - Delta smelt (124):
    - Green sturgeon (124-125):
    - Vernal pool fairy shrimp (125-126):
    - Vernal pool tadpole shrimp (126):
- 3.8.2 Methodology and basis of significance (126-127):
  - Methodology (126):
    - Potential effects were based on
      - Existing documentation
      - 2011 field surveys
        - Conducted on;
          - Levee slopes
          - Landside levee toe – out 15 ft.
          - Waterside levee toe – out 30 ftt.
        - Included;
          - Trees
            - Size
            - Species
            - Health
            - Location
          - Elderberry shrubs
            - Size
            - Location
          - *Does this survey area include all the construction impact zone of the LAR? Was the SCRP GIS database of elderberry shrub locations used? The wording in Section*

EE-126

EE-126

(Cont.)

3.8.6 specifies that the recorded elderberry plants were on and near the levees and not in berm and bank areas where launchable rock trenches and bank protection work would occur. Isn't it very likely that the number of elderberry shrubs along the LAR to be substantially larger?

- Significant impacts occur if
  - The project has substantial adverse effect
    - Directly
    - Through habitat modification
      - On any species identified as
        - Candidate
        - Sensitive
        - Special-status
    - In any local or regional
      - Plans
      - Policies
      - Regulations
    - Or by
      - DFW
      - USFWS
      - NOAA Fisheries.
- Basis of significance (127):
  - Effects are considered significant (substantial?) if project would result in any;
    - Direct or indirect
      - Reduction in
        - Growth
        - Survival
        - Reproductive success
      - Of any species
        - Listed
        - Proposed for listing
      - As
        - Threatened
        - Endangered
      - Under
        - Federal ESA
        - State ESA.
    - Direct
      - Mortality
      - Long-term habitat loss
      - Lowered reproductive success
      - Federal or state species listed as
        - Threatened
        - Endangered
      - Federal species listed as

            - Candidates.
        - Direct or indirect
            - Reduction in
                - Growth
                - Survival
                - Reproductive success of substantial populations
    - Of any
        - Federal species of concern
        - State species listed as
            - Endangered
            - Threatened
        - CNPS listed
            - Plant species
        - Species of special concern
        - Regionally important commercial or game species.
    - Have an adverse effect on species'
        - Designated critical habitat.

- 3.8.3 No action alternative (127-128):
- 3.8.4. Alternative 1 – improved levees (128-136):
    - <u>VELB (128</u>):
        - 250 shrubs were found along the LAR
        - Prior to construction
            - A survey within 100 ft. of construction area will be conducted
                - In accordance with USFWS guidelines
            - Potentially effected shrubs will be
                - Mapped
                - Surveyed
                    - To determine
                        - Size of stems
                        - Location "of shrubs to riparian habitat"
                        - Presence of exit holes.
        - Shrubs that cannot be avoided
            - Would be transplanted
                - Between Nov. and mid-Feb. when plants are dormant.
            - Transplanting procedures will comply with Conservation Guidelines for the VELB (USFWS 1999)
            - Potential impacts due to damage or transplantation include
                - Direct beetle mortality
                - Disruption of lifecycle
        - Temporal loss of habitat
            - May occur due to transplantation
            - Even with compensation measures including
                - Habitat restoration
                - Habitat creation

            - Mitigation plantings would likely require 1 or more years
                - To provide supporting habitat.
        - <u>Associated riparian habitats</u>
            - May take several decades to reach full value.
EE-127
                - *What "associated riparian habitats?" Some that the Corps will plant? Where?*
    - Project is likely to adversely affect VELB.
    - Compensation is discussed in Section 3.8.6
    - Implementation of
        - Avoidance, minimization, compensation measures
            - Impact to VELB would be
                - Less than significant.
- Giant garter snake (129):
- <u>Swainson's hawk (129-130)</u>:
    - <u>134 ac</u>, of riparian habitat (project-wide)
            - Used by Swainson's hawk
                - For;
                    - Roosting
                    - Nesting
            - Will be affected
                - By construction.
EE-128
                - *How is this acreage computed?*
        - Any trees removed
            - Would be mitigated
        - However
            - Temporal losses would be significant due to time delay to recover use values.
    - 2.5 ac of non-native grassland/barren lands (project-wide)
            - Would be removed/disturbed
                - Due to construction at levees
        - Much of it
                - In the Sacto. River and American River area,
            - Where hawks nest and forage.
    - Prior to construction
        - Annual surveys would be conducted
            - Within ½ mi. of anticipated construction areas.
        - If hawks are found
            - Resource agency coordination would occur
                - Appropriate avoidance and minimization measures would be established
                    - Prior to construction.
    - Adverse effect would be significant
        - Due to temporary loss of
            - Nesting habitat
                - Along waterways while new mitigation trees grow.

- Sacramento River winter-run chinook salmon (130):
- Central Valley spring-run chinook salmon (132):
- Central Valley fall-/late fall-run chinook salmon (133):
- Central Valley steelhead (133-134):
- Delta smelt (134-135):
- Green sturgeon (135-136):
- Vernal pool fairy shrimp (136):
- Vernal pool tadpole shrimp (136):

- 3.8.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (137-138):
  - Sacramento bypass and weir (137-138):
- 3.8.6. Avoidance, maintenance, and mitigation measures (138-150):
    - Estimates of compensation measures are based on
        - The largest potential footprint
        - Worst case scenario
      - For the purposes of NEPA compliance

EE-129
          - *Does this include the possibility that the vegetation variance will not apply to the LAR or that it will not be approved??*

EE-130
          - *Based on the 2011 survey area, there could be additional elderberry shrubs impacted. (See comments in Section 3.6.2 above.)*

    - If design refinements result in reduced impacts to vegetation
      - Compensation would be coordinated with the appropriate resource agencies and adjust accordingly.

EE-131
          - *As well as increased impacts??*

  - VELB (138-145):
    - 250 elderberry shrubs were located on the LAR
      - On levee slopes and within
        - 15 ft of the landside toe
        - 30 ft of the waterside toe.
    - In accordance with
          - Conservation Guidelines for VELB (USFWS 1999)
      - Adverse effects would be compensated by;
        - Transplanting shrubs with >1 inch diameter
        - Planting a mix of native riarian/or upland vegetation at a 2:1 And 6:1 ratios
          - Depending on stem diameter
      - Amount of compensation
        - Is based on the 2011 preliminary survey
          - Within the construction footprint

EE-132
          - *Is this the same as the levee slope and 15/30 ft. extension survey above?*

    - On the LAR,
      - Shrubs would be transplanted
      - Additional compensation would be installed
        - On top of rock trenches
          - When possible

- Outside the vegetation free zone
- It is expected that on these trench surfaces
  - Sufficient lands would be available to
    - Plant these shrubs and associated natives.
    - *This implies that there will be at least 89 ac (see note below) of rock trench surface outside the vegetation free zone (surface areas >30 ft from the waterside levee toe (See Section 3.6.6). What does this say about the total area of (and length of) rock trench surface area on the LAR/ARP?*

EE-133

EE-134

    - *What associated natives?*

EE-135

    - *When and if the launchable rock trenches actually launch the rocks due to erosive bank retreat (that is when the project functions as designed), how will the losses of real riparian vegetation along the banks, and the elderberry plants on the rock trench surfaces, be counted as impacts resulting from proper project functioning?*
- If additional lands are required,
  - Off-site plantings could occur
    - At the existing Cal Expo mitigation site
    - Adjacent to the existing mitigation site at River Bend Park

EE-136

    - *More land for mitigation would be needed at River Bend?*
- Based on
  - 2011 survey results
  - Specific shrub stem characteristics assumptions (see text)
  - USFWS compensation requirements
- 66 ac of compensation would be required on the LAR (TABLE 18, p140)

EE-137

    - *Why does the LAR have 83% of the surveyed elderberry shrubs (205 LAR plants /302 total plants = 0.83) ((with many more possible)) but only has 61% of the estimated mitigation area requirements (66 ac LAR/108 ac total = 0.61)?*
- Since the survey was limited to areas within 30 ft. of the waterside of levee toes
  - There are likely many additional shrubs to impacted
    - More compensation will be required.
- PAGE 144: Summary of measures based on
  - *Conservation Guidelines for the VELB (USFWS 1999a)*
- Giant garter snake (145-146):
- Swainson's hawk (145-147):

- To avoid and minimize effects
    - The Corps would implement the following BMP measures;
  - Before ground disturbance
    - All construction personnel would participate in a DFW-approved worker awareness program
      - Present life history
      - Importance of
        - Nest sites
        - Foraging habitat.
  - Breeding season surveys (for Swainson's hawk):
      - For nesting birds
    - Would be conducted
      - For all trees and shrubs that would be removed or disturbed
        - Within 500 ft
        - (0.5 mi. for Swainson's hawk)
      - Of construction activities
    - Completed
      - During at least 2 of the following periods;
        - 1/1 – 3/20
        - 3/20 – 4/5
        - 4/5 – 4/10
        - 6/10 – 7/30
      - With no fewer the 3 surveys completed in at least 2 survey periods
      - With at least 1 of these occurring immediately prior to project initiation
        - (Swainson's Hawk Advisory Committee 2000).
    - Breeding season surveys (for other birds):
      - Migratory bird nest survey could be conducted
        - Concurrent with Swain. hawk surveys
      - With at least 1 survey
        - No more than 48 hr. prior to initiation of project activities
        - To confirm absence of nesting.
    - If area contains no active nests
      - Construction activities could commence
        - Without any further mitigation.
  - If active nests are found;
    - There would be a 0.25 mi buffer
      - Between construction activities and active nests.
    - A qualified biologist would be present on-site
      - To ensure

- That the buffer distance in adequate
- Birds are not showing stress
- If stress could cause nest abandonment
  - Construction activities would cease
  - Until it is determined that fledglings have left the nest.
- If other migratory birds are nesting in or adjacent to the study area the following BMP would be implemented.
  - Tree and shrub removal and other construction activities
    - Would not be conducted during the nesting season (generally 2/15 – 8/31).
      - Depending on species and varying conditions year-to-year.
      - *It is unclear about the buffer distances.*

EE-138

- Implementation of mitigation measure
  - Described below
    - Would avoid, reduce, minimize
      - The significant effect.
  - For Swainson's hawk
    - The Corps will seek a vegetation variance
      - For the lower half of the levee slope
      - Including of LAR levees?
    - <u>Bank protection</u> work site
      - Would be planted with vegetation and trees
        - That over time will provide habitat.
      - *Will this be applied to the LAR?*
      - *This seems to be contrary to the design approach for LAR bank protection work in Section 2.3.1. (See notes above)*

EE-139

EE-140

  - To compensate for 134 ac of riparian habitat supporting
    - Swainson's hawk
    - Other migratory species
    - Approximately 268 ac of replacement habitat will be created
      - As a mitigation area
      - May consider
        - Woodlake
        - Cal Expo
      - *What are the specific riparian habitat types (or structural conditions) that are needed for mitigation? Are there really opportunities for these specific riparian habitat conditions in the Woodlake/Cal Expo areas?*

EE-141

    - **For mitigation in the ARP**
      - Species selected to compensate for riparian corridor removal

- Will be consistent with approved native plant list of the ARP.
- Will prove to be contiguous and create
  - Habitat connectivity
  - Wildlife migratory corridors
  - Support the needs of important wildlife species
- Without compromising;
  - Integrity of flood control facilities
  - Flood conveyance capacity
  - Management goals of the ARPP.
- To comply with the ARPP
  - ARP lands will be evaluated for compensation opportunities
  - For any riparian habitat removed in the ARP.

EE-142
- *Specifically, for impact/mitigation purposes; what type of riparian habitat losses constitutes adverse effects on Swainson's hawk?.*

EE-143
- *What is this acreage of this riparian habitat type in the LAR?*

EE-144
- *How, exactly will this opportunity-evaluation be conducted and by who?*
- Location of ARP compensation lands
  - Will be determined in the design phase
  - Coordinated with SCRP
  - To comply with ARPP objectives and goals

EE-145
- *What level of SCRP coordination is anticipated? What guarantees are in place?*
- It is assumed that sufficient compensation lands are available in the ARP
  - If not other locations in Sacto. Co will be identified
  - And public coordination will occur.
- Additional mitigation may be
  - In the expanded Sacto. bypass
  - Other lands with similar value to those removed.
- Listed fish species (147-149):
- Vernal pool fairy shrimp and tadpole shrimp (149-150):

- **3.9 Cultural resources (150-172):**
  - 3.9.1 Environmental setting (150-162):
    - Regulatory setting (150):
    - Existing conditions (150-162):
      - Prehistoric and ethnographic setting (151-153):
      - Historic setting (153-154):

- Results of the records search (154-155):
- Field survey results (155-156):
- Cultural resource site types (156-159);

      - ARPP
      - Sections 9 and 10 of the Rivers and Harbors Appropriation Act (1899)
      - S W&SR Act (1972)
      - Sacto. City Parks and Recreation Master Plan
      - Sacto. Co. Bikeway Master Plan
      - Old Sacto. State Historic General Plan.
    - Existing conditions (230-234):
      - American River (230-233):
        - Short discussions of
          - ARP
          - SW&SR//FW&SR
            - Designated
              - Recreation
          - ARPP (addressed in Land use, 3.3)
          - ARPP-allowed recreation
          - Jed Smith Bike trail
          - Recreation boating

- ARP-related parks;
  - Discovery Park
  - Sutter's Landing Regional Park
  - Paradise Beach
  - CC CG
  - Guy West Bridge
  - Howe Ave
  - Waterton // Save the American \River Association (Park)
  - Watt Ave
  - Gristmill Park
  - William Pond Recreation Area
  - River Bend Park
  - Soil Born Farms.
- Sacramento River (233-234):
- East side tributaries (234):
- Sacramento bypass (234):

- 3.14.2 Methodology and basis of significance (235):
  - Methodology (235):
    - Impacts to recreation opportunities
      - Are evaluated based on
        - Temporary changes
        - Permanent changes
    - Taking into consideration;
      - ARRP
      - Other regional plans including
        - Sacto. City General Plan
        - Sacto. City Parks and Recreation Master Plan
      - Sacto. Co. Bikeway Master Plan
      - Rivers and Harbors Appropriation Act
      - W&SR Act.
  - Basis of significance (235):
    - Thresholds of significance were,
      - Based on the environmental checklist in Appendix G of the State CEQA Guidelines..
  - Significant adverse effects are determined if any of the following occur;
    - <u>Eliminate or substantially restric</u>t or reduce the
        - Availability
        - Access
        - Quality
      - Of existing recreational
        - Sites
        - Opportunities.
    - Cause substantial <u>long-term disruption</u> in the use of
      - Existing recreational
        - Facility

- Activity.
    - Result in inconsistences or non-compliance
        - With regional planning documents.
    - Result in inconsistences or non-compliance
        - With ARPP.
    - Result in inconsistences with
        - Rivers and Harbors Act
        - W&SR Act

EE-146
- *Do construction activity impacts differ from "long-term disruption?"*

EE-147
- *How does "long-term disruption" differ from "eliminate or substantially restrict?"*

- 3.14.3 No action alternative (235-236):
    - Without project levee improvements
        - Existing problem would continue
            - Potentially leading to future flood-levee failure.
        - Sustained high flows would erode banks in the ARP
            - Over time
                - The ARP
                - And recreational facilities within it
            - Would be lost.
    - No Action Alt. would,
        - Result in
            - Inconsistences
            - Non-compliance
                - With the ARPP.
        - The <u>ARPP states</u>;
            - "<u>Public facilities and private encroachments</u> that inappropriately constrain the operation and maintenance of the flood-control system should be redesigned or relocated"

EE-148
- *Why does this statement imply that the No Action Alt. is inconsistent with the ARPP?*

- "Bank scour and erosion shall <u>be proactively managed</u> to protect public levees and infrastructure, such as bridges, piers, power lines, habitat and recreational resources. These erosion control projects, which may include efforts to anchor berms and banks with rock revetment, shall be designed to minimize damage to riparian vegetation and wildlife habitat, and should include a revegetation program that screens the project from public view, provides for a naturalistic appearance to the site, and restores affected wildlife habitat values."
    - *Why does this statement imply that the No Action Alt. is inconsistent with the ARPP?*

EE-149
- ***Where are these in the ARPP?***

EE-150
- ***Are there other ARPP goals/objectives that relate to the No Action Alt.?***

- No Action Alt. would cause significant impacts to,
    - Recreational facilities

                - That could not be mitigated
                    - As there are no other similar recreational experience resources in the Sacto. region.
- 3.14.4. Alternative 1 – improved levees (236-238):
    - American River (236-237):
        - Construction closures and disturbances
                - Would result in ARPP non-compliance (See No Action Alt. above).
            - <u>Erosion protection measure construction</u> may take 10 years
                - Occurring at multiple locations at the same time
                    - Considered a significant effect
                    - Due to reduced quality of existing recreation activities.
            - <u>Construction closures</u> include;
                - Portions of the levee-top road
                    - Would be closed to pedestrians during construction.
                - Launchable rock trenches
                    - Would disturb several miles of bike trails
                    - Limit access to public parks and boat launches.

EE-151

                - *Why are these short-term impacts inconsistent with the ARPP?*
        - These same issues make the Alt 1 inconsistent with the federal W&SR Act.
            - Specified resource values "shall be preserve in free-flowing conditions, and that their immediate environment shall be protected for the benefit and enjoyment of present and future generations."
                - Potentially affected (construction) resources include;
                    - Paradise Beach
                    - CC GC
                    - Guy West Bridge
                    - Howe Ave boat ramp
                    - Watt Ave boat ramp
                    - Gristmill Park

EE-152

                - *Why are these short-term impacts inconsistent with the National W&SR Act?*
        - Construction activities would entail various closures and impacts during construction.
            - Mitigation measures would be implemented reduce impacts,
                - Construction impacts would significant.
        - Post-construction;

- Recreation facilities would be returned to pre-construction conditions
  - Long-term effect would be less than significant.
  - ***In the No Action Alt. the Corps attribute land and resource losses due to ongoing erosion as a significant recreation impact that is not consistent with ARPP. The proper functioning of the launchable rock trenches anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of habitat and recreation values and will constitute losses of recreation areas, facilities, and values. Why are these impacts, which are implicit to the expected proper functioning of the project as designed, not counted as project impacts?***

EE-153

- Sacramento River (237):
- East side tributaries (238):

- 3.14.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (238):

  - 3.15.1 Environmental setting (239-252):
    - Regulatory setting (239):
      - No applicable state or federal regulations
    - Existing conditions (239-252):
      - Visual resources are;
        - Natural features including
          - Land
          - Water
          - Vegetation
          - Geologic
        - Built features including
          - Buildings
          - Roadways
          - Bridges
          - Levees
          - Other structures
      - A common set of criteria (FHWA 1988) for visual quality includes
        - Vividness:
          - The visual

- power
- memorability
- Of landscape components
  - That combine in visual patterns.
- Intactness:
  - The visual integrity of
    - Natural and constructed landscape
    - And its freedom from encroachments
  - This factor can be present in
    - Urban setting
    - Rural landscapes
    - Naturel settings
- Unity:
  - The visual
    - Coherence
    - Compositional harmony
  - Of the landscape resources.
- Existing visual quality is determined based on het relative degree of
    - Vividness
    - Intactness
    - Unity
  - Apparent
    - In views
    - Visual sensitivity
- Sensitivity is based on;
  - Visibility of the landscape
  - Proximity of viewer to the visual resource
  - Elevation of viewers compared to elevation of the resource
  - Frequency and duration of views
  - Number of viewers
  - Type of viewer individuals and groups
  - Viewer expectations.
- American River (240-243):
  - Main viewer groups;
    - Residents living adjacent to the LAR levees
    - Highway travelers
      - Bus. I-80
      - Fair Oaks Blvd/H St.
      - Howe Ave.
      - Watt Ave.
    - ARP recreational uses
    - LAR boaters
  - Visual environment includes;
    - Urban development on the landside of levees
      - ARP views are blocked by levees

        - Second story views are possible
    - Users on the levee tops
        - Have views of ARP riparian forests and open space lands.
    - ARP resourced provide users with
        - A highly-valued
            - Natural setting
            - Feeling of serenity
        - In a developed urban area
    - ARP provides all of the visual quality of
            - Intactness
            - Vividness
            - Unity
        - In a linear park
            - Which can be viewed with limited urban disruption.
    - The ARP aesthetic values
        - Are those unique qualities that define the ARP experience
            - For ARP users
  - The ARPP flood control policies include:
    - "Bank scour and erosion shall be proactively managed to protect public levees and infrastructure, such as bridges, piers, power lines, habitat and recreational resources. These erosion control projects, which may include efforts to anchor berms and banks with rock revetment, shall be designed to minimize damage to riparian vegetation and wildlife habitat, and should include a revegetation program that screens the project from public view, provides for a naturalistic appearance to the site, and restores affected wildlife habitat values."
- Sacramento River (243):
- East side tributaries (245-250):
- Sacramento bypass (250-252):

- 3.15.2 Methodology and basis of significance (252-253):
  - Methodology (252):
    - Potential impacts based on
        - Review of
            - Scenic vistas
            - Landscapes
      - That could be affected
        - By project-related activities.
    - Visual contracts were examined including
        - Changes in
            - Form
            - Size color
            - Project dominance

          - View blockage
          - Duration of impacts
    - Also considered were
      - Natural setting
        - Vegetation
        - Landforms
      - Placement of project components in relation to existing structures
      - Likely viewer groups.
  - Basis of significance (252-253):
    - Thresholds of significance encompass
      - The factors taken into account
        - Under NEPA
          - To determine significance of action un terms of
            - Context
            - Intensity
    - Thresholds used are based on
      - Appendix G of CEQA Guidelines.
    - Significant impacts would occur if the project
      - Have a substantial adverse effect on a scenic vista
          - Are specific vistas identified?
          - What is substantial?
      - Substantially damage scenic resource,
        - Including but not limited to
          - Trees
          - Rock outcrops
          - Historical buildings
      - Substantially degrade
        - The existing visual character or quality of
          - The site
          - Its surroundings
      - Create a new source of substantial
          - Light
          - Or glare
        - That would adversely affect
          - Day or nighttime
            - Views in the area.
- 3.15.3 No action alternative (253):
    - No project construction activities
      - Therefore would not cause additional effects to visual resources.
    - Visual conditions would remain consistent with present conditions
      - Adverse affects
        - Would be caused by
          - Future flood event
          - Levee failure.

EE-154

- *Unlike other resource sections (ie. LU, vegetation etc.) the Corps does not associate the ongoing bank erosion and berm area that would result from the No Action Alt as resulting in visual impacts; Why not?*

- 3.15.4. Alternative 1 – improved levees (253-256):
  - Barrow sites (253-254):
  - American River (254):
    - Launchable rock trench (LRT) approach
      - Construction:
        - On 11 miles of the 26 mi ARP 200 ac of construction area
          - 65 ac of riparian habitat
            - Removed to construct LRT
          - 135 ac are
            - Levees; that will be degraded to install rock trenches
            - Staging areas

EE-155

          - *So is this then launchable rock trench construction on berms/banks along 11 river miles (22 linear miles of project work along 11 miles of channel) on both sides of the LAR, or a total of 11 linear miles of project work along a shorter reach of the LAR?*
        - Construction will last 10 years
          - Short-term construction activity impacts will be significant.
      - Post construction;
        - Loss of riparian vegetation would have
          - Long-term impact
        - LRT would be designed to
          - Include a <u>planting berm</u>
            - Which would be <u>planted with trees</u> outside the 15 ft. vegetation free zone
            - To compensate for some of the 65 ac of lost riparian habitat.

EE-156

          - *This "planting berm" is not mentioned in Section 2.3.1 nor indicated on Figure 1; it is not mentioned in any other resource impact section of the EIS.*

EE-157

          - *In section 2.3.1 the Corps states that LRT would be constructed outside the natural channel; how would the "planting berm" work and where would it be placed?*

EE-158

          - ***The design description of the LRT approach includes a prohibition against planting deep-rooted trees on the trench***

surface which should preclude riparian trees.

- Shrubs would be transplanted
- Additional compensation would be installed
  - On top of rock trenches
    - When possible
  - Outside the vegetation free zone
  - *In Section 3.8.6 for VELB impacts/mitigation; the Corps states that impacted shrubs would be transplanted, that additional compensation would occur thought planting be on top of rock trenches (when possible), outside the vegetation free zone, and that it is expected that on these trench surfaces sufficient lands would be available to plant these shrubs and associated natives.*

EE-159

    - The VELB use-area of the rock trench surfaces seems to conflict with the 65 ac of riparian habitat revegetation.
    - ***Elderberry shrubs are not an exclusively riparian plant nor does it, on its own, constitute riparian habitat.***

EE-160

    - ***Calling elderberry plants riparian does ot make an elderberry replanting area riparian habitat.***

EE-161

    - ***If the launchable rock trenches truly displace riparian habitat, then the 65 ac of riparian habitat replacement on the launchable rock trench surface should use truly riparian species.***

EE-162

    - ***However the vegetation prohibitions in Section 2.3.1 and the most likely finished elevation of the launchable rock trench surfaces (+/- 20 ft above low water surfaces) seems to preclude truly riparian plant species and thus riparian habitat.***

EE-163

  - However these trees would take many years to grow to similar visual values
    - Considered a significant impact
    - That cannot be mitigated.
  - *These impacts/mitigation actions address construction and project footprint considerations only. Unlike other resource*

EE-164

EE-164 (Cont.)

sections (ie. LU, vegetation etc.) the Corps does not associate the ongoing bank erosion and berm area that would result from the No Action Alt as resulting in visual impacts; Not sure why this is the case. The proper functioning of the launchable rock trenches anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of vegetation, habitat, and recreation values and will constitute lost visual resource quality and value. Why are these impacts, which are implicit to the expected proper functioning of the project as designed, not counted as project impacts?

- Bank protection approach:
  - Construction:
    - Footprint would be
      - Adjacent to the bank
      - Varying distances from public access areas.
    - Activities include;
      - Trees would remain in place
        - Anchored with rock to protect them from future erosion
      - Sites planted with vegetation
      - EE-165 *The design specifications (Section2.3.1) state that "large" trees will remain; all other vegetation will be stripped and bank stabilization work will be done, and "planting berms" would be provided where feasible. The berms are not specifically indicated in Figure 1 and there seems to be notable hedging language.*
      - EE-166 *The bank protect that would have to occur on the steep RR bank in the Corps' "critical reach" will not end up looking like the photos of the Sac State project area. Need a realistic description of bank protection project results on steep banks.*
  - Post construction:
    - Visual impacts only seen from
      - The river
      - The ARP
    - Once vegetation is established
      - The rock will not likely be visible from either

        - The river
        - ARP
- Visual values would take time to reach
    - Likely to take 3-5 years to establish vegetation
    - FIGURES 8-10: indicate revegetation progress thru post-construction year 9 (2001-2010)

EE-167

    - *These figures show an apparent improvement in the visual conditions at this (Sac State) project location. However, the pre-project levee and bank conditions at this site are atypical of most of the intended 11 mile project area.*
        - *Except for the RL Fairbairn-Paradise Beach bank which has levee slopes that are adjacent to the LAR bank, and the frontage of Campus Commons golf course (which is an actively eroding bank [largely due to coarse sediment aggradation in the LAR in RM 6]), most of the existing LAR banks are steep and are heavily wooded with riparian trees.*

EE-168

        - *The Corps proposed "bank protection" approach application at these other more natural bank sites will not have a post-construction configuration as at pictured for the Sac State section and will have decidedly different pre- and post-project visual impacts than those represented by Figures 8-10.*
    - The "<u>full natural environment</u>"
        - Preferred by users

EE-169

    - *Even when revegetation has reached its maximum, the rock bank will be clearly seen from the river.*

EE-170

    - *Even when revegetation has reached its maximum, no observant user could mistake the rocked bank and channel margin from a natural bank.*
- Visual effects
    - Are considered to be less than significant
        - Site would quickly revegetate
        - Provide a <u>natural looking</u> environment

EE-171

EE-172

- <u>Similar to or enhances</u> from existing conditions
    - *It is not likely that these sites will ever "look natural" or look "similar to or enhanced" compared to conditions. There are presently essentially no rare eroded banks – almost all of the banks under consideration are heavily wooded with riparian vegetation with natural un-rocked banks and shorelines.*
    - *As noted above, the Corps proposed "bank protection" approach application at these other more natural bank sites will not have a post-construction configuration as at pictured for the Sac State section and will have decidedly different pre- and post-project visual impacts than those represented by Figures 8-10.*
    - Sacramento River (255):
    - East side tributaries (255-256):
- 3.15.5. Alternative 2 – Sacramento bypass and improve levees (TSP) (256-257):
    - Sacramento bypass (256-257):
- 3.15.6. Avoidance, maintenance, and mitigation measures (257-258):
        - Based on construction and project footprints
    - American River (257):
        - Construction:
            - Impacts to visual resource during construction are
                - Unavoidable
                    - Cannot be mitigated
        - Post construction:
            - Trees will be planted along the waterside edge of the LRT
                        - Where there is sufficient space.
                - Will take time to mature to pre-project visual values
                    - Should not take too long
                        - See project figures
            - Additional trees could be planted
                - At other ARP locations
                    - In compliance with the ARPP
                        - To mitigate tree removal
                    - Which provide a natural environment in a urban area.
            - Short-term effect will be significant.
            - Planted trees will reduce effects to less than significant
                - Once they are established
                    - And provide similar views to those removed.

Questions and issues:

Page 12 - Issues of Vegetation Variance. EIS (p 13) states that this was for the Sacto River;

- It is stated that the vegetation variance would be developed during the design phase.

EE-173 - *Is there any possibility that the vegetation variance would apply to LAR levees?*

EE-174 - *Do vegetation impact/mitigation assessments for the LAR include the assumption that the vegetation variance is approved?*

EE-175 - *If so, what would be LAR vegetation impacts/mitigation estimates for the LAR?*

Page 30 - The Corps states that Bank Protection project elements: consists in placing rock on banks and in some cases levees, when necessary eroded portion of banks would be filled and compacted prior to rock placement; sites would be prepared by clearing and stripping prior to construction, small vegetation and loose material would be removed; in most cases large vegetation would be left in place.

EE-176 - *What size criteria are to be used for small/large?*

EE-177 - *If large trees are left in place will the amount be specified by hydraulic modeling of conveyance? At this project stage, before site specific design and planning, how can it be determined what portions of project banks would have retained trees and at what density; how can an estimate of the expected vegetation impacts be developed?*

EE-178 - *If large trees are left in place, when they die will they be replaced; will natural revegetation be allowed or even possible with the rocked surface?*

EE-179 - *If these trees are expected to die and not be replaced by natural revegetation, how should these trees be counted for impact/mitigation purposes?*

EE-180 - *Should the recreation and visual impact assessment be based on no trees at all on these banks?*

- The Corps states that the excavator will place a <u>large rock berm</u> in the water to an elevation slightly above mean summer flow elevation; a planting trench would be established on this rock surface for revegetation.

EE-181 - *A <u>berm of large rock</u> or a <u>large berm of rock</u>?*

EE-182 - *This berm is not indicated on Figure 1. What size can be expected?*

EE-183 - *Would not a berm added to the foot of the existing banks further narrow the channel resulting in some measure of greater floodflow velocities?*

- *If so does this not add constraining parameters on vegetation occurrence and added vegetation maintenance activities?*

EE-184 - *What is to be the configuration of the "planting trench" and what plants and plant area widths are to be expected?*

EE-185 - *Long-term, what will be the vegetation configuration of the berm and bank protection project element?*

EE-186 - *Are there other bank protection project element design approaches that could result in satisfactory bank protection and meet project objectives;*

- *with better long-term resource results*
- *but perhaps with greater short-term impacts?*

Page 30, other - The Corps states that Launchable Rock Trench project elements: designed to deploy revetment once erosion has removed the bank material beneath it; will be placed outside the channel, located at the toe of existing levees; the bottom of the trench would be constructed to an elevation near the summer mean water surface (to reduce the rock launching distance and the amount of rock required); will be covered with a minimum of 3 ft. of soil; all disturbed areas would be reseeded with native grasses and small shrubs (where appropriate); some vegetation could be permitted over the trench, if planted outside the specified vegetation free zone, and would likely be limited to native grasses, shrubs, and trees with shallow root systems (to ensure the functionality of the launchable rock trench);. and vegetation would only be permitted if 1) it does not put undue burden on flood protection maintenance agencies, 2) it is in locations that do not interfere with channel conveyance capacity.

- Elsewhere (p 65) the Corps states that the maximum rock trench width would be about 70 ft. - In most of the resource impact/mitigation sections the Corps states that portions of the rock trench surface will be used to replace recreational facilities, and vegetation including elderberry shrubs and riparian habitat.

- Also in most of the resource impact/mitigation sections the Corps' treatment the impacts associated with the launchable rock trench project element is limited to construction activities and the post-construction configuration; the discussions do not address the impacts associated with the ultimate functioning of the protect element as designed, that is when it is achieving its design purpose of levee protection at the expense of channel, riparian, and American River Parkway resource protection.

- In the project reach there are few if any situations where 1) the levee toe is within 70 ft of the present channel margin and/or 2) is lower than about 15-20 ft. above the lowflow water surface elevation.

EE-187 *- Given this; and the vegetation limitation described above, how can the Corps expect the rock trench to support riparian revegetation and provide riparian habitat values? By its very nature, riparian vegetation requires sub-irrigation, which seems to be precluded by the Corps' revegetation criteria. Not to mention the hydraulic parameters.*

EE-188 *- With rock trench slope criteria (2:1 and 1:1), each foot of rock trench depth entails 3 ft. of rock trench surface width; a 70 ft. width results in a 23 ft. deep trench if there is no trench bottom width. With most levee toes in the range of 20 above the lowflow channel elevation, with any rock trench bottom width at all, it seems that a 70 ft. rock trench surface width may be more of a typical condition than a maximum width.*

EE-189 *- In most resource sections the Corps states with the No Action Alt. the waterside berm in the ARP would erode overtime, resulting in the loss of land area and various vegetation, wildlife habitat, recreation, and visual resource values; that these losses constitute signification impacts.*

EE-190 *- The Corps does not state what lands (locations and amounts) that are at risk of loss due to the No Action Alternative so impacts associated with and the loss of land area and various vegetation, wildlife habitat, recreation, and visual resource values for this alternative are not quantifiable..*

EE-191 *- However, the proper functioning of the launchable rock trench approach anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. The bank erosion and bank retreat imply the same resource value losses (land area, and various vegetation, wildlife habitat, recreation, and visual resource values) that the Corps attributes to the No Action Alternative. Why shouldn't these same resource losses be attributed to the launchable rock trench protect elements?*

EE-192 *- When the rocks are launched (as per the project design objectives), there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of habitat and recreation values. Why are these impacts, which are implicit to the proper and expected functioning of the* *project as designed, not counted as project impacts (as was the case for the No Action Alt.)?*

- Elsewhere (p 254) the Corps states that launchable rock trenches: would be designed to include a planting berm; which would be planted with trees outside the 15 ft. vegetation free zone; to compensate for some of the 65 ac of lost riparian habitat.

EE-193

- *However the design specifications in Section 2.3.1 does is not mentioned a "planting berm" and it is not mentioned in any other resource impact/mitigation section.*
  - *In Section 2.3.1 the Corps states that launchable rock trenches would be constructed outside the natural channel; how would the "planting berm" work and where would it be placed?*
  - *The design description of the LRT approach includes a prohibition against planting deep-rooted trees on the trench surface which should preclude riparian trees.*

EE-194

  - *Except possibly on RL between Fairbairn and Paradise Beach, are there any portions of the project reach where levee toes (where the trench is to be located) are set close enough to the present LAR bank such that a planting berm (similar to that described for "bank protection" approach) added to the channel margin would be part of the launchable rock trench approach?*

EE-195

- *How are these statements in the visual impacts/mitigation section compatible with the design specification on Section 2.3.1?*

- Elsewhere (p 254) the Corps states that launchable rock trench construction would occur along 11 of the 26 miles of the ARP involving 200 ac of disturbance. In many locations of the EIS the Corps refers to 11 miles of construction work.

EE-196

- *So is this then launchable rock trench construction on berms/banks along 11 river miles (22 linear miles of project work along 11 miles of channel) on both sides of the LAR, or a total of 11 linear miles of project work along a shorter reach of the LAR?*

Page 63, 65

- The Corps states (p 63) that for the No Action Alt., the waterside berm in the ARP would erode overtime, resulting in the loss of ARP lands. An since the ARPP designated most of the lands within the project area for various uses, the No Action Alt. is inconsistent with the ARPP and would be considered a significant effect.

EE-197

- *The Corps does not provide an estimate of potential land, habitat, and recreational facility losses that will be due to the No Action Alt.*

- The Corps states (p 65) for Alternative 1, that the launchable rock trench protection approach is in compliance with ARPP because no lands would be lost and construction impacts would be mitigated. Further LU impacts are considered less than significant and no additional (non-construction) mitigation is required.

EE-198

- *In the No Action Alt. the Corps' attribute land and resource losses due to ongoing erosion as a significant LU impact that is not consistent with ARPP. However, the proper functioning of the launchable rock trench approach anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched, there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of habitat and recreation values. Why are these impacts, which are implicit to the proper and expected functioning of the project as designed, not counted as project impacts (as was the case for the No Action Alt.)?*

Page 65

- The Corps states that the maximum trench width will be 70 ft., and that a total of 65 ac will be disturbed along 11 miles of treatment.

EE-199

- However with design trench slopes (2:1 and 1:1) (p31), a 70 ft. wide trench-top would be 23 ft. deep (70/3=23.3), if it has no bottom width. Design indicates varying trench bottom widths so independently estimating trench top-widths is not possible here. However I'm thinking that most of the levee toe elevations are about 20 ft. above with lowflow water surface which indicates that, if there is to be any bottom-trench width at all, maximum trench surfaces may be in excess of 70 ft. It is possible that 70 ft. could be the average trench surface width.

EE-200

- Does the 65 ac of disturbance exclude staging areas and access ramps etc.?

Page 71-73 - The Corps' long-term modeling concluded that in 50 years the average LAR bed will degrade 4.8 ft and in 100 years it will degrade 5.8 ft. (with maximum degradation RM 1-11, 12-22 of 16-20 ft. and maximum aggradation RM11-12 of 3-4 ft.

EE-201

- Without further discussion and explanation this appears not sensible.

EE-202

- Were the cemented/indurated clay channel bed nick points considered and over these timelines what influence would they have on channel degradation upstream of their locations?

EE-203

- What is the volume of sediment predicted by this modelling to be lost in the LAR over these timelines?

EE-204

- Where does this sediment go?

EE-205

- Have they overlooked that the LAR channel is drowned downstream of RM 5 (due to geologic timescale sea level rise) and that now and in the future (increasing rates of sea level rise), out-fluxing of coarse sediment past this point is not likely. What are the implications of this sea-level rise process on long-term degradation/aggradation in the RM 5-7 reach?

- The Corps stated that irregular channel reaches may not be adequately represented by this model, especially in braided reaches above RM 8.

EE-206

- There are no really braided channel plan forms on the LAR (above RM 8) except possibly a 0.5 mile section at about RM 14/15 (this is really just a short reach recently experiencing over-loaded sediment influx in conjunction with erodible banks – local widening and the development of multiple channels. This "braided" feature is in the process of change and could develop into a single thread channel with time.).

- The complex channel in the RM 11-12 reach is the result of the breaching of off-channel gravel pits – not channel braiding.

- The complex channel configuration at RM 9 downstream of the Watt bridge is due to a natural process of sediment deposition and channel re-configuring resulting from late-date gravel bar mining and the resulting over-widened channel – this is not channel braiding. The source of the sediment that is being deposited downstream of the Watt bridge is most likely due to ongoing scour in the 0.5 mi of channel upstream of the Watt bridge.

- At about RM 6 there is a 0.5 mi braided reach that is due to coarse sediment deposition at the head of the drowned LAR channel reach (RM 0-5) (due to geologic time-scale sea level rise). This is the expected final location of all coarse sediment transported through the LAR.

Page 73 - The Corps concluded that the LAR is sediment starved; that bedrock (likely the cemented/indurated clay member of the Turlock Lake Frm.) has been reached as far downstream as Guy West Bridge which is slowing further degradation; and that without significant bed slope reduction, it will now tend to erode laterally to satisfy need for sediment.

EE-207 *- This conclusion seems to contradict the long-term (50 and 100 years) predictions of significant channel bed degradation presented on p 72 (see notes in outline above).*

Page 74 - The Corps concluded that field review verified erosion of the bank is occurring at RM 9.0 RR, even at lowflow of 7,000 cfs.; erosion of the LAR is continually occurring; which leaves the banks sacred and susceptible to future erosion, especially at high flow events; further reducing the amount of berm separating the channel from the levees; and that the loss of vegetation is leaving the bare soil, which is susceptible to erosion at a lower velocity.

EE-208 *- All of these statements about "erosion" appear to be true **only when applied** to the field-verified erosion at "RM 9.0 RR."*

- This site of erosion is not generally characteristic of the LAR: It is due to local-scale natural channel adjustments underway in response to channel over-widening that occurred in the 1960-70's when the RL attached longitudinal gravel bar was removed for gravel mining purposes. With reduced stream power at this location a regime of net deposition was induced and a medial bar developed which is now morphing into a diagonal bar attached to the RL bank at the bridge. Since the 1970's the process has progressively forced more flow and power to the RR bank causing the Corps' "field-verified" erosion. At the location of the original attached bar, the channel is aggrading to a significant degree making the existing boat ramp dysfunctional.

- This condition in not representative of the LAR in general, nor of the critical RM 6-11 reach but is a local phenomenon, with local symptoms, and local causal factors.

EE-209 *- This bank erosion problem could be corrected with proper local-scale channel restoration actions.*

EE-210 *- The real long-term erosion issue in this critical reach is the sewer main undercrossing at about RM 7. The line was installed as an inverted syphon with one riser at the edge of the RR active channel bank, with revetment armoring on this bank slope. This constitutes a critical channel impingement and constraint which resulted in severe RR bank erosion upstream of the line due to progressive erosive eddy development during the 1986 flood event. Without that armored nick point on the RR bank (and with the inverted syphon riser set back from the channel bank edge), it is most likely that bank erosion along the RR bank at that location during the 1986 event would have been very modest. The presence of this sewer undercrossing in its present configuration limits intelligent channel reconfigure alternatives for dealing with this critical flood conveyance reach.*

EE-211 *- The Corps' flood conveyance actions in this critical reach should be focused on the modification of the existing inverted syphon (setting back the riser and eliminating the bank revetment at the existing riser which anchors the eddy erosion process/dynamic immediately upstream) such that GRR- project (and possible future-flood management) options for stream channel, channel bank, and riparian setting reconfiguration and restoration are maximized not minimized.*

Page 78-82 - The Corps' criteria for hydrology/hydraulic impact significance (P 78) is limited to floodflow magnitude changes and induced inundation risks to safety and damage.

EE-212 *- Does not concern itself with channel stability issues related to hydraulic effects of bank protection and launchable rock trench design approaches.*

EE-213 *- What may be the hydraulic effects of bank protection and launchable rock trench design approaches, particularly when and if launchable rocks are launched due to bank retreat?*

- The Corps stated that project work primarily includes landside levee fixes; that do not change in-channel geometry or characteristics; and therefore would not substantially alter erosion or siltation in the system.

EE-214

- *Can this be said of the proposed 11 miles of bank protection and launchable rock trench work in the LAR/ARP?*
- *What about the bank erosion that would have to occur to launch the launchable rocks where that approach is used?*
- *What about channel hydraulic conditions when and if the launchable rocks are launched (that is when the project functions as designed), how will the new channel configuration affect hydraulics; what are the consequences of these new channel conditions?*

- The Corps stated that the 200-yr flows in the LAR are tied to the changes in Folsom Dam operations; which will be analyzed as part of the ongoing Folsom Dam Water Control Manual Update; the effects of these flows including cumulative effects will be addressed by the Manual Update EIS/EIR.

EE-215

- *Does this mean that the 200-yr LAR flows may not be 115,000?*
- *Does this mean;*
  - *That the impacts of changing the floodflow regime on the LAR will be assessed at a later time?*
  - *That the possible channel implications of the GRR w/o or w/ project conditions do not consider the change in floodflow regime?*
  - *And that the impacts of these flows (increased floodflow magnitudes at more frequent occurrences, reduced floodflow magnitudes at less frequent occurrences) on the LAR channel etc. have not yet been assessed?*

- The Corps stated that since flows are not increased, project effects on hydrology/hydraulics are less than significant; no mitigation is required.

EE-216

- *This conclusion;*
  - *Is dependent on the narrow conception of the "basis of significance" used for hydrology/hydraulic impacts (p 78).*
  - *Seems to ignore the 11-12 miles of bank protection and launchable rock trench work on the LAR.*
  - *Ignores the hydraulic implications of proper project functioning – that is the consequences of the launching of the launchable rocks;*
    - *Consequences of the bank retreat required to launch the rocks.*
    - *Consequences to channel hydraulics after the rocks have been launched – the new channel configuration.*

EE-217 Page 99-100: - *Will the aerial photo overlay of LAR bank protection and launchable rock trench construction footprint be available to SCRP during the NRMP process?*

EE-218 Page 103: - *Could the NRMP be used to assess overall-ARP impacts and implications of mitigation to include greater (short-term) impacts in the construction area with greater long-term mitigation values with restoration/mitigation projects in the Arden/Sacto Bar/Sailor Bar areas?? That is: accept the short-term impacts of temporal riparian vegetation/habitat losses in the construction areas (but re-planting for on-site mitigation) with restoration of industrial impacted areas to riparian habitat.*

EE-219 Page 103-104 - *The discussion of riparian trees on bank protection surfaces seems to be indicate that large trees (as feasible) will be left in place amid placed revetments. Since these revetment surfaces will have*

EE-219 (Cont.) *very poor revegetation success, when these large trees die it is most likely that no trees will replace them. How are these" large trees left in place" counted as impact/mitigation for habitat, recreation, visual, and W&S River values?*

Page 103-104

EE-220 *- The discussion of riparian plantings on the rock trenches appears to conflict with the design description of launchable rock trench features on page 32. As a result it is unclear how to consider the impacts of the Corps' assertion that 130 ac of riparian will be planted on these trench surfaces.*

EE-221 *- When and if the launchable rock trenches actually launch the rocks due to erosive bank retreat (that is, when the project functions as designed), how will the losses of real riparian vegetation along the banks, and the Corps' "riparian plants" on the rock trench surfaces, be counted as impacts resulting from proper project functioning?*

EE-222 *- Since the proper operational functioning of the launchable rock trench approach is predicated on the progressive loss of banks and berms between the channel and the levee, a natural attribute of this approach entails the same losses of lands, vegetation, and wildlife habitat as is attributed by the Corps to the No Action Alternative. Why should the discussion of vegetation and wildlife impacts associated with the launchable rock trench approach be limited to construction aspects and not include impacts associated with its preforming as designed and achieving its functional purpose?*

Pages 117,

- The Corps considered all elderberry shrubs on the waterside of levees as being in the "riparian zone."

EE-223 *- What criteria were applied to make this riparian zone determination?*
- If a particular shrub is found in a defensibly identified riparian area, could this plant be considered "riparian?" That is, when replanted somewhere else could that new site be defensibly considered "riparian habitat?"

EE-224 *- When talking about planting riparian in portions of rock trench surfaces; is the Corps referring to elderberry?*

EE-225 *- When these plants are newly established on rock trench surfaces, given the likely elevation and distance from water surface, could they be defensibly considered as constituting "riparian habitat?"*

EE-226 *- The Corps states that if there is insufficient space for the 66 ac of VELB mitigation on rock trench surfaces along the LAR, additional mitigation area will be needed. Could be at the Cal Expo and River Bend Park mitigation sites. Are these mitigation sites considered as really "riparian?" Certainly not the River Bend Site!!*

EE-227 *- For the LAR area, it is unclear how the 66 ac of VELB mitigation needs relates to the need for 130 ac of riparian mitigation. Can these acreages be clearly sorted out?*

EE-228 *- When and if the launchable rock trenches actually launch the rocks due to erosive bank retreat (that is, when the project functions as designed), how will the losses of real riparian vegetation along the banks, and the elderberry plants on the rock trench surfaces, be counted as impacts resulting from proper project functioning?*

Page 138-139

- It is indicated that there are 250 elderberry plants on the LAR and mitigation is based on this number.

EE-229 *- However this number was based on a 2011 survey of levee slopes and 15 ft. out from the landside toe and 30 ft. out from the waterside toe. Isn't it most likely that many more elderberry plants would be located along the LAR on berm and bank sites where*

EE-229 (Cont.)

launchable rock trenches and bank protection projects would be constructed? It appears that contrary to the introductory statement in the "measures" paragraph, the impact/mitigation is not based on a worst-case case scenario; more (perhaps much more) mitigation than stated may be required. Does the Corps really have suitable mitigation opportunities?

Page 145-147 - To reduce impact/mitigation for Swainson's hawk the Corps

- Will seek a vegetation variance to maintain vegetation on the lower half of the levee slope.

EE-230

- *But in Section 1.4.5 the variance appears to only apply to Sacto R. levees.*
  - *Will it be extended to Amer. R. levees.*
  - *What will be the impact if the variance is not approved?*

- Corps stated that for bank protection works; revetment slopes will be planted with vegetation and trees that over time will provide habitat.

EE-231

- *This seems to contradict the description of bank protection work in Section 2.3.1.*
  - *"Brush/shrubs/small trees" will be removed*
  - *Rocks will be placed among the "larger" riparian trees*
  - *Where feasible; a planting berm will be established*

EE-232

- *It seems the construction result will be revetment slopes with a few "large trees."*
  - *When these few large trees die, why wouldn't the revetment slopes prevent the reestablishment of "large" trees, or really anything?*

EE-233

  - *Under what conditions would a planting berm be established and how large would they be? If the project work uses tight tolerances (which is normally done), i.e. does not over-build conveyance capacity (to limit costs and project construction impacts/mitigation); realistically, what space will be left for planting berms?*

EE-234

  - *If the planting berms extend into the existing channel area wouldn't that result in reduced floodflow conveyance area, and therefore place more constraints on existing vegetation and mitigation revegetation, leading to net reduction in acceptable vegetation (more vegetation management to maintain floodflow conveyance capacity)?*

EE-235

  - *Practically speaking, what impact reduction could be expected from the proposed bank protection construction approach?*

- The Corps stated that 238 ac of riparian mitigation will be needed.

EE-236

- *How much is needed in the ARP?*

EE-237

- *For Swainson's hawk, specifically what riparian vegetation types or structure is needed?*

EE-238

- *Is the Woodlake/Cal Expo site suited for developing this riparian type/structure?*

EE-239

- *How does this 238 ac relate to the need for 66 ac of elderberry mitigation and the 130 ac of riparian habitat mitigation on the LAR/ARP?*
  - *Are they separate and distinct mitigation needs?*
  - *Is there some overlap?*

Page 235, 236-7 - The Corps' discussion of recreation impacts for Alternative 1 is limited to construction and temporary closures.

- For the No Action Alt. the Corps attribute land and recreation resource losses due to ongoing erosion as a significant recreation impact that is not consistent with ARPP (235).

EE-240

- However, the proper functioning of the launchable rock trenches anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched, as designed, there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of recreation areas, facilities, and values which can only be counted as impacts to the existing, pre-project, conditions. Under this levee protection approach, the impacts associated with its proper functioning and design objectives, would be identical in scope and timing with the No Action Alternative.

- Why are these impacts, which are counted as representing significant impacts for the No Action Alternative, not recognized as impacts at all for the launchable rock trench approach?

- Why is the discussion of impacts limited to the construction phase and to the construction/project footprint area?

Page 254 - The Corps states that for Launchable Rock Trench project elements: construction will occur on 11 miles of the ARP, disturbing 200 ac (65 ac of riparian habitat and 135 ac of existing levees and staging areas), lasting 10 years; resulting in significant short-term visual impacts.

EE-241

- So is this then construction on levees/banks along 11 river miles (22 linear miles of project work along 11 miles of channel) on both side of the LAR, or 11 linear miles of project work along a shorter reach of the LAR?

- The Corps states that for Launchable Rock Trench project elements: post-construction will include, a loss of 65 ac of riparian habitat; would be designed to include a planting berm, which would be planted with trees outside the 15 ft. vegetation free zone, to compensate for some of the 65 ac of lost riparian habitat; but given the time delay in the tree plantings reaching maturity, there will be significant long-term visual impacts that cannot be mitigated.

EE-242

- This "planting berm" is not mentioned in Section 2.3.1 nor indicated on Figure 1; it is not mentioned in any other resource impact section of the EIS.

EE-243

- In Section 2.3.1 the Corps states that launchable rock trench would be constructed outside the natural channel; how would the "planting berm" work and where would it be placed?

EE-244

- The design description of the launchable rock trench approach includes a prohibition against planting deep-rooted trees on the trench surface which should preclude riparian trees.

EE-245

- Except possibly on RL between Fairbairn and Paradise Beach, are there any portions of the project reach where levee toes (where the trench is to be located) are set close enough to the present LAR bank such that a planting berm (similar to that described for "bank protection" approach) added to the channel margin would be part of the launchable rock trench approach?

EE-246

- In Section 3.8.6 for VELB impacts/mitigation; the Corps states that impacted shrubs would be transplanted, that additional compensation would occur thought planting be on top of rock trenches (when possible), outside the vegetation free zone, and that it is expected that on these trench surfaces sufficient lands would be available to plant these shrubs and associated natives.

- The VELB use-area of the rock trench surfaces seems to conflict with the 65 ac of riparian habitat revegetation.

- Elderberry shrubs are not an exclusively riparian plant nor does it, on its own, constitute riparian habitat.

EE-246
(Cont.)

- Calling elderberry plants riparian does not make an elderberry replanting area riparian habitat.

- If the launchable rock trenches truly displace riparian habitat, then the 65 ac of riparian habitat replacement on the launchable rock trench surface should use truly riparian species.

- However the vegetation prohibitions in Section 2.3.1 and the most likely finished elevation of the launchable rock trench surfaces (+/- 20 ft. above low water surfaces) seems to preclude truly riparian tree species and thus riparian habitat.

EE-247

- These impacts/mitigation actions address construction and project footprint considerations. And impacts associated with the time delay in riparian tree reestablishment.. Unlike other resource sections (ie. LU, vegetation, etc.), the Corps does not associate the ongoing bank and berm erosion and the loss of land area that would result from the No Action Alt as resulting in visual impacts; Not sure why this is the case.

- The proper functioning of the launchable rock trenches anticipates (and depends on) ongoing bank erosion and retreat to launch the rocks. When the rocks are launched there will be a continuous revetment slope from the levee toe to the eroded channel margin. This slope will be absent of vegetation, habitat, and recreation values and will constitute lost visual resource quality and value. Why are these impacts, which are implicit to the expected proper functioning of the project as designed, not counted as project impacts?

Page 254 - The Corps states that for Bank Protection project elements: construction footprint would be adjacent to the bank; small trees and brush would be stripped; large trees would remain in place, anchored with rock to protect them from future erosion; and the sites will be planted with vegetation.

EE-248

- The design specifications (Section2.3.1) state that "large" trees will remain; all other vegetation will be stripped and bank stabilization work will be done, and "planting berms" would be provided where feasible. The berms are not specifically indicated in Figure 1 and there seems to be notable hedging language.

- Under what circumstances would this "planting berm be feasible and infeasible?

- Where a planting berm is infeasible, what will the post-construction vegetation look like?

EE-249

- The bank protect that would have to occur on the steep RR banks through most of the Corps' "critical reach" will not end up looking like the photos of the Sac State project area (Figures 8-10). Need a realistic description of the "bank protection" approach post-construction conditions on the steep "natural" banks that are presently pervasive through the project reach.

- The Corps states that for Bank Protection project elements: post-construction; visual impacts only seen from the river and the ARP; once vegetation is established the rock will not likely be visible from either the river or the ARP; likely to take 3-5 years to establish vegetation; Figures 8-10: indicate revegetation progress thru post-construction year 9 (2001-2010); visual effects are considered to be less than significant, sites would quickly revegetate and provide a natural looking environment similar to or enhanced from existing conditions.

EE-250

- These figures show an apparent improvement in the visual conditions at this (Sac State) project location. However, the pre-project levee and bank conditions at this site are atypical of most of the intended 11 mile project area.

- Except for the RL Fairbairn-Paradise Beach bank which has levee slopes that are adjacent to the LAR bank, and the frontage of Campus Commons golf course (which is an actively eroding bank [largely due to coarse sediment aggradation in the LAR in the RM 6 area]), most of the existing LAR banks are steep and are heavily wooded with riparian trees.

EE-251

- The Corps proposed "bank protection" approach application at these other more natural bank sites will not have a post-construction configuration as at pictured for the Sac State section and will have decidedly different pre- and post-project visual impacts than those represented by Figures 8-10.

EE-252

- Even when revegetation has reached its maximum, the rock bank will be clearly seen from the river and no observant user could mistake the rocked bank and channel margin for a natural bank.

- It is not likely that these sites will ever "look natural" or look "similar to or enhanced" compared to conditions. There are presently essentially no rare eroded banks – almost all of the banks under consideration are heavily wooded with riparian vegetation with natural un-rocked banks and shorelines.

- As noted above, the Corps proposed "bank protection" approach application at these other more natural bank sites will not have a post-construction configuration as at pictured for the Sac State section and will have decidedly different pre- and post-project visual impacts than those represented by Figures 8-10.

-- END --

Re: Draft American River Watershed Common Features General Reevaluation Report, March 2015

Ms. Baker:

We have reviewed the draft American River Watershed Common Features General Reevaluation Report, March 2015 (dGRR).

First we would like to express our gratitude for extension of the comment period to May 18, 2015. Unfortunately, we did not become aware that there are issues of concern to us with the dGRR until the last public information meeting on April 17, 2015, and, consequently, did not begin review until that time.

We wish to make the following comments on the dGRR.

Our primary concern with the dGRR is the large amount of proposed "erosion protection" on the Lower American River. In addition, we have a couple of more general comments.

Our organization, Save the American River Association (SARA), was instrumental in protecting the lands along the Lower American River from development and in the creation of the American River Parkway. Founded in 1961, we have been protecting and advocating for the River and Parkway for 54 years.

It is our viewpoint that the Lower American River is a Federal and State protected Wild and Scenic River, and the "crown jewel" of Sacramento. Consequently, any proposed actions that would have a significant adverse impact on the River and Parkway must be rigorously and completely justified before adoption by the Corps of Engineers, or State and local flood control agencies. It is clear that the "erosion protection" measures proposed in the dGRR would have an enormous detrimental impact on vegetation, wildlife, recreation, and esthetics of the River and Parkway.

FF-1 However, the justification for the "erosion protection" measures proposed in the dGRR is at best weak, and seems to proceed with a "guilt by association" approach that says if there is clearly concern with erosion risk in one part of the leveed stretch there must be reason for concern with many other areas. This is inappropriate and calls the entire "erosion protection" proposal into question.

FF-2 For example, in Figure 2-7 on p. 2-19 the dGRR presents the American River Velocity Contours from roughly Howe Ave. to Paradise Beach at 115,000, 145,000 and 160,000 cfs. The water velocities in one part of this area are quite high, around 12 feet/second (ft/sec). However, this area is not typical of the rest of the leveed section of the River. The area between roughly Howe Ave. and Paradise Beach has a relatively narrow flood channel between the levees, due to the Corps of Engineers construction of the right bank levee (as part of the Folsom Dam project in the 1950s) close to the left bank levee. However, as shown in Figures 4-4 and 4-5 of the Engineering Appendix Erosion Protection Analysis (Appendix C, Attachment E, pp. 41-2) the narrow section of floodway between roughly Howe Ave. and Paradise Beach is an anomaly. The floodway both upstream and downstream is wider, in many areas much wider, and water velocities are correspondingly lower. Thus, the figure in the dGRR itself is misleading to the reader who does not bore down into the Engineering Appendix.

FF-3 Another figure that is misleading is the dGRR Figure 4-5: TSP Recommended Features along the American River (dGRR p. 4-9). This appears to show selective areas of erosion protection work, with some areas of the left bank and levee impacted and others not impacted. However, when one goes to the Engineering Appendix Erosion Protection Analysis, Figure 6-4, we find that all the sites on the left bank that are not proposed for erosion protection are already sites of "modern revetment repair." Thus, the entire left bank or levee from the confluence of the American with the Sacramento River to the terminus of the levee upstream from the Mayhew Drain would be impacted.

FF-4 One very important feature of the proposed work, bank protection, has inconsistent diagrams between the dGRR itself and the Engineering Appendix. In the dGRR, Figure 4-9, bank protection is shown as rock covering the bank to below the waterline. There is no soil covering the rock. In the Engineering Appendix Erosion Protection Analysis (Appendix C, Attachment E, p. 64) Figures 6-1 and 6-2 show the rock covering the bank and levee covered with soil. Also, figures 6-1 and 6-2 show a trapezoidal soil trench for growth of shielding vegetation that is absent from the dGRR Figure 4-9. We think that it is critically important for any bank protection project to have soil with appropriate vegetation (grasses and small shrubs) covering the rock. We have heard in the past that this makes inspection of the rock more difficult. However, it is fairly obvious that if the soil covering is intact, the rock below must also be in place. We also support the soil trench for growth of shielding vegetation where appropriate.

FF-5 The Engineering Appendix Erosion Protection Analysis (Appendix C, Attachment E, p.7), describing the history of levee construction on the Lower American River, states: "Construction of the south levee of the American River started around 1850 and was completed in the 1910s."

FF-5 (Cont.) There is no further description of south (left bank) levee construction. This description is incomplete and misleading. The levee upstream of the Mayhew Drain (often called the Mayhew Levee) was originally constructed in the mid 1970s, apparently by the company that developed the adjacent Butterfield community. This levee was lower by about three feet than other levees in relation to flood elevation. This levee was raised by about 2.5 feet and widened by the Corps in 2008. The omission of this history in the Erosion Protection Analysis may have contributed to the inappropriate inclusion of this section of river in the proposed erosion protection.

FF-6 Another feature that is worth mentioning is that the dGRR, in Figure 2-6, Problems at Specific Locations in the Study Area (p. 2-15), shows areas of the Lower American River with "Erosion Area(s) of Concern." On the left bank, there is no indication of "erosion concern" upstream from a point about half way between Watt Ave. and the Mayhew Drain. In particular, there is no "erosion concern" on the left bank upstream of the Mayhew Drain, aka the Mayhew Levee area. We find it odd, then, that the proposed plan includes erosion protection work upstream from the point about half way between Watt Ave. and the Mayhew Drain as well as the Mayhew Levee area (dGRR Figure 4-5, p. 4-9).

FF-7 What, from our viewpoint, is the most important about the dGRR and the Erosion Protection Analysis is what is not there. That is, the Erosion Protection Analysis is actually a review of many disparate studies and models, none of which were conducted for the purpose at hand. Perhaps the most useful study is the 2D velocity modeling study by Ayers (2004). But if one asks why the upstream and downstream ends of the right bank are not designated for erosion control and the opposite stretches of the left bank are designated for erosion control, there is no analysis or cogent explanation.

FF-8 We would like to recommend some changes to the erosion protection proposals in the dGRR (Figure 4-5, p. 4-9). First, an additional alternative is desperately needed. This alternative could be called "further study" or "watch and wait." It would involve characterization of the river banks (and levees if appropriate) with sufficient detail that small to moderate erosion events could be documented and quantified. Possibly it could include a comprehensive program of bore holes to characterize the subsurface strata between the river and the levees. This work would be conducted either by the local agencies (Sacramento Area Flood Control Agency, Central Valley Flood Protection Board staff) or by a collaboration between the Corps and the local agencies. Over time, this documentation would allow decisions based on facts to guide further efforts, or to decide that further efforts are not needed. Second, we propose that the left bank from the confluence of the American and Sacramento Rivers to about Paradise Beach should be assigned to this "further study" alternative. So also would the left bank from about Howe Ave. up to the Mayhew Drain (the Mayhew Levee area) be assigned to "further study." Additionally, the right bank upstream from Howe Ave to about half way between Watt Ave. and the Mayhew Drain would be assigned to "further study." Thirdly, the left bank upstream of the Mayhew Drain would be assigned to normal operations and maintenance. The left and right banks between roughly Howe Ave. and Paradise Beach would remain as shown in Figure 4-5. These proposals derive from the flow velocities of the 2D modeling study by Ayers (2004).

The rationale in the foregoing paragraph for placing the left bank upstream of the Mayhew Drain into normal operations and maintenance derives from the following facts. There have been no

FF-8 (Cont.) reports of erosion events along the river bank from either the 1986 or 1997 flood events (Appendix C, Attachment E, pp. 6-7). Also, the 2D modeling studies (Ayers 2004) indicate that the areas of rapid flow are the same in the 115,000 cubic foot/second (cfs) as 160,000 cfs. In addition, overlays of aerial photos from before and after these flood events show no detectable erosion. Finally, there is a quite substantial terrace or bench that is about 200 feet wide between the river and the new levee for most of the length of the levee. The terrace widens to about 500 feet at the upstream end of the levee. Therefore, there is minimal chance of erosion from even large storm events undermining the levee.

In addition, we have some general comments on the dGRR. While many people are familiar with Environmental Impact Statements and Reports and there are ample resources available for becoming more informed, the same is not true of the dGRR. The dGRR would benefit from a description of how the final document is approved, and what uses it may be put to when finished.

FF-9

FF-10 Also, in the dGRR, the acronym "LPP" suddenly appears in the plan description row of the Final Alternative 2 column in table 3-25 (dGRR p. 3-53). We note that this acronym is not in the list of acronyms in the beginning of the dGRR (pp. xi-xiii). We presume that it refers to Locally Preferred Project or Proposal. This raises some important questions that should be addressed. These include who determined what the LPP is and how did they determine it? Also, was this the subject of action by the Board of the Sacramento Area Flood Control Agency or the Central Valley Flood Control Board? Was there public notice, and if so when? This is a particularly important area to elaborate on as the designation of the LPP appears to be the sole justification for the Corps selecting Final Alternative 2 as the "Tentatively Selected Plan" when Final Alternative 1 was the National Economic Development plan.

We thank you, in advance, for your attention to the issues, concerns, and recommendations above.

Sincerely,

James Morgan

Re: Draft American River Watershed Common Features General Reevaluation Report, Draft Environmental Impact Statement/Environmental Impact Report, March 2015

Ms. Baker:

First, let me express my gratitude for extension of the comment period to May 18, 2015. Given the size of the subject documents, the extra time is most appreciated.

I have reviewed in part the Draft American River Watershed Common Features General Reevaluation Report (dGRR), Draft Environmental Impact Statement/Environmental Impact Report (DEIS/DEIR), March 2015. These are my comments.

GG-1

Perhaps the most important shortcomings of the dGRR DEIS/DEIR are in what is not there. I may be reading too much into the text, but I get the distinct impression that the Corps (and possibly cooperating agencies) is/are of the opinion that they could go to construction with only the environmental documentation of this DEIS/DEIR (see text on p. ES-1). I would strongly disagree if that is the case. The DEIS/DEIR is so broad-brush and nebulous that it is not really possible for the public, other stakeholders, or relevant government agencies to assess the environmental impacts or make suggestions towards reducing environmental impacts. I would think that at least one additional Environmental Impact Statement/Report would be needed for each of the major elements of the project: the Lower American River work, the Sacramento Levee and Sacramento Weir work, and the small creeks work. Possibly even more project specific environmental documents would be needed. The final version of the DEIS/DEIR would benefit greatly from an explanation, one way or the other, as to what additional environmental impact statements/reports would be anticipated on the way to construction.

GG-2

The second important element that is missing is alternatives for the Lower American River erosion protection work. Both of the action alternatives in the DEIS/DEIR have the same erosion protection proposal for the Lower American River. Thus, for the Lower American River, the only alternatives are no action and the proposed action. This is inadequate. The Lower American River is a State and Federally protected Wild and Scenic River. It has been called the "crown jewel" of Sacramento, and receives a huge amount of recreational use (too

GG-2 (Cont.)

much in some cases). As the proposed action on the Lower American in the DEIS/DEIR is acknowledged to have significant adverse environmental impacts, it is critically important that one or more alternatives that would reduce these impacts be seriously considered.

GG-3

In that regard, allow me to share an experience that I had with you. I regularly attend the meetings of the Lower American River Task Force (LARTF). The GRR has been the topic of presentations at the LARTF. At the meeting on December 9, 2014, a Sacramento Area Flood Control Agency (SAFCA) representative stated that the dGRR was proposing to do erosion protection work in the area from H street to Watt Ave. In a subsequent meeting, on March 10, 2015, a Corps of Engineers representative stated that erosion protection work was to be in the area from Paradise Beach to Watt Ave. Imagine, then, my shock to discover at the last public information meeting on the dGRR on April 17, 2015, that erosion protection work is proposed on the left (south) bank and levee all the way from the confluence of the American and Sacramento Rivers to the end of the leveed stretch upstream from the Mayhew Drain. Additionally, work on the right bank is proposed upstream from Watt Ave. to about half way between Watt Ave. and the Mayhew Drain.

My purpose in relating the above history is to point out that the Corps (and other agencies?) had recently been considering a much smaller erosion protection work footprint than is presented in the dGRR or the DEIS/DEIR.

I propose an alternative that is taken from comments on the dGRR itself to be submitted by the Save the American River Association:

GG-4

"This alternative could be called 'further study' or 'watch and wait.' It would involve characterization of the river banks (and levees if appropriate) with sufficient detail that small to moderate erosion events could be documented and quantified. Possibly it could include a comprehensive program of bore holes to characterize the subsurface strata between the river and the levees. This work would be conducted either by the local agencies (Sacramento Area Flood Control Agency, Central Valley Flood Protection Board staff) or by a collaboration between the Corps and the local agencies. Over time, this documentation would allow decisions based on facts to guide further efforts, or to decide that further efforts are not needed.... We propose that the left bank from the confluence of the American and Sacramento Rivers to about Paradise Beach should be assigned to this 'further study' alternative. So also would the left bank from about Howe Ave. up to the Mayhew Drain (the Mayhew Levee area) be assigned to 'further study.' Additionally, the right bank upstream from Howe Ave to about half way between Watt Ave. and the Mayhew Drain would be assigned to 'further study.'... The left bank upstream of the Mayhew Drain would be assigned to normal operations and maintenance. The left and right banks between roughly Howe Ave. and Paradise Beach would remain as shown in Figure 4-5. These proposals derive from the flow velocities of the 2D modeling study by Ayers (2004)."

Note that Figure 4-5, cited in the above from the dGRR, is the same as Plate 3 and Plate 4 in the DEIR/DEIS in regard to proposed erosion protection work on Lower American River.

It is critically important that one or more alternatives with smaller footprint(s) for Lower American River erosion protection work be considered in the final environmental document. If this is not the case, the document would be inadequate or deficient under applicable statute and regulations.

GG-5

One other point. The “bank protection” alternative as shown in the lower half of Figure 1 of the DEIS/DEIR (p. 32) has bare rock on the river bank. This method of erosion protection would be significantly improved if the rock was covered with moderately cohesive dirt fill and appropriate vegetation (grasses and shrubs). This would greatly reduce the long-term adverse impacts on vegetation, wildlife, recreation, and esthetics. It would help with public acceptance of erosion protection work. I would note that the rock covering the waterside levee surface in the “launchable trench” alternative is covered with dirt fill and hydroseeded in the upper half of Figure 1. Also, in the dGRR Engineering Appendix Erosion Protection Analysis (Appendix C, Attachment E, p. 64), Figure 6-2 shows the rock covering the river bank is covered with soil. Thus, this is a viable and useful change that should be made to the bank protection alternative.

Thank you for your attention to these comments.

Sincerely

James Morgan

HH

From: Gay Jones [redacted]]
Sent: Monday, May 18, 2015 4:14 PM
To: Baker, Anne E SPK
Cc: [redacted]
Subject: [EXTERNAL] Comments on Draft Environment Impact Statement - EIR (March 2015) and Draft General Reevaluation Report (March 2015)

To Anne Baker,

Thank you for extending the comment period on these reports. However, the broad scope of the aforementioned documents begs for more study.

Following are examples of broad policy concerns and specific area concerns.

1. The best outcome will occur if the USACE works with stakeholder groups at the local level. This cannot be emphasized enough. The Lower American River Task Force is an excellent example of a local stakeholder group. It is imperative to work in concert with local representation. HH-1

2. From the public perspective, the scope of the proposal expanded greatly at the end from what had initially been discussed in print. Hence, more study is necessary. HH-2

3. Due to the numerous variances in the topography, a range of multiple alternatives are needed. HH-3

4. Significant flood control projects have already occurred upstream from Watt Avenue to the Gristmill Recreation Area:

Specifically, the entire levee at Gristmill, including modifications to the Mayhew Drain, was recently completed. This USACE and SAFCA project already meets the American River Parkway Plan 160,000 cfs goal as described on page 100 of your report. HH-4

Rip-rap with soil and plant covering is completed at the four areas deemed important. This includes an area just upstream, river left, from the Waterton Access; the area adjacent to the Larchmont Community Park; and two sites at Gristmill where "rills" occurred during levee construction.

A reassessment for the risk of flooding should be done against the backdrop of these newly completed projects. It seems the "fix-in-place" levee improvements have already been accomplished in these areas upstream, river left, from Watt Avenue.

HH-4 (Cont.)

5. Selected quotes from the American River Parkway Plan used in the report are out of context. "Erosion Control Program" section on page 88 (ARPP) discusses the balancing of many goals, "…relying on methods of protection that minimize habitat impacts…each project must consider the nature of the erosion threat and the most effective method for controlling erosion with the least damage to riparian vegetation, wildlife and the aesthetics of the final product."

HH-5

6. On pages 291 and 292 in your report discussing short term and long term impacts, it seems to justify destroying the habitat to build a levee to protect the habitat. It is a circular argument. The proposal would have such devastating impacts on the environment that there would be no environment to protect.

HH-6

Thank you for the opportunity to briefly comment on your proposals.

Gay Jones

State Water Resources Control Board

May 18, 2015

Ms. Erin Brehmer
Department of Water Resources,
3464 El Camino Avenue Room 200
Sacramento, CA 95821

U.S. Army Corps of Engineers,
Sacramento District,
Attn: Ms. Anne Baker
1325 J Street
Sacramento, CA 95814

Dear Ms Brehmer:

State Water Resources Control Board staff comments on the Draft Environmental Impact Statement/Environmental Impact Report for the American River Common Features General Reevaluation Report

The State Water Resources Control Board staff provides these comments on the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Common Features General Reevaluation Report (Project), to be implemented by the Central Valley Flood Protection Board (CVFPB) in cooperation with the U.S. Army Corps of Engineers (Corps) (State Clearinghouse Number 2009012081).

State Water Resources Control Board (State Water Board) staff have reviewed this report, as noticed at http://www.cvfpb.ca.gov/PublicNotices .

The proposed project would construct fix-in-place levee improvement measures to address seepage, slope stability, erosion, and overtopping concerns identified for the American and Sacramento River, Natomas East Main Drainage Canal, Arcade Creek, Dry/Robla Creeks, and Magpie Creek levees. In addition, the Sacramento Weir and Bypass would be widened to divert more flows into the Yolo Bypass during flood events.

Pursuant to CEQA guidelines, California Code of Regulations (CCR), title 14, section 15096, responsible agencies must specify the scope and content of the environmental information germane to their statutory responsibilities. State Water Board staff has reviewed the Draft EIS/EIR to determine if the proposed Project will have significant adverse impacts to water quality and, ultimately, the beneficial use of waters of the state.

We recognize the great importance of flood protection for the communities and farms of the Sacramento River valley and the tributary streams that would benefit by the proposed project. We understand the enormous economic risk and the risk to human life that exists without a safe, functional levee system. However, significant ecological impacts may result from the proposed project.

II-1 In general, we encourage the Corps and the CVFPB to implement alternatives which conserve to the greatest extent the existing riparian vegetation, especially large mature trees that would not likely pose a threat to the integrity of the levee banks. Alternatives that maximize meander zones should be selected. Setback levees should be used when feasible.

State Water Board staff has prepared the attached comments on the Draft EIS/EIR (see Attachment 1, Table 1). Comments which pertain to the entire project and the entire document, or which are broadly applicable throughout the DEIR/EIS, are presented first. Specific comments about specific sections of text follow in the table, to facilitate location of the sections that are the subject of the comments.

State Water Board staff thanks the CVFPB and the Corps for this opportunity to comment on the proposed project. If you have questions regarding any of the comments in this letter or Table 1, please contact:

GENERAL COMMENTS – JURISDICTION AND AUTHORITIES				
1. AUTHORITY T All waters of the state are protected under California law pursuant to the Porter-Cologne Water Quality Control Act (Porter-Cologne). All surface waters and groundwater are considered waters of the state, which include, but are not limited to, aquifers, drainages, streams, washes, ponds, pools, and wetlands. Surface water bodies may be permanent, intermittent, ephemeral or seasonal. Additional protection is provided for waters of the United States (WOUS) under the federal Clean Water Act (CWA). The Regional Water Quality Control Boards (RWQCB); and in this case, the Central Valley RWQCB, have the responsibility for protecting water quality in accordance with their regional water quality control plans (basin plans). The basin plans provide regulations pertaining to the protection of water quality and implementation measures to carry out the Basin Plan provisions in the region. Any discharges of waste that may affect water quality and, ultimately, the beneficial uses of waters of the state may be regulated by the Water Boards. . II-2 Water Board staff request that the final environmental document refer to the basin plans and incorporate mitigation measures that consider all applicable water quality standards, prohibitions, and provisions found there.				
2. FEDERAL AND STATE JURISDICTION Some waters of the state are "isolated" from waters of the U.S., or do not have a "significant nexus" to WOUS. It is important to note that some of these non-federal waters of the state may occur in the project area, and may be subject to impacts by the proposed project. When impacts may occur as a result of project activity to any waters of the state, regardless of federal jurisdiction,, a Report of Waste Discharge (ROWD) must be submitted to the appropriate Regional Water Quality Control Board, and Waste Discharge Requirements (WDRs) must be obtained from that Regional Water Board before the activity commences.				

	Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)			
Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	
II-3 We request that the Project proponent consult with the Corps and the Water Boards when performing the necessary jurisdictional determinations for surface waters within the project area, to ensure that the full extent both state and federal jurisdictional areas are accurately verified, and to ensure that appropriate regulatory pathways are followed.				
3. BENEFICIAL USE ANALYSES II-4 We request that the FEIR/EIS identify and list the beneficial uses of the identified surface waters, as outlined in the basin plans, and evaluate the project's potential impacts to those beneficial uses. All mitigation measures proposed for the protection of surface waters should present evidence that the mitigation avoids, minimizes or compensates for all potentially impacted beneficial uses.				
4. NEED FOR SYSTEM-WIDE PLANNING CONTEXT: II-5 Project planning should be conducted in the context of ecosystem-wide assessments and evaluation of the existing system for long term sustainability.[1] This includes sustainability of the Sacramento Flood Control System from a flood risk reduction perspective and an ecosystem restoration perspective (providing more frequently inundated floodplain habitat and allowing natural river processes to continue). Coordination with SAFCA projects is needed. How the Project compliments the Central Valley Flood Conservation Strategy should be highlighted (http://www.water.ca.gov/conservationstrategy/)				
8. RELIANCE ON ASSUMPTIONS THAT VARIANCES AND A PROPOSED SYSTEM WIDE IMPROVEMENT FRAMEWORK (SWIF) WILL BE DEVELOPED As stated in section 1.1 (p. 1) *"The alternatives being analyzed assume a vegetation variance would be obtained for the lower one half of the waterside levee slope on all waterways. This would allow vegetation to remain in place unless required for construction. Additionally, the No Action alternative assumes that the non-Federal sponsor would prepare a System Wide Implementation Framework (SWIF) to bring the levees into compliance with*				

[1] See, for example, Florsheim, J. et al. 2008. BioScience (2008) 58 (6): 519-529. doi: 10.1641/B580608 http://bioscience.oxfordjournals.org/content/58/6/519.full

	Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)			
Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	

Corps' Engineer Technical Letter (ETL) 1110-2-583 Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures over the next 20 to 40 years."

This is reiterated in section 1.4.5 (p. 11) where vegetation and encroachment compliance are discussed. Throughout the EIR-EIS, it is assumed that a variance from the Corps would be obtained to allow for greater retention of existing vegetation than the baseline provided in the Corps ETL 1110-2-583..

Impacts and mitigations described are contingent upon adoption of a System Wide Improvement Framework (SWIF). The SWIF is an agreement between the Corps and the non-Federal sponsor that allows the [local management agency] LMA to defer compliance with [the Corps rules on vegetation management for levees] ETL 1110-2-583. This proposed Framework is not yet adopted, and may take many different forms when it is completed.

II-6

These uncertainties lie at the basis of the entire analysis presented. No alternatives are discussed for cases where the Corps denies variance requests. Discussion of the range of possible forms that future SWIF agreements is not presented.

For these reasons, the alternatives presented do not represent a full range of possibilities. Alternatives that describe impact scenarios in the absence of a Corps variance should be provided. Alternatives that describe a reasonable range of forms that the SWIF may take are also needed.

9. INCLUSION of SAFCA PROJECTS IN THE "FUTURE WITHOUT PROJECT CONDITION"

The Sacramento Area Flood Control Agency (SAFCA) is preparing an *Environmental Impact Report for the North Sacramento Streams, Sacramento River East Levee, Lower American River, and Related Flood Improvements/Levee Accreditation Project*; this document is being prepared simultaneously with the proposed American River Common Features Project. This proposed SAFCA project would affect many miles of levees in the Common Features Project area, and proposes to do so on a schedule that could be in advance of many Common Features Project elements by many years.

II-7 Consideration of these proposed SAFCA projects should be provided in this "Future Without Project Condition" section of the EIR. A discussion of how these SAFCA projects would interact with the proposed Project should also be provided.

	Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)

Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	
COMMENTS ON SPECIFIC TEXT IN THE DOCUMENT				
10	ES		12	**DREDGE AND FILL IMPACTS TO WATERS OF THE STATE NOT DISCLOSED OR DISCUSSED IN THE EXECUTIVE SUMMARY.** II-8 Table ES.3 summarizes environmental effects and mitigation measures for three project alternatives. No effects are listed for direct impacts to surface waters of the state, including waters of the U.S. Table ES.3 mentions effects to Hydrology, Water Quality, Special Status Species, Vegetation and Wildlife. None of these topics adequately discloses impacts to waters due to the physical manipulation of the channels and levees that are to modified by the proposed Project. The Executive Summary the Final EIR/EIS should address these effects specifically; it should not be assumed that vegetation or habitat impacts are the same as impacts to waters.
		1.4.5	12	**VEGETATION AND ENCROACHMENT VARIANCE** **SWIF = system wide improvement framework** "The ARCF GRR project description (Section 2.0 below) assumes that the variance and SWIF agreements are both in place. The variance is included as a part of the proposed alternatives, while the SWIF would be a part of the future condition, both with or without the project in place" • II-9 What happens if the variance is not approved? • II-10 When is action by the Corps on the variance request expected? II-11 Much of the concern regarding levee improvements focuses on the disposition of vegetation, especially large, old trees, that are within or near the levee footprint. The proposed SWIF criteria cited in the Draft EIR/EIS states that, "Based on the engineering inspection and

		Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)			
	Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	
II-11 (Cont.)					evaluation, trees and other woody vegetation that do not pose an unacceptable threat need not be removed (bullet 1).” Bullet two continues: “In cases of levee repair or improvement projects, vegetation within the project footprint shall be removed as part of construction activities. “ This statement should be qualified as per the SWIF criteria above to emphasize that vegetation in the project footprint that does not pose an unacceptable threat need not be removed.
II-12		**3**	3.6.1	94	The regulatory setting for vegetation and wildlife impacts lists only local government agencies and ordinances. The Regional Water Quality Control Board, through the Clean Water Act section 401 certification process, should be included. Inclusion of the Department of Fish and Wildlife and the US Fish and Wildlife Service, and the various species and habitat protection laws they enforce, would also be appropriate here.
II-13		**3**	3.6.2	97-98	Chapter 3.6 describes the affected environment and environmental consequences of the alternatives proposed on vegetation and wildlife. In particular, section 3.6.2 describes the methodology and basis of significance used for this analysis. One effect described which could rise to the level of significance is: *“Substantial effects on a sensitive natural community, including Federally protected wetlands and other waters of the U.S., as defined by Section 404 of the Clean Water Act.”* This statement of significance does not recognize the need for protections of wetlands and other waters under state law. Recommended rewording of this statement: *Substantial effects on a sensitive natural community, including all waters of the state as defined by Porter-Cologne, which may also include Federally protected wetlands and other waters of the U.S., as defined by Section 404 of the Clean Water Act.*

Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)

	Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	
II-13 (Cont.)					Note again that protection of vegetation and habitats that occur as wetlands, streams and associated riparian areas does not necessarily provide protection of all beneficial uses of waters of the state. The link between habitat functions, hydrologic functions, and water quality and protections provided under CWA section 404 and 401, and Porter-Cologne should be clearly disclosed as part of the discussion of impacts, significance, and mitigation proposals.
II-14			3.6.6	103	Loss of very large native trees is a significant concern for water quality as well as for fish and wildlife. The discussion of vegetation impacts and mitigations often does not clearly distinguish between loss of smaller trees (which grow back to size sooner) and loss of tall, old riparian and near floodplain overstory trees such cottonwoods. These take many decades to replace. The temporal lag for loss of this riparian forest element is therefore significant, and it may not be possible to fully mitigate for this loss. Analysis of all water quality effects, such as loss of shading on water temperature over time, associated with the loss of very large trees should be provided and should be considered when making mitigation plans.
II-15			3.6.6	103	Compensatory mitigation is proposed as follows: *"To compensate for the removal of 65 acres of riparian habitat, approximately 130 acres of replacement habitat would be created. Species selected to compensate for the riparian corridor removal would be consistent with the approved list of trees, shrubs, and herbaceous plants native to the Parkway."* How and where would this "habitat" be created? While the State Water Boards may not consider some riparian areas to be waters of the state and U.S., impacts to riparian areas often lead to adverse effects on water quality – including, but not limited to, impacts to aquatic plants and wildlife. For this reason, the State Water Board recommends that proposals for riparian mitigation are clearly described in the EIR-EIS. Although riparian mitigation sites may not be permitted under CWA section 404 or as dredge and fill discharges under Porter-Cologne, State Water Board staff would categorize compensatory mitigation sites in a manner that is consistent with the Clean Water Act

		Table 1: State Water Board Staff Comments on Specific Contents of the Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) for the American River Watershed Common Features General Reevaluation Report (SCH No. 2005072046)			
	Com-ment No.	**Chapter**	**Section/ Sub-section**	**page**	
II-15 (Cont.)					mitigation rule, the "404(b)(1) guidelines," In these guidelines, we find that *Compensatory mitigation* means "the restoration (re-establishment or rehabilitation), establishment (creation), enhancement, and/or in certain circumstances preservation of aquatic resources for the purposes of offsetting unavoidable adverse impacts." The term "creation" is generally avoided in favor of the term "establishment." If the proposed mitigation sites could appropriately be characterized by this definition, the EIR should acknowledge that the CWA definitions are in use. If some other definition is intended, that definition should be provided as part of the proposal.
II-16			3.6.6	103	What is the source of approval for this "approved list" of plants to be used in this mitigation effort? Recent research is showing that a diverse set of plants is needed for successful revegetation efforts. In addition to the common species, representatives of the uncommon species – which may make up a large proportion of the species list of a site, but only a very small percentage of overall prevalence or dominance – is necessary at the planting stage. These less common species have been shown to not repopulate areas after revegetation with dominant species, even decades after restoration work. Timing of revegetation is also critical in that it should not be assumed that a single episode of planting can be sufficient. Repeated cycles of planting over many years should be considered to help mimic natural patterns of recruitment and succession.
II-17			3.6.6	103	Compensatory mitigation site plans and restoration plans for areas of temporary disturbance should include a long term commitment to monitoring of the performance and condition of the site. All monitoring and assessment should be conducted using methods that are consistent with guidance provided by the California Water Quality Monitoring Council.
II-18			4.2.4,	286	The discussion of cumulative effects on special status species focuses on condition of riparian vegetation, and once again assumes issuance of a variance from the Corps. No discussion or analysis of alternatives where the variance is not obtained is provided.

County of Sacramento Comments on the Draft EIS/EIR for the American River Common Features GRR

Dear Ms. Baker:

Thank you for providing Sacramento County the opportunity to provide comments on the proposed project's Draft EIS/EIR (Document). These comments supplement the comments we provided verbally to the recorder at the April 15th meeting at the Tsakopoulos Library Galleria. The County's concerns are primarily related to impacts to the American River Parkway (Parkway) and secondarily associated with the project's
JJ-1 proposed soil borrow operations. Our concerns with the Parkway analysis include impacts that have not been evaluated and a lack of specificity in the project and alternatives descriptions.

JJ-2 This project may result in loss of use, access, and subsequently, revenue, to the
Sacramento County Department of Regional Parks (Parks Department), through daily
fees, special event fees, annual pass sales, and other park revenues. In particular,
JJ-3 potential impacts to the Campus Commons Golf Course were not disclosed. In
JJ-4 addition, project areas may not have viable detour routes for equestrians on the
Parkway's designated equestrian/hiking trails. Access to angling, wildlife viewing,
JJ-5 rafting and other river-based activities may be limited by construction activities.
Furthermore, special events such as Eppie's Great Race, May is Bike Month activities,
JJ-6 fun runs, and other trail-based events use facilities that could be closed, detoured out of
the Parkway, or otherwise impacted by construction. All of these impacts may result in
loss of Parks revenue, which should be mitigated.

In addition to loss of revenue, the Parks Department may incur additional costs due to
the construction of this project. New ramps and haul roads may increase social trails
JJ-7 (unofficial trails) and visitor use in some areas, leading to additional natural resource
damage, fire risk and suppression costs, social trails management, maintenance, and
ranger patrol to areas not previously utilized by the public. The additional on-going

costs to manage these areas could be mitigated through funding a social trails management plan.

JJ-8 The Document describes the impacts associated with detouring traffic from the paved trails on the American River Parkway. To avoid past USACE contractor difficulties of communicating trail detour information, we recommend that mitigation include funding a public outreach program that is staffed by Parks Department personnel. A Parks Department staffed outreach program would maximize communication with the target audience, minimize confusion, and provide greater overall coordination to better mitigate recreational impacts. Mitigation, of longer term construction detours, on the south side of the Parkway, could also include completion of the planned Two Rivers Trail, to provide alternative detour options that minimize the impacts of detouring traffic onto surface streets.

JJ-9 We would like the project to have the potential to consider borrow sites on the American River Parkway, as there may be areas where park managers desire floodplain lowering. JJ-10 In addition, please be advised, that many of the proposed borrow sites will require County and State permitting, pursuant to the Surface Mining and Reclamation Act (SMARA). The County Department of Community Development is the SMARA lead agency for unincorporated Sacramento County and should be contacted early in the process once a borrow site is known.

In addition to the comments above, we request clarification regarding the clearing and stripping of small vegetation on bank protection sites:

JJ-11
1. What criteria are established to determine which vegetation is large and which is small?

JJ-12
2. If large trees are to be left in place, will these trees be considered in the hydraulic modeling for conveyance? And if modeled, will this information be sufficient to replace these trees (with new plantings) when they die without having to re-model the roughness coefficient and conduct new permitting through the Central Valley Flood Protection Board.

JJ-13
3. What kind of vegetation, both planted and naturally occurring, will be allowed to occur on top of either alternative?

JJ-14
4. Will trees that die during or after the project is completed, due to construction impacts, be mitigated?

JJ-15
5. Figure 1 of the bank protection area does not include a planting berm, but it is indicated in the text: Should a planting berm be indicated in Figure 1 and how would it work?

JJ-16
6. The discussion of the vegetation variance in section 1.4.5 appears to be specific to the Sacramento River: Will this variance also apply to the levees on the American River?

JJ-17
7. Have project impacts been evaluated should the vegetation variance not be applied to the American River levees?

JJ-18

8. As an element of the restoration of disturbed areas, native grasses and small shrubs would be planted "where appropriate." What criteria are used to determine the appropriateness of the replanting?

JJ-19

9. In the "no action" alternative, it is assumed that the land and habitat loss will happen over time: Can this loss, and timing of loss, be estimated with existing modeling?

We also have reservations and concerns about the consequences of choosing launchable rock trench for protection of the Parkway levee. Our specific questions include:

JJ-20

1. The design indicates a maximum width of 70 feet and 23 foot deep trench: Is the 70 foot width measured at the bottom or the top, and what is the total footprint required to terrace a 23 foot deep trench?

JJ-21

2. In the "no action" alternative, the expected bank erosion is listed as a significant impact, while at the same time; the launchable rock trench also would allow significant bank erosion to occur: Why are the impacts of the launchable rock trench, including the loss of habitat and land, not disclosed as significant project impacts?

We understand from participating in the April 15th public comments session that this Document was written at a program level, but this was not apparent in the Document itself. Please clearly state in the Document that there will be additional project level
JJ-22 environmental analysis, with a commitment to additional outreach and cooperative planning. Ongoing coordination of site specific designs on the Parkway should also be
JJ-23 coordinated with recommendations from the Lower American River Task Force.

If you have any questions please contact John Lundgren at (916) 874-8043 or lundgrenj@saccounty.net.

Sincerely,

for - Catherine Hack

RE: American River Common Features

Dear Ms. Baker,

I am writing to encourage the Army Corps of Engineers, Sacramento District, to continue to work with local districts and agencies as they move forward with the proposed levees along the American River Parkway.

The American River Parkway is of great value to our community. I understand the importance of your work, and appreciate the considerations that are being undertaken during the planning stages of this project. However, I do encourage you to consider the feedback from agencies such as Sacramento Regional Parks and the Butterfield - Rivera East Community Association.

It is my firm belief that by working together, a plan can be made that will balance safety and flood resilience with access to natural habitats and recreation areas. Again, I thank you for your diligent work on this matter. Please do not hesitate to reach out to me should you ever require my assistance.

Sincerely,

Ken Cooley

Ken Cooley
Assemblymember, 8th District

Comment Number	Commenter	Method of Submission	Category	Response
A-1	Sandra Maxwell	Public Meeting Transcript	Flood Insurance	Verano Street is not located immediately adjacent to any of the planned work activity areas. The proposed project would strengthen levee stability and improve flood protection for the Sacramento region. The determination of flood insurance rates does not relate to the environmental analysis contained in the EIS/EIR. Cleanup of trash and other debris is a City and/or County maintenance issue.
B-1	Beverly Nason	Public Meeting Transcript	Construction Impacts	Comment noted. Minimization and mitigation measures are proposed to reduce potential impacts from construction vibration.
B-2	Pamela Bigelow	Public Meeting Transcript	O&M and Construction Impacts	The trees that would be removed as part of the ARCF GRR are limited to the trees that would be directly impacted by construction of the project. The Corps understands the commenter's concerns related to the use of staging areas within existing developed neighborhoods. However, such staging areas are necessary to carry out the proposed project. The Corps will minimize disturbance in the staging areas to the extent feasible. The commenter's concern for this potential fire hazard is appreciated and this issue will be brought to the attention of the appropriate State levee maintenance agency.
B-3	Shirley Short	Public Meeting Transcript	Public Meeting Format	The purpose for the public meeting was to provide interested members of the public and agencies with an opportunity to provide comments on the environmental analysis and to respond to questions regarding the proposed project.
B-4	Craig Carroll	Public Meeting Transcript	Vegetation Removal, Privacy During Construction, and Encroachment removal.	Under the ARCF GRR, the trees proposed for removal are limited to the trees that would be directly impacted by construction of the project. High hazard tree removal is a separate action being conducted by SAFCA. The Corps tagged trees in 2011 as part of preliminary vegetation surveys that were used to establish a baseline condition and effects analysis for this EIS/EIR. The Corps tags do not indicate that a tree is proposed for removal. The Corps appreciates the commenter's concern over privacy during construction; however privacy fences between construction activities and adjacent properties are not proposed as part of the project. Permitted encroachment removal would be coordinated between the non-federal sponsors and the owners, and would be replaced following construction.
C-1	John Lundgren, on behalf of Jeff Leatherman	Public Meeting Transcript	Recreation Impacts	The recreation section of the EIS/EIR has been updated with more detail, including these concerns. The Corps is committed to coordinating with County Parks prior to implementation of construction.
C-2	John Lundgren	Public Meeting Transcript	Borrow Sites	The Corps or its contractor would consult with Sacramento County and ensure receipt of all applicable permits prior to construction. The Corps has not proposed any activities in the Dry Creek Parkway, however SAFCA has proposed a borrow site within the parkway. SAFCA would coordinate with Sacramento County regarding any work in the Dry Creek Parkway if that borrow site is selected for use.
D-1	Pat Hara and Jack Burrows	Public Meeting Transcript	Flood Insurance	This comment does not relate to the environmental analysis contained in the EIS/EIR; the comment is noted.
D-2	Judith Scott	Public Meeting Transcript	Public Meeting	Thank you for your comments.
E	Lissa McKee	Comment Sheet	Various	Thank you for your comments.
F	Carolyn Baker	Comment Sheet	Tree Removal	SAFCA intends to implement the specific levee improvements in the North Sacramento Streams and Sacramento River East Levee areas; other improvements identified in the ARCF GRR would be implemented by the Corps. The Corps Sacramento District will apply for a variance to the vegetation policy and if granted would only remove vegetation within the footprint necessary for construction under the ARCF GRR. The local maintaining agencies are responsible for any further vegetation maintenance activities.

G	Ellen Broms	Comment Sheet	O&M and Construction Impacts	SAFCA understands the commenter's concerns related to the use of staging areas within existing developed neighborhoods. However, such staging areas are necessary to carry out the proposed project. SAFCA will minimize disturbance in the staging areas to the extent feasible. SAFCA's Vegetation Management Decision Key (included as Appendix B of the Levee Accreditation Program DEIR) states that fruit- and nut-bearing trees will be assessed and removed from both landside and waterside levee slopes. Fruit- and nut-bearing trees at these locations were identified as high-hazard trees for removal as part of the proposed project. The locations of trees that would be removed as part of the proposed project are shown on Exhibit 3-17 in Chapter 3, of SAFCA's EIR "Project Description" (page 3-110 of the DEIR).
H	Mary Schwartz	Comment Sheet	Public Meeting Format & Construction Schedule	The Corps will ensure that the commenter's address is added to the final mailing list. Comments regarding meeting format and schedule are noted.
I-1	Dan Kopp	E-mail	Vegetation Removal	The tagged trees by your house may not necessarily be associated with this project, but your description of the locations of the tagged trees sound like they could be from the 2011 tree survey that was conducted by this project. The 2011 tree survey was conducted as preliminary information only and does not necessarily indicate that the trees will be removed. The trees were tagged and logged into a GIS database for data purposes only. No trees have been definitely identified for removal at this time. In the preconstruction engineering and design phase of the project following Congressional authorization, site-specific analysis would be conducted prior to construction to determine specific impacts, including which trees would be need to be removed for construction purposes only.
I-2	Dan Kopp	E-mail	Wildlife Impacts	Tree removal would occur outside of the nesting season and would be monitored by a biologist to ensure that no impacts occur to nesting birds.
I-3	Dan Kopp	E-mail	Typos	Thank you for your comment.
J-1	Stan Jones	E-mail	Public Accessibility During Construction	It is unclear what the purpose would be for providing "viewing areas" for members of the public to see the project-related construction activities. Furthermore, such "viewing areas" would result in a safety hazard for members of the public in proximity to construction equipment, and would not reduce the environmental impacts of the proposed project in any way.
J-2	Stan Jones	E-mail	Public Levee Access	Levee encroachments would be replaced following construction based on existing CVFPB encroachment permits.
J-3	Stan Jones	E-mail	Tree Removal	SAFCA proposes to remove high hazard vegetation as a part of their Levee Accreditation Program. The specific locations of proposed high hazard vegetation can be found in SAFCA's EIR on Exhibits 3-18 (Chapter 3, "Project Description"), and 4.6 3a through 4.6 3d (Section 4.6, "Biological Resources – Terrestrial"). Details regarding the evaluation criteria for trees and other vegetation that would be removed are contained on pages 3 48 through 3 50 of Chapter 3, "Project Description," and in DEIR Appendix B.
K-1	Janet Fullwood	E-mail	Seepage	Both SAFCA and the Corps propose to address seepage concerns through the construction of seepage cutoff walls, including at the location of the commenter's home.
K-2	Janet Fullwood	E-mail	O&M	SAFCA is proposing to construct the seepage and stability improvements in this portion of the ARCF project area. SAFCA will bring this issue to the attention of the appropriate State levee maintenance agency. SAFCA also notes that proposed Conservation Strategy Policy SSP-1 requires that construction vehicles and equipment must be cleaned inside and out at an authorized washing facility before arrival at the project construction areas and must be inspected in an attempt to ensure they are free of soil and debris that could harbor nonnative plant seeds, roots, or rhizomes. If invasive or noxious weeds are already present in portions of the project areas, vehicles must be cleaned before moving from infested areas to areas that are weed free. Exterior cleaning must consist of pressure washing vehicles and equipment, with close attention paid to the tracks, feet, and/or tires and on all elements of the undercarriage. Vehicle cabs must be swept out, and refuse must be disposed at an approved off-site location.
L	James Geary	E-mail	Public Levee Access	Levee encroachments would be replaced following construction based on existing CVFPB encroachment permits.
M	Maggie Beddow	E-mail	Public Levee Access	Levee encroachments would be replaced following construction based on existing CVFPB encroachment permits.

N-1	United Auburn Indian Community of the Auburn Rancheria	E-mail	Alternatives	CEQA Guidelines 15126.6(e)(2) refers to the identification of the No Action Alternative, which was included in accordance with the cited regulations. Identification of the Least Environmentally Damaging Practicable Alternative (LEDPA) is required as a part of the Section 404(b)(1) Analysis and is included in Appendix E of the EIS/EIR. For this project, Alternative 2 is identified as the LEDPA.
N-2	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps attempts to avoid impacts to known cultural resources wherever possible. The consideration of setback levees, stability berms, and seepage berms, is made and incorporated where feasible. The Corps welcomes the opportunity to consider the specific design features the UAIC would like incorporated to reduce the potential for direct cultural impacts. Corps cultural resources staff followed up with UAIC in a letter dated July 7, 2015, in a staff-to-staff consultation meeting on August 6, 2015, and in emails dated August 10 and 17, 2015 requesting this specific information. The Corps has not only consulted during the planning phase, and will continue to consult with UAIC throughout the design and construction phases of the project.
N-3	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps values the role that Native American tribes, including the UAIC, has as a Tribe, government, and partner. UAIC is identified within Section 5.0 (Compliance with Applicable Laws, Policies, and Plans) as a Native American tribe. Within Section 6.0 (Consultation and Coordination) there is extensive description of efforts to consult with tribes, including UAIC. These concerns and a process for addressing them are reflected in the Programmatic Agreement for ARCF as well as the EIS/EIR. As a consulting party, the UAIC, and its comments, are given consideration by the Corps from the initiation of consultation through to the fulfillment of the Section 106 process, and in many cases, beyond. The Corps has not only consulted during the planning phase, and will continue to consult with UAIC throughout the design and construction phases of the project.
N-4	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps appreciates the opportunity to consider tribe/tribal values throughout the document. The Corps has added to section 3.9.1 "Cultural Resources Site Types" descriptions for Traditional Cultural Properties and Traditional Cultural Landscapes which address sites of importance to tribes, and are resource category types directly related to tribal values that tribes have indicated to the Corps are important. Language has been added to ES.9 (Areas of Controversy and Unresolved Issues) to consider effects to cultural resources and resources significant to tribes.
N-5	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The NEPA/CEQA process allows participation through the public comment period. Further, we are currently engaged in government-to-government consultation with the UAIC. The Corps and the CVFPB will provide the updated EIS/EIR to the Tribe at the next public review period (tentatively scheduled for January 2016) and welcome the Tribe's ongoing participation at that time.
N-6	United Auburn Indian Community of the Auburn Rancheria	E-mail	Alternatives	The Corps has considered a reasonable range of alternatives, as required by NEPA. The Corps considered a wide variety of alternatives to reduce flood risk to the city of Sacramento. Further, the Corps provided an extensive explanation for all alternatives considered, but not carried through. Because the levees surrounding the City are in such poor shape, the most effective plan to reduce that risk is to improve the existing levees in place. A setback levee with a seepage berm is recommended for the Sacramento Bypass north levee which would approximately double the floodplain area. The remainder of the levees are adjacent to urban development with little to no available land for a levee setback or seepage berm. These levees would be improved with a slurry cutoff wall through the center of the levee. The top half of the levee would be removed to create a construction platform while the bottom half of the levee on both sides would remain intact.

N-7	United Auburn Indian Community of the Auburn Rancheria	E-mail	Public Review	The Corps and CVFPB would supplement the EIS/EIR in accordance with NEPA/CEQA regulations, if needed. Under CEQA, a lead agency is required to recirculate an EIR when significant new information is added to the EIR after public notice is given of the availability of the draft EIR for public review under Section 15087 but before certification. As used in this section, the term "information" can include changes in the project or environmental setting as well as additional data or other information. New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect (including a feasible project alternative) that the project's proponents have declined to implement (14 CCR Section 15088.5). Under NEPA, the Corps shall prepare supplements to either draft or final environmental impact statements if: (i) The agency makes substantial changes in the proposed action that are relevant to environmental concerns; or (ii) There are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts (40 CFR 1502.9[c]). Additionally, under NEPA the Corps is required to circulate the Final EIS to the public prior to approval. Currently release of the Final EIS is tentatively scheduled for early 2016.
N-8	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps appreciates UAIC's suggestion to evaluate effects to cultural resources and propose treatment prior to construction beginning. The Programmatic Agreement (PA) (Enclosure 1 of Appendix C of the DEIS/DEIR) includes stipulations (Stipulation III - "The HPMP [which provides the framework by which remaining identification, evaluation of eligibility, findings of effect, and resolution of adverse effect efforts] shall be developed after execution of the Agreement, but before construction commences." and Stipulation IV - "The Corps shall complete any identification and evaluation, and as necessary, any evaluation of effects to Historic Properties prior to proceeding with construction") for the identification and evaluation of cultural resources as construction details become available. Additionally, the PA outlines many potential treatment options for adverse effects to historic properties, not limited to data recovery. These potential treatment options would be developed in consultation with the SHPO and Native American tribes.
N-9	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps has added to section 3.9.1 "Cultural Resources Site Types" descriptions for Traditional Cultural Properties and Traditional Cultural Landscapes which address sites of importance to tribes, and are resource category types directly related to tribal values that tribes have indicated to the Corps are important. The PA includes procedures to consult with tribes on identification, eligibility, and evaluation determinations (Stipulations III, IV, VI, XI) for sites of importance to tribes, throughout its implementation.
N-10	United Auburn Indian Community of the Auburn Rancheria	E-mail	Alternatives/Cultural	Preservation in place is considered as a potential mitigation for cultural resources. Where appropriate, avoidance is the preferred mitigation measure. The Corps has added to section 3.9.1 "Cultural Resources Site Types" descriptions for Traditional Cultural Properties and Traditional Cultural Landscapes which address sites of importance to tribes, and are resource category types directly related to tribal values that tribes have indicated to the Corps are important. The PA includes procedures throughout implementation to consult with tribes on identification, eligibility, and evaluation determinations (Stipulations III, IV, VI, XI) for sites of importance to tribes.
N-11	United Auburn Indian Community of the Auburn Rancheria	E-mail	Utilities/Cultural	Utility relocations, including PG&E lines, are addressed in the EIS/EIR under the Utilities Section (Section 3.16). There is the potential that relocation of underground utility lines could impact cultural resources. During the design phase of the project, site-specific analysis would occur prior to construction, including any impacts associated with utility relocations and associated cultural resources impacts. The Corps will continue to consult with UAIC throughout the design and construction phases of the project.

N-12	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cumulative/Cultural	The cumulative impacts to cultural resources are considered in the EIS/EIR. NEPA and CEQA require the consideration of unavoidable impacts to cultural resources, to include cumulative impacts. The cumulative impact section does not state that "cultural resources are typically not subject to cumulative effects". The document states that "cumulative overall impact to non-renewable cultural resources is likely, as well as significant and unavoidable." The section further states that the project is addressing effects (to include mitigation) through the execution of a PA.
N-13	United Auburn Indian Community of the Auburn Rancheria	E-mail	Borrow/Staging	At this time, no borrow sites and staging areas have been identified for the project. Typical impacts of borrow activities have been analyzed throughout the EIS/EIR, including some updates in the Final EIS/EIR based on project review. If additional impacts occur beyond those described in this EIS/EIR, the Corps would produce a supplemental NEPA/CEQA document, as appropriate.
N-14	United Auburn Indian Community of the Auburn Rancheria	E-mail	Vegetation	For the purposes of this EIS/EIR, the Corps took a conservative approach in analyzing wetlands, and considered all potential wetlands jurisdictional. Wetland delineations will be conducted on a site-specific basis prior to construction. If the delineation determines that there are significant impacts to wetlands beyond those addressed in this document (Sections 3.5, 3.6, and 3.8), then a supplemental NEPA document may be required.
N-15	United Auburn Indian Community of the Auburn Rancheria	E-mail	Construction Details	A Corps project does not take into consideration the requirements for FEMA. Local entities work directly with FEMA to determine if they are in a regulatory floodplain and the implications of any land use restrictions. For bank protection work on the Sacramento River, it is likely that barges will be used.
N-16	United Auburn Indian Community of the Auburn Rancheria	E-mail	NEPA	During the preconstruction engineering and design phase of the project, the Corps will be designing each phase of the project on a site-specific basis. During this site-specific design, an analysis will be conducted to determine whether the impacts are consistent with those described in this EIS/EIR or whether supplemental NEPA analysis would need to occur.
N-17	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	Thank you for your comment regarding the potential need for vibration or compression effects of the project on cultural resources. These types of studies have not been conducted but may be considered appropriate at a later stage of the project once more specific design details are known. Effects to historic properties will be evaluated in accordance with Stipulations III and IV of the PA.
N-18	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	Thank you for your comment regarding the potential need for vegetation impacts of the project on cultural plants, including mounds or cultural landscapes. These types of studies have not been conducted but may be considered appropriate at a later stage of the project once more specific design details are known. During the design phase, site specific analysis would occur and localized effects at each site would be evaluated to determine what additional studies may need to occur.
N-19	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	The Corps appreciates the suggestion and will consider this as future mitigation for the project, which would be determined through the execution of the PA. At present the Corps is not aware of an existing mitigation bank for cultural resources.
N-20	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	Regarding post-approval technical studies for cultural resources, 36 CFR Part 800.14(b)(1)(ii) allows that a PA be used when effects on historic properties cannot be fully determined prior to approval of an undertaking. Specific to the project, the PA will allow for the Corps to follow the Section 106 process to identify historic properties, evaluate their National Register eligibility, assess potential adverse effects, and, if necessary, resolve adverse effects. Regarding other technical studies, the ARCF GRR is a study that evaluates the alternatives and proposes a plan for authorization by Congress. Following Congressional authorization, further studies will occur during the design phase, including site specific engineering and environmental analyses, such as construction plans and specs, wetland delineations, and other more detailed design-level efforts.
N-21	United Auburn Indian Community of the Auburn Rancheria	E-mail	Climate Change	Raising structures was analyzed in the initial array of alternatives in the GRR under "Non-structural Measures" and eliminated from further consideration, and explained why. In the EIS/EIR, this process is summarized in Section 2.1.2 under "Non-Structural Measures".

N-22	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	Under "Cultural Resource Types" there is a section that describes Traditional Cultural Properties (TCPs) that is directly quoted in part from National Parks Service Bulletin 38. A section to describe the Advisory Council on Historic Preservation's definitions of traditional cultural landscapes has also been added to this section. The Corps will continue to consult with the UAIC and other tribes throughout the implementation of the project regarding the importance of place, setting, and landscape to the tribe and will follow up with a request for this information.
N-23	United Auburn Indian Community of the Auburn Rancheria	E-mail	Cultural	NAHC is listed in the EIS/EIR's list of recipients as a State agency that received a copy of the draft report.
O-1	California Department of Transportation	Letter	Bridge Design/H&H	Concur. The Corps will evaluate site-specific conditions, including impacts to critical bridges during site-specific design in the design phase of this study known as Preconstruction, Engineering and Design (PED).
O-2	California Department of Transportation	Letter	Bridge Design	Where project features interface with Caltrans bridges, appropriate steps in PED phase will be taken to coordinate bridge access.
O-3	California Department of Transportation	Letter	Bridge Design/H&H	Concur. The Corps will evaluate site-specific conditions, including impacts to bridge embankments during site-specific design in the design phase of this study known as Preconstruction, Engineering and Design (PED).
O-4	California Department of Transportation	Letter	Bridge Design	Any bridge modifications to incorporate project features will be designed based on current Caltrans design codes and criteria.
O-5	California Department of Transportation	Letter	Bridge Design	Project flood features, including floodwall and levee heights, will be coordinated during PED phase.
O-6	California Department of Transportation	Letter	Transportation	Prior to construction, the Corps and/or its construction contractor will prepare a Traffic Control and Road Maintenance Plan. Hauling by barge is possible for bank protection repairs on the Sacramento River. For this measure, the Corps will consider hauling by barge to reduce truck traffic impacts.
O-7	California Department of Transportation	Letter	Transportation	Detours would be provided during construction for all impacted bike trails. Levee encroachments would be replaced following construction based on existing CVFPB encroachment permits.
O-8	California Department of Transportation	Letter	Transportation	The Corps will continue to provide documents to CalTrans for review, as appropriate.
P-1	California Department of Fish and Wildlife	Letter	Biological Resources	Section 3.6 has been expanded to include analysis of habitat types in the study area, including sensitive habitats. State-listed species have been added to the analysis in Section 3.8.
P-2	California Department of Fish and Wildlife	Letter	Vegetation	Section 3.6 has been expanded to include impact analysis to sensitive species. Habitat maps of the study area have been added as Appendix B of the EIS/EIR.
P-3	California Department of Fish and Wildlife	Letter	Fisheries	The analysis in Section 3.7.5 has been expanded to elaborate on potential impacts to fish species in the Sacramento Bypass, to include fish passage through the bypass and stranding.
P-4	California Department of Fish and Wildlife	Letter	Fisheries	The impact analysis in Section 3.7.4 has been expanded to address predation at bank protection sites.
P-5	California Department of Fish and Wildlife	Letter	Vegetation	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
P-6	California Department of Fish and Wildlife	Letter	Fisheries	The Corps is not proposing to alter the existing Sacramento Bypass under this action. The Corps is proposing to design the newly widened Sacramento Bypass in a manner to ensure positive drainage, which would prevent further stranding of fish in this area.
P-7	California Department of Fish and Wildlife	Letter	Agriculture	Concur. The final EIS/EIR will be updated to reference the current land uses in the proposed widened Bypass area.

P-8	California Department of Fish and Wildlife	Letter	Land Use	After project construction, the CVFPB will evaluate the appropriate course of action regarding the future land use in the Bypass.
P-9	California Department of Fish and Wildlife	Letter	Recreation Impacts	The CVFPB staff coordinated with CDFW to discuss recreation impacts in the Sacramento Bypass, and the recreation section of the EIS/EIR has been updated in response to those discussions to elaborate on impacts to recreation and access. Through these discussions, it was determined that no additional mitigation measures to address recreation impacts needed to be added to the EIS/EIR at this time.
P-10	California Department of Fish and Wildlife	Letter	Recreation Impacts	The CVFPB staff coordinated with CDFW to discuss recreation impacts in the Sacramento Bypass, and Section 3.14.5 of the EIS/EIR has been updated in response to those discussions to include potential restrictions for hunting during some aspects of construction. However, it is anticipated that there would be no conflict for the majority of the construction period, because construction would be occurring outside of the existing bypass with the levee providing a barrier between the wildlife area and the construction area.
P-11	California Department of Fish and Wildlife	Letter	Land Use/GGS	After project construction and turn over, the CVFPB will evaluate the appropriate course of action regarding the future land use in the Bypass. Impacts to GGS associated with removal of canals has been coordinated with USFWS and is included in the Biological Opinion appended to the final EIS/EIR.
P-12	California Department of Fish and Wildlife	Letter	Invasive Species	Section 3.6 was updated to include impact analysis and measures to prevent the spread of invasive species during construction of the project.
P-13	California Department of Fish and Wildlife	Letter	Fisheries	Language was added to the EIS/EIR in both the project description and the Fisheries analysis to reflect that during construction, the expanded bypass would be sloped to the south and graded in a manner consistent with the existing bypass to provide positive drainage.
P-14	California Department of Fish and Wildlife	Letter	Special Status Species	The new north levee of the Sacramento Bypass would be consistent with the existing north levee of the bypass. Impacts to listed species were analyzed with this design considered.
P-15	California Department of Fish and Wildlife	Letter	HTRW	The local sponsors are required to acquire all necessary lands and easements to facilitate the project. Lands acquired for the project must be free of contamination. As a result, they would be required to ensure that the appropriate parties remediate the landfill prior to providing the lands to the Corps for project implementation. As a result, the landfill remediation is not considered to be a part of the proposed action. Any environmental compliance activities associated with the remediation would be the responsibility of the entity conducting the remediation of the site.
P-16	California Department of Fish and Wildlife	Letter	Borrow Sites	Thank you for your comment. We will take this into consideration when selecting final borrow sites during the preconstruction engineering and design phase of the project.
P-17	California Department of Fish and Wildlife	Letter	Borrow Sites	At this time, no borrow sites have been identified for the project. Typical impacts of borrow activities have been analyzed throughout the documents, including some updates in the Final EIS/EIR based on project review. If additional impacts occur beyond those described in this document, the Corps would conduct supplemental NEPA/CEQA compliance analyses, as appropriate. If a borrow site is used as a future mitigation site, the conditions of the site would be improved to provide mitigative habitat beyond the existing condition of a borrow site. Borrow site restoration only includes returning it to pre-project conditions. Mitigation would involve creation of new habitat beyond what was existing prior to borrow activities.
P-18	California Department of Fish and Wildlife	Letter	Borrow Sites	Thank you for your comment. We will take this into consideration when selecting final borrow sites during the preconstruction engineering and design phase of the project.
P-19	California Department of Fish and Wildlife	Letter	Land Use	The EIS/EIR has been updated to describe the existing land use and public access in the Sacramento Bypass, and its operations by both CDFW and DWR.
P-20	California Department of Fish and Wildlife	Letter	Editorial/Land Use	Editorial changes to the EIS/EIR have been made as recommended. After project construction, the CVFPB will evaluate the appropriate future land uses in the Bypass.

P-21	California Department of Fish and Wildlife	Letter	Fisheries	The Corps has not conducted any studies at this time to assess fish passage through the Sacramento Bypass. As a term and condition of the NMFS Biological Opinion, the Corps has committed to conducting monitoring in order to assess these effects. Section 3.8 of the EIS/EIR has been updated to include fish passage measures, measures to prevent stranding, and the other terms and conditions of the Biological Opinion. The final Biological Opinion, with a finding of no jeopardy to listed species, is included as Appendix J of the EIS/EIR.
P-22	California Department of Fish and Wildlife	Letter	Fisheries	Section 3.8 of EIS/EIR has been updated to include further discussion of impacts to listed fish species from stranding and passage concerns. In accordance with the NMFS Biological Opinion, the mitigation section has been updated to reflect the terms and conditions and reasonable and prudent measures, including proposed fish passage measures for the study. Prior to construction, detailed design will occur and these measures will be refined and expanded. At that time, an analysis will occur to determine whether additional NEPA analysis needs to occur. Additional coordination with the resource agencies and other local action agencies would occur during detailed design to ensure that the project is designed to allow for fish migration and passage through the bypasses.
P-23	California Department of Fish and Wildlife	Letter	Fisheries	Concur, the construction window discussion has been updated. A general assumption of August 1 to November 30 was assumed, however this assumption will be reconsidered on a site-specific basis, depending on what species are known to be present and the proposed construction activities at each site.
P-24	California Department of Fish and Wildlife	Letter	Project Design	Concur. Site specific designs would occur during the preconstruction engineering and design phase of the project, to include consideration of fish stranding.
P-25	California Department of Fish and Wildlife	Letter	BA	The compensation times cited in the BA were developed during ongoing consultation with NMFS and USFWS through a variety of Corps programs and are based on the species' life cycles.
P-26	California Department of Fish and Wildlife	Letter	BA/Fisheries	The final BA was transmitted to NMFS and USFWS on 4/3/15 and Biological Opinions have been received from USFWS and NMFS (Appendix J). The Corps acknowledges CDFW's comments and concerns, and should consultation be reinitiated, the Corps will consider incorporating these comments.
P-27	California Department of Fish and Wildlife	Letter	BA/Fisheries	Comment noted.
P-28	California Department of Fish and Wildlife	Letter	BA/Fisheries	Comment noted.
P-29	California Department of Fish and Wildlife	Letter	BA/Fisheries	The life cycles discussion in the EIS/EIR has been updated to focus more on what stages are expected to occur in the study area.
P-30	California Department of Fish and Wildlife	Letter	BA/Fisheries	The Corps' Sacramento River Bank Protection Project has been monitoring bank protection sites to determine optimal designs and effects of these sites on juvenile salmonid species. The results of these studies will be used during site-specific design of the ARCF GRR project to ensure that bank protection sites include features that benefit salmonid species long-term. Additional monitoring of salmonid species is not proposed for this action; however, the Corps intends to initiate a green sturgeon monitoring program under this project to evaluate effects and optimal designs for this species. The details of this program are included in Section 3.8 of the final EIS/EIR and are also discussed in the NMFS Biological Opinion and the Mitigation Monitoring Plan.
P-31	California Department of Fish and Wildlife	Letter	EIS/EIR	CDFW's comments have been addressed as appropriate for this phase of the project and the level of design that currently exists in this Corps SMART Planning study. More detailed design on many aspects of the project will occur following Congressional authorization of the project, and further coordination will occur at that time. During detailed design of the project, an analysis will occur to determine whether further NEPA/CEQA compliance will be required.
Q-1	U.S. Department of the Interior	Letter	Construction Schedule	Tables 4 and 6 of the Draft EIS/EIR show the proposed construction schedule for each alternative, respectively. These tables indicate that construction would take approximately 10 years. For the American River Parkway, Tables 4 and 6 show that construction would occur over 9 of the 10 construction years, sometimes with multiple sites in the Parkway occurring during the same year.

Q-2	U.S. Department of the Interior	Letter	Recreation Impacts	Each construction season would vary depending on the length of the reach being constructed and applicable species work windows. Proposed mitigation for recreation would be implemented, as described in the document, with coordination occurring in advance with Sacramento County and the public. Note that the cumulative effects analysis specifically states that at the time of this analysis, no additional heavy construction projects are expected to occur within the Parkway at the same time as the recommended plan and thus no cumulative effects are assumed. During site-specific design, an analysis will occur to determine whether further NEPA or CEQA documentation would be required.
Q-3	U.S. Department of the Interior	Letter	Vegetation Impacts	The Corps will ensure that the construction contractor adheres to all required BMPs during construction, including ensuring that all appropriate mitigation and restoration is completed.
Q-4	U.S. Department of the Interior	Letter	Recreation	The Corps has added the Wild and Scenic Rivers Act to the Recreation Regulatory Setting.
Q-5	U.S. Department of the Interior	Letter	Coordination	Section 6.3 has been updated to include language regarding coordination with the National Park Service. The Corps will continue coordination with the NPS throughout the design phase of the project.
R-1	Sacramento County Department of Transportation	Letter	Transportation	The Corps will ensure that site-specific traffic studies are completed during the preconstruction engineering and design phase of the project once borrow sites, staging areas, and haul routes are defined for each construction area. If these studies result in impacts beyond those disclosed in this EIS/EIR, then supplemental NEPA documents would address these impacts.
R-2	Sacramento County Department of Transportation	Letter	Transportation	The Corps will ensure that a Traffic Plan is completed by the construction contractors, coordinated with SACDOT, and implemented during construction, to include all required BMPs and mitigation measures discussed in this EIS/EIR.
S-1	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	The Corps has updated the EIS/EIR to reflect that on-road haul trucks will comply with 2010 standards.
S-2	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	Concur. The Corps will update the air quality emission calculations to include the differences between Alternatives 1 and 2.
S-3	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	Concur. This mitigation measure has been removed from the EIS/EIR.
S-4	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	Concur. The Corps has updated the Air Quality section to clarify that the required mitigation for off-road equipment would be the SMAQMD enhanced exhaust controls. However, the Corps will encourage their contractors to use Tier 4 equipment as well to further reduce emissions.
S-5	Sacramento Metropolitan Air Quality Management District	Letter	Climate Change	Concur. The final EIS/EIR will include language acknowledging SMAQMD GHG thresholds for use in supplemental analyses.
S-6	Sacramento Metropolitan Air Quality Management District	Letter	Climate Change	Concur. The Corps revised the referenced GHG mitigation measure and significant threshold discussions in the final EIS/EIR to remove the 7,000 metric ton presumptive threshold.
S-7	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	Tables 1a and 1b have been added to Appendix D for the final EIS/EIR.
S-8	Sacramento Metropolitan Air Quality Management District	Letter	Air Quality	Concur. The Corps will ensure that all applicable SMAQMD rules are identified prior to and during construction.
T-1	State Lands Commission	Letter	Real Estate	The Corps will ensure that appropriate coordination occurs with SLC prior to construction.

T-2	State Lands Commission	Letter	Real Estate	Thank you for your comment and for notifying us up front. We will contact State Lands Commission if we have any questions.
T-3	State Lands Commission	Letter	Real Estate	Construction of the proposed project would not restrict or impede the easement rights of the public. Any in-water construction activities would occur on the bankside and would allow for recreation traffic to continue as normal.
T-4	State Lands Commission	Letter	EIS Revisions	Concur. This paragraph has been revised as requested.
T-5	State Lands Commission	Letter	Turbidity	Section 3.5.6 of the EIS/EIR includes specific mitigation measures to control sediment release during construction. Additional mitigation, as needed, may be coordinated with the CVRWQCB as a part of the Water Quality Certification process during the preconstruction engineering and design phase of the project.
T-6	State Lands Commission	Letter	Turbidity	The Corps proposes BMPs in Section 3.5 to reduce potential water quality effects, including turbidity. The proposed project will ensure that the Basin Plan turbidity standards are not exceeded during construction.
T-7	State Lands Commission	Letter	Cultural	In the event of a cultural resource discovery, the landowner would be notified. Due to the size and scope of the project, this includes many landowners, to include the State Lands Commission. As a result, the general term "landowner" is used throughout the documents. This process is described further in the PA.
T-8	State Lands Commission	Letter	Cultural	The MMRP documents the proposed mitigation associated with this project. The MMRP does not identify specific landowners or parcels, and rather focuses on general mitigation measures to be implemented throughout project construction. At this time, there is no proposed mitigation that the SLC is associated with, and therefore there is not an outlet to add language to the MMRP per this request. The Corps will coordinate with the SLC, as necessary, during the construction phase.
T-9	State Lands Commission	Letter	Cultural	Concur. In the event that cultural resources are discovered on California State Lands Commission lands during construction or any other phase of the project, the commission would be contacted.
T-10	State Lands Commission	Letter	Sea Level Rise	Concur. The Corps addressed Sea Level Rise in the final EIS/EIR in the Climate Change Section.
T-11	State Lands Commission	Letter	Sea Level Rise	Concur. Comment noted.
T-12	State Lands Commission	Letter	Contact	The Corps will ensure that all project related documents are provided to the State Lands Commission, as appropriate.
U-1	Kim Tremaine	Letter	Cultural Resources	Thank you for your comment. The Programmatic Agreement that has been executed for this project will guide future identification of potential historic properties to occur when design details are better known and prior to construction. The Corps is aware of the potential for subsurface sites and will employ a variety of methods, which are to be determined, to identify sites. Consideration of effects to historic properties will be completed through implementation of the PA (Stipulation III and IV). Further, the PA also includes procedures to follow in the event of the discovery of unknown historic properties (Stipulation IX).
V-1	Kim Tremaine	Letter	Geotech	The Corps is required to conduct a Probable Failure Mode Analysis, which is currently in progress through the Corps' Risk Management Center. The RMC is currently conducting the Probable Failure Mode Analysis, which corresponds with the Total Conditional Performance Analysis. This study will be completed prior to authorization of the project.
V-2	Kim Tremaine	Letter	Geotech	There is a significant amount of existing field data that was evaluated for the study. The data will be expanded as needed during PED. Additionally, the Folsom Dam Water Control Manual Update is conducting a channel stability assessment on the American River. In the design phase of the project, the design will be updated as appropriate to reflect the findings of the channel stability assessment. We are unaware of any "fine grained geophysical data" that leads us to a change in our conclusions, however if any data is found, we will incorporate this data during the design phase.

W-1	Delta Stewardship Council	Letter	Systemwide Evaluation/GRR	A wide variety of possible alternatives was considered, including features throughout the watershed, to find ways to reduce the flood risk to the City of Sacramento. USACE has developed a hydraulic model of the Sacramento River which allows us to analyze the effects of modifications to the flood management system. Because the levees surrounding the City are in such poor shape, the analysis showed that most effective plan to reduce the flood risk is to improve the existing levees. A setback levee is recommended for the north levee of the Sacramento Bypass which would approximately double it's floodplain area. The remainder of the levees are adjacent to urban development with little to no available land for a levee setback. The ongoing Central Valley Integrated Flood Management Study (CVIFMS) is a multi-purpose watershed study that is considering the larger, regional scale benefits associated with flood risk management, ecosystem restoration and other water resource related purposes.
W-2	Delta Stewardship Council	Letter	Risk Analysis/GRR	The ARCF GRR identifies the Federal interest in a flood risk management project, and is not constrained by, nor seeks to achieve FEMA levee accreditation standards and local laws such as SB-5. The extent that the recommended plan complies with FEMA and SB-5 standards is a determination required to be made by the non-federal sponsor.
W-3	Delta Stewardship Council	Letter	GRR/Coordination	The Project Delivery team (PDT) for the American River Common Features GRR is made up of staff from USACE as well as staff from the Department of Water Resources (DWR) and the Sacramento Area Flood Control Agency (SAFCA). During the development and evaluation of the alternative plans, weekly team meetings were held to coordinate information and report on the status of analysis. Part of this coordination included reports from the sponsors on activities they are involved in, including the Basin-wide feasibility study. Widening of the Sacramento Bypass was identified by the sponsors as a feature that would be consistent with and supportive of the goals of the Basinwide Feasibility Study.
W-4	Delta Stewardship Council	Letter	GRR/Variance	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
W-5	Delta Stewardship Council	Letter	Variance	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
W-6	Delta Stewardship Council	Letter	CVFIMS	Thank you for your comment. The Central Valley Integrated Flood Management Watershed Study (CVIFMS) will include an assessment of existing and future conditions of the Sacramento River watershed in order to develop recommendations for future actions that integrate co-equal objectives of long-term water supply, flood risk management, and ecosystem sustainability. Assessment of future conditions will include consideration of reasonably foreseeable future actions within the watershed and their effects to watershed resources and function.
W-7	Delta Stewardship Council	Letter	Alternatives	A wide variety of possible alternatives was considered to find ways to reduce the flood risk to the City of Sacramento. Because the levees surrounding the City are in such poor shape, the most effective plan to reduce that risk is to improve the existing levees in place. A setback levee is recommended for the Sacramento Bypass north levee which would approximately double the floodplain area. The remainder of the levees are adjacent to urban development with little to no available land for a levee setback. In areas along the river where bank protection is recommended, riparian vegetation can be maintained and expanded. There is also an opportunity to establish riparian vegetation in the widened portion of the Sacramento Bypass.

X-1	Delta Stewardship Council	Letter	Compliance	The Central Valley Flood Protection Board recognizes its obligations under the Delta Reform Act and the Delta Plan regulations, and the importance of the Delta's co-equal goals. The Board will promote the inclusion of the Delta Stewardship Council's recommendations into future project specific environmental analyses, and the lead agencies intend to initiate additional public involvement and agency coordination prior to project implementation.
X-2	Delta Stewardship Council	Letter	Risk Analysis	Results of the risk analyses are included in the GRR, which is a companion document to the EIS/EIR. The potential for downstream effects is addressed in Section 3.4 of the EIS/EIR and the Hydraulic Appendix to the GRR.
X-3	Delta Stewardship Council	Letter	O&M	The Corps typically updates the O&M Manual during the construction phase of the project. General O&M activities are discussed in the draft EIS/EIR in Section 2.3.4. The Corps reviewed the resource sections to ensure that the effects of these activities are analyzed throughout the document. The existing O&M Manual is available upon request from the Corps.
X-4	Delta Stewardship Council	Letter	Variance	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
X-5	Delta Stewardship Council	Letter	Mitigation	The Corps will mitigate on-site to the maximum extent feasible. Any off-site mitigation is required to be as close to the impact area as possible. The Corps will strive to mitigate on the same waterway when possible, but for some impacts onsite mitigation is not possible and would be compensated through the purchase of mitigation bank credits.
X-6	Delta Stewardship Council	Letter	Variance	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
X-7	Delta Stewardship Council	Letter	Alternatives	The proposed bank protection measure on the American and Sacramento Rivers allow for opportunity to restore and improve SRA habitat in most reaches of the study area. Through ongoing coordination under the Sacramento River Bank Protection Project, the Corps and NMFS have developed a number of options for self-mitigating bank protection sites that include mitigative features that restore SRA habitat. Additionally, mature trees are proposed to remain in place on the lower waterside levees, to protect existing SRA whenever possible. More information about these measures are included in the Mitigation and Monitoring Plan and Biological Opinion, both of which are appended to the EIS/EIR.
X-8	Delta Stewardship Council	Letter	Invasive Species	The Fisheries section has been updated to include analysis of predation at bank protection sites.
X-9	Delta Stewardship Council	Letter	Invasive Species	The Corps has updated the EIS/EIR to include analysis of invasive species and measures to be implemented during construction to manage these species. These measures will be included in the mitigation and monitoring plan, as well as the project's plans and specs prior to construction. No separate invasive species plan has been developed at this time.
X-10	Delta Stewardship Council	Letter	Adaptive Management	An adaptive management plan was developed for the project and included as part of the Mitigation Monitoring Plan, which is appended to the EIS/EIR.
X-11	Delta Stewardship Council	Letter	Delta Plan	The Corps has added language to the environmental setting of the EIS/EIR acknowledging the project's relationship to the Delta Plan and discussing any inconsistencies between the documents.

Y-1	Delta Protection Commission	Letter	Environmental Effects	During the design phase of the project, following Congressional authorization, the Corps and its local partners intend to look at the proposed measures on a site-by-site basis in an attempt to minimize impacts from those described within this effects analysis, as appropriate.
Y-2	Delta Protection Commission	Letter	Recreation	Comment noted. The Corps does not propose to construct new bike trails under the recommended plan.
Z-1	Metropolitan Water District of Southern California	Letter	Project Design/Water Control Manual	Thank you for your comment. Your consideration for habitat restoration opportunities within the Yolo Bypass is noted. The ARCF study used a conservative characterization of future flood management operations at Folsom Dam assuming the Joint Federal Project (JFP) is complete. The Folsom Dam future operations reflected in the ARCF study are based on the operations identified in the Folsom Dam Modification and Folsom Dam Raise Projects PACR (2007). The purpose of the Folsom Dam and Lake Water Control Manual Update (WCM Update) is to carry out a more detailed analysis of how to revise operation rules for Folsom Dam to reduce flood risk based on the capabilities of the JFP, to reflect operation capabilities created by improved weather forecasts, and to potentially reduce the volume of flood control reservation in Folsom Lake at any particular time in comparison to the operations that have been in effect since 1995. Any proposed refinements to operation rules at Folsom identified in the WCM Update are being evaluated on their effectiveness in meeting the flood risk management objectives as well as on their effects to the other project purposes of Folsom Dam. Those other project purposes are: water supply (agricultural and M&I), hydropower, water quality, sustain fish and wildlife resources, and recreation. The WCM Update is evaluating potential effects to these other project purposes on a local and regional basis. Because Folsom Dam and Lake is a key facility in the Central Valley Project, the WCM Update is utilizing the CalSim II model and outputs to measure effects within the larger CVP/SWP system. Along the lower American River and beyond its confluence with the Sacramento River, the WCM Update will be evaluating resource effects to a greater level of detail, utilizing HEC ResSim and RAS models and output to measure changes in flow frequency, duration, rate, and stage, among other variables, on a sub-monthly timestep. The expectation of the WCM Update is that, through an iterative modeling process, operation rules at Folsom Dam will be refined to be able to not only meet the flood risk management objectives of the JFP, but to also minimize, avoid, or possibly provide incidental beneficial effects to the other Folsom Dam project purposes. Results of the WCM Update will be used to better-inform the detailed design of the ARCF selected plan.
AA-1	U.S. Environmental Protection Agency	Letter	HTRW	The local sponsors are required to acquire all necessary lands and easements to facilitate the project. Lands acquired for the project must be free of contamination. As a result, they would be required to ensure that the appropriate parties remediate the landfill prior to providing the lands to the Corps for project implementation. As a result, the landfill remediation is not considered to be a part of the proposed action. Any environmental compliance activities associated with the remediation would be the responsibility of the entity conducting the remediation of the site.
AA-2	U.S. Environmental Protection Agency	Letter	Air Quality	The Air Quality analysis in Section 3.11 has been reevaluated to confirm that currently the proposed project is not exceeding de minimus thresholds.. As a result, a Conformity Analysis is not required at this time. During the design phase of the project, the project will be refined on a site-specific analysis, and if these adjustments result in exceedance of de minimus thresholds, coordination with the EPA will occur, as required.
AA-3	U.S. Environmental Protection Agency	Letter	Air Quality	The measures and assumptions that were factored into the emissions estimates are described in Section 3.11.2 under "Methodology", and are also detailed in the Air Quality Appendix.
AA-4	U.S. Environmental Protection Agency	Letter	Air Quality	The Corps is responsible for ensuring that all commitments in the EIS/EIR are implemented during construction. Additionally, the construction contractor is required to coordinate directly with SMAQMD during construction to ensure that they are meeting required air quality commitments.

AA-5	U.S. Environmental Protection Agency	Letter	Air Quality	Emissions estimates in the final EIS/EIR do not exceed de minimus thresholds. The Corps is including proposed mitigation in order to further reduce these emissions beyond the estimates provided. A draft conformity determination is not required, since estimated emissions do not exceed de minimus thresholds. If at the time of site-specific design prior to construction, further air quality estimates do exceed de minimus thresholds, then the Corps would consult with the EPA, as required, and prepare a draft conformity determination at that time.
AA-6	U.S. Environmental Protection Agency	Letter	Air Quality	Thank you for your comment. The Corps intends to push for reductions through the use of higher tiered equipment during construction.
AA-7	U.S. Environmental Protection Agency	Letter	Air Quality	Thank you for pointing the errors out. We have fixed these as requested for the final EIS/EIR.
AA-8	U.S. Environmental Protection Agency	Letter	SB5	The State has established a standard for urban flood protection in California which applies to cities with populations greater than 10,000 inhabitants. This standard requires levees to withstand flows with a top elevation equal to the mean 200-year water surface profile, plus three feet of freeboard, plus an allowance for wave run-up, plus one foot to account for climate change. USACE does not identify a target level of risk reduction but rather identifies the plan which reasonably maximizes net benefits. The analysis to identify the plan which maximizes net benefits was done with an awareness of the State's goal for urban flood protection for the purpose of informing the State of where the individual plans fall with regards to the State's standards. Neither of the final alternatives is currently able to contain a 1/200 ACE event with 90% assurance. The levee improvements along the Sacramento River will increase the assurance to a level close to 90% but the assurance for the levees along the American River will remain low for the 1/200 ACE. It will be contingent upon the local community to prove to the State that the aggregate flood risk management projects meet the State's standard. The EIS/EIR has been updated to reflect this.
AA-9	U.S. Environmental Protection Agency	Letter	O&M	This reference from the EIS/EIR was in error. Operation of the Sacramento Weir and Bypass would not be deferred until after construction is complete. General assumptions on the future operation of the Sacramento Weir and Bypass are included in Chapter 2 of the final EIS/EIR, however these assumptions will be refined during the preconstruction engineering and design phase of the project. Page 102 of the EIS/EIR has been updated to address this error.
AA-10	U.S. Environmental Protection Agency	Letter	Wetlands	The final EIS will include a mitigation and monitoring plan that will include plans for future mitigation/compensation sites. Wetland delineations will not be completed until the design phase of the project to allow for potentially changing conditions between the study phase and construction of the proposed project.
AA-11	U.S. Environmental Protection Agency	Letter	Climate Change	Section 3.12 has been updated to reflect the CEQ draft guidance and to ensure that it is clearly stated that all GHGs contribute to climate change.
BB-1	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction. A SWPPP would be prepared prior to construction.
BB-2	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction.
BB-3	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction. The Corps would ensure that project construction complies with the regulations contained in the permits.
BB-4	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps does not issue a permit to itself. However, the Corps will ensure that the project complies with the substantive requirements of Section 404 through the preparation of a Section 404(b)(1) analysis, which is included with the EIS/EIR as Appendix E.

BB-6	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps will ensure that prior to initiation of construction, a Section 401 Water Quality Certification is obtained, as necessary, for impacts to waters of the U.S.
BB-7	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction.
BB-8	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction.
BB-9	Central Valley Regional Water Quality Control Board	Letter	Construction Permits	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction.
CC-1	Sacramento Regional County Sanitation District	Letter	Utilities	The Corps will coordinate with SRCSD during the design phase of the project, as appropriate.
DD-1	Joseph O'Connor	Letter	Mayhew Levee Project	The Corps looked at seven alternatives that would have extended the Mayhew levee upstream to high ground. These alternatives were not cost efficient due to the required real estate acquisition costs, and there would be mitigation required for the removal of trees. The local sponsor was not willing to partner in any of these alternatives. Therefore, the Mayhew Plug was the selected alternative, because it provided most of the 200-year level of flood protection for the least cost, and required no mitigation. Additional work in order to complete the last 4-6 inch tie-in would require the removal of a private fence, the removal of a large (heritage) tree and three smaller trees, and approximately 20 cubic yards of soil to be imported and compacted on private property. Due to the rare frequency that a flood event would reach this elevation, the additional effort and expense required for closing this minimal deficit in the levee height is not cost effective. It should be noted that the height of the levee in this location is almost three feet above the 200-year design water surface elevation, even with the reduced levee height at that location. Should a flood event occur that reaches the top of the plug, sandbagging would be required to close this gap.
EE-1	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Additions per the below comments have been incorporated.
EE-2	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The Corps is committed to implementing all proposed mitigation measures as listed at the end of each resource section during the construction phase of the project.
EE-3	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design Phase	During PED, a more substantial site specific design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-4	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Additional clarifying language was added regarding balancing the risk between additional flow being released causing further distress of the levee versus the risk of a dam failure.

EE-5	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	The cited Bureau and DWR reports were cited to provide additional background on the history of Folsom.
EE-6	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	The levees have had an established emergency condition of 152,000 cfs since completion of the north levee on the American River in 1957. The 160,000 cfs condition was added to the Folsom water control manual after 1986. Language to this effect has been added.
EE-7	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Some clarifying language was added. However, the stage in Folsom was in the surcharge pool which mandates emergency operations to avoid dam failure.
EE-8	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Concur that it is a State standard and State defined criteria. The ARCF GRR project documents do not state that performance should be determined through Corps criteria.
EE-9	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Modeling developed for the Sacramento and San Joaquin River Basin Comprehensive Study showed that substantially more flow reached the combination of the Yolo Bypass and Sacramento River just downstream of Fremont Weir these waterways were designed to convey. However, the language was revised to conform with past published accountings of this event.
EE-10	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Language in this section was modified. Geotechnical problems were also cited as leading to the levee failures that occurred.
EE-11	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	An additional statement about the PMF was added to this section. The Corps concurs that the purpose of the project is to pass certain magnitude flood flows downstream without levee failure, but the influence of Folsom and the JFP is important to identify the problems affecting the study area.
EE-12	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	Eyewitness verbal accounts cite that there was less than a foot of freeboard during the 134,000 cfs release in certain reaches of the American River. However, the sentence was rewritten to state that during the 1986 event, the design freeboard was encroached upon risking the potential of overtopping.
EE-13	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Velocities/Erosion	Chapter 2.3.1 of the GRR and Section 3.4 of the EIS/EIR have been updated to show a range of velocity conditions for justification of the erosion protection.
