# BAND-TAILED PIGEON POPULATION STATUS, 2014

TODD A. SANDERS, U.S. Fish and Wildlife Service, Division of Migratory Bird Management, 1211 SE Cardinal Court, Suite 100, Vancouver, WA 98683

*Abstract:* This report summarizes information on the abundance and harvest of band-tailed pigeons (*Patagioenas fasciata*) in the western United States and British Columbia from 1968 through 2013. The all-bird Breeding Bird Survey (BBS) provides an annual index to abundance of Pacific Coast and Interior band-tailed pigeons since 1968, while the Mineral Site Survey (MSS), implemented in 2004, was developed specifically to index abundance of Pacific Coast band-tailed pigeons. Harvest and hunter participation are estimated from the Migratory Bird Harvest Information Program. The BBS provided evidence that the abundance of Pacific Coast band-tailed pigeons decreased ( $-2.0\%$  per year, credible interval =  $-3.4$  to  $-0.8$ ) over the long term (1968–2013). Trends in abundance during the recent 10- and 5-year periods were inconclusive for both the BBS and MSS. Current (2013) estimates of total harvest, active hunters, and total hunter days afield were 6,700 (4,154–9,246) pigeons, 3,300 hunters, and 6,200 (4,154–8,246) days afield. Composition of harvest was 33% hatching year birds during the 2013 season. For Interior band-tailed pigeons, the BBS provided evidence that abundance decreased ( $-5.6\%$  per year, 95% CI =  $-9.6$  to  $-2.3$ ) over the long term (1968–2013). Trends in abundance during the recent 10- and 5-year periods were inconclusive. Current (2013) estimates of total harvest, active hunters, and total hunter days afield were 1,600 (128–3,072) pigeons, 1,000 hunters, and 2,000 (800–3,200) days afield. Wing collections were too few to estimate the proportion of hatching year birds in the harvest during the 2013 season.

Band-tailed pigeons are managed cooperatively by state and provincial wildlife agencies, the U.S. Fish and Wildlife Service, and the Canadian Wildlife Service. Their management is detailed in population-specific (Pacific Coast and Interior) management plans (Pacific and Central Flyway Councils 2001, Pacific Flyway Council 2010).

Maintenance of band-tailed pigeon populations in a healthy, productive state is a primary management goal. Management activities include population and harvest assessment, harvest regulation, and habitat management. Each year, counts of band-tailed pigeons heard and seen are conducted by state, provincial, federal, and other biologists in the western United States and British Columbia to monitor population status. The resulting information is used by wildlife administrators to set annual hunting regulations.

## DISTRIBUTION AND ABUNDANCE

Band-tailed pigeons are divided into six subspecies, only two of which occur north of Mexico, and each of those occupies a disjunct geographic distribution in western North America: the Pacific Coast and Interior (Fig. 1). The coastal subspecies (*P. f. monilis*) breeds

from extreme southeastern Alaska and western British Columbia south into Washington, Oregon, California, and extreme western Nevada, primarily west of the Cascade and Sierra Nevada ranges, into Baja California; and winters from central California into northern Baja California. Some in Mexico and southern California and the few wintering north of southern California may represent non-migratory population segments. The interior subspecies (*P. f. fasciata*) breeds from northern Colorado and eastcentral Utah south through Arizona, New Mexico, extreme western Texas into the Sierra Madre Occidental of Mexico; and winters from northern Mexico south to at least Michoacan. Some interchange occurs between the two subspecies (Schroeder and Braun 1993).

Little is known about the demographics of band-tailed pigeon populations because their habits and habitat make it impractical to locate and observe or trap an adequate sample of birds. However, in the early 1970s the total population size was approximated at 2.9–7.1 million birds in the Pacific Coast region and <250,000 birds in the Interior region (estimated from harvest reports and band recovery rates, Braun 1994). This demonstrates the likely sizes and disparity between the two populations at that time.

**Figure 1.** Distribution of Pacific Coast (*P. f. monilis*) and Interior (*P. f. fasciata*) band-tailed pigeons in North America (after Braun et al. 1975).

## ECOLOGY

Band-tailed pigeons inhabit coniferous forests primarily where they are highly mobile habitat generalists. Individuals potentially travel long distances (up to about 32 miles) daily to feed and drink. They exhibit high fidelity to nesting and other areas, but can be nomadic depending on food availability. Food availability appears to be a major determinant of abundance, distribution and productivity. Their diet includes buds, flowers, and fruits of deciduous trees and shrubs, especially oak, madrone, elder, dogwood, cherry, cascara, and huckleberry, but varies seasonally and with location. Early migrants are readily attracted to grain fields and fruit orchards dispersed below the forested hills where they nest, particularly before the onset of natural foods, which are preferred. Adults, especially in summer and particularly the Pacific Coast region, frequently visit natural springs and water bodies high in sodium concentration where they drink and peck at the soil between long periods of roosting in nearby trees.

Band-tailed pigeons nest primarily in conifers within closed-canopy conifer or mixed hardwood and conifer forest stands, but also occasionally in hardwoods and shrubs. Nest placement is highly variable ranging from 6 to 120 feet above ground, but is generally near the bole and in dense foliage. Adults are presumably monogamous, and clutches almost invariably consist of one egg. Some nesting pairs may complete up to 3 nesting cycles a year. A study in west central Oregon documented an average of 1.7 nests initiated per pair (Leonard 1998). Sequential nest attempts have not been documented for the Interior population. Both parents incubate the egg and brood the squab. Nestlings are fed curd-like crop milk formed from the inside lining of the crop of both adults. Nesting band-tailed pigeons are sparsely scattered, but congregate to feed, drink, and consume supplemental minerals and during migration.

Comprehensive material on the life history of the band-tailed pigeon may be found in Keppie and Braun (2000), Braun (1994), Jarvis and Passmore (1992), and Neff (1947).

## MANAGEMENT

Band-tailed pigeons are a valued game bird offering a different type of pursuit than any other game bird. Hunting of band-tailed pigeons has been allowed in all states within the species' range except Texas. However, seasons have been periodically closed due to concern about overharvest. Seasons have been closed in one or more states within each population during 55 (Interior) and 29 (Pacific Coast) of the last 101 years (1913–2013) (Appendices A and B).

Monitoring information about population status is presently limited to annual estimates of relative abundance and harvest (absolute harvest and age ratios in the harvest). Long-term population declines have led to especially restrictive hunting regulations for the last 22 years in the Pacific Coast states (9-day season with a 2-bird bag limit, California has a season in each of 2 zones), but regulations have remained relatively liberal in the Interior states (30-day season with a 5-bird bag limit, New Mexico has a 20-day season in each of 2 zones, Arizona and Utah opted for a 2 bird bag limit in 2013) (Appendices A and B). Hunter participation and harvest have reached all-time lows for both populations (Pacific and Central Flyway Councils 2001, Pacific Flyway Council 2010).

Currently, band-tailed pigeon abundance is thought to be limited primarily by food availability resulting from habitat alteration associated with land management practices. Also, band-tailed pigeons are subject to Trichomoniasis, a parasitic disease caused by a single-celled protozoan, *Trichomonas gallinae*, which was introduced by exotic pigeons and doves. Virulent strains of *T. gallinae* have caused major mortality events or epizootics in band-tailed pigeons in addition to less visible, chronic losses. Periodic annual losses from *T. gallinae* in the Pacific Coast population can exceed harvest by 2 to 3 times (Stromberg et al. 2008).

The single greatest challenge in the monitoring and management of band-tailed pigeon populations is the lack of reliable information on population size (D. J. Case and Associates 2011). Existing surveys for this species provide only trends in abundance and no information about absolute population size. Furthermore, trend estimates from existing surveys may be unreliable because sample sizes (routes or mineral sites) and pigeon counts at sample sites are low, variances are high, and coverage of habitat by survey routes or sites is poor, especially for the Interior region.

## **MONITORING METHODS**

### **The Breeding Bird Survey**

The North American Breeding Bird Survey (BBS) is an all-bird survey that provides an annual index of abundance for both Interior and Pacific Coast populations of band-tailed pigeons (Sauer et al. 2007). The BBS started primarily in the eastern U.S. in 1966, central U.S. in 1967, and far west in 1968. The survey is based on thousands of routes distributed along secondary roads across the United States and Canada. Each route is 24.5 miles in length and consists of 50 stops or count locations at 0.5 mile intervals. At each stop, a 3-minute count is conducted whereby every bird seen within a 0.25 mile radius or heard is recorded. Surveys start one-half hour before local sunrise and take about 5 hours to complete. Data for birds heard and seen at stops are combined for BBS analyses.

### **Mineral Site Survey**

Past monitoring efforts for the Pacific Coast population relied on the BBS, which includes all birds, and other band-tailed pigeon specific surveys in Oregon (visual counts at mineral sites in August) and Washington (audio counts along transects in June). There was no specific monitoring program in California or British Columbia. In the interest of developing a uniform, range-wide survey of Pacific Coast band-tailed pigeons, U.S. Geological Survey scientists examined the effectiveness of existing survey methods in detecting long- and short-term changes in abundance indices (Casazza et al 2005). Results suggested that counts of pigeons seen near mineral sites adopted from the Oregon protocol had the greatest power to detect short-term (3- to 5-year) trends in the data (Casazza et al. 2005). Additional research illustrated impacts of rainfall on mineral site surveys (Overton et al. 2005). The result of this work was the Mineral Site Survey (MSS), developed to provide an annual index to abundance of Pacific Coast band-tailed pigeons. Additional work is needed, however, to determine the reliability of counts at mineral sites to index abundance of band-tailed pigeons.

The MSS was developed and initiated on an experimental basis in 2001 (Casazza et al. 2003), and became operational in 2004. The survey is a coordinated effort among state and provincial wildlife agencies in California, Oregon, Washington, and British Columbia, and the U.S. Fish and Wildlife Service and Canadian Wildlife Service. The MSS involves a visual count of band-tailed pigeons at select mineral sites throughout the population's range ( $n = 51$ ; 12 in California, 21 in Oregon, 14 in Washington, and 4 in British Columbia) during July from one-half hour before sunrise to noon. These counts provide an index of abundance. Unfortunately, a similar survey for Interior band-tailed pigeons is not possible because the birds in this area do not use mineral sites (Sanders and Jarvis 2000).

### **Harvest Information Program**

Wildlife professionals have long recognized that reliable harvest surveys are needed to estimate the magnitude of harvests and monitor the impact of hunting. In past years, a compilation of non-uniform,

periodic state harvest surveys have been used to obtain rough estimates of the number of band-tailed pigeon hunters and birds killed. Thus, the data were of limited use at a population range level. Those data are no longer collected by states (with the exception of New Mexico and Utah).

Beginning in 1952, the U.S. Fish and Wildlife Service conducted a national harvest survey annually (Mail Questionnaire Survey), but it was based on a sampling frame that included waterfowl hunters and so harvest of non-waterfowl species could not be estimated reliably. To remedy this problem and address challenges associated with combining state surveys, the U.S. Fish and Wildlife Service and state wildlife agencies initiated the national, Migratory Bird Harvest Information Program (HIP) in 1992. This Program was designed to enable the U.S. Fish and Wildlife Service to conduct nationwide surveys that provide reliable annual estimates of the harvest of migratory game birds including band-tailed pigeons. Under HIP, states provide the U.S. Fish and Wildlife Service with the names and addresses of all licensed migratory bird hunters each year, and then surveys are conducted to estimate harvest and hunter participation (total harvest, number of active hunters, days hunted, and seasonal harvest per hunter) in each state. All states except Hawaii have participated in HIP since 1998. Useable estimates of band-tailed pigeon harvest and hunter participation became available in 1999.

## **Parts Collection Survey**

The Parts Collection Survey (PCS) is a secondary component of the national harvest survey, which began in 1961. The PCS is the primary means by which the composition (species, age, and sex) of the annual harvest is assessed. The survey selects a random sample of hunters registered with the program. These persons are sent envelopes and asked to return one wing from each bird harvested. All wings received annually are examined at wing bees, one in each of the four flyways, in which the wings are categorized by species, age, and sex. Band-tailed pigeons were included in the PCS beginning in 1994.

## **Estimation of Trends in Abundance**

Beginning with the 2010 annual status report, BBS and MSS trends were estimated using a log-linear

hierarchical model and Bayesian analytical framework (Sauer et al. 2008, Sauer et al. 2010) instead of the previously used route regression approach (Link and Sauer 1994). Both methods provide trend and annual index values that are generally comparable. The hierarchical model, however, has a more rigorous and realistic theoretical basis than the weightings used in the route regression approach, and the indices and trends are directly comparable as trends are calculated directly from the indices unlike the former analysis.

With the hierarchical model, the log of the expected value of the counts is modeled as a linear combination of strata-specific intercepts and trends, a random effect for each unique combination of route and observer, a year effect, a start-up effect on the route for first year counts of new observers, and over-dispersion. Most of the parameters of interest are treated as random effects and some parameters are hierarchical in that they are assumed to follow distributions that are governed by additional parameters. The model is fit using Bayesian methods. Markov-chain Monte Carlo methods are used to iteratively produce sequences of parameter estimates which can be used to describe the distribution of the parameters of interest. Once the sequences converge, medians and credible intervals (CI, Bayesian confidence intervals) for the parameters are estimated from the subsequent replicates. Annual indices of abundance are defined as exponentiated year and trend effects, and trends are defined as ratios of the year effects at the start and end of the interval of interest, taken to the appropriate power to estimate a yearly change (Sauer et al. 2008). Trend estimates are expressed as the average percent change per year over a given time period, while indices are expressed as the number of pigeons seen and heard per route (BBS) or seen per site (MSS).

Annual indices of abundance were calculated for each state, province, and region (groups of states and provinces). Short- (recent 5-year period), intermediate- (recent 10-year period) and long-term (all years with data) trends were evaluated for each state or province and region. We present the median and 95th percentile credible intervals for estimates. The extent to which trend credible intervals exclude zero can be interpreted as the strength of evidence for an increasing or decreasing trend. Thus, there is evidence of a positive trend if the CI > 0 and there is evidence of negative trend if the CI < 0. If the CI contains 0, then there is inconclusive evidence about

**Figure 2.** Abundance indices (dashed lines) and 95% credible intervals (solid lines) for the Pacific Coast population of band-tailed pigeons based on results from the North American Breeding Bird Survey (1968–2013) and Mineral Site Survey (2004–2013; scaled by dividing the index by 10).

trend in abundance. The reported sample sizes are the number of routes or sites on which trend estimates are based, which includes any route or site on which band-tailed pigeons were ever encountered. For the MSS, we used only data starting in 2004 when the survey became operational. Also we limited sites to those naturally occurring with known source of mineral that would likely be accessible for counting in the future and that had at least 2 annual surveys.

## MONITORING RESULTS

### The Breeding Bird Survey

Results of the BBS are presented in Figs. 2–3 and Tables 1–3. The trend in the median annual count of Pacific Coast band-tailed pigeons seen and heard per route since 1968 decreased 2.0% per year (CI = –3.4 to –0.8). Trends for Pacific Coast pigeons during the recent 10- and 5-year periods were inconclusive.

Similarly for Interior band-tailed pigeons, the trend in the median annual count since 1968 decreased 5.6% per year (CI = –9.6 to –2.3). Trends for Interior pigeons during the recent 10- and 5-year periods were inconclusive. Caution should be used in interpreting results, particularly for the Interior region, because sample sizes (routes) and pigeon counts per route are low, variances are high, and coverage of habitat by BBS routes is poor.

**Figure 3.** Abundance indices (dashed lines) and 95% credible intervals (solid lines) for the Interior population of band-tailed pigeons based on results from the North American Breeding Bird Survey, 1968–2013.

### Mineral Site Survey

Results from the MSS were inconclusive for trend in the median annual count of Pacific Coast band-tailed pigeons seen at mineral sites since the survey became operational in 2004 and in the last 5 years (Fig. 2, Tables 4 and 5). Annual indices of Pacific Coast band-tailed pigeon abundance by state are provided in Table 6.

The MSS and BBS show similar results for Pacific Coast pigeons over the recent 10 years in that the estimated trend in annual pigeon counts is inconclusive (Fig. 2, Tables 2 and 4).

### Harvest Information Program

Results of the HIP are presented in Tables 7–9 for Pacific Coast band-tailed pigeons and Tables 10–12 for Interior band-tailed pigeons. Preliminary estimates from 2013 indicated total harvest, active hunters, and total hunter days afield for Pacific Coast band-tailed pigeons were 6,700 (95% confidence interval = 4,154–9,246) pigeons, 3,300 hunters, and 6,200 (4,154–8,246) days afield, respectively. For Interior band-tailed pigeons during 2013, total harvest, active hunters, and total hunter days afield were 1,600 (128–3,072) pigeons, 1,000 hunters, and 2,000 (800–3,200) days afield, respectively.

## Parts Collection Survey

Results of the PCS are presented in Tables 13 and 14. Composition of Pacific Coast band-tailed pigeon harvest during 2013 was 33% hatching year birds based on a total sample of 33 birds. Composition of Interior band-tailed pigeon harvest during 2013 was not estimable because too few wings were received. Caution should be used in interpreting state-specific estimates with small sample sizes. Also, numbers are an index to recruitment and not adjusted for differential vulnerability to harvest between age classes. Consequently, the annual composition of the harvest may not be representative of the population.

There is not adequate data to evaluate current differential vulnerability rates between juvenile and adult birds (juvenile:adult). There is, however, some band-recovery data for male and females combined during 1968–1976 for the Interior population and during 1962–1977 for the Pacific Coast population. Based on a comparison of harvest rates, estimates of juvenile per adult pigeon in the harvest are variable among years and range from  $0.20 \pm 0.20$  to  $5.62 \pm 5.92$  with a mean of  $1.90 \pm 0.60$  for the Interior population and  $0.55 \pm 0.24$  to  $1.54 \pm 0.81$  with a mean of  $1.05 \pm 0.10$  for the Pacific Coast population (T. A. Sanders, U.S. Fish and Wildlife Service, unpublished data). These results suggest that, on average, juvenile and adult birds have nearly equal probability of harvest in the Pacific Coast population. Equal vulnerability of age classes seems plausible considering that most pigeons are harvested at concentration areas (e.g., mineral sites, feeding sites, and mountain passes) without use of decoys. In the Interior population, juvenile birds appear twice as likely to be harvested compared to adults, but precision of the estimate is not great. It is unknown whether these mean age-related vulnerability estimates apply to more recent years. If they do, then the proportion of juvenile birds in the Pacific Coast population, and possibly the Interior population, may be as estimated from PCS.

## ACKNOWLEDGMENTS

Personnel of state wildlife agencies and the U.S. Fish and Wildlife Service (USFWS) cooperated in collecting the data presented in this report. Special thanks to Levi Souza (CA), Brandon Reishus (OR), Don Kraege (WA), and Andre Breault (BC) for their

role in coordination of the MSS and providing data. John Sauer (USGS) analyzed BBS data, cooperated in development of the analytical framework for MSS data, and provided statistical support. Khristi Wilkins and Robert Raftovich (USFWS) provided the HIP and PCS data. Ken Richkus, Rebecca Rau, Pam Garrettson, Frank Rivera-Milan, and Mark Seamans (USFWS) reviewed a draft of this report.

<sup>a</sup> Arizona used a zoned season during 2005–2009. The season in the southern zone was shorter than in the northern zone listed in the table with a delayed opening date of 1 (2006–2009) or 2 (2005) weeks and same closing date. The North Zone was defined as Management Units 1–15C, 16A, 17–20A, 23, and 24A; and the South Zone 15D, 16B, 20B, 20C, 21, 22, and 24B–46.

<sup>b</sup> New Mexico used a zoned season beginning in 1974. The northern zone was defined as that area lying north of U.S. Highway 60 and the southern zone in that area lying south of U.S. Highway 60. The zones were redefined in 1975. The northern zone was that area lying north and east of a line following U.S. Highway 60 from the Arizona state line east to Interstate Highway 25 at Socorro and thence south along Interstate Highway 25 to the Texas state line. The southern zone was that area lying south and west of a line following U.S. Highway 60 from the Arizona state line east to Interstate Highway 25 at Socorro and thence south along Interstate Highway 25 to the Texas state line.
