Acknowledgments

This report provides population status, recruitment information, harvest trends, and other information for the Mid-Continent (MCP) and Rocky Mountain (RMP) Populations of sandhill cranes. Information was compiled with the assistance of a large number of biologists from across North America. We acknowledge the contributions of: D.S. Benning, J.L. Drahota, R.C. Drewien, J.W. Solberg, P.P. Thorpe, and D.L. Fronzak for conducting annual aerial population surveys; R.C. Drewien for conducting RMP productivity surveys; E.M. Martin, K.D. Richkus, and M.H. Gendron for conducting the U.S. and Canadian Federal harvest surveys for the MCP; J. Bohne for compiling harvest information collected on sandhill cranes in the Pacific Flyway; G.L. Krapu for providing preliminary results from satellite-transmittered MCP cranes; and D.S. Benning, E.L. Boeker, D.H. Johnson, and W.L. Kendall for consultation on the analysis of data on the status of cranes. B.A. Andres and G.L. Krapu reviewed and provided comments on this report. We especially want to recognize the support of the state and provincial biologists in the Central and Pacific Flyways for the coordination of sandhill crane hunting programs and especially the distribution of crane hunting permits and assistance in conducting of annual cooperative surveys.

STATUS AND HARVESTS OF SANDHILL CRANES

MID-CONTINENT AND ROCKY MOUNTAIN POPULATIONS 2007

David E. Sharp, Central Flyway Representative, Division of Migratory Bird Management, U.S. Fish and Wildlife Service, Denver, Colorado

Kammie L. Kruse, Wildlife Biologist, Division of Migratory Bird Management, U.S. Fish and Wildlife Service, Denver, Colorado

James A. Dubovsky, Chief of Migratory Bird Coordination, Division of Migratory Birds and State Programs, U.S. Fish and Wildlife Service/Region 6, Denver, Colorado

Abstract: Compared to increases recorded in the 1970s, annual indices to abundance of the Mid-Continent Population (MCP) of sandhill cranes have been relatively stable since the early 1980s. The Central Platte River Valley, Nebraska, spring index for 2007, uncorrected for visibility bias, was 302,600 sandhill cranes. The photo-corrected, 3-year average for 2004-06 was 378,420, which is within the established population-objective range of 349,000-472,000 cranes. All Central Flyway States, except Nebraska, allowed crane hunting in portions of their States during 2006-07. About 10,120 hunters participated in these seasons, which was similar to the number that participated in the previous year season. Hunters harvested 17,631 MCP cranes in the U.S. portion of the Central Flyway during the 2006-07 seasons, which was 3% lower than the estimated harvest for the previous year. The retrieved harvest of MCP cranes in hunt areas outside the Central Flyway (Arizona, New Mexico, Alaska, Canada, and Mexico combined) was estimated at 13,048 during 2006-07. The preliminary estimate for the North American MCP sport harvest, including crippling losses, was 35,341 birds, which is 3% lower than the previous year's estimate. The long-term (1982-2004) trends for the MCP indicate that harvest has been increasing at a higher rate than population growth. The fall 2006 pre-migration survey for the Rocky Mountain Population (RMP) was not completed due to engine problems with the survey aircraft. The 3-year average for 2003-05 was 19,633 sandhill cranes, which is within established population objectives of 17,000-21,000 for the RMP. Hunting seasons during 2006-07 in portions of Arizona, Idaho, Montana, New Mexico, Utah, and Wyoming, resulted in a harvest of 907 RMP cranes, a 29% increase from the harvest of 702 the year before, and a record high harvest for this population.

Introduction

The MCP of sandhill cranes, numerically the most abundant of all North American crane populations, is comprised of lesser (Grus canadensis canadensis) and greater (G. c. tabida) subspecies of sandhill cranes. A third intermediate-sized subspecies, the Canadian sandhill crane (G. c. rowanii), was identified in the MCP (Walkinshaw 1965); however, recent genetic investigations question the existence of this third subspecies (Rhymer et al. 2001, Peterson et al. 2003, Jones et al. 2005). The MCP was believed to have > 500,000 individuals during the 1990s (Tacha et al.1994). The breeding range extends from northwestern Minnesota northeastward into western Quebec, then northwest through Arctic Canada, Alaska, and into eastern Siberia. The MCP wintering range includes western Oklahoma, New Mexico, southeastern Arizona, Texas, and Mexico (Fig. 1). Extensive, spring aerial surveys on major concentration areas that are corrected for observer visibility bias on major concentration areas, provide annual indices of abundance used to measure population trends. These surveys are conducted in late March, at a time when birds that wintered in Mexico, Arizona, New Mexico, and Texas usually have migrated northward to spring staging areas, but before spring "break-up" conditions allow cranes to move into Canada (Benning and Johnson 1987). The MCP Cooperative Flyway Management Plan established regulatory thresholds for changing harvest regulations that are based on an objective of maintaining sandhill crane abundances at 1982-2005 levels (i.e., spring index of 349,000-472,000 [411,000 ± 15%]). Sandhill crane hunters are required to obtain either a Federal crane hunting permit or register under the Harvest Information Program (HIP) to hunt MCP cranes in the U.S. The permits or HIP registration records provide the sampling frame to conduct annual harvest surveys. In Canada, the harvest survey is based on the sales of Federal Migratory Bird Hunting Permits, which are required for all crane hunters.

The RMP is comprised exclusively of greater sandhill cranes that breed in isolated, wellwatered river valleys, marshes, and meadows of the U.S. portions of the Central and Pacific Flyways (Drewien and Bizeau 1974). The highest nesting concentrations are located in western Montana and Wyoming, eastern Idaho, northern Utah, and northwestern Colorado. The RMP migrates through the San Luis Valley (SLV) in Colorado and winters primarily in the Rio Grande Valley, New Mexico, with smaller numbers that winter in the southwestern part of New Mexico, in southeastern Arizona, and at several locations (14) in the Northern Highlands of Mexico (Fig. 2). During 1984-96, the RMP was monitored during a spring stopover in the SLV. However, cranes from the MCP also began to use this area, which confounded estimates of RMP abundance. In 1996, a fall pre-migration (September) survey replaced the spring count as the primary tool for monitoring population change. The RMP Cooperative Flyway Management plan established a population objective, and surveys to monitor recruitment and harvest levels that are designed to maintain a stable abundance between 17,000 -21,000 birds (Pacific and Central Flyway Councils 2007). The plan contains a formula for calculating allowable annual harvests to achieve population objectives. All sandhill crane hunters in the range of the RMP must obtain a state permit to hunt cranes, which provides the sampling frame for independent state harvest estimates and allows for assignment of harvest quotas by state. In many areas, harvest estimates are supplemented by mandatory check-station reporting.

Mid-Continent Population of Sandhill Cranes

No sport hunting seasons for MCP cranes were allowed in the U.S. between 1916 and 1960. In the Central Flyway, areas open to hunting were gradually expanded during 1961-74, but since that time have remained relatively stable. Operational hunting seasons are now held annually in portions of Colorado, Kansas, Montana, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, and Wyoming. Nebraska is the only Central Flyway state that currently does not have a sandhill crane sport hunting season. Areas open to crane hunting in the Central Flyway during 2006-07 are shown in Fig. 3.

During 1961-74, hunters gradually improved their knowledge of sandhill cranes and improved their hunting success. During 1975-85, a tradition of sandhill crane hunting became established. Together with improvements in equipment (decoys, calls, clothing, blinds, etc.) and a shift from pass-shooting and hunting on roosts to decoy-hunting in fields, crane hunter success increased (Sharp and Vogel 1992). Dubovsky and Araya (2007) found that in the late 1990s and early 200s hunters were more successful in harvesting 2 or 3 cranes per day than they were during the early 1980s. However, since the late 1990s, average seasonal bags have declined for the Flyway.

In North Dakota, sandhill crane seasons resumed in 1968 and were incrementally expanded thereafter. During 1968-79, the numbers of counties open for crane hunting increased from 2 to 8. From 1980-92, the number of counties with open seasons increased to 30 and were grouped into two zones. Beginning in 1993, the zones were eliminated and Federal frameworks were fully utilized for the designated hunting area (Sharp and Cornely 1997). In 1993, Kansas became the ninth Central Flyway state to initiate a crane hunting season within established Federal frameworks. As with most other states, initial seasons in Kansas were more restrictive than Federal frameworks allowed. In 2001, designated hunt areas in North Dakota and Texas were expanded, with the new areas having reduced frameworks.

MCP harvest areas have remained relatively constant from year to year; however, the levels of harvest vary with respect to many factors including changes in hunting pressure, land use, and environmental factors. Most shifts in annual harvests occur locally, but large- scale changes in harvest distributions have also occurred. Since the late 1990s, harvests have increased in Saskatchewan, while harvests have declined in North Dakota (Fig. 4). Causal factors for these changes have not been determined, but are likely different for these two areas because birds staging in Saskatchewan are largely not from the same group that are harvested in North Dakota (G.Krapu, Northern Prairie Wildlife Research Center, personal communication). Increased hunting pressure in Saskatchewan has likely contributed to increases in harvests; whereas, declines in harvests in North Dakota appear to be more complex and involve several interrelated factors. The factors that may have contributed to declines are changes in hunting pressure, conversion of crop land to grass cover, and environmental conditions.

The MCP included at least 510,000 sandhill cranes in March 1982, the last extensive survey involving high-altitude vertical photography of major spring migration staging concentrations. Beginning in 1982, an intensive photo-corrected ocular-transect survey of Nebraska's Central Platte River Valley (CPRV) and ocular assessments from other spring staging areas have been used to monitor the annual status and trends for this population (Table 1). Use of the CPRV count in the development of annual harvest

recommendations relies on the premise that >90% of the MCP are in the CPRV at the time of the annual survey. Recent research with radio-telemetered birds suggests that the proportion of MCP cranes in the CPRV during the survey varies by year (G. Krapu, Northern Prairie Wildlife Research Center, personal communication). Annual variability in weather patterns can reduce the percentage below 90% in some years, such as this spring when fair weather prompted birds to migrate to the Dakotas by the time of the survey. However, conducting the survey a few days earlier or a few days later likely would not result in a 'better' count (i.e., a higher proportion of birds being in the CPRV), because birds migrate into and out of the area continuously (G. Krapu, Northern Prairie Wildlife Research Center, personal communication).

The March 2007 index for the CPRV, which has not yet been corrected for visibility bias (Table 1, Fig. 5) was 302,600 birds. Survey biologists indicate that few birds remained on migration areas south of the CPRV; however, several flocks were reported further north in the Dakotas at the time of the survey. The annual photo-corrected estimates and 95% confidence intervals for the CPRV portion of the survey indicate a relatively stable (P = 0.98) population trend for the MCP since 1982 (Fig. 6). The average index for photo-corrected counts during 2004-06 is 378,420 cranes, which is 10% lower than the previous 3-year average of 422,157 (Solberg 2007), and remains within the management threshold objective levels (349,000-472,000) for this population of cranes) (Fig. 7).

Since 1975, special Federal Sandhill Crane Hunting Permits or HIP certification have been required for all crane hunters participating in seasons in the Central Flyway. A sample of these permittees are mailed questionnaires soon after the completion of each hunting season. The resulting responses enable estimation of hunting activities and success (Martin 2006).

During the 2006-07 seasons in the Central Flyway, 85,924 hunters were either HIP-certified or obtained crane hunting permits, which were not limited in number (Table 2), with 10,120 of these individuals hunting at least one time (Table 3). The number of active hunters was the highest recorded since HIP was implemented (Fig. 8). The number of hunters in Texas (55%) and North Dakota (32%) combined comprised 87% of all sandhill crane hunters in the Central Flyway. Federal frameworks allowed daily bag/possession limits of 3/6, which most states selected (only portions of North Dakota and Texas had lower bag and possession limits). Specific dates selected by states in the Central Flyway for 2006-07 were similar to those of previous hunting seasons (Table 4).

An index to crippling-loss rates (number of cranes lost/[number of cranes lost + retrieved]) in the U.S. portion of the Central Flyway has declined ($R^2 = 0.887$, P < 0.01) from over 16% in 1975 to a preliminary estimate of about 10% during the most recent hunting season (Fig. 9). The number of days afield remained steady at about 3.5 days per hunter (Fig. 10). The preliminary estimate of seasonal bag per hunter also remained at about 1.9 birds per hunter (Fig. 11). The preliminary estimate of retrieved and unretrieved mortality associated with the sport harvest in the Central Flyway (19,682) was similar to the previous year's estimate (Fig. 12). The increasing trend ($R^2 = 0.546$, P < 0.01) in the Central Flyway's harvest of MCP cranes during 1975-2006 likely was related to the gradual increase in hunter opportunity combined with improved knowledge of crane behavior, hunting techniques, and hunter success (Sharp and Vogel 1992, Dubovsky and Araya 2007).

Cranes from the MCP are also harvested in the RMP hunt areas in Arizona, New Mexico, Alaska (Table 5), Canada, and Mexico. The final estimate for the 2006-07 sport harvest in Canada (Manitoba and Saskatchewan) has not been completed, but will likely be near 9,500 (Table 6). The estimated harvest estimate for Alaska and the RMP hunt areas in Arizona and New Mexico combined was 759 birds for 2006-07. For Alaska, sandhill crane harvest in harvest zones 1-6 is believed to be mostly MCP cranes and zones 7-12 are sandhill cranes from the Pacific Population of lesser sandhill cranes. There also is some intermingling of MCP cranes with RMP cranes in portions of New Mexico and Arizona; however, bag checks allow estimates of specific harvests for each population. There are no annual harvest surveys in Mexico, but annual MCP harvests probably are <10% of the retrieved harvest in the U.S. and Canada (R. Drewien and D. Nieman, personal communication). This assumed low level of harvest was supported by an independent assessment of harvest in Mexico (Kramer et al. 1995). The 2006-07 preliminary estimate of retrieved and unretrieved kill of MCP cranes by sport hunters was 35,341, 3% lower than last year's estimate of 36,330 (Table 7, Fig. 13).

To assess the relative rates of change between population size (abundance) and harvest, we used linear regression on the natural log-transformed values for these variables for the years 1982-2004. Because >10% of the MCP occurs outside the CPRV in the spring of some years, we combined the photo-corrected counts in the CPRV with the ocular cruise estimates from areas outside the CPRV for analyses of population abundance. For harvest, we used only the estimates of retrieved harvest for the Central Flyway, RMP hunt areas in Arizona and New Mexico, Alaska, and Canada, because crippling-loss rates for the latter three areas are unknown and no empirical estimates of harvest from Mexico are available. Regression of the log-transformed values indicate a non-significant slope for the abundance values (P = 0.20; $R^2 = 0.078$; slope = +0.7% per year change), suggesting no trend in the abundance of cranes over the time frame. However, the regression of the harvest values suggested an increase in the rate of harvest over that same time period (P < 0.01; $R^2 = 0.67$; slope = +2.6% per year) (Fig. 14). These results suggest that the increase in the rate of harvest is increasing faster than the rate of growth in crane abundance.

The abundance and harvest trajectories of MCP cranes have diverged during the 1982-2004 period, with harvest increasing at a faster rate than numbers of birds (Fig. 13). These divergent trends cannot continue indefinitely. Therefore, initial tools have been developed (e.g., Araya and Dubovsky 2007, Dubovsky and Araya 2007) that will assist managers in structuring changes in harvest regulations should such a need arise in the future. Results suggest that a bag-limit reduction of 1 bird per day may reduce state-specific harvests by 4% to 23%, whereas fairly large restrictions in season framework dates may be needed to realize a perceptible decrease in harvest.

Subsistence harvest levels of MCP sandhill cranes historically were poorly documented. However, the recent U.S./Canada Migratory Bird Treaty Amendment will result in improvements to sandhill crane harvest-monitoring programs in both the U.S. and Canada. Intensive studies conducted on the Yukon-Kuskokwim (Y-K) Delta, Alaska, in 1999 reported an MCP harvest of 3,907 adults and fledged young and of 920 eggs. These estimates are similar to long-term averages (1989-98) of 3,362 adults and fledged young and 547 eggs taken by subsistence hunters on the Y-K Delta. Efforts are being

made to gather additional information on subsistence harvests for the remainder of Alaska, Siberia, and Canada.

Rocky Mountain Population of Greater Sandhill Cranes

The RMP was not hunted in the U.S. from 1916 until 1981, when Arizona initiated the first modern-day season. Since 1982, hunting programs have been guided by a cooperative management plan, including a harvest strategy that has been periodically updated and endorsed by the Central and Pacific Flyways (Kruse et al. 2007). Special limited hunting seasons during 2006-07 resulted in an estimated harvest of 907 RMP sandhill cranes (Table 8), which was 29% higher than the previous year and a record high harvest for the population (Fig. 15).

Counts conducted in the SLV during the spring migration suggested that the number of RMP cranes was relatively stable during 1984-96 (Table 9). However, survey biologists found that these estimates contained increasing numbers of the MCP (lesser subspecies). An adjustment, using ground-derived proportions, was made to correct for the lesser subspecies but was not a viable approach for the long-term (Benning et al. 1996). In 1996, the survey was discontinued (Fig. 16). In 1997, an attempt was made to survey these cranes during the fall (October) in the SLV, but MCP cranes also were present at that time. Biologists concluded that neither a spring nor a fall count in the SLV would result in a reliable index to the abundance of the RMP. As an alternative, a cooperative 5-state September pre-migration staging-area survey, experimentally tested in 1987 and 1992, has been ongoing operationally since 1995. Because no other known crane population co-mingles with them during that time, the September pre-migration survey for the RMP appears to be a good alternative to either a spring or fall survey in the SLV. This fall survey was designated as the official count for the RMP in 1997 (Table 10). Although operational in 1995 and 1996, the survey was variable in timing and survey effort. What appears to be a decrease in the population estimates (Fig. 16) in 1995 and 1996 is likely more an artifact of inconsistent survey effort. The 2005 fall survey resulted in an index of 20,865 birds (Drewien et al. 2005). The 2005 survey was determined to be reliable by survey biologists and the resulting 3-year average of 19,633 is within the established population objectives (17,000 - 21,000) (Fig. 17). portion of the survey could not be completed in the fall of 2006 because of aircraft engine problems, so the 2005 population estimate is the most recent available for determining harvest allocation for the 2007-08 hunting season. The Service has arranged for a backup aircraft, so no problems are anticipated for successful completion of the 2007 fall survey.

During 1986-95, important breeding areas in the Intermountain West experienced extremely dry conditions and indices of recruitment (% juveniles) were low (generally between 4-6%) (Fig. 18). A return to more favorable breeding conditions during 1996-99 resulted in higher recruitment rates (8-12%), but drier conditions resulted in lower production during 2000-02. There was some improvement in breeding areas in 2003-04 and recruitment rates again increased to above average levels. Biologists believe that the production outlook for the 2007 breeding season will remain above average. Based on population and recruitment indices for 2004-06, management guidelines allow for a maximum take of 1,321 birds during 2007-08 hunting seasons.

Discussion and Research Implications for Management of Sandhill Cranes

- 1. Satellite transmitters placed on sandhill cranes during spring at the Platte River. Nebraska, allowed the tracking of MCP cranes as they traversed U.S. states, provinces and territories in Canada, northeastern Asia, and Mexico during 1998-2003. The study tracked about 150 cranes during their annual cycle and will have far-reaching management implications, including: 1) resolving critical issues related to harvest regulations, 2) determining spatial and temporal distribution patterns of subspecies, 3) assessing annual bias of population estimates, 4) identifying breeding, migration, and wintering habitat affinities to better target habitat conservation programs, and 5) refining techniques for monitoring a wide range of species of migratory birds that spend parts of their annual cycle in remote regions of North America or Asia. Satellite tracking information is available at the following Internet address (G.L. Krapu, Northern Prairie Wildlife Research Center,, personal communication): http://www.npwrc.usgs.gov/perm/cranemov/cranemov.htm
- 2. A research study to estimate survival rates from leg-banded RMP cranes was completed several years ago (Drewien et al. 2000). Although this information provided insight into distributions, fidelity, and mortality factors, the sample size was inadequate to accurately estimate survival rates. A new study will estimate survival rates from approximately 10,000 resighting observations of RMP color-marked and neck-collared cranes (Drewien et al. 2002). Further, the researchers will attempt to develop a model of recruitment for these cranes. The overall goal is to develop a model of population dynamics, which would allow improvements in the harvest strategy for this population of cranes.
- 3. The agricultural landscape, on which sandhill cranes depend for a portion of their annual cycle, has undergone dramatic changes in recent years. In particular, some areas have experienced changes in the types of crops being planted, harvest efficiency has increased, and genetically modified crops are being introduced. Additionally, ongoing and proposed research by the Northern Prairie Wildlife Research Center will investigate how reduced waste grain availability in the Platte River Valley may affect the distribution and abundance of cranes. Results of these studies will enable managers to better target habitat actions which will benefit cranes.
- 4. A landscape-scale study of sandhill crane habitats is being conducted by Tandi Perkins and Leigh Fredrickson with collaborators from the U.S. Fish and Wildlife Service, the States, and the government of Mexico. The study is looking at the annual life cycle of RMP cranes and the ability of the landscape to meet requirements of the cranes at each stage of their cycle, from breeding grounds in Idaho and Montana to wintering grounds in Mexico. Currently, biologists and managers lack information about the distribution, availability, and quality of wetland foraging habitats at a local landscape scale, and how anthropomorphic changes to the landscape may be impacting birds. Understanding the temporal dynamics of wetland and agricultural habitats in this changing system and how birds respond to these changes is critical for the future management of this population.

² A proportion of the Alaskan harvest is composed of lesser sandhill cranes from the Pacific Coast Population

³ Harvest data are from state harvest surveys for only the MCP portion of the state, except in 1977-81, 1986, 1991, and 1998-99 where

federal MQS state totals are prorated by the long-term percent MC cranes; data from 2000 forward are MC portion from HIP.

⁴ This MC harvest for AZ and NM represents MC sandhill cranes that were harvested in RMP areas and are not represented in the CF MC Sandhill Crane Federal Harvest Survey

⁵ HIP used instead of the Federal Permit for TX (1997-present), CO (1998-present), ND (2002-present), and OK and KS (2006-present). NM uses a combination of electronic and paper permits.

^{*} No estimate is available.

² Unknown harvests (Mexico) were assumed to be 10% of harvests in the U.S. and Canada.

³ Unretrieved kill as reported by hunters is used for the Central Flyway; for the remainder of harvest areas, it is assumed to be 20% of retrieved harvests.

⁴ There is no estimate available for AK in that year.

2006 ³						NS	

¹ Incomplete survey efforts in years prior might have resulted in lower estimates; the official count begins in 1997.

Raw estimate adjusted by photography for estimation bias
 Population estimate adjusted to remove the number of lesser sandhill cranes (non-RMP cranes).

² In October 1997, a special survey was also conducted in the SLV, Colorado and other areas, which resulted in a total of 27,090 Rocky Mountain and Mid-Continent cranes being counted.

³ In 2006, the survey was not conducted due to mechanical issues with the survey plane. $S:\CF_D\projects\CRANES\mcp\Shcranerep.xls$ 06/15/07

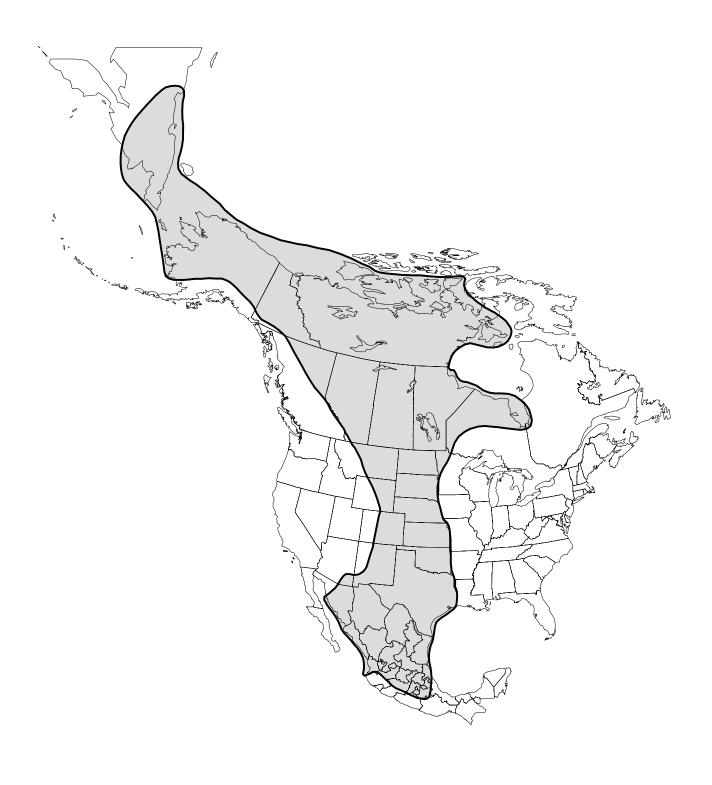

Fig. 1. Approximate range of Mid-Continent sandhill cranes (based on figures in Sharp et al. 2000, Tacha et al. 1994, and data from radio-telemetered birds provided by G. Krapu, Northern Prairie Wildlife Research Center, Jamestown, ND).

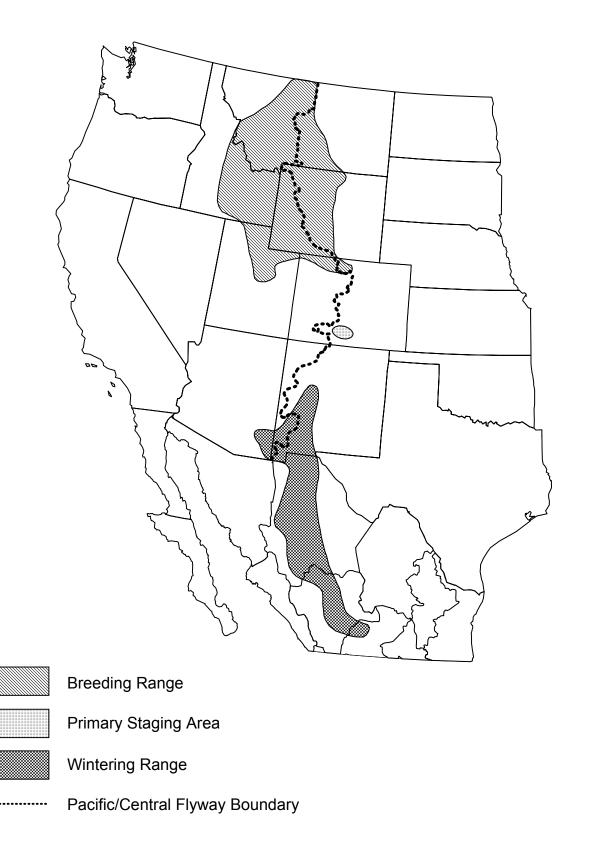

Figure 2. Approximate range of the Rocky Mountain Population of greater sandhill cranes.

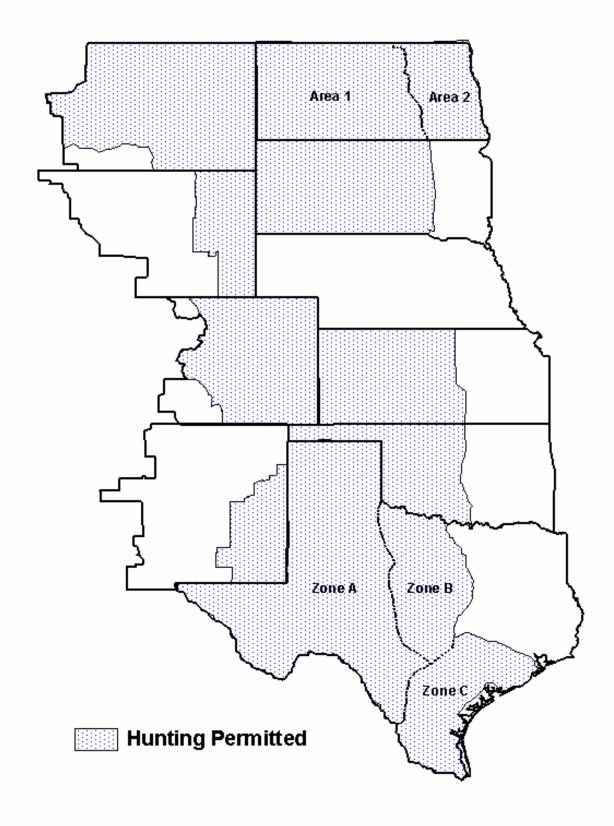

Figure 3. Areas open to the hunting of Mid-Continent sandhill cranes by Federal frameworks in the Central Flyway states, 2005-06.

Figure 4. Annual harvests of Mid-Continent sandhill cranes in Saskatchewan and North Dakota, 1980-2006.

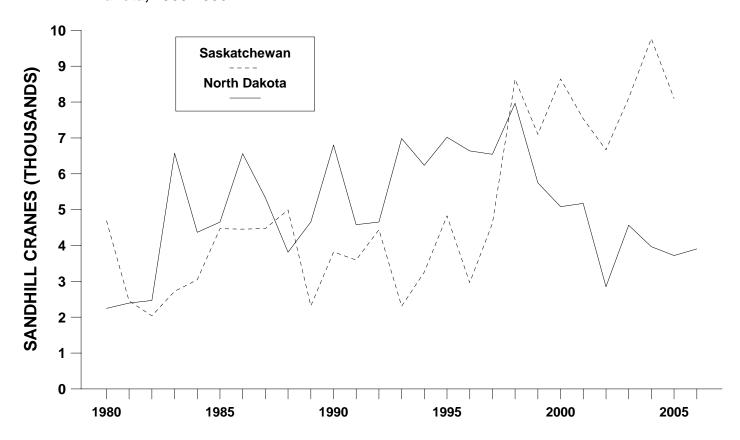

Figure 5. Spring population indices for Mid-Continent sandhill cranes on the Central Platte River Valley, Nebraska.

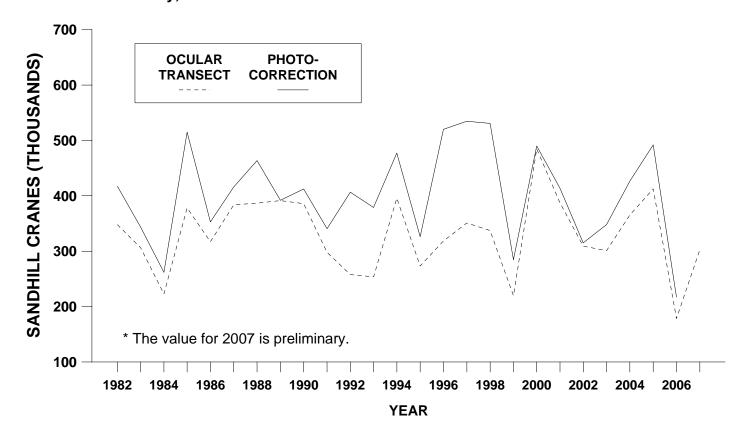

Figure 6. Photo-corrected spring population estimates (solid line) and the 95% confidence intervals (dashed lines) for Mid-Continent sandhill cranes on the Central Platte River Valley, Nebraska.

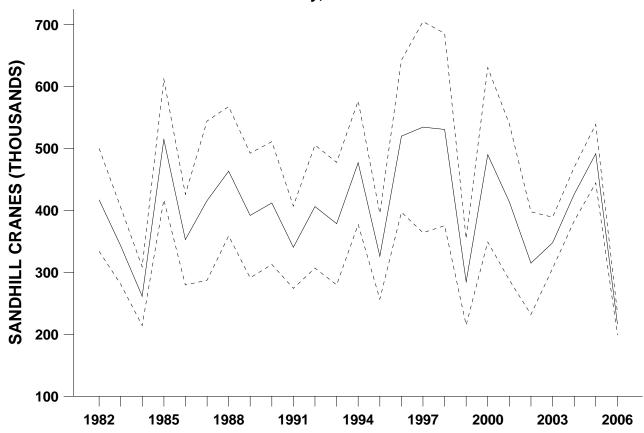

Figure 7. Annual and three-year average photo-corrected ocular transect spring population indices and population objective thresholds for Mid-Continent sandhill cranes.

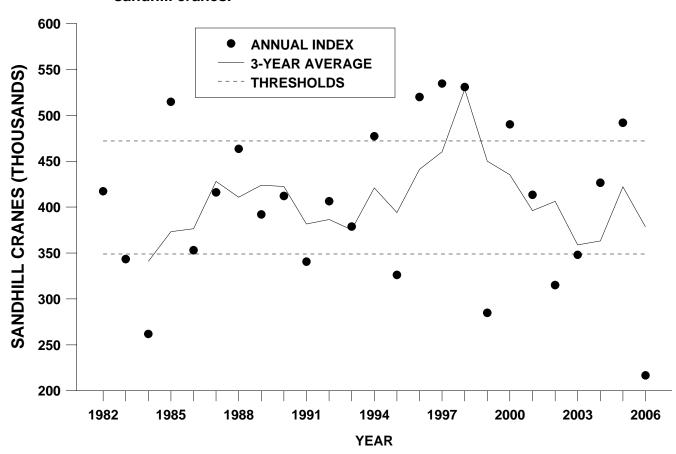

Figure 8. Active Mid-Continent sandhill crane hunters in the U.S. portion of the Central Flyway.

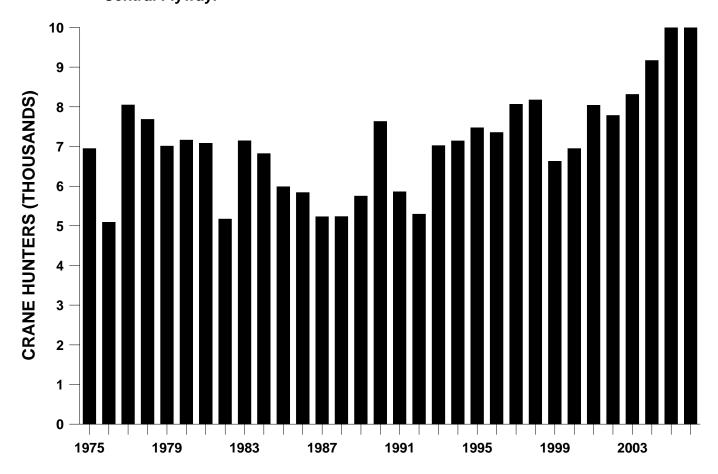

Figure 9. Crippling loss rate (number lost/[number retrieved + lost]) of Mid-Continent sandhill cranes in the U.S. portion of the Central Flyway.

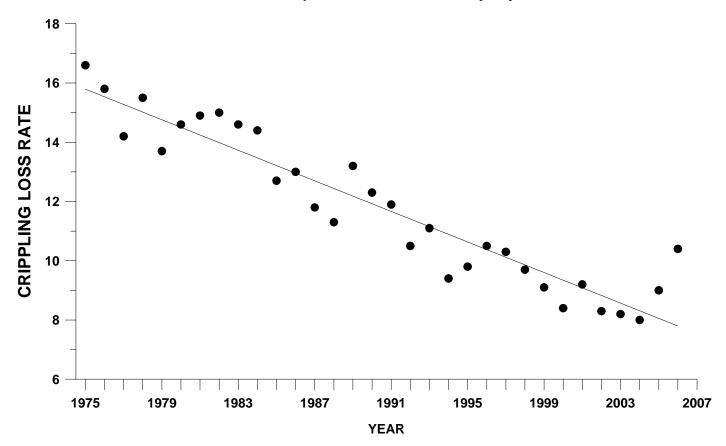

Figure 10. Average number of hunting days afield reported by active Mid-Continent sandhill crane hunters in the U.S. portion of the Central Flyway.

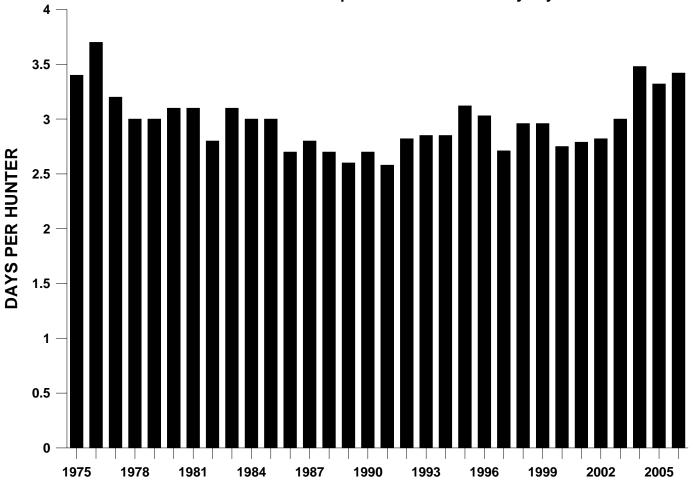

Figure 11. Seasonal bag per Mid-Continent sandhill crane hunter in the U.S. portion of the Central Flyway.

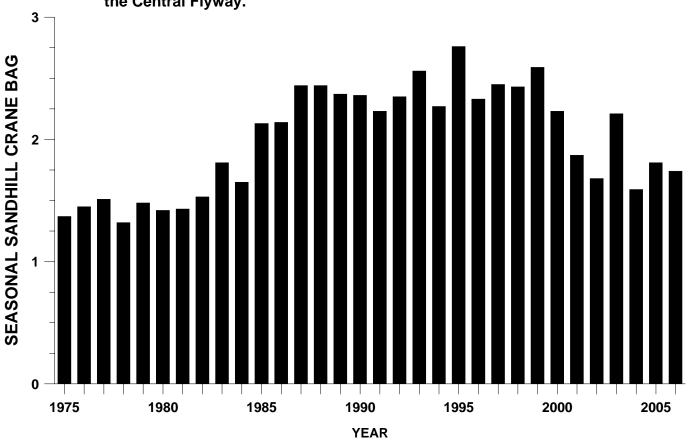

Figure 12. Estimated hunting mortality (retrieved and unretrieved) of Mid-Continent sandhill cranes in the U.S. portion of the Central Flyway.
