A flex life specification has not been established for coils used in the Transvene leads (e.g., 6999). However, electrode coils have been tested for comparison to established conductor coil specifications. Since electrode coils experience much less severe flexing than that seen by conductor coils, the electrode coil used in the Model 6999 was flexed (at (b)(4) radius) in order to characterize its flex life performance relative to Medtronic's established standard; the Model 6907.

For the purpose of data reporting, Medtronic has historically compared lead flex life to the Model 6907. The Model 6907 has approximately 20 years of field experience. Of approximately (b)(4) sold, only (b)(4) conductor coil fractures have been reported in this time (b)(4) Therefore, ANY lead with a flex life equal to or greater than the Model 6907 is considered safe and effective for its intended use. This is the basis for the design requirement of a median failure time of (b)(4) cycles, or greater, at a bend radius of (b)(4) inches. Therefore, since the median flex lives of the non-insulated electrode coil of the Model 6999 lead exceeds the (b)(4) cycle requirement at (b)(4) inches, the coil is considered acceptable.

The median failure time of the Model 6999 non-insulated (b)(4) (b)(4) cycles) and (b)(4) (b)(4) cycles) electrode coils both exceed (b)(4) cycles and are therefore considered acceptable and reliable for their intended use relative to flex life.

Note that in addition to the aforementioned flex testing of just the electrode coils of the Model 6999 patch lead, the composite patch electrode was subjected to (b)(4) month life test. This composite design effectively enhances the flex life of the electrode coils by virtue of having the silicone core and surrounding silicone patch body dampening and supporting the electrode coils.

The difference in flex life of these coils can be attributed to the coil design. Several factors are considered in the design of all electrode coils. These factors determine characteristics of the coil such as flex fatigue resistance. Because the design parameters are unique to the individual coil design and differ from other coil designs, direct comparison cannot be made between the coils of different leads.

The flex life of a coil is dependent on the outer diameter of the coil, the diameter of the wire and the spacing of the wire. The outer diameter of (b)(4) and (b)(4) coils are identical, however, the diameter of the wires, (b)(4) inch and (b)(4) inch respectively, giving the (b)(4) coil reduced flex fatigue resistance. However, the spacing of the (b)(4) coil is twice that of the (b)(4) (b)(4) coil. Increases in spacing contribute to a reduction in flex fatigue resistance. Therefore, the reduced spacing gives the (b)(4) coil greater resistance to flex failure.

The flex test protocol provides a uniform, accelerated method for evaluating electrode coils in terms of the flexural fatigue life. The test fixture induces three types of forces on the test samples, (b)(4) and (b)(4) The failure mechanism seen in the flex test performed on the Model 6999 lead was that of (b)(4) (b)(4) occurs when a point on the coil(s) is(are) held (b)(4) while the remaining coil is (b)(4) The (b)(4) forces eventually fatigue the metal and the (b)(4)

The redundant design of the Model 6999 lead was intended to eliminate the effect of an electrode coil failure from completely removing the coil from the electrical circuit. A failure would need to occur in two locations on the same coil loop before any portion of the electrode coil would be removed from the electrical circuit. The (b)(4) coil carries approximately (b)(4) of the total current of the patch.

Damage to one or two of the electrode coils of the Model 6999 lead can range from (b)(4) of the electrode coil with no loss of electrical continuity, to (b)(4) of the electrode coil loop. Any damage to the electrode coils that does not affect electrical continuity would not affect patient treatment.

However, (b)(4) of an electrode coil would not affect patient treatment due to the (b)(4) design of the lead. A (b)(4) in any (b)(4) of the design would not remove any portion of the electrode coil from the electrical circuit. This holds true for (b)(4) with discontinuities in the electrode coil, i.e., the electrode coils would still remain in the circuit.

Animal studies simulating the loss of certain of the coil (b)(4) in subcutaneous patch electrodes have been conducted. Impedance data was gathered from (b)(4) (b)(4) implanted with (b)(4) patch configuration at (b)(4) A special subcutaneous patch electrode which had separate electrical connections for each coil was used. This allowed for selective removal of (b)(4) from the circuit and a measurement of the effect on impedance.

The data in Table 1 demonstrate that impedance increases if coils are removed from the circuit and the increase will be associated with a change in electric field distribution. A small effect on DFT would be expected if both innermost coils failed. If one or both of the outer coils failed the increase in DFT would be somewhat larger, however, in neither case would it represent a serious threat to treatment of the patient. Also, it is important to bear in mind that this experiment simulated complete removal of (b)(4) or (b)(4) from the circuit, a condition which has not been observed in either the bench testing or the clinical study.

8. **Please specify the section of each lead assembly that was flexed during life testing. Does this section include the electrode coil? The results of the tests should be included.**

RESPONSE:

Both the insulated lead body (conductor coil(s) and insulation(s)) and the non-insulated defibrillation electrode portion of lead Models 6963, 6966 and 6999 were flexed during the Lead System Life Test. The test method as described on page 505 of the PMA inadvertently states that only the Model 6999 defibrillation electrode (patch) was flexed. In fact, the insulated lead body and the non-insulated defibrillation electrode were flexed on all leads. An updated version of the test method is attached that clarifies these items.

The defibrillation electrode section of lead Model 6963 which was flexed included the (b)(4) long defibrillation coil. A schematic is shown below:

(b)(4)

(b)(4)

The defibrillation electrode section of lead Model 6966 also included the (b)(4) long defibrillation coil. A schematic is shown below:

(b)(4)

(b)(4)

The defibrillation electrode section of lead Model 6999 includes the entire molded patch assembly. A (b)(4) was developed to flex the assemblies. A schematic of the lead and test fixture are shown below:

(b)(4)

(b)(4)

Test (b)(4) for Flex Test of Patch Body

Per the test protocol, the insulated lead body and the non-insulated defibrillation electrode portion of lead Models 6963, 6966 and 6999 were flexed (b)(4) cycles at each of (b)(4) monitors, for a total of (b)(4) flex cycles. All three lead Models met this requirement and were fully functional at the completion of the (b)(4) long test. The (b)(4) Model 6966 and (b)(4) Model 6963 leads have been placed onto the flex tester and are being further flexed to (b)(4) cycles. The Model 6999 leads were not specifically tested beyond the life test requirement of (b)(4) cycles as this has been completed via similarity to the Model 6921 patch lead. The design of the lead Model 6999 is functionally equivalent to the Model 6921 epicardial lead which has demonstrated a flex life in excess of (b)(4) cycles (reference PMA P900061, Amendment submitted October 31, 1991).

10. The data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test. Correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

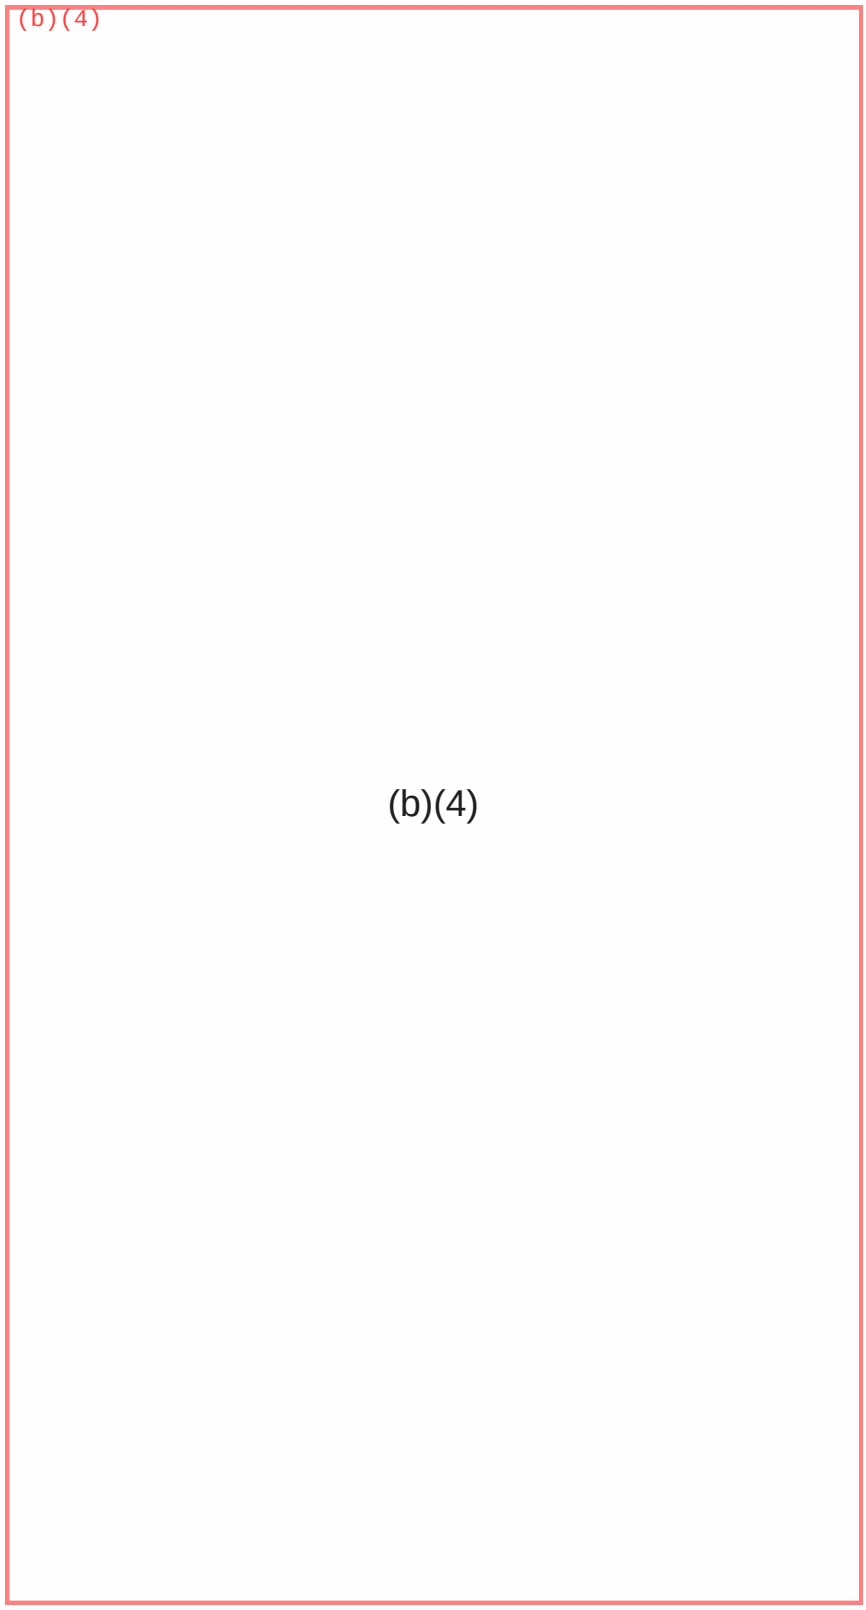
RESPONSE:

A separate lead is required for those tests which are considered destructive by the nature of the test. This includes lead joint tensile strength testing, crimp/weld pull strength testing, flex testing, anchoring sleeve testing and life testing. Therefore, it is not possible to get meaningful results from sequential testing of these tests.

Sequential testing, however, of non-destructive tests are performed throughout the qualification process, wherever possible. This includes thermal shock, resistance and stiffness testing. See the bench testing flow diagram on the following page. These data were presented in the non-clinical bench testing section of this PMA.

(b)(4)

Bench Testing Flow Diagram



11. Discuss the differences in battery life or energy requirements between the epi-lead system and the Transvene™ system.

RESPONSE:

The longevity of the Model 7217B device depends upon several factors including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the frequency of high voltage capacitor charging, and on the pacing load. The first three parameters depend on the specific patient needs and are not related to the implanted lead system. The pacing load, or the pacing impedance of the system, is different for the two lead systems (Epicardial and Transvene).

The epicardial lead system impedance measured clinically ranges from (b)(4) (b)(4) ohms acutely. The mean is (b)(4) ohms. The Transvene lead system impedance measured clinically ranges from (b)(4) ohms acutely. The mean is (b)(4) ohms. The greater the system impedance, the less energy required for both bradycardia and anti-tachy pacing. The greatest battery drain occurs when bradycardia pacing is required 100% of the time. The anti-tachy portion is relatively insignificant.

To summarize, the battery life of the Model 7217B PCD device depends upon several factors, the most significant of which is the need for 100% (fulltime) pacing for bradycardia. The lead system impedance has an influence on the energy required to pace. The Transvene lead system is slightly more efficient as verified by the impedance values measured clinically.

12. An update of the chronic animal studies should be provided.

RESPONSE:

Two chronic animal studies are updated in response to this deficiency. These include Study Nos. 2 and 4, as presented in the March 31, 1992 PMA application.

Study No. 1 was acute; an update is not relevant. Study No. 2 was essentially completed at the time the March 31, 1992 PMA application was submitted. However, a pathology status report, post-study, is presented in this response for completeness. Study No. 3 was also completed at the time of the March 31, 1992 PMA application; therefore, an update is not relevant. Study No. 4 was presented in the March 31, 1992 PMA and included data through (b)(4) weeks. An update is included through approximately (b)(4) weeks.

(b)(4)

13. **An update of the clinical experience of the Transvene™ Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, lead orientations including patch location, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.**

RESPONSE:

An updated clinical experience report is provided in Volume 2 of this PMA Amendment. The data is presented as it was in our original (March 31, 1992) Transvene PMA application.

The updated experience is inclusive of 757 patients followed for an average of six months.

14. Please discuss your clinical data which support the claim which states that the Transvene™ Lead System improves both perioperative and long term patient morbidity.

RESPONSE:

In order to evaluate the impact of the PCD Transvene System on perioperative and long term patient morbidity, patient hospital stay post implant and the incidence of complications in patients with implant durations greater than six months was evaluated.

Hospital stay is an indicator for improved patient morbidity since it represents the amount of time required for patient recovery. Patients undergoing thoracotomy procedures generally require additional time for recovery due to the invasiveness of the procedure and related pulmonary complications.

In the case of the PCD Transvene System, the mean time for hospital stay post implant of the system was 7.2 days. This compared with a mean post implant hospital stay for the PCD Epicardial System of 10.3 days. This difference in hospital stay was statistically (b)(4) (b)(4) A shorter hospital stay for the patients who received a PCD Transvene System indicated that these patients were able to recuperate more quickly from the implant procedure due to the fact that a thoracotomy was not required. Those patients who require a thoracotomy have the added perioperative risk of complications associated with a thoracotomy such as pulmonary complications.

In the case of long term patient morbidity, Medtronic is not claiming that the PCD Transvene System improves long term patient morbidity. Instead, the long term patient morbidity should be similar to that reported with the PCD Epicardial System.

Analysis was performed to determine the types of complications which occurred in patients with implant durations of equal to or greater than six months. It is not expected that the PCD Transvene System would improve long term patient morbidity but rather should not increase the patient risk over long implant durations.

There were (b)(4) patients who received a PCD Transvene System in whom the implant duration was equal to or greater than six months. Of these patients (b)(4) (18.9%) experienced a medical event which was classified as a complication. It should be noted that these complications may have

occurred at any time during the implant duration and not necessarily after six months of implant duration.

As a comparison in the PCD Epicardial System, a total of (b)(4) patients have implant durations equal to or greater than six months. In this patient group, (b)(4) patients (14.1%) have experienced a medical event which was classified as a complication.

Thus based on this clinical data, the use of the PCD Transvene System results in a shorter hospital stay post implant and does improve perioperative morbidity. In addition, the use of the PCD Transvene System does not place the patient at increased long term morbidity.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

RESPONSE:

Patients who are generally considered for implantation of an ICD System have a history of moderate to severe cardiovascular dysfunction. These patients have a history of coronary artery disease, cardiomyopathy, congestive heart failure as well as depressed left ventricular function. The multiple concomitant cardiovascular disease processes place these patients at increased perioperative mortality after a thoracotomy procedure.

There is a class of patients who cannot tolerate the thoracotomy required for the placement of the epicardial patch lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with epicardial lead system, implantation in the following patient groups may not be possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who cannot tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality after a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, the PCD Transvene System is the only therapy available. The PCD Transvene System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, options for future therapy remain available; e.g. CABG is associated with decreased morbidity and mortality if there has been no prior open chest surgery.

In the case of the PCD Epicardial System, 35 patients expired in the perioperative period with a perioperative mortality of 4.7%. These patients, again due to there underlying cardiovascular disease, could not tolerate a thoracotomy. Lehman, et al [Lehman, et al. Implantable Cardioverter Defibrillators in Cardiovascular Practice: Report of the Policy

Conference of the North American Society of Pacing and Electrophysiology. PACE. 1991;12:969-79.] reports a perioperative mortality of 2.5% - 5.4% in a multicenter experience with an AICD Epicardial System. These patients again represent a group which could not tolerate a thoracotomy for implantation of an ICD System.

In the case of the PCD Transvene System, (b)(4) patients were initially screened for a PCD Transvene System. Of this group, 757 received a PCD Transvene System with **28.3%** of the patients (214/757) receiving the system despite not meeting the recommended implant criteria. The physician felt that in these cases the potential morbidity and mortality associated with the thoracotomy required for an epicardial defibrillation lead system outweighed the risk of not meeting the Medtronic recommended defibrillation requirement. It should be noted that the majority of these patients (97.3%) who received a PCD Transvene System, had at least a 10 Joule safety margin between the lowest successful defibrillation energy and the maximum output of the PCD Device (34J).

The use of an ICD System that requires a thoracotomy for implantation of the defibrillation lead system has been a mainstay in the treatment of ventricular tachyarrhythmias for over ten years. The system has performed remarkably as witnessed by its positive effect on sudden cardiac death mortality.

However, with the use of the ICD System in sicker patients, the need for an implantation procedure that decreases perioperative risk has arisen and lead to the development of a nonthoracotomy defibrillation lead system. But, there will continue to be patients, such as those undergoing concomitant cardiovascular surgery or patients who do not the meet recommended defibrillation implant criteria with the PCD Transvene System, who will receive an ICD System with an epicardial defibrillation lead system.

16. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

RESPONSE:

A summary table of this data and relevant discussion is provided below.

PCD™ Transvene™ System Data Summary		
	All Patients (3 Electrode Systems)	Patients with 6 months of Follow-up
Number of Patients	(b)(4)	
Device Months Follow-up		
Mean Follow-up Time		
Maximum Follow-up Time		
Number, % Male Number, % Female

Lead Orientation: RV-CS-SQ RV-SQ-SVC RV-CS-SVC		
Mean LED		
Mean DFT		
Spontaneous VT: Number of Patients Number of Episodes % Success		
Spontaneous VF: Number of Patients Number of Episodes % Success		
One Year Overall Survival One Year SCD Survival		
Patients with complications		

(b)(4)

The patient population (b)(4) with six months of follow-up are predominantly male (80.2%) with a mean age of 58.0 years. In the majority of patients the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. The treatment efficacy for this patient population was 99.0% for spontaneous VT episodes, and 98.7% for spontaneous VF episodes, which is equivalent to the total patient population 98.7% and 99.1% respectively. Overall survival at one year for these patients is 99.4% and sudden cardiac death survival at one year was 100.0%. (b)(4) (18.3%) of the patients followed for six months had a complication.

Based on the data above, the PCD™ has performed safely and reliably for patients followed for 6 months or greater.

17. Please discuss your clinical experience (treatment efficacy, lead orientation, complications and survival rates) of the patients who have been followed for 1 year and more.

RESPONSE:

A summary table of this experience and relevant discussion is provided below.

PCD™ Transvene™ System Data Summary		
	All Patients (3 Electrode Systems)	Patients with 12 months of Follow-up
Number of Patients	757	115
Device Months Follow-up	4246.4 mo	1835.5 mo

Mean LED	16.0 (n=702)	15.2 (n=105)
Mean DFT	14.8 (n=316)	13.8 (n=62)
Spontaneous VT: **Number of Patients** **Number of Episodes** **% Success**	 226 5430 98.7%	 60 1770 98.9%
Spontaneous VF: **Number of Patients** **Number of Episodes** **% Success**	 198 973 99.1%	 37 248 98.8%
One Year Overall Survival **One Year SCD Survival**	95.3% 99.8%	100.0% 100.0%
Patients with complications	138 18.2%	24 20.9%

The patients population (b)(4) with 12 months or more of follow-up is predominantly male (79.1%) with a mean age of 57.0 years. In the majority of patients (48.7%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. The treatment efficacy for this patient population was 98.9% for spontaneous VT episodes, and 98.8% for VF episodes, which is equivalent to the overall patient population with 98.7% and 99.1% respectively. Overall and sudden cardiac death one year survival for this patient population is 100.0% since all patients have been followed for one year or greater. In the patients followed for 12 months or more there has been one death which is classified as non-sudden cardiac. This death occurred 684 days (22.5 months) post implant. (b)(4) (20.9%) of the patients followed for 12 months had a complication.

Based on the data above, the PCD™ has performed safely and reliably for patients followed for 12 months or greater.

18. **Provide a detailed discussion of the clinical experience (implant duration, lead orientations, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene™ System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.**

RESPONSE:

For purposes of the PCD Transvene System, the recommended implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not necessary.

Of the 757 patients who received a PCD Transvene System, 214 patients (28.3%) received the system despite not meeting the recommended implant criteria.

Table 1 summarizes the physician justification for implanting the PCD Transvene System despite not meeting the recommended defibrillation implant criteria.

PCD Transvene System Patients Not Meeting Implant Criteria Physician Justification 6/24/92	
Reason	**Number of Patients**
LED < 24 Joules	170 (79.4%)
Difficult to Induce VF	24 (11.2%)
Patient Condition	20 (9.4%)
TOTAL	214

Table 1: Physician Justification for Patients Not Meeting Implant Criteria - 6/24/92

It should be noted, however, that 90.7% (194/214) of these patients had at least a 10 Joule defibrillation safety margin between the lowest successful defibrillation energy and the maximum output of the PCD Device (34J). Table 2 provides clinical data on this group of patients who received a PCD Transvene System.

PCD Transvene System Patients Not Meeting Implant Criteria Clinical Experience 6/24/92	
Patient Characteristics

Noncardiac	100%
Overall	97.4%

Table 2: Patients Not Meeting Implant Criteria Clinical Experience - 6/24/92

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD Transvene System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N=11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N=6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N=3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these twenty patients, ventricular fibrillation has been induced at a chronic follow-up visit in 15 patients (75%) and in all cases successful defibrillation with the implanted PCD Transvene System was documented.

The overall spontaneous VF episode efficacy for this patient group was 92.6%, however, further review indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There has been one reported patient death, (Patient (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 93.8%. This lower overall one year survival may be due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

The recommended implant criteria for the PCD Transvene System is defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. However, in some cases, the investigators felt that the patient's medical condition precluded a PCD Epicardial System implant with a thoracotomy approach and its associated morbidity and mortality. This clinical experience indicates that the PCD Transvene System performed safely and effectively in this patient population.

19. A breakdown of the different lead orientations within the patient population, and the treatment efficacy reported for each configuration should be included.

RESPONSE:

The following table shows the clinical data by type of lead system for the three lead systems presented in the Transvene™ PMA clinical report. the majority of patients (718 or 94.8%) received used a subcutaneous patch as part of their defibrillation lead system. The majority of patients (65.5%) received a lead in the Superior vena cava; 29.3% received a lead in the Coronary Sinus. Only 39 patients or 5.2% received a totally transvenous three lead system.

The performance of these three lead systems in terminating episodes of spontaneous ventricular tachycardia and ventricular fibrillation was very good. All systems had at least a 98.5% success rate in treating spontaneous episodes of ventricular tachycardia and at least a 98.8% success rate in treating spontaneous episodes of ventricular fibrillation. The RV/SVC/SQ and RV/CS/SVC lead systems had a 1 year actuarial survival of 100.0%. The RV/CS/SQ lead system had a 1 year actuarial survival of 99.4%. All of these lead systems have performed safely and effectively.

PCD™ Transvene System Lead Systems

Table DEF19: Data Summary: Implanted Lead System

20. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead orientations during implant.

RESPONSE:

Proposed changes to the Model 7217B PCD technical manual are provided in the attachment following this response, see section from technical manual, "Implanting the PCD Device - Implantation Procedure." Specific areas relative to the sequence of testing with different lead orientations during implant are highlighted for reference.

Implantation Procedure

Overview

Patients should undergo the following procedures before implant of the PCD device to help determine if they are appropriate candidates for a PCD system:

- Electrophysiologic evaluation to determine the patient's ventricular arrhythmia and how it responds to different therapies,
- Exercise stress test to determine the patient's maximum sinus rate, and
- Cardiac catheterization to determine if there is a need for concomitant surgery.

Clinical studies indicate that patients who fail a transvenous lead implant and immediately receive an epicardial lead system may be at higher risk than those patients who received the epicardial leads more than one day later. If patients do not meet the implant criteria for a transvenous lead system, physicians should consider the patients' number and duration of induced VF episodes before proceeding to an epicardial lead implant.

Implanting the PCD device and corresponding lead system involves seven main steps:

- Operative Set-Up
- Lead System Implantation and Evaluation
- Defibrillation Efficacy Testing
- Connecting the Leads to the PCD Device
- Placing the PCD Device
- PCD System Evaluation
- Closing

During implantation, the PCD system requires an appropriate Medtronic programmer and MemoryMod cartridge and the Medtronic External Tachyarrhythmia Control Device (ETCD) to evaluate and monitor the implanted lead system and therapy efficacy.

Each of the above steps is explained in the following sections. At the end of this chapter, instructions for replacing a PCD device and implanting a PCD device with a chronically implanted lead system are also given.

Operative Set-Up

The preparation and procedures before implanting the lead system are grouped into four main steps: assembling the necessary equipment, setting up the equipment, pre-programming and testing the PCD device, and pre-programming and testing the ETCD and auxiliary equipment.

Necessary Equipment

The equipment listed below should be available for each implant. Duplicates of sterile items should also be on hand.

- Model 7217B PCD device
- External Tachyarrhythmia Control Device (ETCD)
- Appropriate Medtronic programmer and printer
- Appropriate MemoryMod software cartridge
- Cardioversion/defibrillation and pacing/sensing leads
- Appropriate adaptors
- External defibrillator
- Pacing system analyzer (PSA)
- Patient cable for connecting lead system to the ETCD
- EGM cable to connect the programmer to the ETCD
- Cable (and connector pins if necessary) to connect a pacing system analyzer to the ETCD or a surgical cable to connect the PSA directly to the leads
- Test load for discharging high-voltage shocks from the ETCD
- Cables for connecting the EGM output of the ETCD and Marker Channel output of the programmer to a hospital monitor/recorder
- Appropriate batteries for the pacing system analyzer and ETCD
- Extra printer paper for the pacing system analyzer and programmer/printer
- Sterile bag to place over programming head and cable
- Implant documentation forms

Some optional equipment includes an external fibrillation source or stimulator, tape or multi-channel recorder, dual-channel oscilloscope, and appropriate cables.

Equipment Set-Up

Set up the ETCD/programmer with the appropriate MemoryMod cartridge, an external defibrillator, and auxiliary equipment such as monitors, recorders, a fibrillator, and their related cabling. Also, connect the test load to the ETCD.

Pre-Programming and Testing the PCD Device

Prepare the PCD device for implant by doing the following:

1. Interrogate the device while it is still in its sterile package and print out a full report.

2. Review the battery status. Devices with an initial battery voltage less than 6.1 volts before charging should not be implanted. If the device is charged without obtaining the initial voltage, it should be implanted only if the battery voltage reaches 6.1 volts or more within thirty minutes after charging.

3. Test the charge circuit by charging the capacitors to the maximum output. The charge time must meet the following requirements:
   - If the charge time is less than or equal to 10 seconds, implant the device. If it is greater than 10 seconds, wait 5 minutes, discharge (dump) the capacitors, and then perform a second charge.
   - If the second charge time is less than or equal to 10 seconds, implant the device. If it is greater than 10 seconds, do not implant the device.

4. While still in the sterile package set the device parameters for implant as appropriate for the patient.

5. Ensure that VT and VF Detection are programmed OFF.

Pre-Programming and Testing the ETCD & Auxiliary Equipment

To prepare for lead system evaluation and defibrillation efficacy testing, do the following:

1. Verify that the ETCD's battery status is acceptable.

2. While recording the ETCD's output signals and the Marker Channel output from the printer, calibrate the hospital's monitoring/recording equipment.

3. Test the ETCD's high-energy output capability using the test load.

Lead System Implantation and Evaluation

The PCD lead system uses electrodes designed to carry high current for cardioversion or defibrillation. The cardioversion/defibrillation electrodes (PULSE1, PULSE2, and COMMON) must be specifically suited for this purpose and have a large electrode surface area to reduce cardioversion/defibrillation thresholds and minimize tissue damage possibly caused by the high cardioversion/defibrillation currents.

While the PCD is connected to the leads, no metal portion of any electrode should contact the metal of any other electrode. If the electrodes are in contact during a cardioversion or defibrillation therapy, the current will bypass the heart and may also damage the PCD device.

Pacing occurs between a pacing/sensing lead and one of the cardioversion/defibrillation leads (COMMON). Sensing is accomplished through two pacing/sensing electrodes. Either epicardial or endocardial leads may be used. To reduce the effects of electromagnetic interference (EMI), the PACE/SENSE and SENSE2 electrodes should be positioned adjacent to each other, and where separate leads are used, the lead wires should be routed together with several loose twists.

Depending on what kind of operative approach is used to implant the leads, the PCD Device can use two different kinds of lead systems: an epicardial lead system or a Transvene™ lead system. Each system is described briefly below. See the appropriate Lead Technical Manual for more details.

The physician chooses the lead system that best meets the patient's needs. Patient factors that affect the decision include the following:

- Overall size of the patient's heart,
- Size and location of previous infarcts, aneurysms, or bypass grafts, and
- Surgical approach.

The epicardial lead system uses two or three epicardial patch leads for cardioversion/defibrillation.

Three patch sizes allow the physician the flexibility to meet the varying patient conditions. Clinical experience has shown that approximately half of all patients receive a three-patch system; the other half receives two patches. Three patches may be required initially if the physician expects difficulty in meeting defibrillation implant criteria. Adding a third patch to a two-patch system may be required if the implant criteria cannot be met with the two-patch system.

The Transvene™ non-thoracotomy lead system can use two or three leads in four different areas:

- A tripolar lead in the right ventricle (RV).
- A unipolar lead in the coronary sinus (CS) and/or superior vena cava (SVC).
- A subcutaneous (SQ) patch lead.

Cardioversion/defibrillation occurs between the COMMON electrode (cathode) and one or two anodes. These electrodes can be any of the following: the CS lead, the SVC lead, the RV coil, or the SQ patch. Sensing occurs between the tip and ring of the tripolar RV lead. Pacing occurs between the tip of the RV lead and the COMMON electrode.

Lead system implantation and evaluation consists of placing the lead system, connecting the leads for pacing and sensing measurements, performing pacing and sensing measurements, and verifying lead connections. Each step is explained in the following sections. See the appropriate lead technical manual for more details.

Placing the Lead Systems

Placing the Epicardial Lead System

Depending on the physician's preference, a variety of surgical approaches can be used to implant the lead system, such as a limited thoracotomy or median sternotomy.

Placing Pacing/Sensing Leads:
The pacing/sensing leads should be placed close to the ventricular apex to avoid sensing P-waves. Approximately 1 cm should separate the electrodes from each other.

Placing Epicardial Patch Leads:
Suture two or three patch leads to the epicardium or pericardium in locations that produce optimal defibrillation, pacing, and sensing. In all locations, place the leads so that they encompasses the maximum amount of cardiac mass and they have approximately equal amounts of mass between them.

For a two-patch system, a typical approach is to use an anterior right ventricular patch as COMMON and a posterolateral left ventricular patch as PULSE2. For a three-patch system, a typical approach is to use a posterior ventricular septal patch as COMMON, an anterior right ventricular patch as PULSE1, and an anterolateral left ventricular patch as PULSE2. The PULSE1 and PULSE2 patches should be the same size.

Placing Transvene™ Leads

CAUTION: If insertion is done via a subclavian approach, the lead should be positioned far laterally to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead may eventually cause the conductor to fracture, may cause damage to the insulation, or may cause other damage to the lead. This may result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, may also precipitate pinching and subsequent fracture of the lead. If significant resistance is encountered during a subclavian stick implant procedure, do not force the lead by adjusting patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. In such cases it is recommended that an alternate venous entry site be used.

There are several possible lead systems that can be evaluated depending on the desired pathway and physician placement preference.

Three Lead System:

- Right ventricle, superior vena cava, and subcutaneous patch.
- Right ventricle, coronary sinus, and subcutaneous patch.
- Right ventricle, coronary sinus, and superior vena cava.

Two Lead System

- Right ventricle, coronary sinus.

- Right ventricle, subcutaneous patch.
- Right ventricle, superior vena cava.

For recommendations on the order of lead system evaluation refer to "Defibrillation Efficacy Testing" (the next section of this manual).

The RV, CS, and SVC lead should be implanted using standard transvenous implant techniques. Follow the general guidelines below for initial positioning of the Transvene™ lead system (the final positions will be determined by defibrillation threshold tests):

- Position the RV lead tip in the right ventricular apex.
- Advance the CS lead tip to just under the left atrial appendage, if possible.
- Place the SVC lead tip approximately 5 cm proximal to the right atrium and SVC junction.
- Place the SQ patch lead along the left midaxillary with the center over the fourth-to-fifth intercostal space.

Other positioning recommendations to consider:

- The CS lead position should be considered unacceptable if the proximal end of the CS defibrillation coil is at or outside the CS ostium.
- A cutaneous patch electrode may also be used during acute testing to minimize invasive procedures. Once defibrillation efficacy has been demonstrated, a permanent subcutaneous can be implanted.
- The subcutaneous patch may be placed subcutaneously, submuscularly, or directly on the periosteum of the ribs. The patch may be repositioned, if necessary, to meet the implant defibrillation efficacy criteria.
- If the Transvene™ lead system implant criteria cannot be met, an epicardial lead system may be evaluated, as described in this section.
- If the CS lead is proving difficult to position, a temporary pacing catheter can be positioned in the coronary sinus ostium. This can be used as a guide to cannulate the coronary sinus with the permanent lead.

Connecting the Leads for Pacing and Sensing Measurements

Depending on the physician's preference, two approaches can be used to connect a pacing system analyzer (PSA) to the implanted leads: passing through the ETCD or by direct connection. See the appropriate ETCD or PSA technical manual for connecting instructions.

Performing Pacing and Sensing Measurements

For a Transvene™ lead system, the pacing connections should be the RV tip electrode as cathode (-) and the defibrillation COMMON electrode as anode (+). Sensing measurements should be made between the RV tip and RV ring electrodes.

For an epicardial lead system, the PACE/SENSE electrode serves as the cathode (-) for pacing and the COMMON patch electrode serves as the anode (+). Measure between this patch electrode and each pacing/sensing electrode to obtain the best pacing threshold. Designate the best pacing/sensing electrode as PACE/SENSE. The other electrode should be SENSE2.

Listed below are the acceptable PCD system implant values for acute and chronically implanted lead systems.

	Acceptable Implant Values	
Measurements Required	**Acute Lead System**	**Chronic Lead System**
Capture threshold	≤ 1.5 V - epicardial	≤ 3.0 V - epicardial
(at 0.5 ms pulse width)	≤ 1.0 - endocardial	≤ 3.0 V - endocardial
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Also, check that P- and T-wave oversensing are not occurring by pacing at the maximum output (5.4 V, 1.59 ms) and sensing at the maximum sensitivity (0.3 mV).

Defibrillation Efficacy Testing

Verifying Lead Connections

After connecting all of the leads to the ETCD, confirm that the sensing leads are connected properly by observing sensed events on the Marker Channel telemetry. Verify the cardioversion/defibrillation lead connections to the ETCD by delivering a low-energy shock (0.6 joules) synchronously into sinus rhythm.

Listed below are the expected values for the voltage, current, impedance, and energy.

	Approximate Expected Values	
Parameter	**Epicardial**	**Transvene™**
Stored Joules (Energy):	0.6	0.6
Applied Joules (Energy):	Depends on impedance and pulse width	Depends on impedance and pulse width
PULSE1		
Peak Volts:	100	100
Peak Amps:	1-5	0.7-2.5
Path Ohms:	20-100	40-150
PULSE2		
Peak Volts:	100	100
Peak Amps:	1-5	0.7-2.5
Path Ohms:	20-100	40-150

If the path resistance measurements (ohms) do not fall within these ranges, check the lead connections and lead placements and tighten or reposition if necessary.

CAUTION: Implanting the PCD device when the path resistance is less than 20 ohms may damage the device.

Performing Defibrillation Efficacy Testing

After checking the lead connections, test defibrillation efficacy to show the ability to properly treat ventricular fibrillation. Before testing defibrillation efficacy, ensure an external defibrillator is charged for a rescue shock. Use the ETCD to perform the following:

1. Program the ETCD to properly detect VF with an adequate safety margin (sensitivity = 1.2 mV, VF NID = 18, FDI = 320 ms).
2. Program the VF therapy parameters (energy, pathway, and pulse width) to the desired settings. See Table 5 in "General Device Information" for information on choosing optimal pulse widths.
3. Induce VF using AC stimulation or the fibrillation induction feature present in the ETCD. See the appropriate programmer manual for specific instructions on inducing VF with the ETCD.
4. Convert the arrhythmia using the ETCD and lead system.

To demonstrate reliable defibrillation efficacy with acute or chronic leads, it is recommended that VF be initiated and terminated three out of four times at a stored output energy of 18 joules or less. The protocol shown in Figures 22 and 23 are suggested. If more than one of the four VF inductions are not terminated by the ETCD and lead system, the decision to implant the PCD device should be re-evaluated.

At their option, physicians may also test for ventricular tachycardia therapy efficacy after testing for defibrillation efficacy.

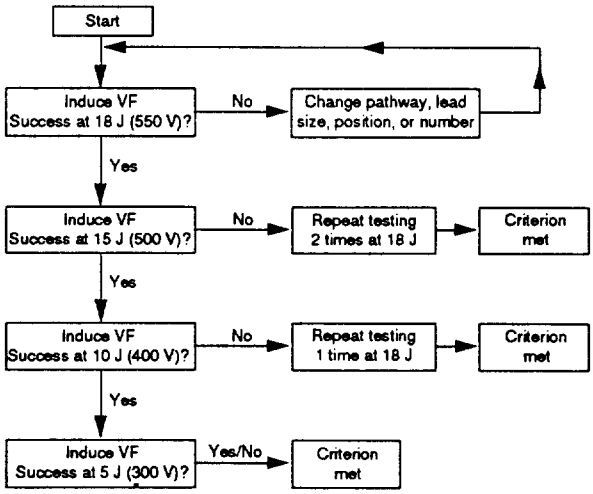

Figure 22. Defibrillation Efficacy Protocol Flowchart

Evaluating VF Sensing

While testing for defibrillation efficacy, evaluate VF sensing by reviewing the Marker Channel symbols and electrograms and checking for post-shock T-wave sensing. If VF sensing is not appropriate, it may be necessary to reposition the leads and repeat the VF inductions.

665

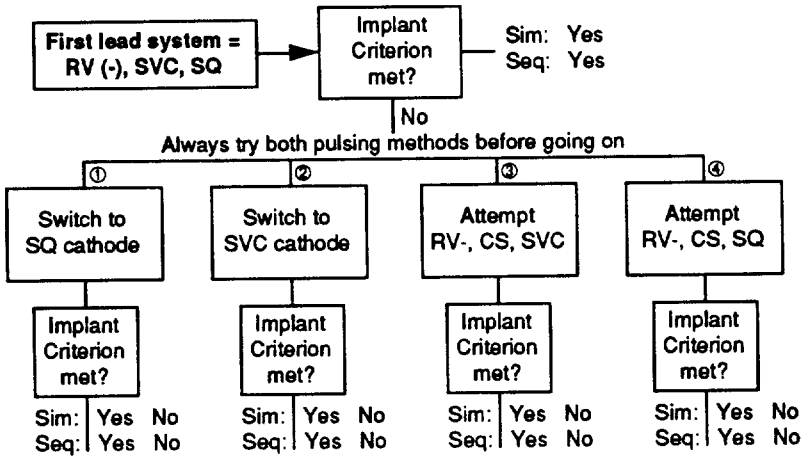

Figure 23. Transvene™ Lead System Evaluation Protocol Flowchart

Connecting the Leads to the PCD Device

The Model 7217B PCD device is connected to a lead system consisting of either two or three cardioversion/defibrillation electrodes. Figures 24 and 25 illustrate these two connection configurations. Both the PULSE2 and COMMON electrodes are used in either configuration. The PULSE1 electrode is required in a lead system that uses the sequential or simultaneous therapy current pathway, but it is not required when the single pulse therapy is used. When the PULSE1 electrode is not used, the 6.5 mm plug provided with the PCD device must be positioned in the lower left port of the connector block.

The COMMON, PULSE2 and PULSE1 lead connectors must be of the 6.5 mm style. If the lead connector is not the correct size, an adaptor designed for use in a 6.5 mm port must be positioned on the lead connector.

In either configuration shown in Figures 24 and 25, both a PACE/SENSE and a SENSE2 electrode are required. The PACE/SENSE and SENSE2 lead connector must be either the Medtronic low-profile bipolar or the IS-1[1] bipolar style. The PACE/SENSE electrode must be on the pin of the lead connector and the SENSE2 electrode must be on the ring of the lead connector. If two unipolar myocardial leads are used for pacing and sensing, insert their connectors into an appropriate adaptor that will fit into the PCD device's bipolar pacing/sensing port. See the appropriate lead technical manual for more details.

CAUTION: For questions about lead—pulse generator compatibility, consult your Medtronic representative or call Medtronic Technical Services at our 24-hour toll-free number, 1-800-328-2518.

1. IS-1 refers to a draft International Connector Standard (ISO/DIS 5841-3; 1989) whereby generators and leads so designated are assured of a basic mechanical fit.

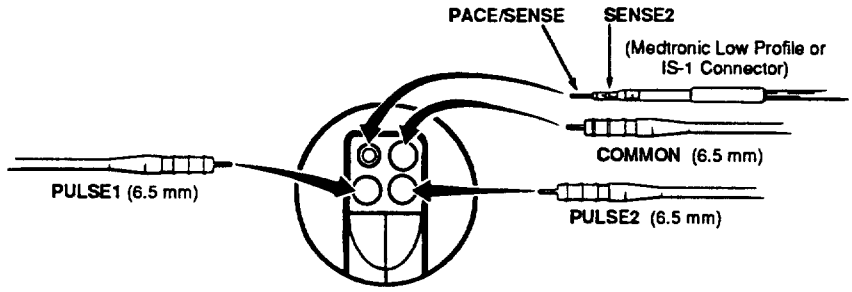

Figure 24. The Three Cardioversion/Defibrillation Electrode System

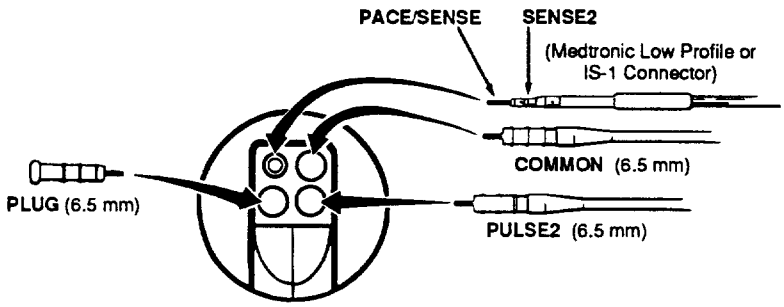

Figure 25. The Two Cardioversion/Defibrillation Electrode System

It should be noted that the insertion depth of an IS-1 lead pin is less than the insertion depth of a low-profile lead pin. The insertion mark for the IS-1 lead connector on the connector module (Figure 26) indicates that the IS-1 lead pin may not be inserted any further than the bar. Since the pin cavity is longer than the IS-1 requirement, the front part of the pin cavity will be empty when using an IS-1 lead.

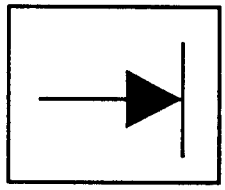

Figure 26

To connect each of the leads and plug, if required, to the PCD device:

1. Place a lead or plug into the appropriate port as shown in Figure 24 or 25.
2. Ensure full insertion of the connector pin by observing it protrude into the pin viewing area (i.e., beyond the metal block of the connector).
3. Pass the hex wrench through the associated grommet and tighten the setscrew securely by turning clockwise until tight. For the PACE/SENSE and SENSE2 connector, tighten both setscrews.

If there is difficulty with lead insertion due to the setscrew obstructing the port, turn the setscrew counterclockwise—but only until the port becomes clear.

> **CAUTION:** Counterclockwise rotation beyond this point may disengage the setscrew from the connector block.

The setscrews must be tightened securely using the hex wrenches provided with the PCD device. The hex wrenches are designed to yield at the handle when overtorqued, thus preventing damage to the socket of the setscrew. **Do not use Medtronic blue handled, right angle, or allen-type wrenches** since they possess torque capabilities far greater than intended for this device.

PCD System Evaluation

After connecting the leads to the PCD device, test the defibrillation efficacy of the PCD system. Before testing defibrillation efficacy, ensure an external defibrillator is charged for a rescue shock. Perform the following:

1. Program the PCD device to appropriately detect and treat the VF episode.
2. If using external fibrillation equipment, place the PCD device in magnet mode (VT and VF Detection are suspended).
3. Induce VF using external fibrillation equipment or the fibrillation feature present in the PCD device. If using external fibrillation equipment, apply the signal between the PACE/SENSE terminal of the PCD and an indifferent electrode attached to body tissue. The SENSE2 terminal may be used instead of the PACE/SENSE terminal with an indifferent electrode. See the appropriate programmer manual for specific instructions on inducing VF with the PCD device.

   > **CAUTION:** When using external fibrillation equipment, make only one connection to the PCD lead system. This connection should be disconnected immediately after VF is induced.

   > **CAUTION:** DO NOT MOVE THE PROGRAMMING HEAD from the beginning of detection through delivery of the shock. If the head is moved, remove it from the PCD device to allow the device to operate automatically. Replacing the head during the sequence may suspend VF Detection or abort the therapy.

4. After verifying sustained VF, press the CANCEL MAGNET key and then the PROGRAM key to allow automatic VF detection and therapy delivery to convert the arrhythmia.[1]
5. Observe the ECG signal and Marker Channel symbols for proper detection and therapy. Proper sensing following therapy delivery must be observed. Wait ten seconds after VF has been terminated before interrogating the device and printing a partial summary report of the data.
6. Program VT and VF Detection OFF before closing.

1. When using the fibrillation feature present in the PCD device, pressing the CANCEL MAGNET key and then the PROGRAM key prior to induction of VF will cause VF Detection to be enabled immediately after the end of the fibrillation sequence.

Placing the PCD Device

To ensure telemetry and programming function post-implant, the Model 7217B PCD device must be placed within 5 cm of the skin and with the engraved side facing toward the skin.

The Model 7217B PCD device has two suture holes located in the connector assembly. Use of these suture holes may help secure the device in the subcutaneous pocket, thus minimizing rotation and/or migration of the device post-implant. Penetration of the holes can be achieved with normally available surgical needles.

Closing

At closing perform or verify the following:

- All leads are sutured or positioned for chronic implant.
- All leads are fully inserted into the PCD device connector and all setscrews are tight.
- Place the PCD device in the pocket within 5 cm of the skin and with the **engraved side toward the skin.**
- Ensure that there are no kinks in the leads. If using separate PACE/SENSE and SENSE2 leads, lightly intertwine them with several twists.
- Close the pocket.
- Program VF Detection and Therapies ON.
- Interrogate the device and print a full summary to document the post-operative programmed status of the PCD device.

Replacing a PCD Device

To replace a Model 7217B PCD device:

1. Program VT and VF Detection OFF.
2. Carefully dissect the leads and the PCD device free from the surrounding tissues in the pocket. Be especially careful not to nick or breach the lead insulation inadvertently during the process of exposing the PCD system.
3. Insert the proper hex wrench through the slits in the rubber grommet and loosen the setscrew by turning counterclockwise.
4. Gently retract the lead connectors from the connector ports.
5. If any lead pin shows signs of pitting or corrosion, the entire lead should be evaluated and tested to assure the integrity of the system.
6. Take pacing, sensing, and defibrillation efficacy measurements.
7. Connect the leads to the replacement device.
8. Evaluate the defibrillation efficacy of the PCD system.
9. Place the PCD device and close.
10. Return the explanted device after cleaning/gas sterilizing to your Medtronic representative for device evaluation.

Implanting a PCD Device With a Chronic Lead System

When implanting a PCD device that connects to a chronically implanted lead system, evaluate the following to ensure the device will detect and treat ventricular arrhythmias appropriately:

1. Integrity of the chronic patch leads. Evaluate by chest X Ray, inspection, or test shock.
2. Chronic pacing and sensing measurements (see "Performing Pacing and Sensing Measurements" in "Implantation Procedure"). Repositioning the chronic leads or implanting new pacing/sensing or patch leads may be necessary.
3. Defibrillation efficacy (see "Defibrillation Efficacy Testing" in "Implantation Procedure"). Repositioning the chronic leads or positioning a third patch lead may be necessary to meet the defibrillation efficacy protocol (Figure 22).
4. VF sensing (see "Evaluating VF Sensing" in "Defibrillation Efficacy Testing"). Repositioning the chronic leads or implanting new pacing and sensing leads may be required.
5. Fit of the connectors in the PCD device (see "Connecting the Leads to the PCD Device" in "Implantation Procedure"). The leads must be properly inserted into the connector block for the device to function properly.

21. Please provide the P-values as listed in Table IV-B and IV-C of the original PMA application for the new patient population.

RESPONSE:

Comparison of Model 7216A and Model 7217B

Table IV-B summarizes the results of statistical analysis comparing the Model 7216A to Model 7217B. No parameters were found to be statistically significant between the two PCD™ models at a 0.05 significance level.

PCD™ Transvene™ System
7216A and 7217B
Summary of Variables Tested

CATEGORY	7216A	7217B	(b)(4)
Mean Age	62.4	59.4	
Number, % Male Number, % Female	15 83.3% 3 16.7	595 80.5% 144 19.5%	
Mean Ejection Fraction	37.8%	35.5%

Table IV-C: Summary of Variables Tested on Lead Configurations - 6/24/92

Of the variables analyzed in tables IV-C sex and cardiomyopathy showed a statistically significant difference between the three lead configurations at a 0.05 significance level. The difference in sex and percentage of patients with cardiomyopathy becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170).

22. **Please discuss the reasons why some patients dropped out of the study, either withdrawn alive or lost to follow-up. There were 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2 month period.**

RESPONSE:

To be consistent with the rest of these deficiency responses, Medtronic has elected to answer this deficiency with the updated clinical data base. The clinical report presented as the response to deficiency #13 has 631 patients with a 1 month follow-up and 496 patients with a 3 month follow-up. This is a difference of 135 patients. Twelve of these patients died during this follow-up period and 5 were explanted because of device infection. Fifteen (15) patients missed their 3 month follow-up time window and were included in the 6 month window. The remaining patients were not lost to follow-up but had not yet reached the 3 month follow-up window.

23. For the comparison of complications/observations rates for the PCD™ versus the AICD™, please provide the following:

a. the number of complications and patients for the PCD™ and AICD™ populations;

b. the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate Problematic VT/VF Therapy Delivery"; and

c. a discussion of the pocket infection rate of the PCD™ and the AICD™ and the lead related complications of the PCD™ Transvene™ System versus the PCD™ Epicardial System.

RESPONSE:

For the purposes of comparison of reported complications/ observations between the PCD Transvene System and the AICD Epicardial System, the AICD System patient population was that described in Winkle, et al, Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article only discussed specific reported complications and not all reported complications. Thus, the total number of complications and patients cannot be provided. In the case of the PCD Transvene System, as of June 24, 1992, there have been 138 complications reported in 138 patients. For purposes of this PMA, complications were defined as a symptomatic or asymptomatic clinical event with potential adverse effects, which CANNOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

Failure to cardiovert/defibrillate was defined as the continuation of an **induced** ventricular tachyarrhythmia despite all cardioversion/defibrillation therapies having been delivered. This was due to increased cardioversion or defibrillation energy requirements caused by a change in the patient status or loss of integrity of the implanted defibrillation lead system.

Inappropriate or problematic VT/VF therapy delivery was defined as the delivery of VT and/or VF therapy in response to a rhythm other than VT or VF, such as atrial fibrillation with a rapid ventricular response, sinus tachycardia or device issues such as a loose set screw. In all cases, the PCD Device performed appropriately based

on the programmed VT/VF detection criteria however the delivery of therapy was not for an episode of sustained VT or VF.

In the Winkle, et al experience, information was only provided on the patients in whom pocket infection resulted in explant of the AICD System. The incidence of pocket infection that required explant of the AICD system was 2.2% In the PCD Transvene System, the incidence of pocket infection that resulted in explant of the implanted system was 2.0%. As a further reference, the incidence of pocket infection that resulted in the explant of the implanted system in the PCD Epicardial System was 1.9%. Thus the reported incidence of pocket infection was similar in all three patient groups.

For purposes of the PCD Transvene and Epicardial Systems, "Lead Related " complications includes lead dislodgement, lead fracture and perforation. Table 1 provides a comparison of the reported lead related complications in the two patient populations.

PCD Transvene System versus PCD Epicardial System Lead Related Complications 6/24/92		
Category	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**
Right Ventricle Perforation	5 (0.7%)	-
Subclavian Vein Thrombosis	1 (0.1%)	-
Patch Crinkling	7 (0.9%)	1 (0.1%)
Pace/Sense Lead System Fracture	-	7 (0.9%)
Lead Body Fracture	4 (0.5%)	4 (0.5%)
Lead Body Silicone Wear	-	2 (0.3%)
Lead Body Abrasive Wear	-	2 (0.3%)
Cardiac Vessel Abrasion	-	6 (0.8%)
Dislodgement	33 (4.4%)	7 (0.9%)
TOTAL	**50 (6.6%)**	**28 (3.8%)**

Table 1: PCD Transvene System versus PCD Epicardial System Reported Lead Related Complications - 6/24/92

Each system has specific lead complications related only to that system, however the incidence of lead dislodgement in the two patient groups was clinically different. In both systems, the clinical impact of a lead dislodgement is the potential for inappropriate therapy delivery, nondetection of VT/VF or ineffective VT/VF therapy for an episode of VT/VF. Also in both systems, reoperation is usually required to reestablish a lead system that provides adequate defibrillation efficacy. The incidence of lead dislodgement in the PCD Epicardial System was 0.9% while in the PCD Transvene System the incidence of lead dislodgement was 4.4%. This difference was not unexpected since in the PCD Epicardial System, the patch leads are usually physically sutured either to the epicardium or pericardium resulting in marked decrease in potential for dislodgement.

In the case of the PCD Transvene System, there were typically two or perhaps three transvenous leads implanted. Though the leads are secured by suturing the anchoring sleeve at the venous entry site,

they are more suspectable to dislodgement due to patient activity, particularly movement of the upper extremities.

Lead dislodgements are not specific to the PCD Transvene System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers demonstrated a high lead dislodgement rate of at least 20%. (Smyth PND, et al. Permanent pervenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery 1976;72:565-570.) Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads used with the current market release ICD System to be 6.3% (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications and Survival in Patients with Malignant Ventricular Arrhythmias. JACC Vol.11. No.6 June 1988: 1278-86).

In 47 patients (53%) the lead dislodgement was identified prior to the patient's discharge from the hospital. Therefore more than half of the dislodgements were identified prior to the patient being in an outpatient setting where the risks of a lead dislodgement are greater. None experienced an episode of spontaneous VT/VF prior to the identification of the lead dislodgement.

In the remaining 40 patients, 21 patients experienced spontaneous VT episodes and 24 experienced spontaneous VF episodes prior to diagnosis of the lead dislodgement. The spontaneous VT episode efficacy was 97.9% and the spontaneous VF episode efficacy was 99.3% None of these episodes required Therapy #4 for successful termination. None of patients experienced episodes of VT/VF where the PCD Transvene System was ineffective in terminating the episode due to the lead dislodgement.

Though the incidence of dislodgement was higher in the PCD Transvene System, the clinical outcome was identical in the two patient groups - there have been no reported patient deaths secondary to a lead dislodgement in either patient group.

24. **Some Transvene™ patients were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these patients to those who did not undergo the hollow can evaluation.**

RESPONSE:

Pocket infection was reported in 23 of the 757 patients (3.1%) who received a PCD Transvene System patients. In 15 of the cases (2.0%), all of which were classified as complications, the pocket infection resulted in explant of the entire implanted PCD Transvene System. Four of the patients subsequently had a new PCD Transvene System implanted while the remaining patients still have not had a new system implanted. In 8 cases classified as an observation, the infection was successfully treated with antibiotic therapy. **As of the date of this report, none of the thirty patients who were evaluated with the Model 10388 hollow can electrode developed a pocket infection.** These patients will continue to be monitored and the incidence of pocket infection will continued to be reported to the agency in subsequent submissions.

25. Please discuss and/or provide the following regarding the 1 year actuarial survival comparison of mortality between the PCD™ and the AICD™:

a. the statistical test that was used to compare survival; and

b. the two survival or life tables by year of follow-up.

RESPONSE:

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 was used. A copy of this summary was obtained through the Freedom of Information Act.

In order to compare the PCD Transvene System one year sudden cardiac death and overall survival to the Ventak-P Epicardial System, a confidence interval analysis was performed which indicated there was a statistical difference in the reported overall mortality. [PCD Transvene System = 95.6%; Ventak-P Epicardial System = 90.8%]

The Ventak-P Epicardial System summary only provided one year sudden cardiac death and overall survival. Information was not provided on when the patient deaths occurred or individual implant duration for patients who received a Ventak-P Epicardial System. Therefore, we are unable to provide survival or life tables by year of follow-up for the Ventak-P Epicardial System.

26. Please discuss the statistical techniques used to derive the P-values in Table XI G-2, page 862, Vol. 5 and Table J-2, page 54, Vol. 1.

RESPONSE:

The information contained in Tables J-2 (page 54) and XI G-2 (page 862) from volume 1, provide the survival probability at one year for the various categories and conditions presented in each table. The unique feature of survival analysis is that it permits the estimation and comparison of groups survival experience during the follow-up (in this case one-year) and may be used for the analysis of any dichotomous response variable such as a nonfatal or an adverse effect. In this situation the probabilities represent the percentage of patients in the specified category who are alive at one-year.

The survival probabilities in these two tables were estimated using the Cutler-Ederer or otherwise referred to as the actuarial method. The Cutler-Ederer procedure is a widely accepted method which estimates survival probabilities uniformly across time. The P-values were calculated using the Wilcoxon survival test which compares the overall survival experience between groups. If a P-value was 0.05 or less the comparison was classified as being statistically different. All calculations were conducted using the statistical software SAS.

ADDITIONAL DEFICIENCIES

1. **Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?**

RESPONSE:

The Model 6966 is a tripolar lead intended for transvenous implantation into the right ventricle. For this purpose design characteristics which are conducive to small diameter leads are important. Polyurethane offers unique combinations of physical properties needed for implantable devices such as cardiovascular leads. Among these are, elasticity and strength. Polyurethane has distinct advantages with regards to these characteristics over silicone for a tripolar lead design. These are discussed below.

1) The modulus of elasticity of polyurethane is greater than silicone. This means that the insulation material absorbs more of the force that the lead is subjected to in situ, and less of the force is transferred to the coil and other components of the lead.

2) The strength of a given cross-sectional area of polyurethane is greater than that of an equivalent cross-sectional area of silicone. This allows the use of thinner tubing when using polyurethane as the insulation material which translates into smaller diameter leads. In addition, the greater strength of polyurethane facilitates the torque transfer from connector pin to helix. This is necessary for extension/retraction of helix electrode leads such as the Model 6966.

In addition, both (b)(4) and (b)(4) polyurethanes used in the Model 6966 lead have been used for other, Medtronic, commercially available, implantable, cardiovascular leads. Polyurethanes have been shown to be biocompatible, and enhancements in processing have significantly reduced the potential for metal induced oxidation (MIO) and environmental stress cracking. Furthermore, polyurethanes offer other material properties such as, elongation, flexibility and low thrombogenicity which makes them suitable for cardiovascular leads.

2. **Discuss the biostability tests (stress cracking, metal induced oxidation, etc.) performed on the (b)(4) polyurethane. Why was a different polyurethane chosen for the inner coil?**

RESPONSE:

Biostability testing performed on the two types of polyurethane is discussed in detail in Appendices 1 and 2. This includes testing on polyurethane (b)(4) and (b)(4) Extensive testing has been performed and results have demonstrated the biostability of both (b)(4) and (b)(4)

Polyurethane (b)(4) was chosen for the inner coil of the 6966 lead because its design was based on another lead with an extendable/retractable helix electrode, specifically the Model 4058M lead. The Model 4058M is comprised of (b)(4) for the inner insulation and (b)(4) for the outer insulation. This combination of insulation materials allows for a small diameter, flexible, screw-in lead with acceptable torsional (torque transfer) characteristics comparable to a unipolar screw-in polyurethane lead.

Specifically, the stiffness imparted to the inner coil due to the use of (b)(4) as the inner insulation, facilitates torque transfer. However, if the entire lead was comprised of (b)(4) it would be too stiff. Therefore, (b)(4) insulation was chosen to maintain flexibility of the lead.

Additional information on biostability testing is presented below.

Background

Medtronic performs in-depth reliability assurance testing on all cardiac pacing leads. The nature of the testing is such that an overall assessment of lead safety or integrity can be determined from it. Since one of the Transvene leads, Model 6966, is a pace/sense lead in addition to being a cardioversion/defibrillation lead, it was evaluated in a manner similar to other pacing leads in addition to specific testing designed to assess effects of cardioversion/defibrillation (as were the other Transvene leads, Models 6963 and 6999).

Testing consisted of electrical and mechanical evaluation, flexing of coils and insulated lead bodies, tensile strength testing, stiffness evaluation, leak testing, biocompatibility and biostability testing. This is consistent with all bradycardia (brady) pace/sense leads. Regarding cardioversion/ defibrillation capabilities, the Model 6966/6884 was also subjected to a

series of accelerated, in-vitro tests specifically designed to simulate severe, potential, implant conditions. This included high voltage multiple pulse discharge testing and high voltage crush testing. Data demonstrated that the Model 6966/6884 lead satisfies device design requirements for cardioversion/defibrillation, in addition to pacing/sensing, and is therefore acceptable for its intended application.

A specific test was performed to evaluate the polyurethane insulation of the Model 6966/6884 lead. This was the standard, (b)(4) day, (b)(4) test modified to include high voltage shocking.

The rationale for performing (b)(4) testing via a modified process to include high voltage shocking is as follows. The standard, Medtronic (b)(4) protocol was modified to include high voltage (b)(4) shocking in order to evaluate the effects (if any) voltages in excess of typical brady pacing voltage (e.g., (b)(4) would have on the polyurethane insulation while it was subjected to the accelerated bench testing. (b)(4) shocks was selected because it is approximately (b)(4) times the estimated life of present-generation, implantable, cardioversion/defibrillation devices.

Metal Induced Oxidation

The (b)(4) day (b)(4) test was developed as an accelerated, in-vitro (bench) test to evaluate metal-induced oxidation (MIO) in polyurethane leads. Significant data related to polyurethane degradation mechanism and how to prevent (minimize) it has been provided to FDA over the years. A detailed, chronological discussion which describes polyurethane lead history and research regarding MIO as a degradation mechanism is provided in Appendix 1.

The (b)(4) test method includes visual and microscopic examination and electrical impedance measurements every (b)(4) days throughout the (b)(4) day test period in order to assess the lead integrity.

The lead integrity requirements relative to (b)(4) testing for defibrillation leads are identical to those for brady leads. That is, no visible sign(s) of MIO after (b)(4) days in (b)(4) In addition, there must be greater than (b)(4) impedance as measured between conductors.

(b)(4) testing of the Model 6966/6884 has shown no degradation (cracking or breaching) after (b)(4) days in (b)(4) (standard testing time). These results are similar to other leads with (b)(4) conductor coils.

Additional (b)(4) information is provided below.

(b)(4) History/Test Development

In the early 1980s, when Medtronic became aware of the problem with the Model 6972 leads, preliminary conclusions indicated that (b)(4) were a potential cause of polyurethane degradation. Subsequent research over the years has demonstrated that certain metal ions, such as the those found in (b)(4) conductor coils, in contact with polyurethane can cause degradation. More recently, research has shown that an effective method for preventing metal ion-polyurethane contact (and therefore degradation) is through the use of a barrier coating between the conductor coil and insulation. An effective barrier coating is platinum. It is precisely for this reason that Medtronic has been designing new polyurethane leads, including the Model 6966/6884, with platinum sputtered (barrier coated) conductor coils.

(b)(4) has very stringent test requirements. Specifically, lead samples evaluated in (b)(4) are required to show no signs of MIO, in order to satisfy design requirements. Samples must be free of any sign(s) of MIO as examined visually (b)(4) after (b)(4) days in (b)(4) That is, there must be no evidence of MIO after (b)(4) days in (b)(4) Therefore, there is not a statistical confidence level associated with the results. Over the years, (b)(4) sample sizes have varied from (b)(4) test units.

It should be noted that over the past (b)(4) years (approximately) Medtronic has been designing cardiovascular leads with barrier coated (platinum sputtered) conductor coils. Since then, design assurance testing for new leads has included (b)(4) testing. Some of the recently designed leads subjected to (b)(4) testing and FDA approved or judged substantially equivalent are:

Models 4004/4504, P830061/S6, Feb. 10, 1989
Models 4082/4582, K896313, March 6, 1990
Model 4023/4523, P830061/S10, August 7, 1991
Model 4024/4524, P830061/S12, August 19, 1991

All of these leads (totaled in excess of (b)(4) samples) showed no failures (insulation breaches) or visual evidence (cracks) of MIO degradation after (b)(4) days in (b)(4) All of these leads were still functional after (b)(4) days in (b)(4) The sum total of barrier coated polyurethane leads evaluated in (b)(4) over the past (b)(4) years is significantly more than (b)(4) samples; all of them have demonstrated that a barrier coating, such as a

platinum sputter coating, effectively eliminates, or at least minimizes, MIO by simply preventing the (b)(4) conductor coil from direct contact with the polyurethane insulation.

In setting up the (b)(4) test of the Model 6966/6884 leads it was apparent that the lead design, from a materials perspective (e.g., the conductor coil, insulation, etc.), was very similar to the previously tested leads (Models 4004/4504, etc). Therefore, it was reasonable to expect similar (b)(4) test results. Nonetheless, (b)(4) Model 6966/6884 lead samples were subjected to testing according to design assurance requirements. Given the relatively high confidence established over the past (b)(4) years that platinum sputtered conductor coils will remain functional and free of MIO after (b)(4) days in (b)(4) (b)(4) Model 6966/6884 samples were considered sufficient for testing.

After (b)(4) days in (b)(4) the (b)(4) Model 6966/6884 leads did not have any visual evidence (cracks) of MIO degradation. All leads were still functional after (b)(4) days in (b)(4) These results were in keeping with all other platinum sputtered, barrier coated leads previously tested in (b)(4)

Environmental Stress Cracking

Additional testing applicable to the biostability of the Transvene leads consists of environmental stress cracking (ESC) evaluation. Significant testing of transvenous, polyurethane leads and prototype leads (comprised of (b)(4) and (b)(4) as the 6966 lead is) has demonstrated that leads that incorporate state-of-the-art processing enhancements, i.e., barrier coating and thermal annealing in an inert environment, exhibit minimal ESC and MIO. ESC testing, as well as additional MIO testing, is discussed in detail in Appendix 2.

Conclusions

With respect to biostability of the Model 6966/6884 lead, barrier coated (platinum sputtered) (b)(4) (b)(4) coils have been shown to be effective in preventing direct contact between polyurethane insulation and (b)(4) coils, and therefore, MIO degradation in the Model 6966/6884 cardioversion/defibrillation lead. Additionally, thermal annealing polyurethane leads in an inert environment (as the Model 6966/6884 lead is) has been shown to significantly minimize ESC.

3. Based on the results of the life test, what is the life expectancy of the leads? Please include your assumptions.

RESPONSE:

The purpose of this life test, also referred to as "Lead System Testing," was/is to simulate extreme conditions for a relative measure of the effect of the combination of flexing and high-energy pulsing on the electrical and mechanical performance of the lead. It was/is not intended to correlate to lead life expectancy.

However, during the development of the investigational protocol for the NTL leads, we were encouraged by the FDA to develop a test model whereby the transvenous lead system was evaluated under extreme conditions. Subsequently, the life test as presented in this PMA (and several Medtronic NTL IDE supplement submissions) was developed.

Results of the multiple-pulse, high voltage pulsing in conjunction with flex testing, and crush testing demonstrated that electrical shock, mechanical flexing and crushing yield acceptable lead performance.

The system testing, is consistent with the flex testing presented in the non-clinical bench testing section of the Transvene PMA. Additionally, the system testing is consistent with the long-term field experience for the Model 6907, which is the basis for the flex life test requirement of (b)(4) cycles. Note that the Model 6907 has more than twenty years field experience. Of approximately (b)(4) sold, only (b)(4) coil fractures have been reported in this time (b)(4) Therefore, any lead with flex life equal to or greater than the Model 6907 is considered safe and effective for its intended use.

4. Provide a side-by-side comparison between the Model 6999 and the epicardial patch lead.

RESPONSE:

A side-by-side comparison is presented below of the Model 6999 and the medium epicardial patch, Model 6921M. The Model 6999 has (b)(4) embedded throughout the silicone to provide a sightly stiffer backing for the subcutaneous placement of the lead. The Model 6921 has an embedded (b)(4) around the outer electrode coil loop, and slightly thinner silicone adhesive for a more flexible patch to facilitate placement either extra or intra pericardially.

Model 6999 - Model 6921 Comparison

	Model 6999	Model 6921M
Polarity:	(b)(4)	
Placement:		
Fixation:

5. Discuss the possible interactions between implanted pacemaker leads and the Transvene™ leads. Also, discuss the effects of the leads on the tricuspid valve and the host vein.

RESPONSE:

In the PCD Transvene System patient population of 757 patients, (b)(4) (b)(4) patients who had previously implanted bradycardia pacemakers retained these devices post implant of the PCD Transvene System. (b)(4) patients the device was a DDD pacemaker, (b)(4) patients a DDD-R pacemaker, in (b)(4) patient a VVI-R pacemaker and in the final patient a AAI pacemaker.

Clinical experience with (b)(4) patients indicates that bradycardia pacemakers, including dual chamber devices, can be safely implanted in conjunction with a PCD Transvene System

The PCD device technical manual recommends that if the patient meets the PCD device implant criteria the physician should explant a previously implanted pacemaker and remove or cap the leads. However if the pacemaker must be retained due to conduction disease or for hemodynamic reasons the following recommendations are provided:

- If a unipolar pacemaker is implanted, it must be explanted.
- If a previously implanted pacemaker has a switchable polarity option, it must be programmed to the bipolar configuration.
- If a previously implanted pacemaker with a switchable polarity option has the potential to be reset to the unipolar configuration by defibrillation shocks, it should be explanted.

If the bradycardia pacemaker is to remain implanted, evaluations are performed to ensure that there are no deleterious interactions between the devices. In particular, it should be demonstrated that the PCD device does not sense pacemaker output pulses when the pacemaker is programmed to its maximum output amplitude and pulse width and when the PCD device is programmed to a sensitivity of 0.3 mV for testing.

To avoid inappropriate interaction between the two devices, the bradycardia pacemaker should be programmed to the minimum selectable rate, pulse width, amplitude and least sensitive setting clinically possible.

Finally, the bradycardia pacemaker lead system should be carefully monitored to ensure that defibrillation shocks do not result in loss of output or capture from the pacemaker.

Possible interactions between implanted pacemaker leads and the PCD Transvene Lead System are as follows:

Physical Interaction

Possible insulation wear from the contact and movement between the leads could occur. This had not occurred,however, in the PCD Transvene System Study among the 16 patients who have a concomitant bradycardia pacemaker.

There is a potential risk of subclavian vein thrombus. There were 4 patients who developed a subclavian vein thrombus in this study. These patients, however, did not have a concomitant bradycardia pacemaker.

Electrical Interaction

Possible damage to pacemaker leads from defibrillation shocks could occur. There have been no reported incidents of this occurring in this subgroup of patients. The bradycardia pacemaker lead system should be carefully monitored to ensure that the defibrillation shocks do not result in loss of output or capture from the pacemaker.

If the bradycardia pacemaker is to remain implanted, evaluations are performed to ensure that there are no deleterious interactions between the devices. In particular, it should be demonstrated that the PCD device does not sense pacemaker output pulses when the pacemaker is programmed to its maximum output amplitude and pulse width and when the PCD device is programmed to a sensitivity of 0.3 mV for testing.

There have been no reports of inappropriate interaction between the PCD and bradycardia device in the 16 patients in whom the bradycardia device was retained after the PCD Transvene System was implanted.

Possible Effects on Tricuspid Valve and Host Vein

Possible effects of the leads on the tricuspid valve include injury, rupture, dissection, or damage to the valve. There have been no reported Complications or Observations involving the tricuspid valve in this study, acutely or chronically, nor have there been reported problems related to the tricuspid valve as of 6/24/92.

Possible effects of the leads on the host vein include injury to the vessel, perforation, claudication, and clot formation. There have been 4 patients who developed a subclavian vein thrombus. One patient required explant of the leads and the other 3 patients received thrombolytic therapy with resolution.

6. **The Transvene™ leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Transvene™ leads which support this capability.**

RESPONSE:

There is no data available that allows for a comparison of the crush resistance of the Transvene leads to other commercially available leads. Medtronic makes no claims relative to crush testing/resistance of the leads.

6. **The Transvene™ leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Transvene™ leads which support this capability.**

RESPONSE:

There is no data available that allows for a comparison of the crush resistance of the Transvene leads to other commercially available leads. Medtronic makes no claims relative to crush testing/resistance of the leads.

7. Are there patients currently implanted with the Model 6895 and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

RESPONSE:

Of the 757 patients who received a PCD Transvene System, 718 patients have an implanted lead system which incorporates a subcutaneous patch electrode. Of these patients, 5 patients (0.7%) have a Model 10317 subcutaneous patch electrode, 249 patients (34.7%) have a Model 6895 subcutaneous patch electrode and 464 patients (64.6%) have a Model 6999 subcutaneous patch electrode.

The incidence of potentially patch related complications and observations in this patient group was evaluated. The overall incidence of seroma at the subcutaneous patch site was 1.1%, the overall incidence of hematoma at the subcutaneous patch site was 1.4% and the overall incidence of subcutaneous patch crinkling was 1.7%. Table 1 provides the incidence of these complications and observations by implanted subcutaneous patch lead model. There was no difference in the incidence of reported complications and observations based on the lead model implanted.

8. Please list the reasons for not performing pre-hospital discharge testing.

RESPONSE:

The Pre-Hospital discharge evaluation is performed to assure the implanted PCD™ Transvene™ system is performing properly. This is usually the first time ventricular tachycardia detection and therapies are evaluated and is also an appropriate time to assure ventricular fibrillation detection and therapy parameters are programmed appropriately. Evaluating these programmable parameters involves induction of ventricular tachyarrhythmias and titration of programmed parameters.

There are a total of 753 Pre-Hospital Discharge forms included in this clinical report representing 719 patients. Patients have multiple Pre-Hospital Discharge forms if they were readmitted for system modification after the initial implant procedure. Thirty-eight patients did not have a Pre-Hospital discharge form. Sixteen of these 38 patients had a subsequent follow-up form, because their hospital stay was long enough to be in the 1 month follow-up window. The remaining patient's Pre-Hospital Discharge form was not entered into the PCD™ data base before the data cutoff for this analysis. All patients are evaluated by the investigator before hospital discharge to determine if the patient's condition and the device operation are appropriate for hospital discharge.

Six-hundred (600) or 79.7% of these 753 Pre-Discharge evaluations had either ventricular tachycardia or ventricular fibrillation induced and the corresponding therapies evaluated.

The reasons for not performing inductions include:

- Adequate Implant Testing: If the patient is a primary ventricular fibrillation patient and the implant defibrillation therapy efficacy was within acceptable limits, the investigator often elects not to subject the patient to additional episodes of ventricular fibrillation.

- Previous implant: If a patient was receiving a device after having a previous device explanted and had demonstrated therapeutic efficacy with previous programming, the investigator could elect not to subject the patient to additional tachyarrhythmic episodes.

- Patient request: Some patients do not want additional inductions beyond the absolute minimum to assure efficacy. If implant defibrillation efficacy was known and the patient had extensive preimplant electrophysiologic testing, the investigator may agree with this patient request.

- Postponement: If the patients underlying medical condition is such that induction of tachyarrhythmias would pose a significant health risk, the investigator may elect to postpone additional inductions until the patient's condition improves.

The PCD™ study protocol asks that patients be induced at the pre-hospital discharge evaluation, and the majority do (79.7%), the primary responsibility for patient care rests with the physician investigator. The very high 1 year sudden cardiac death survival rate of 99.8% indicates that the PCD™ Transvene™ is being evaluated and followed to an appropriate level. The PCD™ Transvene™ system and the implant and follow-up procedures used in this clinical study have been demonstrated to provide safe and effective treatment for serious life threatening ventricular tachycardias.

9. The number of spontaneous episodes of the patients followed for 6 months and beyond should be provided.

RESPONSE:

A total of 329 patients with the PCD™ Transvene™ System have been followed for a minimum of 6 months or beyond. There has been a total of 3752 spontaneous episodes of VT in 130 patients (39.5% - 130/329) with an overall efficacy rate of 99.0% and 667 spontaneous episodes of VF in 120 patients (36.5% - 120/329) with an overall efficacy rate of 98.7%.

Table 9-1 presents the total number of VT episodes that were treated with a specific therapy type (Ramp, Burst, or Cardioversion) and how effective that therapy type was in terminating the episode. Also included in this table is the number of episodes (# success) successfully treated by all four therapies.

PCD™ Transvene™ System Spontaneous VT Episodes Therapeutic Efficacy			
	# Success	**# Episodes**	**% Success**
Ramp	2046	2244	91.2%
Burst	1432	1558	91.9%
Cardioversion	235	276	85.1%
	# Success	**Cumulative #**	**Cumulative %**
VT Therapy #1	3474	3474/3752	92.6%
VT Therapy #2	158	3632/3752	96.8%
VT Therapy #3	59	3691/3752	98.4%
VT Therapy #4	22	3713/3752	99.0%

Table 9-1: PCD™ Transvene™ System - Spontaneous VT Episodes Therapeutic Efficacy

Table 9-2 presents the total number of VF episodes (# success) successfully treated by all four therapies.

PCD™ Transvene™ System Spontaneous VF Episodes Therapeutic Efficacy			
	# Success	Cumulative #	Cumulative %
VF Therapy #1	563	563/667	84.4%
VF Therapy #2	72	635/667	95.2%
VF Therapy #3	19	654/667	98.1%
VF Therapy #4	4	658/667	98.7%

MEDTRONIC CONFIDENTIAL

e. Biostability

Introduction

The objective of this section is to present information relative to the biostability of Medtronic polyurethane cardiac pacing leads.

First, a history of polyurethane cardiac pacing leads will be presented. This includes discussion of Medtronic's first polyurethane lead products and relevant field performance. An overview of Medtronic's field performance data base is also included. The primary polyurethane failure mechanisms will be discussed in general, and then specifically, as they relate to individual lead models. This will be followed by a detailed discussion of the unipolar and bipolar (atrial and ventricular) polyurethane lead products comparing configuration, materials and processes as they have changed, i.e., been improved over time. Lead characteristics will also be related to field performance.

Following configuration, materials and processing features and field data, will be a discussion of lead failure mechanisms and accelerated test procedures for their evaluation. This includes recent polyurethane lead research and results, both in-vitro and in-vivo testing methods and rationale. Models 4004/4504 biostability data are then presented.

Finally, conclusions relative to the Models 4004/4504 and the supporting biostability data will be clearly established.

The intent of the discussion is to put into perspective the implementation of lead improvements as they were validated over time. That is, Models 4003/4503 utilized the state-of-the-art in configuration, materials and processes, and now, approximately three years later, Models 4004/4504 are incorporating more recent state-of-the-art lead technology.

Summary: History of Polyurethane Pacing Leads

Polyurethane elastomers have been extensively studied and evaluated for use in implantable devices. Polyester polyurethanes were of major interest in the artificial heart program in the 1960s but lacked the necessary hydrolytic stability. Polyether polyurethanes (e.g., (b)(4) (b)(4) were introduced in the early 1970s. These polymers are hydrolytically stable under implant conditions and offer unique combinations of physical properties needed for implantable devices such as pacing leads. These properties include high tear strength, tensile strength, elongation, modulus of elasticity, flexibility and low thrombogenicity, etc.

The first human implant of a permanent polyurethane insulated lead occurred in 1975. This was a neurologic device insulated with (b)(4) (b)(4) The first cardiac pacing leads (b)(4) (b)(4) were implanted in humans in 1977. Four models (Medtronic Models 6971, 6972, 6991U and 6990U) were released to the U.S. market in April-June, 1980. The "market release" of these devices was based on human clinical and canine studies as well as extensive biocompatibility and biostability tests of the materials per se.

MEDTRONIC CONFIDENTIAL

The performance of these early polyurethane insulated leads appeared to be excellent. On May 15, 1981, Medtronic received their first explanted lead (a Model 6991U) exhibiting signs of what now is known to be an environmental stress cracking phenomenon, (ESC), previously unknown in this type of polymer. ESC is defined as the generation of cracking or crazing of lead insulation in-vivo in the presence of excess stress. As of today, leads made by improved processes are known to have dramatically reduced ESC failures. Several Model 6972 leads were returned in late 1981 that had ESC failure at the site of fixating ligatures. An anchoring sleeve was placed on the lead (instead of separately placed in the package) as of February, 1982 to protect the lead from ligature induced ESC.

In late 1982-early 1983 it was discovered that some other additional mechanism (not ESC) was causing degradation of the polyurethane inside Model 6972 leads. This mechanism was subsequently identified as metal induced oxidation (MIO), generally associated with leakage of body fluids into the lead lumen and with the presence of metal ions and/or metal ion complexes such as the conductor coil and polyurethane tubing. MIO results in oxidative degradation of the polyurethane insulation

material. This mechanism was also previously unknown in polyurethanes. Meanwhile, as demonstrated by acceptable human clinical performance, the biostability of other (b)(4) (b)(4) insulated leads (including the Model 6971, the unipolar version of the Model 6972) continued to be excellent. Figure IV in the Medtronic Product Performance Report, June 1988, see Appendix A, presents unipolar and bipolar ventricular lead survival probabilities. Note that all leads except Models 6972 and 4002 (a variation of the 6972) have demonstrated survival probabilities comparable to the silicone lead Models 6961/6962.

Differences in insulation failures and ultimately lead failure rates between unipolar and bipolar leads can be attributed to configuration differences. A bipolar lead is more complex than a unipolar lead. Bipolar leads have two conductor coils and therefore two insulators (inner and outer), and more joints. Therefore, they are more susceptible to fluid leakage and/or compromised bond joints. Note the following configuration differences between Medtronic bipolar (Model 6972) and unipolar (Model 6971) pacing leads.

Model 6972 insulation minimum wall thickness was (b)(4) for both outer and inner tubings, whereas the Model 6971 minimum wall thickness was (b)(4) In other words, the Model 6971 was (b)(4) that of the inner or outer insulations of the Model 6972. Thicker insulations are known to be more resistant to tubing failure mechanisms.

In addition to polyurethane failure mechanisms, the thinner insulations of the Model 6972 were more susceptible to stylet perforation as well as scalpel cuts, nicks, etc., encountered at implant, and also suture damage if anchoring sleeves were not used. In all of the above circumstances, the Model 6971 was more resistant to failure due to its thicker insulation.

The potential for interference fit, that is tubing with an inner diameter smaller than the coil outer diameter, was more constrictive (smaller) for the 6972 than the 6971. Outer coil to outer tubing minimum clearance was (b)(4) and inner coil to inner tubing minimum clearance was (b)(4) for the 6972. For the 6971, the minimum clearance was (b)(4)

Sale of the Models 6971/6972 were discontinued in 1985/1984, respectively. Even though the

MEDTRONIC CONFIDENTIAL

Model 6971 continued to perform well, sales were discontinued due to the introduction of the Target Tip® family of pacing leads, Models 4011, 4012 (ventricular) and 4511, 4512 (atrial). The Target Tip family continues to demonstrate excellent performance. Reference Figures IV and V, Medtronic Product Performance Report, Appendix A.

Appendix B contains additional information on the performance of Medtronic pacing leads.

Monitoring Lead Field Performance

Medtronic monitors the human field performance of implantable pacing leads through three different sources: 1) Returned Product Analysis (RPA), 2) Medtronic CardioCare telephone monitoring service, and 3) a multi-center (eleven) U.S. clinical study of lead performance referred to as the Chronic Lead Study (CLS). Thorough descriptions of these sources are presented in Medtronic's Product Performance Report (Appendix A).

Relevant data from the CLS and RPA are presented in this biostability section as they relate to long-term lead performance. The CLS uses

clinically derived actuarial data to track and monitor real-time lead performance. In some cases the quantity of leads sold is relatively small and the minimum number of implants for statistically significant data are not yet available (Models 4003/4503, 4016, 4016A) and, therefore significant survival probabilities are not available. The RPA data base examines electrical and visual characteristics of leads, primarily to identify failure mechanisms. However, since leads are commonly not removed, RPA data cannot be used for monitoring the survival probabilities of leads.

Models 4003, 4503 As State-of-the-Art

Data from the Product Performance Report demonstrate the excellent performance of Medtronic's polyurethane pacing leads. With the exception of Models 6972, 4002 and 6991U, all bipolar and unipolar leads perform well. Complications with these models are related primarily to the insulation and have since been corrected. Several configuration, material and process conditions were subsequently modified after Medtronic's experiences with the Models 6971/6972 and 6991U. These conditions were as follows:

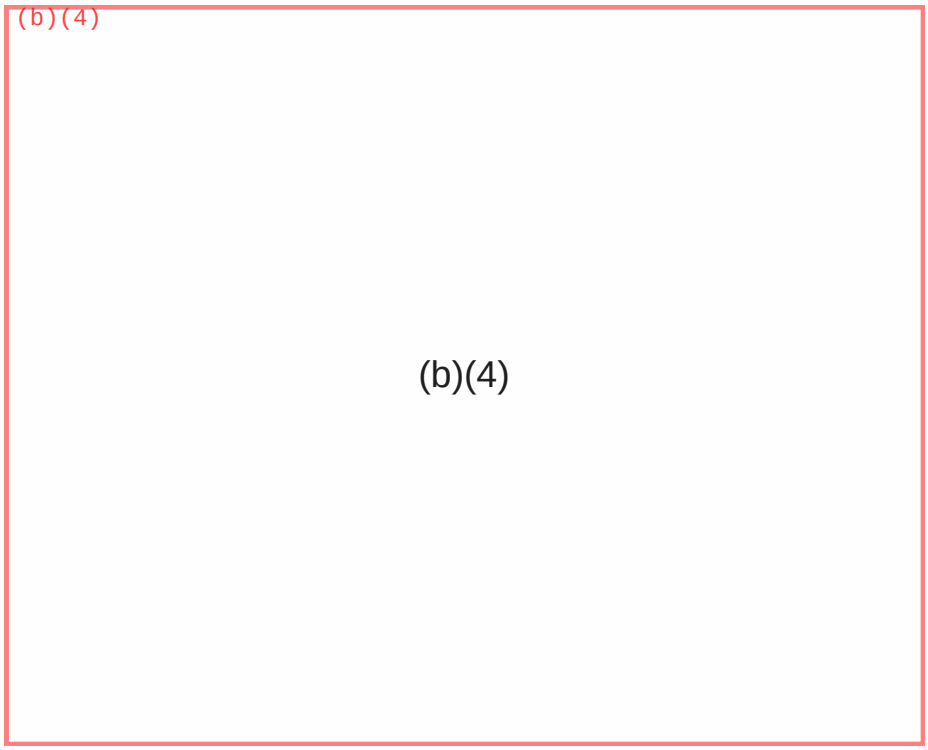
- Use of thicker insulation (tubing).
- (b)(4) (b)(4) for conductor coils versus (b)(4) (b)(4)
- Thermal annealing versus solvent stress relieving of insulation and/or the assembled device. Typically polyurethane tubings were solvent stress relieved and lubricated in order to facilitate manufacture of the lead. However, newer configurations (b)(4) (b)(4) lead tubing prior to or after device assembly to relieve residual stress thereby minimizing the potential for ESC.
- Assured clearance between insulation and conductor coil versus potential for interference fit.

The Models 6957/6957J incorporated thicker insulation and (b)(4) (b)(4) of tubing. The Models 4011/4511 and 4012/4512 incorporated thicker insulation and (b)(4) (b)(4) of the assembled device. As shown in the Product Performance Report (Figures IV and V), these leads are performing well.

Survival probabilities of unipolar leads (after 6971) are as follows:

Unipolar Polyurethane Leads

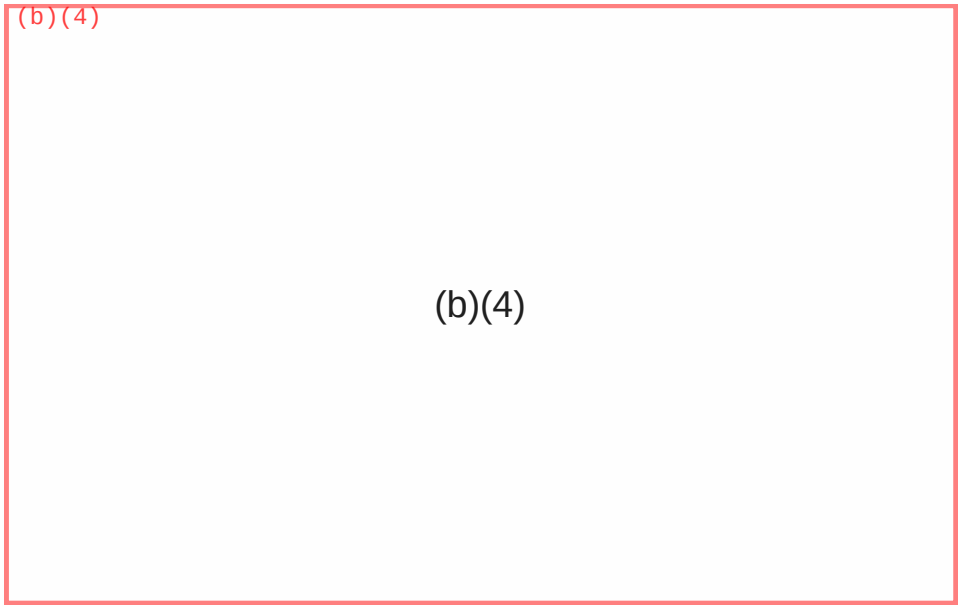
(b)(4)



Survival probabilities of bipolar leads (after 6972) are as follows:

Bipolar Polyurethane Leads

(b)(4)



Tables e-VI-3 and e-VI-4 further demonstrate the improvements with respect to polyurethane biostability.

Table e-VI-3
Insulation Failures*

Model	Initial+ Implants	Active Implants	Insulation Failures
(b)(4)	(b)(4)		

Table e-VI-4
Insulation Failures*

Model	Initial+ Implants	Active Implants	Insulation Failures
Ventricular			
(b)(4)	(b)(4)		

Note the excellent survival probabilities and low occurrence of insulation failures. Reference Appendix B for additional descriptions of lead insulation performance.

In addition to the aforementioned conditions, state-of-the-art during development of the Models 4003/4503 also included the use of thermal forming mandrels for joint construction to eliminate residual stress in joints. In order to facilitate tubing overlaps in lead joint construction, mandrels are used to thermally preform the tubing to the appropriate size. Adhesive is then applied to the joint to assure a secure fit.

Long-term clinical data on the Models 4003/4503 are not yet available. However, the Models 4003/4503 incorporated the positive features of the Models 6957/6957J and therefore clinical performance is expected to be comparable. Twelve month clinical data indicate this is true, see Figure e-VI-1 (Appendix C) and Table e-VI-1.

In conclusion, the Models 4003/4503 as state-of-the-art pacing leads differ from the Models 6971/6972 in the following respects which

Medtronic considers as positive attributes in terms of lead biostability:

- (b)(4)
- (b)(4)
- (b)(4)
- (b)(4)
- (b)(4)

State-of-the-art bipolar leads, i.e., Models 4004/4504, are identical to the unipolar Models 4003/4503 with the following additional improvements:

- (b)(4)
- (b)(4)
- (b)(4)

These additional features cannot yet be proven clinically, however, accelerated testing information (presented later in this section) will confirm this improved performance expectation.

In order to further demonstrate that polyurethane as used in Medtronic pacing leads is biostable and, therefore, a safe and effective insulation material for long-term implant, the following information relative to Medtronic polyurethane pacing leads is provided:

- A detailed comparison of lead configuration, materials, and processing for Medtronic's major line of bipolar and unipolar polyurethane pacing leads.

  Tables e-VI-5 and 6, and e-VI-7 and 8, present configuration, materials and processing characteristics for unipolar and bipolar polyurethane pacing leads. In comparing unipolar leads, Models 4003/4503 are the most current state-of-the-art in polyurethane lead development and for the bipolar leads, Models 4004/4504 are the most current state-of-the art.

(b)(4)	(b)(4)		

DETAILED COMPARISON: CONFIGURATION, MATERIALS, PROCESSING--UNIPOLAR VENTRICULAR AND ATRIAL PACING LEADS, MODELS 4003, 4011, 6957, 6971, 4503, 4511, 6957J, 6993, and BIPOLAR VENTRICULAR AND ATRIAL PACING LEADS, MODELS 4004, 4012, 4016, 4016A, 4504, 4512, 6990U.

Only those characteristics relative to polyurethane are discussed. Other features are presented in the tables for completeness purposes only.

Configuration Similarities

- All incorporate (b)(4) (b)(4) polyurethane insulation (tubing) over the conductor coil(s) and/or memory coil (atrial leads).

Configuration Differences

- The comparative models all differ with respect to minimal insulation (wall) thickness. These differences are primarily due to the desired lead body diameters. The Model 4003's insulation thickness is between that of the Model 6971 and 6957 and larger than the Model 4011. The Model

4503's insulation thickness is between that of the Models 6993 and 6957J, and identical to the Model 4511. The thicker insulation of the Models 6957 and 6957J was a result of desired mechanical characteristics, e.g., torque transfer. Models 4004, 4012, 4016 and 4016A outer insulation thicknesses are significantly larger than the Model 6972. Models 4004 and 4012 inner insulation thickness are identical, as are Models 4504 and 4512 and 4016 and 4016A. Lead insulation thickness is one factor of the lead design that is important in terms of lead biostability. Thicker insulation is not deformed as much when tight ligatures are placed on it. Thus stress applied at implant (securing lead to vein or muscle facia) is less than that which would occur if a thinner insulation were used.

- The Models 4003, 4503 and comparative leads differ with respect to interference fit (tubing-to-coil clearance). As noted in the tables, the Models 4003/4503, 6957/6957J and 4511 leads have clearance between the conductor coil or no interference fit. The unipolar Models

4011, 6971 and 6993, and bipolar Models 4012/4512, 6972 and 6990U have/had the potential, due to the dimensional tolerances associated with the conductor coil and insulation, of creating a situation where interference fit between the conductor coil and insulation exist(ed). The importance here is that relative to ESC, when there is interference fit, there is a potential for stresses of the lead insulation to occur, and if these stresses weren't subsequently relieved, could potentially cause environmental stress cracking of the insulation. As mentioned earlier, the Models 4003/4503, 6957/6957J, and 4511 do not have interference fit and therefore no residual stresses are imposed upon the lead insulation. The Models 4011 and 4012/4512 have the potential for interference fit but are thermally annealed after lead assembly to relieve any residual stresses in the insulation.

- Models 4004/4504 and 4016A incorporate a barrier coating between the conductor coil and insulation. All other lead models do not have a barrier coating.

Material Similarities

- All incorporate (b)(4) as the outer insulation (tubing) material. (Unipolar leads have only outer insulation.)

Material Differences

- All Models except the Models 6971/6972 and 6993 have (b)(4) conductor coils. Models 6971/6972 and 6993 leads had (b)(4) (b)(4) (b)(4) conductor coils. (The 6993 had an (b)(4) outer memory coil.) (b)(4) (b)(4) conductor coils reduce the possibility of stylet perforation because (b)(4) is a more (b)(4) conductor.

- Models 4016 and 4016A use (b)(4) (b)(4) for the inner insulation. All other bipolar leads incorporate (b)(4) (b)(4) for both the inner and outer insulation.

- The barrier coating on the Models 4004/4504 and 4016A is a sputter coat of platinum. All other leads do not have a barrier coating.

Processing Similarities

- All models incorporate manufacturing operations that are intended to relieve residual stresses that may have been introduced during the extrusion process. The Models 4003/4503 and 4004/4504 insulation is thermally annealed as are the Models 6957/6957J, 4016, 4016A (and Models 4011/4511, 4012/4512 after device assembly) to reduce stress.

Processing Differences

- The Models 6971/6972, 6990U and 6993 leads underwent a stress relieving operation in which the insulation was soaked in solvent to relieve residual stresses that may have been introduced during the extrusion process. The Models 4003/4503, 4004/4504, 4016 and 4016A do not use solvent for stress relieving.

- Expansion (b)(4) (b)(4) on the Models 4003/4503, 4004/4504, 4016 and 4016A are formed by using mandrels of specified diameters during the thermal stress relieving/ annealing process. This is not

applicable to the Models 6957/6957J, 6971/6972, 6990U, 6993, 4011/4511 and 4012/4512. (Note: Models 4011/4511 and 4012/4512 are thermally annealed after device assembly to reduce residual stresses.)

- Models 4004/4504 and 4016A insulation (tubing) is thermally stress relieved in an inert atmosphere. Thermal annealing in an inert atmosphere protects the tubing surface from oxidative degradation during the annealing proces.

In summary, Models 4003/4503 and 4004/4504 differ from the very early designs of polyurethane leads (Models 6971/6972 and 6993/6990U) in the following respects. Medtronic considers these to be positive attributes, in terms of lead biostability:

1) Thicker insulation,

2) Assured clearance between insulation and conductor coil versus potential interference fit,

3) (b)(4) versus (b)(4) conductor,

4) Thermal annealing instead of solvent stress relieving.

5) Thermal forming mandrels instead of solvent dilation/lubrication for joint construction,

In addition, the Models 4004/4504 also incorporate:

6) A protective barrier coating between conductor coil and insulation, and

7) Thermal annealing in an inert atmosphere.

More Recent Polyurethane Lead Research

There has been significant research data generated on polyurethane (b)(4) (b)(4) since the Model 6972 lead, focusing on two failure mechanisms, MIO and ESC.

MIO

In order to better understand MIO, Medtronic developed an accelerated bench test to reproduce in-vitro a condition seen in-vivo, and to use this test as a predictor for polyurethane lead performance with respect to MIO. This Medtronic

test is known as (b)(4) (b)(4) is a (b)(4) solution to which (b)(4) (b)(4) is added to make it (b)(4) saline.

Results of (b)(4) testing have demonstrated that MIO can be minimized by preventing certain metal ions from contacting polyurethane. An effective method of preventing (b)(4) (b)(4) polyurethane contact is through the use of a barrier coating between conductor coil and insulation. An effective barrier coating is platinum. In addition, thermally annealing polyurethane in an inert atmosphere has been proven to enhance polyurethane (b)(4) resistance to MIO.

Therefore, two improvements incorporated into the Models 4004/4504 are:

- Barrier coating the conductor coils with platinum, and
- Thermal annealing tubing in an inert atmosphere (e.g., (b)(4)

Both of these improvements have been proven by (b)(4) The Model 4016A pacing lead also incorporated these improvements (reference Document Control Number K873962, Judged substantially equivalent on February 2, 1988).

A. Introduction and Study Design

(b)(4)

(b)(4)

(b)(4)

(b)(4)

Table II-A1 illustrates the chronology of these studies and the polyurethane processing enhancements. The methodology and findings of these five studies is the subject of this complete and in-depth report. A discussion of the study design immediately follows.

Table II-A1. Chronology of Implemented Polyurethane Processing Lead Enhancements

	Polyurethane Lead Enhancements and Year Canine Study Initiated				
	1984	1984	1987	1988	1989
(b)(4)	(b)(4)				
(b)(4)	(b)(4)				

Specific polyurethane tubing insulation wall thickness and (b)(4) resin formulation are presented in Table II-A2. This table is organized to indicate specific tubing insulator factors that were subjected to canine biostability implants in each model studied.

Re: P920015
Medtronic® Transvene® Lead System
Filed: April 1, 1992
Amended: August 27, September 21, October 27 and November 5, 1992,
March 29, June 2, 14, July 9, October 12, and November 3, 1993

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed its review of your premarket approval application (PMA) for the Medtronic® Transvene® Lead System. The Medtronic® Transvene® Lead System (Models 6963, 6966 and 6999), (hereafter referred to as the Transvene® Leads) with Medtronic Pacer-Cardioverter-Defibrillator (PCD®) Model 7217B Multiprogrammable Tachyarrhythmia Control System (hereafter referred to as the PCD™ Transvene® System) is intended for single long-term use and each lead is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead. The lead system has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should: (1) have survived at least one episode of a cardiac arrest presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or (2) in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously, or can be induced, despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the Transvene® Lead clinical study, no conclusions were drawn from the data obtained on this specific patient group.

Prior to Transvene® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Transvene® System.

We are pleased to inform you that the PMA is approved subject to the conditions described below and in the "Conditions of Approval for Implantable Defibrillators and Programmers" (enclosed). You may begin commercial distribution of the device upon receipt of this letter.

Expiration dating for this device has been established and approved at 2 years.

The sale, distribution, and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520(e) of the Federal Food, Drug, and Cosmetic Act (the act) under the authority of section 515(d)(1)(B)(ii) of the act.

The device is further restricted within the meaning of section 520(e) under the authority of section 515(d)(1)(B)(ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

In addition to the postapproval requirements, postmarket surveillance should track the explanted Transvene® leads for evidence of metal ion oxidation (MIO).

CDRH will publish a notice of its decision to approve your PMA in the FEDERAL REGISTER. The notice will state that a summary of the safety and effectiveness data upon which the approval is based is available to the public upon request. Within 30 days of publication of the notice of approval in the FEDERAL REGISTER, any interested person may seek review of this decision by requesting an opportunity for administrative review, either through a hearing or review by an independent advisory committee, under section 515(g) of the act.

Failure to comply with the conditions of approval invalidates this approval order. Commercial distribution of a device that is not in compliance with these conditions is a violation of the act.

All required documents should be submitted in triplicate, unless otherwise specified, to the address below and should reference the above PMA number to expedite processing.

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

In addition, under Section 522(a) of the act, manufacturers of certain types of devices identified by the act or designated by FDA are required to conduct postmarket surveillance studies. FDA has identified under Section 522(a)(1(A) the device cleared for marketing by this order as requiring postmarket surveillance.

Within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce you are required to submit to FDA certification of the date of introduction into interstate commerce, a detailed protocol which describes the postmarket surveillance study, and a detailed profile of the study's principal investigator that clearly establishes the qualifications and experience of the individual to conduct the proposed study. For your information, general guidance on preparing a protocol for a postmarket surveillance study is enclosed.

Submit five (5) copies to:

Postmarket Studies Document Center
Suite 405 (HFZ-107)
1801 Rockville Pike
Rockville, Maryland 20852

Within sixty (60) days of receipt of your protocol, FDA will either approve or disapprove it and notify you of the Agency's action in writing. Do not undertake a postmarket surveillance study without an FDA approved protocol.

Failure to certify accurately the date of initial introduction of your device into interstate commerce, to submit timely an acceptable protocol, or to undertake and complete an FDA approved postmarket surveillance study consistent with the protocol, will cause your product to be misbranded and could lead to the imposition of civil money penalties or other regulatory actions. Any distribution of a misbranded device is a violation of the act and may result in a number of FDA enforcement actions, including (but not limited to) withdrawal of your PMA.

If you have questions concerning postmarket surveillance study requirements, contact the Postmarket Surveillance Studies Branch at (301) 594-0639.

Under Section 519(e) of the act (as amended by the Safe Medical Devices Act in 1990), manufacturers of certain devices must track their products to the final user or patient so that devices can be located quickly if serious problems are occurring with the products. The tracking requirements apply to (1) permanent implants the failure of which would be reasonably likely to have serious adverse health consequences; (2) life sustaining or life supporting devices that are used outside of device user facilities the failure of which would be reasonably likely to have serious adverse health consequences; and (3) other devices that FDA has designated as requiring tracking. Under Section 519(e), FDA believes that your device is a device that is subject to tracking because it is a permanent implant whose failure would be reasonably likely to have serious adverse consequences. FDA has designated your device for tracking.

FDA's tracking regulations, published in the FEDERAL REGISTER on August 16, 1993, appear at 21 CFR Part 821. These regulations set out what you must do to track a device. In addition, the regulations list example permanent implant and life sustaining or life supporting devices that FDA believes must be tracked at 21 CFR § 821.20(b) and the devices that FDA has designated for tracking at 21 CFR § 821.20(c). FDA's rationale for identifying these devices is set out in the FEDERAL REGISTER (57 FR 10705- 10709 (March 27, 1991), 57 FR 22973-22975 (May 29, 1992), and 58 FR 43451-43455 (August 16, 1993)).

If you have questions concerning this approval order, please contact Doris Terry at (301) 594-1523 or Arnold Alpert, Ph.D., at (301) 594-2186.

Sincerely yours,

Susan Alpert, Ph.D., M.D.

Radiological Health

Enclosures

Issued 11-5-93

CONDITIONS OF APPROVAL
FOR IMPLANTABLE DEFIBRILLATORS AND PROGRAMMERS

APPROVED LABELING. As soon as possible, and before commercial distribution of your device, submit three copies of an amendment to this PMA submission with copies of all approved labeling in final printed form to the PMA Document Mail Center (HFZ-401), Center for Devices and Radiological Health, Food and Drug Administration (FDA), 1390 Piccard Drive, Rockville, Maryland 20850.

ADVERTISEMENT. No advertisement or other descriptive printed material issued by the applicant or private label distributor with respect to this device shall recommend or imply that the device may be used for any use that is not included in the FDA approved labeling for the device. If the FDA approval order has restricted the sale, distribution and use of the device to prescription use in accordance with 21 CFR 801.109 and specified that this restriction is being imposed in accordance with the provisions of section 520(e) of the act under the authority of section 515(d)(1)(B)(ii) of the act, all advertisements and other descriptive printed material issued by the applicant or distributor with respect to the device shall include a brief statement of the intended uses of the device and relevant warnings, precautions, side effects and contraindications.

PREMARKET APPROVAL APPLICATION (PMA) SUPPLEMENT. Before making any change affecting the safety or effectiveness of the device, submit a PMA supplement for review and approval by FDA unless the change is of a type for which a "Special PMA Supplement-Changes Being Effected" is permitted under 21 CFR 814.39(d) or an alternate submission is permitted in accordance with 21 CFR 814.39(e). A PMA supplement or alternate submission shall comply with applicable requirements under 21 CFR 814.39 of the final rule for Premarket Approval of Medical Devices.

All situations which require a PMA supplement cannot be briefly summarized, please consult the PMA regulation for further guidance. The guidance provided below is only for several key instances.

A PMA supplement must be submitted when unanticipated adverse effects, increases in the incidence of anticipated adverse effects, or device failures necessitate a labeling, manufacturing, or device modification.

A PMA supplement must be submitted if the device is to be modified and the modified device should be subjected to animal or laboratory or clinical testing designed to determine if the modified device remains safe and effective.

A "Special PMA Supplement - Changes Being Effected" is limited to the labeling, quality control and manufacturing process changes specified under 21 CFR 814.39(d)(2). It allows for the addition of, but not the replacement of previously approved, quality control specifications and test methods. These changes may be implemented before FDA approval upon acknowledgement by FDA that the submission is being processed as a "Special PMA Supplement - Changes Being Effected." This acknowledgement is in addition to that issued by the PMA Document Mail Center for all PMA supplements submitted. This procedure is not applicable to changes in device design, composition, specifications, circuitry, software or energy source.

Alternate submissions permitted under 21 CFR 814.39(e) apply to changes that otherwise require approval of a PMA supplement before implementation of the change and include the use of a 30-day PMA supplement or annual postapproval report. FDA must have previously indicated in an advisory opinion to the affected industry or in correspondence with the applicant that the alternate submission is permitted for the change. Before such can occur, FDA and the PMA applicant(s) involved must agree upon any needed testing protocol, test results, reporting format, information to be reported, and the alternate submission to be used.

POSTAPPROVAL REPORTS. Continued approval of this PMA is contingent upon the submission of postapproval reports required under 21 CFR 814.84 at intervals of 1 year from the date of approval of the original PMA. Postapproval reports for supplements approved under the original PMA, if applicable, are to be included in the next and subsequent annual reports for the original PMA unless specified otherwise in the approval order for the PMA supplement. Two copies identified as "Annual Report" and bearing the applicable PMA reference number are to be submitted to the PMA Document Mail Center (HFZ-401), Center for Devices and Radiological Health, Food and Drug Administration, 1390 Piccard Drive, Rockville, Maryland 20850. The postapproval report shall indicate the beginning and ending date of the period covered by the report and shall include the following information required by 21 CFR 814.84:

(1) Identification of changes described in 21 CFR 814.39(a) and changes required to be reported to FDA under 21 CFR 814.39(b).

(2) Bibliography and summary of the following information not previously submitted as part of the PMA and that is known to or reasonably should be known to the applicant:

(a) unpublished reports of data from any clinical investigations or nonclinical laboratory studies involving the device or related devices ("related" devices include devices which are the same or substantially similar to the applicant's device); and

(b) reports in the scientific literature concerning the device.

If, after reviewing the bibliography and summary, FDA concludes that agency review of one or more of the above reports is required, the applicant shall submit two copies of each identified report when so notified by FDA.

In addition to the above and in order to provide continued reasonable assurance of the safety and effectiveness of the device for its intended use, the annual postapproval reports shall include, separately for each model number (if applicable), the following information known by or reported to the applicant:

(1) The number of pulse generators domestically implanted and the number of reported explants and deaths.

(2) A breakdown of the reported deaths into pulse generator related and non-pulse generator related.

(3) A breakdown of the reported explants into the numbers reported at end of battery life, having complications unresolvable by programming and for other reasons with safety and effectiveness issues which can be derived from the reports stated.

(4) The number of pulse generators returned to the applicant for cause from domestic sources with a breakdown into the numbers currently in analysis, operating properly, at normal battery depletion and failed, with the failure mechanisms described.

(5) A cumulative survival table for the pulse generators.

(6) The number of programmers and modules shipped and the number of returns with a breakdown into the numbers currently in analysis, operating properly and failed, with the failure mechanisms described.

ADVERSE REACTION AND DEVICE DEFECT REPORTING. As provided by 21 CFR 814.82(a)(9), FDA has determined that in order to provide continued reasonable assurance of the safety and effectiveness of the device, the applicant shall submit 3 copies of a written report identified, as applicable, as an "Adverse Reaction Report" or "Device Defect Report" to the PMA Document Mail Center (HFZ-401), Center for Devices and Radiological Health, Food and Drug Administration, 1390 Piccard Drive, Rockville, Maryland 20850 within 10 days after the applicant receives or has knowledge of information concerning:

(1) A mixup of the device or its labeling with another article.

(2) Any adverse reaction, side effect, injury, toxicity, or sensitivity reaction that is attributable to the device and

(a) has not been addressed by the device's labeling or

(b) has been addressed by the device's labeling, but is occurring with unexpected severity or frequency.

(3) Any significant chemical, physical or other change or deterioration in the device or any failure of the device to meet the specifications established in the approved PMA that could not cause or contribute to death or serious injury but are not correctable by adjustments or other maintenance procedures described in the approved labeling. The report shall include a discussion of the applicant's assessment of the change, deterioration or failure and any proposed or implemented corrective action by the applicant. When such events are correctable by adjustments or other maintenance procedures described in the approved labeling, all such events known to the applicant shall be included in the Annual Report described under "Postapproval Reports" above unless specified otherwise in the conditions of approval to this PMA. This postapproval report shall appropriately categorize these events and include the number of reported and otherwise known instances of each category during the reporting period. Additional information regarding the events discussed above shall be submitted by the applicant when determined by FDA to be necessary to provide continued reasonable assurance of the safety and effectiveness of the device for its intended use.

REPORTING UNDER THE MEDICAL DEVICE REPORTING (MDR) REGULATION. The Medical Device Reporting (MDR) Regulation became effective on December 13, 1984, and requires that all manufacturers and importers of medical devices, including in vitro diagnostic devices, report to FDA whenever they receive or otherwise became aware of information that reasonably suggests that one if its marketed devices

(1) may have caused or contributed to a death or serious injury or

(2) has malfunctioned and that the device or any other device marketed by the manufacturer or imported would be likely to cause or contribute to a death or serious injury if the malfunction were to recur.

The same events subject to reporting under the MDR Regulation may also be subject to the above "Adverse Reaction and Device Defect Reporting" requirements in the "Conditions of Approval" for this PMA. FDA has determined that such duplicative reporting is unnecessary. Whenever an event involving a device is subject to reporting under both the MDR Regulation and the "Conditions of Approval" for this PMA, you shall submit the appropriate reports required by the MDR Regulation and identified with the PMA reference number to the following office:

Division of Postmarket Evaluation (HFZ-520)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850
Telephone (301) 594-1144

Events included in periodic reports to the PMA that have also been reported under the MDR Regulation must be so identified in the periodic report to the PMA to prevent duplicative entry into FDA information systems.

Copies of the MDR Regulation and an FDA publication entitled, "An Overview of the Medical Device Reporting Regulation," are available by written request to the above address or by telephoning (301) 594-1140.

To the Manufacturer:

The attached draft guidance represents an attempt by the Center for Devices and Radiological Health (CDRH) to provide general guidance to manufacturers of a broad spectrum of devices. On review, some have taken this guidance as requiring Phase IV clinical studies. This is not the intention of the attached document nor is it the goal of Required Postmarket Surveillance (RPS) studies. The primary objective of RPS studies is the study of the performance of the device after marketing as it is to be used in the general population for which it is intended.

Generally, the primary variables to be studied are morbidity or mortality in the population on whom the device has been used or in whom the device has been implanted. The major interest lies in device failure and its attendant impact on the patient. Additionally, however, expected major complications should be monitored to be certain that the incidence of such complications is not unacceptably high in the population for which the device was intended when used according to manufacturer's instructions.

You are free to choose whatever design you wish as long as you can persuade CDRH that the study is scientifically sound. For example, a two-tiered approach has been proposed which may be acceptable in some circumstances as a postmarket surveillance study. What appears in the attached draft guidance is a listing of study elements which should be considered in the conduct of a scientifically sound postmarket study. Some studies will incorporate more features than others. When a topic discussed in the draft guidance is not needed for your specific study, it is only necessary to discuss the exclusion of that item in the protocol.

Currently, CDRH is working with industry to redraft the guidance to prevent the misconception that postmarket surveillance under Section 522(a)(1) of the Federal Food, Drug, and Cosmetic Act requires an elaborate extension of the premarket clinical investigation. Until such guidance is available, questions on specific elements of study design may be directed to Anita Rayner at the phone number listed in the draft guidance document.

DRAFT

GUIDANCE TO MANUFACTURERS ON THE DEVELOPMENT OF REQUIRED POSTMARKET SURVEILLANCE STUDY PROTOCOLS UNDER SECTION 522(a)(1) OF THE FEDERAL FOOD, DRUG, AND COSMETIC ACT

INTRODUCTION

Under Section 522(a)(1) of the Federal Food, Drug, and Cosmetic Act (Act) all manufacturers of certain types of devices identified in the Act are required to conduct postmarket surveillance studies. It has been determined by the Agency that the device cleared for marketing by the attached letter is subject to Section 522(a)(1) of the Act.

Within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce, you are required to submit to the Agency a detailed protocol that describes your proposed postmarket surveillance study, and you are to certify the exact date the device was first introduced or delivered for introduction into interstate commerce. As described in the Act, the protocol must be designed to produce useful information evaluating the safety and effectiveness of the device. The Agency has sixty (60) days to approve or disapprove a protocol and principal investigator. The manufacturer will be notified in writing of the Agency's determination and should wait for this notification before initiating the study. Failure to submit a protocol within the specified timeframe, provide appropriate reports to the Agency, or complete an Agency approved postmarket surveillance study consistent with the protocol will constitute a violation of the Act.

For your reference, the Agency has included this general guidance on preparing a protocol for a postmarket surveillance study. In addition to submitting the protocol, you must also include a detailed profile of the study's principal investigator. This profile should clearly establish the qualifications and experience of the individual to conduct the proposed investigation.

The Agency strongly encourages manufacturers to consult with appropriate professionals experienced in data management, research design, methodology, and statistical analysis in designing a potential postmarket surveillance study. It is usually most cost effective to utilize these individuals as early as possible in the study design process.

PURPOSE OF REQUIRED POSTMARKET SURVEILLANCE

It is recognized that not all device related problems, whether of design, mechanical, electrical, or human origin, are going to be

observed in the limited investigations that usually precede Agency approval to commercially market a device. Moreover, the preliminary estimates of the various performance characteristics, adverse effects, and related parameters obtained in pre-approval testing are also subject to further refinement as actual clinical experience and the size of the data base increases.

The primary purpose of required postmarket surveillance is to provide an early warning system to alert the health care community to any potential problems with a given device within a reasonable time of the initial marketing of the device. This postmarket surveillance is intended to provide crucial information not available in current passive reporting mechanisms such as MDR or user reporting by requiring the manufacturer to conduct active investigations of device performance in actual use. Secondarily, such studies will provide the public, health care professionals, industry, and government with additional useful information regarding device safety and effectiveness.

PURPOSE OF GUIDANCE

The purpose of this guidance document is to assist manufacturers in the preparation and submission of postmarket surveillance study protocols that are required under Section 522(a)(1) of the Federal Food, Drug, and Cosmetic Act.

Please submit five (5) copies of your proposed postmarket surveillance study protocol to:

Postmarket Studies Document Center
Room 408 (HFZ-107)
Center for Devices and Radiological Health
12720 Twinbrook Parkway
Rockville, Maryland 20852

CONTENTS OF THE POSTMARKET SURVEILLANCE SUBMISSION

The Agency recognizes that the planning and conduct of each postmarket surveillance study will be essentially device dependent. Within certain limitations, the basic assumption of postmarket surveillance is that a reasonable assurance of safety and effectiveness (risks and benefits) or substantial equivalence, of a given device has already been demonstrated through the premarket approval or premarket notification process, respectively.

The manufacturer shall address each of the following issues when presenting a proposed protocol to the Agency. While the Agency has offered some suggestions or examples under each heading, no single protocol has been identified to meet the requirements of required

postmarket surveillance. The manufacturer has the flexibility to design a surveillance program appropriate to the subject device provided the inclusion or exclusion of each of the following issues is discussed and justified.

I. ORGANIZATIONAL AND ADMINISTRATIVE ELEMENTS

The first section of the protocol is concerned with organizational and administrative elements of the submission. Most of this information relates to basic manufacturer and device identification (see the attached Checklist for details). This section also requires the manufacturer to certify the date the device was first introduced or delivered for introduction into interstate commerce.

The submission shall be numbered by section and organized according to the outline provided by the enclosed protocol checklist and the entire submission must also be sequentially numbered from the Table of Contents through the last page of text or data. A detailed Table of Contents with appropriate listings of sections, tables, graphs, figures, appendices, etc. is also required. The page numbering sequence in the Table of Contents should correspond to the sequential numbering system.

II. SURVEILLANCE PROTOCOL

A. STUDY OBJECTIVES

The manufacturer shall identify precisely the objectives of the proposed surveillance study in the protocol. The Agency recommends that the manufacturer limit the number of objectives to a well defined minimum in an effort to produce clear data and analyses that are designed to provide reasonable assurance that the device is operating safely and effectively when used as intended in the target population.

B. STUDY VARIABLES

The manufacturer shall clearly define all relevant study variables that are to be included in the investigational plan. As appropriate, the manufacturer should include data on patient survival rates, device failure rates, morbidity and/or mortality associated with the device, etc. Each parameter should be defined in words, and where appropriate, in mathematical terms. Any information which the manufacturer can provide concerning the identified variables will be extremely helpful in the review of the submitted protocol. For example, for each variable, an expected range of values could be presented along with other appropriate statistical summaries and estimates that may be known from earlier

clinical experience.

The Agency believes that if these studies are to be useful in serving as early warning systems designed to avert potential catastrophes, and to evaluate safety and effectiveness on a large scale, the data must be amenable to appropriate statistical evaluation. This requires that the manufacturer collect pertinent denominator data for all study variables (especially important in rate calculations). "Pertinent denominator data" refers to the use of appropriate numbers in all calculations. In general, a pertinent denominator will refer to the actual number of devices in use in the study population (as opposed to number of devices manufactured, shipped, or delivered) during a given phase of the postmarket surveillance study. Conversely, it would be inappropriate to use the large number of shipped devices as the denominator in a ratio-type computation in order to artificially lower the corresponding failure rate, or to incorrectly use a smaller number in the denominator to artificially raise a success rate.

The discussion of appropriate use of denominator data will be considered critical in reviewing the proposed protocol. The Agency believes that analyses without meaningful denominators will not result in obtaining the most reliable information to best serve the interests of the public health.

C. STUDY DESIGN

The primary function of good study design is to control sources of error or bias. In general, the principal objective of good study design is the identification of these potential sources of bias before beginning the study. It is then a matter of determining how to utilize available research techniques to control these factors during the study.

In the case of postmarket surveillance studies, much may already be known about the problems and sources of bias because of previous experience in the non-clinical and clinical trials required to obtain marketing approval. This prior experience should have also highlighted another important aspect of study design - the identification of critical variables and their associated uncertainty.

This type of information allows for more precise formulation of research objectives, hypotheses, and allocation of other resources. For this reason, the Agency strongly recommends that manufacturers devote sufficient time to the planning of postmarket studies and consult with appropriate professionals early in the design process.

Proper study design and a clear presentation of the selected associated methodology to achieve the stated research objectives

will facilitate postmarket protocol approval and thus eliminate unnecessary delays and the associated expense in time and resources. Accordingly, a proposed postmarket study protocol should include: a discussion of design issues such as the type of study to be utilized; the study size; the data collection plan and associated forms; the follow-up plan; data quality control mechanisms; the length and proposed endpoint of the study; and the proposed analytical plan.

The manufacturer should address each of the following items in designing a proposed protocol or provide an explanation as to why a particular section does not apply in a given situation.

1. Type of Study

Discuss the proposed study design including control selection, stratification, matching criteria if needed, etc. For example, morbidity and mortality data may require prospective follow-up, case-control design, etc. A device failure analysis of retrieved implants may require an engineering and/or materials analysis including complete description of test method, specification of all experimental errors, etc. The appropriateness of a given design will vary from device to device and depend on the surveillance objectives. The Agency does not require a specific study type be used during the postmarket study, and recognizes the need to be flexible in allowing for creative, valid strategies. However, it is incumbent upon the manufacturer to fully justify the type of study proposed for a given device.

2. Study Size

The manufacturer should provide a complete description of the proposed sample size. This should include any assumptions or formulas, with references, that are used for sample size determination.

a. Source(s) of Patient or Device Data

Specify identification of study subjects. For example, in a follow-up study, treated and un-treated subjects need to be defined and identified from sources such as hospital logs, physician records, population listings, etc. In case-control studies, the sources of both cases and controls need to be described in detail.

The manufacturer should also supply a full description of subject inclusion/exclusion criteria that will be used in selecting subjects for the actual study.

b. Representativeness of Data

If pooling from different sources, such as private practices, medical centers, or cities is planned, a detailed justification for combining such data must be presented. For example, a single medical center may not provide enough patients to meet the target number, although three centers would. In such a situation, the comparability and uniqueness of each center should be discussed in terms of relevance to the study. Data collection, processing, and analysis strategies are examples of factors that illustrate a common protocol is being used across investigational sites, and should be presented as evidence supporting the pooling of data.

3. Data Collection Plan and Forms

Explain which variables will be collected. For example, patient name, address, age, sex, device serial number, manufacturing date, duration of use etc. Specify how the data will be obtained, for example, from personal interview, hospital medical record, specific laboratory analysis, etc., and the timing of collection of the different variables. For example, some will be obtained at the beginning, while others may be collected at the conclusion of the study. It is suggested the manufacturer include copies of data collection forms if available.

4. Follow-up Plan

For studies requiring follow-up of patients, a plan is needed to describe how subjects will be followed, e.g., through the patient's personal physician, personal interviews, monthly phone calls, relatives, etc. For patients who become "apparently" lost, explain the procedures that will be used to find them.

5. Data Quality Control

Detailed procedures for monitoring data to ensure accuracy should be discussed. For example, a subset of patients may have duplicate data collected by two people, or certain mutually exclusive terms may exist such that records can be compared using automated techniques to rule out data entry error. Techniques for anticipating, identifying, and correcting errors should be described.

6. Length/End of Study

When will data collection end? The conclusion of the study can be in terms of an absolute date, relative date, attainment of minimal sample size or number of person-years of follow-up, etc. However, the manufacturer should justify the selected method.

7. Proposed Analytical Plan

This section should be a description of all on-going, interim, and final analyses to be performed. The discussion of any proposed statistical tests should include assumptions, formulas, references, and a brief explanation of why the selected tests are appropriate for the situation. Interim analyses designed to demonstrate that device performance is within the expected values should be outlined here, along with a proposed reporting schedule for the analyses.

D. REPORTING REQUIREMENTS

The manufacturer is required to submit plans that describe interim, and final reporting mechanisms. Each plan should outline the proposed reporting objectives and the rationale for the selection of each objective, a complete description of what information will be reported, what mechanism the manufacturer will use to report this information, and proposed reporting timeframe(s).

It is important to note that reports to the Agency in these instances must be made in addition to reports submitted in compliance with the Medical Device Reporting Regulation.

1. Interim Reporting

In addition to describing the contents and mechanisms for interim reporting, the manufacturer will identify benchmark points in the study. These benchmark points represent critical phases in the conduct of the postmarket surveillance study and will also serve as report due dates. Unless noted otherwise, these interim communications will require a report of study progress by the Principal Investigator and a summary of the analyses of available data gathered under the protocol. At a minimum, interim reporting should be done at the following study benchmarks: initiation of the study, one-year post-initiation, the mid-point of the study (this may be time or subject dependent depending upon the study design), and the completion of data collection.

2. Final Report

At the conclusion of the study, the manufacturer must submit a final report that shall summarize the results of the study. All analyses and evaluations of these results must directly address the original study objectives. These results must include a clear presentation of patient and/or device data. All data that support statistical results or conclusions must be adequately referenced, and the report will provide detailed patient listings of all available data along with appropriate summary tables.

These summary tables should be concerned with all study variables, timeframes, or other factors as related to study objectives, or

statistical analyses. Where laboratory analyses of devices are performed, the analysis of errors associated with the test method must be included.

III. PRINCIPAL INVESTIGATOR

The law directs the Agency to determine if the proposed principal investigator of the study has sufficient qualifications and experience to conduct this surveillance. Typically, the principal investigator of an investigation is an individual who actually conducts the investigation, that is, under whose direction postmarket investigations of the device are conducted.

In the event of an investigation that is conducted by a team of individuals, the term principal investigator refers to the individual who is the designated leader of the team. For purposes of Section 522 of the Act, the Agency extends this definition to include study monitors, i.e., individuals who are qualified by training and experience to oversee and manage an investigation, but who may not necessarily be active investigators in the study. It should be noted that such individuals must also be qualified by training and experience to conduct these investigations.

The principal investigator or monitor is responsible for ensuring that the investigation is conducted in accordance with any signed agreements, the investigational plan, and any applicable Agency regulations. In addition, if applicable, the principal investigator/monitor protects the rights, safety and welfare of subjects.

In order that the Agency may determine that an individual is qualified by both training and experience to conduct a postmarket surveillance study, the sponsor shall submit a detailed Curriculum Vitae of the proposed investigator; a statement of the investigator's relevant training and experience - including the dates, location, extent, and type of experience; and, if the investigator was ever involved in an investigation or research program that was terminated other than by contractual agreement, an explanation of the circumstances surrounding the termination.

In addition, the manufacturer is required to submit a statement signed by the investigator who has agreed to conduct the investigation in accordance with the protocol, applicable Agency regulations and guidance, and conditions of approval that may have been imposed by the Agency. Finally, the investigator shall submit a disclosure of financial interests that are directly or indirectly affected by the sales and distribution of the device that is the subject of this postmarket investigation. Any subsequent change in financial interest should also be reported to the Agency.

CHANGES TO THE POSTMARKET SURVEILLANCE STUDY

The manufacturer will notify the Postmarket Surveillance Studies Branch of any proposed changes in ongoing studies. A proposed change must be submitted for Agency approval prior to execution. For example, if there is a change in the principal investigator of the study, the manufacturer must submit information regarding the qualifications and experience of the proposed replacement.

THE PROTOCOL CHECKLIST

A copy of the Postmarket Surveillance Protocol Checklist is attached to this guidance document. This checklist summarizes the topics listed in the Contents of the Postmarket Surveillance Submission section. A presentation and discussion of these issues are necessary to evaluate any study that is designed to comply with the law and result in the collection of useful data or other information necessary to protect the public health and to provide safety and effectiveness information for the device.

The purpose of the protocol checklist is to provide Agency reviewers and manufacturers alike with an outline of what the Agency believes are the essential administrative and research issues that must be addressed by any proposed surveillance protocol. This checklist in effect represents those general items that the Agency considers the minimum information it would need in order to evaluate the scientific validity of a proposed postmarket surveillance study.

In a protocol submission, the manufacturer must include a discussion of each item on the checklist or explain why a particular issue is not applicable to a postmarket surveillance study of the subject device. A protocol submitted for review that does not address the minimum requirements as specified in the checklist will be considered administratively incomplete and not approved. Protocols that are found to be administratively complete will be reviewed by an appropriate scientific and technical review committee.

Satisfying the immediate administrative requirements of the protocol checklist does not necessarily imply that a proposed protocol will be subsequently approved by the review committee. Approval of the postmarket surveillance study will be based upon the appropriate selection of study objectives relative to critical device variables, the scientific and technical merits of the proposed research design as it relates to the stated objectives, and the qualifications of the proposed principal investigator.

AGENCY CONTACT OFFICE

This guidance is subject to future revision, and the Agency welcomes any suggestions to improve either the document or the associated review process. If there are any comments or questions regarding this guidance, please contact the Postmarket Surveillance Studies Staff at the address below:

DEPARTMENT OF HEALTH AND HUMAN SERVICES

FOOD AND DRUG ADMINISTRATION

[DOCKET NO. _____]

PREMARKET APPROVAL OF MEDTRONIC® TRANSVENE® LEAD SYSTEM

AGENCY: Food and Drug Administration.

ACTION: Notice.

SUMMARY: The Food and Drug Administration (FDA) is announcing its approval of the application by Medtronic, Inc., Minneapolis, MN, for premarket approval, under section 515 of the Federal Food, Drug, and Cosmetic Act (the act), of Medtronic® Transvene® Lead System. After reviewing the recommendation of the Circulatory System Devices Panel, FDA's Center for Devices and Radiological Health (CDRH) notified the applicant by letter on DEC 9 1988, of the approval of the application.

DATE: Petitions for administrative review by (insert date 30 days after date of publication in the FEDERAL REGISTER).

ADDRESS: Written requests for copies of the summary of safety and effectiveness data and petitions for administrative review to the Dockets Management Branch (HFA-305), Food and Drug Administration, Room 1-23, 12420 Parklawn Drive, Rockville, MD 20857.

SUPPLEMENTARY INFORMATION: On April 1, 1992, Medtronic, Inc., Minneapolis, MN, 55432, submitted to CDRH an application for premarket approval of Medtronic® Transvene® Lead System. The device is a transvenous defibrillation lead system and is intended for single long-term use and each lead is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillator lead. The lead system has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should: (1) have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or (2) in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously, or can be induced, despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the Transvene® Lead clinical study, no conclusions were drawn from the data obtained on this specific patient group.

Prior to Transvene® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Transvene® system.

On August 2, 1993, the Circulatory System Devices Panel, an FDA advisory panel, reviewed and recommended approval of the application. On , CDRH approved the application by a letter to the applicant from the Acting Director of the Office of Device Evaluation, CDRH.

A summary of the safety and effectiveness data on which CDRH based its approval is on file in the Dockets Management Branch (address above) and is available from that office upon written request. Requests should be identified with the name of the device and the docket number found in brackets in the heading of this document.

OPPORTUNITY FOR ADMINISTRATIVE REVIEW

Section 515(d)(3) of the act (21 U.S.C. 360e(d)(3)) authorizes any interested person to petition, under section 515(g) of the act (21 U.S.C. 360e(g)), for administrative review of CDRH's decision to approve this application. A petitioner may request either a formal hearing under Part 12 (21 CFR Part 12) of FDA's administrative practices and procedures regulations or a review of the application and CDRH's action by an independent advisory committee of experts. A petition is to be in the form of a petition for reconsideration under 10.33(b) (21 CFR 10.33(b)). A petitioner shall identify the form of review requested (hearing or independent advisory committee) and shall submit with the petition supporting data and information showing that there is a genuine and substantial issue of material fact for resolution through administrative review. After reviewing the petition, FDA will decide whether to grant or deny the petition and will publish a notice of its decision in the FEDERAL REGISTER. If FDA grants the petition, the notice will state the issue to be reviewed, the form of the review to be used, the persons who may participate in the review, the time and place where the review will occur, and other details.

Petitioners may, at any time on or before (insert date 30 days after date of publication in the FEDERAL REGISTER), file with the Dockets Management Branch (address above) two copies of each petition and supporting data and information, identified with the name of the device and the docket number found in brackets in the heading of this document. Received petitions may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday. This notice is issued under the Federal Food, Drug, and Cosmetic Act Section 520(h), 90 Stat. 554-555, 571 (21 U.S.C. 360e(d), 360j(h)) and under authority

delegated to the Commissioner of Food and Drugs (21 CFR 5.10) and redelegated to the Director, Center for Devices and Radiological Health (21 CFR 5.53).

_____

SUMMARY OF SAFETY AND EFFECTIVENESS DATA

I. General Information

Device Generic Name: Transvenous Defibrillation Lead System

Device Trade Name: Medtronic® Transvene® Lead System

Applicant's Name and Address: Medtronic, Inc.
7000 Central Avenue N.E.
Minneapolis, MN 55432

Premarket Approval (PMA) Application Number: P920015

Date of Panel Recommendation: August 2, 1993

Date of Notice of Approval to the Application: DEC 9 1993

II. Indications for Use

The Medtronic® Transvene® Lead System (Models 6963, 6966 and 6999), (hereafter referred to as the Transvene® Leads) with Medtronic Pacer-Cardioverter-Defibrillator (PCD®) Model 7217B Multiprogrammable Tachyarrhythmia Control System (hereafter referred to as the PCD® Transvene® System) is intended for single long-term use and each lead is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead. The lead system has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should: (1) have survived at least one episode of a cardiac arrest presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or (2) in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced, despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the Transvene® Lead clinical study, no conclusions were drawn from the data obtained on this specific patient group.

Prior to Transvene® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic

evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Transvene® system.

III. Device Description

The PCD® Transvene® System consists of the following:

- Model 6963 Unipolar, Endocardial, Coronary Sinus or Superior Vena Cava Lead;
- Model 6966 Tripolar, Endocardial, Screw-In Ventricular Lead;
- Model 6999 Unipolar, Subcutaneous, Oval Patch Lead;
- commercially available Model 7217B PCD®,
- commercially available Model 5355 External Tachyarrhythmia Control Device (ETCD) and ETCD™ accessories such as the Model 5418 and 5419 Patient Cables, Model 5414 Test Load, Model 5417 Electrogram Cable and Model 6701 Lead End Cap; and
- commercially available Model 9788 MemoryMod™ Software Module.

The PCD® Transvene® Lead System is implanted using a transvenous approach to the right heart. This means that PCD® therapy may be provided without the necessity of a thoracotomy (open chest surgical procedure) for lead placement.

The PCD® Transvene® System may be programmed to deliver cardioversion and defibrillation therapies in 1 of 3 different configurations. The configurations include the following: single (a single pulse delivered over one pathway; a simultaneous pulse delivered over two pathways; and, two sequential pulses separated by a very short interval delivered over two different pathways.

The lead configurations to be used depend on the desired pathway and the physician's placement preference. The available configurations involve using 2 or 3 leads to deliver therapies. A PCD® Transvene® System using two leads delivers cardioversion and defibrillation pulses between two electrodes. The lead system consists of either of the following combinations: right ventricle and coronary sinus; right ventricle and superior vena cava; or right ventricle and subcutaneous patch. A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes to the COMMON (designated PCD® connection) defibrillation electrode. The lead system may have the following combinations: right ventricle, superior vena cava and subcutaneous patch; right ventricle, coronary sinus and subcutaneous patch; and right ventricle, coronary sinus and superior vena cava.

A. Model 6963 Unipolar, Endocardial, Coronary Sinus or Superior Vena Cava Lead

The Model 6963 Unipolar, Coronary Sinus or Superior Vena Cava, Transvenous Lead (hereafter referred to as the Model 6963 Lead) is designed for the delivery of cardioversion and defibrillation pulses in the coronary sinus or superior vena cava.

The Model 6963 Lead has a platinum alloy electrode and silicone insulation which surrounds a low resistance platinum alloy conductor coil. The Model 6963 Lead has a 6.5 mm connector.

B. Model 6966 Tripolar Endocardial, Screw-In Ventricular Lead

The Medtronic Transvene Model 6966 Tripolar, Endocardial, Screw-In Ventricular Lead (hereafter referred to as the Model 6966 Lead) is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. The Model 6966 Lead has three electrodes: the helix, ring and coil. The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; the coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses. The Model 6966 Lead has a 6.5 mm connector.

The helix is made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool.

The ring electrode is made of platinum alloy and is located proximal to the helix and connects electrically to the connector ring of the bipolar leg of the bifurcation.

The defibrillating coil electrode is made of platinum and is most proximal to the pulse generator and connects electrically to the connector pin of the unipolar leg of the bifurcation.

C. Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead

The Medtronic Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead (hereafter referred to as the Model 6999 Patch Lead) is designed for the delivery of cardioversion and defibrillation pulses in the subcutaneous or submuscular space of the left lateral chest wall.

The Model 6999 Patch Lead has a low resistance MP35N conductor coil and platinum alloy electrode coils for cardioversion and defibrillation. The Model 6999 lead has a 6.5 mm unipolar connector.

IV. Contraindications

The PCD® Transvene® System is contraindicated in the following:

- patients with transient ventricular tachyarrhythmias due to reversible causes, e.g., drug intoxication, electrolyte imbalance, sepsis or hypoxia; and

- patients with transient ventricular tachyarrhythmias due to other factors, e.g., myocardial infarction and electrocution.

When tricuspid valvular disease or a mechanical heart valve is present, use of a ventricular endocardial lead (the Model 6966) is contraindicated.

The PCD® Transvene® Lead System is also contraindicated for the sole use of detection and treatment of atrial arrhythmias.

V. Warnings

The warnings for the Transvene Leads include the following:

- Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

- Do not attempt to use the Transvene® Lead system with any device other than a Medtronic implantable tachyarrhythmia control device for which it has been tested. While there has been no testing of the Transvene® leads with a non-Medtronic device, the potential adverse consequences of using such a combination may include, but are not limited to, undersensing cardiac activity and failure to deliver necessary therapy.

- Two anchoring sleeves are provided with the leads (Models 6963 and 6966). Both anchoring sleeves should be used as described in the section of the manual "Anchoring the Lead" to assure adequate fixation.

- If patients do not meet the implant criteria (demonstration of a 10 Joule safety margin) for a transvenous lead system, physicians should consider implanting an epicardial cardioversion/defibrillation lead system. If an epicardial system is to be implanted after testing a transvenous system, consider performing the procedure at a later date. The Transvene® clinical study showed a 9.3 percent perioperative death rate for patients failing the implant criteria for a Transvene® system and receiving

an epicardial system. This compares to 0.7 percent for those patients receiving a Transvene® system without the additional epicardial surgical procedure.

In addition the following warnings apply to the Model 6999 Lead.

- The Model 6999 Lead is not intended for epicardial or pericardial placement since testing has not been performed to determine if epicardial or pericardial use is safe or effective.

- The Model 6999 Leads have palpable nodes on the insulation side of the patch which must face the skin surface to assure the electrode surface is facing the heart. If the insulation side of the patch is facing the heart cardioversion/defibrillation energy may be inadequate to reliably convert arrhythmias.

- Placement of the patch over nerve tissue may result in nerve damage.

VI. Precautions

The precautions for use of the Transvene® Leads include the following:

- Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, or whenever arrhythmias are possible or intentionally induced during post-implant testing.

- Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

- Leads should be handled with great care at all times. Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.

- Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile surgical gloves that have been wiped with a sterile moist sponge or equivalent.

- Do not immerse leads in mineral oil, silicone oil, or any other liquid.

- Use ethylene oxide only. Do not resterilize more than one time.

- Do not use surgical instruments to grasp the lead or connector pin when tunneling.

- Chronic repositioning or removal of the lead may be difficult because of the fibrotic tissue. However, if a lead must be

removed or repositioned, proceed with extreme caution. If a lead is abandoned, it should be capped to avoid transmitting electrical signals. Return all removed or unused leads or portions thereof to Medtronic.

The following precautions apply to the Model 6963 and 6966 Leads:

- Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g., the cephalic vein.

- To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

- Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

- Avoid placing the lead under extreme tension or angulation to prevent dislodgement and possible lead fracture. Do not grip the lead with surgical instruments.

- To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end.

- Do not use the anchoring sleeve tabs for suturing.

- Do not use surgical instruments to grasp the lead or connector pin when tunneling.

- Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

The following precaution applies only to the Model 6966 Lead: The maximum number of revolutions of the electrode fixation tool needed to extend or retract the helix is 20. Exceeding the maximum revolutions may damage the lead.

VII. Alternative Practices and Procedures

Cardioversion and defibrillation is an accepted treatment for the indications described in Section II above. The most reliable method for increasing the survival of persons at high risk of sudden cardiac death is the prompt treatment of ventricular fibrillation and hemodynamically unstable ventricular tachycardias by the application of a high energy electrical discharge to the heart. The most widespread alternative chronic treatment is the suppression of ventricular tachyarrhythmias with antiarrhythmic drug therapy. Other commercially available automatic implantable pacer cardioverter defibrillator systems, may also meet the needs of the patients with the conditions described in Section II above.

VIII. Marketing History

On November 1991, Medtronic, Inc. began marketing the PCD® Transvene® System outside the United States. Approximately 2000 PCD® Transvene® Systems were marketed with no adverse effects reported. The system has not been removed from any market for reasons of safety and effectiveness.

IX. Potential Adverse Effects

The potential adverse effects related to the use of endocardial leads include, but are not limited to the following patient-related conditions: fibrillation or other arrhythmias, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, infection, endocarditis, constrictive pericarditis, pneumothorax, hemothorax, and tissue necrosis.

Other potential adverse effects known to be related to the lead system, include the following: lead dislodgement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of detection, cardioversion, defibrillation, or pacing therapies.

X. Summary of Studies

A. Electrical Testing

Electrical resistance testing was performed to ensure proper functioning of the Transvene® Leads. Seventeen Model 6963 Leads, 35 Model 6966 Leads and 18 Model 6999 Leads were tested.

Electrical resistance was measured on all of the Transvene Leads at 21 degrees Centigrade (C). All samples met the design specifications.

B. Environmental Analysis Testing

Environmental Analysis testing was performed to determine the leads' resistance to thermal stresses (shocks) when subjected to temperature extremes. Fifteen Transvene® Leads of each model were subjected to a temperature range of 45 degrees C to 70 degrees C. After shock testing, visual inspection and electrical resistance measurements were performed. There were no visual defects and the electrical resistance of all the samples met the design specifications.

C. Mechanical Testing

The mechanical integrity of the Transvene® Leads was assessed. The leads and/or assemblies were subjected to the following:

- flex testing;
- composite pull strength testing;
- crimp and weld pull strength testing;
- insertion and withdrawal force testing; and
- leakage testing;

1. Flex Testing

Flex testing was performed to evaluate the integrity of the leads when subjected to bending stresses intended to simulate in vivo conditions. The flex testing consisted of mounting 11 samples of insulated conductor coils and 11 samples of uninsulated electrode coils of each of the Transvene® Leads in a lead flex test fixture. The insulated conductor coils and uninsulated electrode coils were flexed at 21 degrees C and at a bend radius of 00.236 inches. All samples exceeded the specifications.

2. Composite Pull Strength Testing

Composite pull strength testing was performed to evaluate the overall pull strength of the lead and connections. Fifteen Transvene® Leads of each model were boiled in Ringer's solution or soaked in normal saline and pull tested while wet, utilizing a tensile testing machine. The samples were pulled until failure at a rate of 5 inches per minute. The initial failures were then analyzed statistically for the confidence level in meeting the specification for the composite lead which is 1.0 pound (lb) minimum. All samples met or exceeded specifications.

3. Crimp and Weld Pull Strength Testing

Crimp and weld pull strength testing was performed to evaluate the strength of the connections of the PCD® Transvene® System. Fifteen subassemblies of each Transvene® Lead were pull tested by using a tensile testing machine. The samples were pulled until failure at a rate of 4 inches per minute with forces from 1 lb to 3.0 lbs. All samples met or exceeded the design specifications.

4. Insertion and Withdrawal Force Testing

Insertion and withdrawal force testing was performed to ensure compatibility of the Transvene Leads with the PCD® Model 7217B. Twenty-five samples of each Transvene® Lead were tested at an insertion force greater than or equal to 3.0 lbs and a withdrawal force less than or equal to 2.5 lbs. The results of testing demonstrated no physical changes. All measurements were within specifications.

5. Leakage Testing

Fluid leakage tests were conducted on the lead assemblies and the connector of the Model 7217 B PCD® to determine if there was fluid leakage. Ten samples of each Transvene® Lead were tested. Electrical impedance was measured from the case of the Model 7217B PCD® to the lead connections while immersed in fluid. All samples met specifications.

D. Life Testing

In addition to the above tests, life testing was performed to assess the overall integrity of the Transvene® Leads. Testing included subjecting 15 samples of each Transvene® Lead model to soaking, flexing and high-voltage pulsing. A separate test which involved crushing the leads was performed on 10 samples each of the Models 6963 and 6966 leads. Electrical resistance values were measured before and after all tests. The results demonstrated that all of the Transvene® Lead models met the acceptance criteria.

E. Biocompatibility

The biocompatibility of the tissue contact materials used in the Transvene® Leads has been well established historically. These materials include polyurethane, silicone rubber, silicone rubber/titanium dioxide and platinum/iridium. The results of USP/Tripartite testing (hemolysis, toxicity, pyrogenicity, mutagenicity tests) demonstrated that all of the materials were non-hemolytic, non-pyrogenic, non-toxic, non-mutagenic and biocompatible.

F. Animal Studies

The Transvene® Leads were evaluated in acute and chronic animal studies to assess the toxicity of the leads as well as its stability over a minimum of 2 years. One acute study and 3 chronic studies were performed.

The objective of the acute study was to quantify the amount and nature of shock-induced damage to the myocardial tissue resulting from multiple, high energy defibrillation shocks delivered via the Transvene® Leads. The results of the study of 7 canines revealed only minimal shock-induced necrosis (less than 0.1-0.5 percent by weight), which did not result in functional impairment of the cardiac tissue. The findings demonstrated that the Transvene® Leads did not cause significant myocardial damage in canines and could be safely implanted in humans.

The objective of the chronic studies was to evaluate the suitability for human clinical use, and to evaluate the chronic stability of the Transvene® Leads by monitoring defibrillation and pacing thresholds. The studies also assessed the amount and nature of shock-induced damage to the myocardial tissue resulting from defibrillation energy. The results of the studies on 16 canines demonstrated that the performance of the PCD® Transvene® System conformed to specifications and design requirements. Stable pacing and defibrillation thresholds and appropriate intracardiac sensing over at least a 2-year period were demonstrated.

G. Clinical Studies

The primary objectives of the study of the PCD® Transvene® System include the following: evaluating and monitoring the system in the detection and treatment of ventricular tachycardia (VT) and ventricular fibrillation (VF); estimating the survival from sudden cardiac death and overall survival.

A total of 78 investigative centers participated in the clinical study. There were 35 centers in the United States and 43 outside the United States. The clinical experience covered a total of 762 implants of the PCD® Transvene® System in 757 patients as of February 1, 1993. The performance of the patients was compared to the Ventak® Model 1600 AICD™ population (historical control with 292 patients, approved for marketing on May 2, 1991) and the Medtronic PCD® Epicardial System population (concurrent control with 742 patients, approved for marketing on February 11, 1993).

1. Follow-up Schedule

All patients enrolled in the clinical study underwent extensive pre-implant testing as well as operative testing. In addition, patients were evaluated prior to hospital

discharge, 1 month post implant, 3 months post implant and then at intervals of every 3 months. At implant, an evaluation was performed to demonstrate proper detection and termination of VF by the PCD® Transvene® System. At the follow-up intervals, regular testing was performed to evaluate chronic stability of the programmed therapy and sensing parameters. This testing included the following: assessing the relative stability of the energy required for patient treatment; evaluating manual charge times; measuring battery voltage; and evaluating the stability of the implanted Transvene® Leads. In some cases additional testing, which included inductions of arrhythmias, was performed at the physician's discretion to evaluate spontaneous events.

2. Patient Population

The patient population enrolled in the clinical study was predominately male (610, 80.6 percent) with a mean age of 59.4 years. In 377 (49.8 percent) patients, the primary indication for implant was recurrent, sustained VT without an episode of sudden cardiac death. Coronary artery disease was the primary disease process in 561 (74.1 percent) patients. These patients had a mean reported ejection fraction of 35.6 percent.

The mean documented implant duration for the patient population was 11.7 months and ranged from implant to 37.4 months. The documented cumulative implant duration was 8,895 months. There are 657 (86.8 percent) patients with implant durations equal to or greater than 6 months.

Patients may use either 2 or 3 Transvene® Leads to deliver therapy. All 757 patients were implanted with 3 Transvene® Leads. Of these, 574 patients (75.8 percent) were programmed to a sequential defibrillation pathway (3-lead system), 178 patients (23.5 percent) were programmed to a simultaneous defibrillation pathway (3-lead system), and 10 patients (1.3 percent) were programmed to a single defibrillation pathway (2-lead system). The configuration chosen was dependent on the patient's history, condition, and anatomy, and the pathway which would deliver the least energy to defibrillate. Both the 2 and 3-lead systems can be used, and were used successfully to treat the patient's ventricular tachyarrhythmia. This was determined by assessing the patient's defibrillation threshold (DFT) prior to implant. In the patient population, the mean DFT was 14.8 Joules (J).

Prior to implanting the PCD® Transvene® System, the patient had to have 3 out of 4 successful defibrillations at 18 J or less. The need for a change in this implant criteria was

demonstrated during the clinical study. Subsequently, approval was received under the investigational device exemptions (IDE) regulation to make the change. This change allowed implant when there are 2 consecutive successful terminations at 24 J or less, or 3 out of 4 successful defibrillations at 24 J or less. Even though the patient population was comprised of patients who were subject to the original implant criteria, adequate data were provided to support the new implant criteria.

3. Spontaneous and Induced Episode Experience

Of the 757 patients who received a PCD® Transvene® System, 597 (78.9 percent) patients either experienced a spontaneous VT and/or VF episode or had VT and/or VF induced during a post-implant electrophysiological (EP) study (354 of the 597 patients had induced episodes of either VT or VF or VT and VF during the follow-up periods). A total of 458 of the 757 patients (60.5 percent) experienced 12,009 episodes of spontaneous VT and VF that were detected and treated by the PCD® Transvene® System. Of these 458 patients, 141 patients (18.6 percent) experienced VT only, 142 patients (18.8 percent) experienced VF only, and 175 patients (23.1 percent) experienced VT and/or VF. The overall success rate of the PCD® Transvene® System in terminating these spontaneous episodes included the following: for VT only, 98.3 percent (9,864 of 10,027); for VF only, 98.4 percent (1,951 of 1,982) and for VT and/or VF, 98.4 percent (11,815 of 12,009).

The incidence of unsuccessful termination of a "true" (no indication of atrial fibrillation or sinus tachycardia) spontaneous episode of VT despite delivery of all four therapies was 0.7 percent (68 of 10,027). The remaining 0.9 percent (95 of 10,027) were episodes of sinus tachycardia or atrial fibrillation where the device responded appropriately based on the programmed detection parameters, however, the device was unsuccessful in terminating the arrhythmia.

The incidence of unsuccessful termination of a "true" episode of VF despite delivery of all four therapies was 0.3 percent (5 of 1,982). The remaining 1.3 percent (26 of 1,982) were episodes of sinus tachycardia and atrial fibrillation.

4. Complications and Observations

For purposes of the clinical study, the reported medical events were identified as complications and observations. A complication was defined as a symptomatic or asymptomatic clinical event with potential adverse effects, which can not be treated or resolved by reprogramming the device, and

requires invasive intervention. An observation was defined as a symptomatic or asymptomatic clinical event which either does not require invasive intervention, or which can be corrected by reprogramming the device.

There have been a total of 176 complications identified in 147 patients and 212 observations identified in 178 patients. Thus 19.4 percent (147 of 757) of the patients have experienced a complication and 23.5 percent (178 of 757) have experienced an observation. The most frequently reported complications were pocket infection (3.2 percent, 24 of 757), lead fractures (1.2 percent, 9 of 757), and lead dislodgement (11.4 percent, 86 of 757). In an attempt to reduce the lead dislodgement, modifications were made to the lead anchoring sleeve and a second sleeve was added to the lead. Analysis on 439 patients implanted with the two anchoring sleeves showed a dislodgement rate of 2.3 percent (10 of 439). Within the first 30 days of implant 34.8 percent (135 of 388) of the complications and observations occurred; 42.8 percent (166 of 388) occurred between 1 and 6 months and the remaining 22.4 percent (87 of 388) occurred at or greater than 6 months.

5. Explants

There have been 63 (8.3 percent) pulse generators explanted. Reasons for explant were patient deaths (22), infection (22), cardiac transplant (9), device performance (6), and lead system issues (4) which included 1 case each of twiddler's syndrome, fractured RV lead, increased DFT and dislodged RV lead. Of the 6 cases related to device performance, the reasons were: failure of an integrated circuit in 3 devices; hermetic leakage at the input to one of the integrated circuits in 1 device; and random component failure in 2 devices.

There were 77 patients who had received a pulse generator and were no longer active in the study. The reasons included the following: patient death (51), explant due to infection (17) and heart transplant (9).

6. Survival Data

There were 51 patient deaths reported (6.7 percent, 51 of 757). For the entire study, 5 deaths were classified as sudden cardiac (0.7 percent, 5 of 757), 31 were classified as non-sudden cardiac (4.1 percent, 31 of 757) and 15 were classified as non-cardiac (2.0 percent, 15 of 757). Of the 51 deaths, 7 patients had the PCD® programmed OFF at the time of death (includes 1 of the 5 sudden cardiac deaths). Thus, there were 7 patient deaths where PCD® therapy was unavailable due to the device being programmed OFF. The

decision to deactivate the device is usually made when the physician is concerned about the potential development of atrial fibrillation with rapid ventricular response or sinus tachycardia that might be detected as a ventricular tachyarrhythmia which can result in delivering inappropriate therapy.

Actuarial survival analysis was done on all patients who were either evaluated for implantation or in whom the PCD® Transvene® System was implanted. Thus the analysis was done from the perspective of intention to treat. Those patients in whom the PCD® was programmed OFF at the time of death or in whom no PCD® was implanted were included in the survival analysis. The 1 year survival probabilities for the intention to treat were as follows: sudden cardiac death (99.5 percent); non-sudden cardiac (96.2 percent); all cardiac (95.8); and non-cardiac (98.1 percent). These probabilities were calculated using the Kaplan Meier statistical package. Overall survival (from death due to all causes) was 93.3 percent. The actuarial projections did not include perioperative deaths (deaths which occurred within 30 days of implant), except in the calculation of 1 year survival from death due to all causes. The perioperative mortality was 0.7 percent (5 of 757): 2 sudden cardiac deaths; 2 non-sudden cardiac deaths; and 1 non-cardiac death.

The 1 year sudden cardiac death actuarial survival rate for the PCD® Transvene® System was 99.5 percent as compared to 98.6 percent for the historical control and 98.9 percent for the concurrent control. The 1 year survival rate from death due to all causes was 93.3 percent for the PCD® Transvene® System, 90.8 percent for the historical control and 88.6 percent for the concurrent control.

XI. Conclusions Drawn From Studies

The results of the laboratory and animal testing and the clinical study of the PCD® Transvene® Lead System demonstrated that the system, including all the associated components, performs according to its design intent and is safe and effective for use. One year survival rates from sudden cardiac death included the following: PCD® Transvene® System (99.5 percent), historical control (98.6 percent) and concurrent control (98.9 percent).

XII. Panel Recommendations

The Circulatory System Devices Panel reviewed this application at a public meeting on August 2, 1993, and recommended approval for the PCD® Transvene® Lead System. The recommendation for approval was based on

modifications to the labeling which should include the following: diagrams which show proper insertion of the endocardial Transvene® Leads and how the Model 6999 Patch lead should be applied to the subcutaneous tissue; a warning which states that the Model 6999 Patch lead is not for use on the pericardium or epicardium; pictures or diagrams of the various electrode configurations which serve as a guide for selection; a reference about using 5-minute intervals between VF inductions during testing; a warning which states that after extensive testing with a nonthoracotomy lead system a thoracotomy should be delayed at least 2 days (the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 percent to 9.3 percent); guidance regarding separating pacemaker leads from the Transvene® Leads; a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement; and information regarding placing the leads via the cephalic vein when possible. In addition, the panel recommended that postmarket surveillance track the explanted Transvene® Leads for evidence of metal ion oxidation (MIO).

XIII. FDA Decision

On October 27, 1993, FDA found Medtronic Inc.'s facilities in compliance with the Device Good Manufacturing Practices regulation (21 CFR part 820).

FDA concurred with the recommendation of the Circulatory System Devices Panel. In addition, on September 23, 1993, in an approvable letter to the applicant, FDA required that the labeling should be modified to include the following: effectiveness data on the different lead configurations via the different pathways; information and/or recommendations about implanting the leads and testing the different configurations (for example, when to use a 2-lead versus a 3-lead configuration and when to implant in the SVC versus the CS); information or recommendations regarding implanting in patients who do not have the 10 J safety margin; information about how the incidence of infection can be reduced; a warning regarding the use of dual anchoring sleeves on the RV, SVC and CS leads; and an explanation regarding the necessity for explant and return of the lead upon the patient's death. In addition, FDA requested that the manufacturer note the following: The indications and contraindications for use of the Medtronic® Transvene® Lead System must be the same (with certain modifications) as those for the Medtronic® PCD® Epicardial System. Modifications pertaining to the labeling included the following: The second indication was changed to read as follows: "poorly tolerated, sustained ventricular tachycardia and/or fibrillation which recurs spontaneously or can be induced despite the best antiarrhythmic drug therapy". The following note in the labeling was also recommended: "The clinical outcome of hemodynamically stable, sustained VT patients is not fully known. The safety and effectiveness of the PCD® System in this subgroup of VT patients has not been determined." The technical manuals for Transvene® Leads must state that the leads are for use together as a system. The labeling (where

appropriate) must be consistent in all Transvene® Lead manuals. The information regarding the Transvene® Leads in the Medtronic® PCD® Epicardial manual must also be included in the Transvene® Lead manuals. There should be an identifying mark on the package label of the Transvene® Leads which distinguishes nonthoracotomy leads from thoracotomy leads. The Warnings and Precautions in the labeling must be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991. The manufacturer should also provide a copy of the Patient's Manual which includes a reference to the use of nonthoracotomy leads with the PCD® models.

On October 12, and November 3, 1993, Medtronic, Inc. submitted an amendment to the application providing the information recommended by the panel and required by FDA.

FDA approval is subject to the applicant's compliance with the "Conditions of Approval for Implantable Defibrillators and Programmers" (Attachment A), and the conditions that (1) the sale, distribution, and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520 (e) of the Federal Food, Drug and Cosmetic Act (the act) under the authority of section 515 (d) (1) (B) (ii) of the Act; and (2) that the device is further restricted within the meaning of section 520 (e) under the authority of section 515 (d) (1) (B) (ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

XIV. Approval Specifications

The post approval recommendations are discussed above in Section XIII.

DEC 9 1993

Re: P920015
Medtronic® Transvene® Lead System
Filed: April 1, 1992
Amended: August 27, September 21, October 27 and November 5, 1992,
March 29, June 2, 14, July 9, October 12, and November 3, 1993

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed its review of your premarket approval application (PMA) for the Medtronic® Transvene® Lead System. The Medtronic® Transvene® Lead System (Models 6963, 6966 and 6999), (hereafter referred to as the Transvene® Leads) with Medtronic Pacer-Cardioverter-Defibrillator (PCD®) Model 7217B Multiprogrammable Tachyarrhythmia Control System (hereafter referred to as the PCD™ Transvene® System) is intended for single long-term use and each lead is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead. The lead system has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should: (1) have survived at least one episode of a cardiac arrest presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or (2) in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously, or can be induced, despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the Transvene® Lead clinical study, no conclusions were drawn from the data obtained on this specific patient group.

Prior to Transvene® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Transvene® System.

We are pleased to inform you that the PMA is approved subject to the conditions described below and in the "Conditions of Approval for Implantable Defibrillators and Programmers" (enclosed). You may begin commercial distribution of the device upon receipt of this letter.

Expiration dating for this device has been established and approved at 2 years.

The sale, distribution, and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520(e) of the Federal Food, Drug, and Cosmetic Act (the act) under the authority of section 515(d)(1)(B)(ii) of the act.

The device is further restricted within the meaning of section 520(e) under the authority of section 515(d)(1)(B)(ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

In addition to the postapproval requirements, postmarket surveillance should track the explanted Transvene● leads for evidence of metal ion oxidation (MIO).

CDRH will publish a notice of its decision to approve your PMA in the FEDERAL REGISTER. The notice will state that a summary of the safety and effectiveness data upon which the approval is based is available to the public upon request. Within 30 days of publication of the notice of approval in the FEDERAL REGISTER, any interested person may seek review of this decision by requesting an opportunity for administrative review, either through a hearing or review by an independent advisory committee, under section 515(g) of the act.

Failure to comply with the conditions of approval invalidates this approval order. Commercial distribution of a device that is not in compliance with these conditions is a violation of the act.

All required documents should be submitted in triplicate, unless otherwise specified, to the address below and should reference the above PMA number to expedite processing.

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

In addition, under Section 522(a) of the act, manufacturers of certain types of devices identified by the act or designated by FDA are required to conduct postmarket surveillance studies. FDA has identified under Section 522(a)(1(A) the device cleared for marketing by this order as requiring postmarket surveillance.

Within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce you are required to submit to FDA certification of the date of introduction into interstate commerce, a detailed protocol which describes the postmarket surveillance study, and a detailed profile of the study's principal investigator that clearly establishes the qualifications and experience of the individual to conduct the proposed study. For your information, general guidance on preparing a protocol for a postmarket surveillance study is enclosed.

Submit five (5) copies to:

Postmarket Studies Document Center
Suite 405 (HFZ-107)
1801 Rockville Pike
Rockville, Maryland 20852

Within sixty (60) days of receipt of your protocol, FDA will either approve or disapprove it and notify you of the Agency's action in writing. Do not undertake a postmarket surveillance study without an FDA approved protocol.

Failure to certify accurately the date of initial introduction of your device into interstate commerce, to submit timely an acceptable protocol, or to undertake and complete an FDA approved postmarket surveillance study consistent with the protocol, will cause your product to be misbranded and could lead to the imposition of civil money penalties or other regulatory actions. Any distribution of a misbranded device is a violation of the act and may result in a number of FDA enforcement actions, including (but not limited to) withdrawal of your PMA.

If you have questions concerning postmarket surveillance study requirements, contact the Postmarket Surveillance Studies Branch at (301) 594-0639.

Under Section 519(e) of the act (as amended by the Safe Medical Devices Act in 1990), manufacturers of certain devices must track their products to the final user or patient so that devices can be located quickly if serious problems are occurring with the products. The tracking requirements apply to (1) permanent implants the failure of which would be reasonably likely to have serious adverse health consequences; (2) life sustaining or life supporting devices that are used outside of device user facilities the failure of which would be reasonably likely to have serious adverse health consequences; and (3) other devices that FDA has designated as requiring tracking. Under Section 519(e), FDA believes that your device is a device that is subject to tracking because it is a permanent implant whose failure would be reasonably likely to have serious adverse consequences. FDA has designated your device for tracking.

FDA's tracking regulations, published in the FEDERAL REGISTER on August 16, 1993, appear at 21 CFR Part 821. These regulations set out what you must do to track a device. In addition, the regulations list example permanent implant and life sustaining or life supporting devices that FDA believes must be tracked at 21 CFR § 821.20(b) and the devices that FDA has designated for tracking at 21 CFR § 821.20(c). FDA's rationale for identifying these devices is set out in the FEDERAL REGISTER (57 FR 10705-10709 (March 27, 1991), 57 FR 22973-22975 (May 29, 1992), and 58 FR 43451-43455 (August 16, 1993)).

If you have questions concerning this approval order, please contact Doris Terry at (301) 594-1523 or Arnold Alpert, Ph.D., at (301) 594-2186.

Sincerely yours,

Susan Alpert, Ph.D., M.D.

RE: P920015
Medtronic® Transvene® Lead System
Filed: April 1, 1992
Amended: August 27, September 21, October 27 and November 5, 1992, March 29, June 2, 14, and July 9, 1993

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed its review of your premarket approval application (PMA). The Circulatory System Devices Panel which also reviewed your PMA, recommended to CDRH at the August 2, 1993, panel meeting that the PMA be considered approvable. CDRH is pleased to inform you that the PMA is approvable subject to your submission of the following:

1. The labeling should be modified to include the following directions for use:

   a. diagrams which demonstrate the proper insertion technique and final anatomic position of the intravascular leads and the Sub-Q patch;

   b. defibrillation efficacy data on the different lead configurations, various polarity combinations and sequential versus simultaneous discharges;

   c. information and/or recommendations regarding specific implantation techniques and methods of testing the different configurations. For example, when is it recommended to use a two-lead configuration versus a three-lead configuration, when to implant in the superior vena cava (SVC) versus the coronary sinus (CS), and how the most advantageous position of the Sub-Q patch is determined;

   d. information or recommendations, based on your experience, regarding implantation in patients who do not have at least a 10 Joule safety margin;

   e. information aimed at reducing the incidence of infection;

   f. instructions stressing the importance of pausing between inductions of ventricular fibrillation (VF) at the time of implantation for at least a specified period of time in order to

decrease morbidity and mortality. The comments and the pause duration suggested should be based on the experience of the primary investigators in your study;

g. information regarding the change in defibrillation thresholds that one may expect with time as based on the experience of your investigators in your study;

h. guidance and techniques for separating permanent pacemaker leads from the Transvene® leads to minimize the interaction between the two devices, and diagnostic methods which can be employed at implant or predischarge to confirm the absence of adverse interaction;

i. a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement (x-rays should be done at 3-month intervals for 1 year);

j. information regarding techniques for placing the leads via the cephalic vein when possible; and

k. an explanation regarding the necessity for explant and return of the leads upon the patient's death.

2. The labeling should be modified to include the following warnings:

a. a statement that the Sub-Q patch lead is not for use on the pericardium or epicardium, because it is too inflexible to be used as such;

b. stronger and more specific language regarding the use of dual anchoring sleeves on the right ventricle (RV), SVC, and CS leads. Based on the experience of your investigators, please describe the techniques used to fixate the lead at the insertion into the vein to minimize dislodgment; and

c. information which states that after extensive VF inductions at implant testing with the nonthoracotomy lead system, serious consideration should be given to delaying the thoracotomy for at least 2 days. Please include a statement which states that the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 to 9.3 percent.

3. In addition you should note the following:

a. The indications and contraindications for use of the Medtronic® Transvene® Lead System must be identical (except for certain modifications which pertain to the Transvene® Leads and those described below) to those for the PCD™ Epicardial System. Please change your second indication to read: Poorly tolerated,

sustained ventricular tachycardia and/or fibrillation which recurs spontaneously or can be induced despite the best antiarrhythmic drug therapy. Please also include the following statement in your indications section:

Note: The clinical outcome of hemodynamically stable, sustained VT patients is not fully known. The safety and effectiveness of the PCD● Transvene System in this subgroup of VT patients has not been determined.

b. The technical manuals for the Transvene● Leads must state that the leads are for use together as a system. The labeling (where appropriate) must be consistent in all of the Transvene● Lead manuals. The information regarding the Transvene● Leads in the PCD● Manual must also be included in the Transvene● Lead manuals.

c. There should be an identifying mark on the package label which distinguishes nonthoracotomy leads from thoracotomy leads.

d. The Warnings and Precautions in the labeling must be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991, (a copy of this memorandum was previously sent to you).

4. Provide a copy of the Patient's Manual which includes a reference to use of the non-thoracotomy leads with the PCD● models.

The PMA must be amended to include your concurrence with, or suggested revision of, the enclosed "Conditions of Approval for Implantable Defibrillators and Programmers."

The condition that the sale, distribution and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520(e) of the Federal Food, Drug, and Cosmetic Act (the act) under the authority of section 515(d)(1)(B)(ii) of the act.

The device is further restricted within the meaning of section 520(e) under the authority of section 515(d)(1)(B)(ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

In addition to the above, an FDA inspection must find that the manufacturing facilities, methods and controls comply with applicable device Good Manufacturing Practice Regulations (21 CFR Part 820). If applicable, amend the PMA to include required manufacturing information not previously submitted.

This is to advise you that, following receipt of an approvable letter, an applicant is required by 21 CFR 814.20(e) to update its pending PMA with new safety and effectiveness information learned about the device from ongoing or completed studies that may reasonably affect an evaluation of the safety or effectiveness of the device or that may reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling. This updated reporting is limited to studies sponsored by the applicant or to which the applicant has reasonable access. The update report shall be consistent with the data reporting provisions of the protocol. Any update report shall be submitted in three copies as an amendment to the PMA and shall include the FDA reference number assigned to the PMA.

CDRH will issue an approval order after the requested information has been reviewed and determined to be acceptable. You may not begin commercial distribution of the device until you have received an approval order.

As provided by 21 CFR 814.44(e)(2), you may amend your PMA as requested, or withdraw it, or you may treat this letter as a formal denial of approval. If you choose the latter, you may request administrative review,.either through a hearing or review by an independent advisory committee, under section 515(d)(3) and 515(g) of the act by filing a petition with the Food and Drug Administration, Dockets Management Branch (HFA-305), Room 1-23, 12420 Parklawn Drive, Rockville, Maryland 20857, within 30 days of the date you receive this letter. A petition for administrative review must be submitted in accordance with general administrative procedures for submission of documents to the Dockets Management Branch (21 CFR 10.20) and in the form of a petition for reconsideration (21 CFR 10.33). After reviewing the petition, FDA will decide whether to grant or deny the petition and will publish a notice of its decision in the FEDERAL REGISTER. If FDA grants the petition, the notice will state the issues to be reviewed, the form of the review to be used, the persons who may participate in the review, the time and place where the review will occur, and other details.

The above requested information must be submitted in the form of an amendment (3 copies). Unless you amend this PMA to request an extension, and the extension is approved, FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). Any request for an extension must be submitted within the 180-day period, justify the need for the extension, and provide a reasonable estimate as to when the requested information will be submitted.

All amendments to the PMA must be submitted in triplicate to the address below and shall reference the above PMA number to expedite processing.

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

In addition, under Section 522(a) of the act, manufacturers of certain types of devices identified by the act or designated by FDA are required to conduct postmarket surveillance studies. FDA has identified under Section 522(a)(1)(A) the above noted device as requiring postmarket surveillance.

Upon approval and within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce you will be required to submit to FDA certification of the date of introduction into interstate commerce, a detailed protocol which describes the postmarket surveillance study to include the evaluation of the explanted leads for evidence of metal ion oxidation (MIO), and a detailed profile of the study's principal investigator that clearly establishes the qualifications and experience of the individual to conduct the proposed study. For your information, general guidance on preparing a protocol for a postmarket surveillance study is enclosed.

At that time you should submit five (5) copies to:

Postmarket Studies Document Center
Room 408 (HFZ-107)
12720 Twinbrook Parkway
Rockville, Maryland 20852

Within sixty (60) days of receipt of your protocol, FDA will either approve or disapprove it and notify you of the Agency's action in writing. Do not undertake a postmarket surveillance study without an FDA approved protocol.

Failure to certify accurately the date of initial introduction of your device into interstate commerce, to submit timely an acceptable protocol, or to undertake and complete an FDA approved postmarket surveillance study consistent with the protocol, will cause your product to be misbranded and could lead to the imposition of civil money penalties or other regulatory actions. Any distribution of a misbranded device is a violation of the act and may result in a number of FDA enforcement actions, including (but not limited to) withdrawal of your PMA.

If you have questions concerning postmarket surveillance study requirements, contact Postmarket Surveillance Studies Branch at (301) 594-0639.

Finally, on August 16, 1993, the Final Rule for Device Tracking was published in the FEDERAL REGISTER, pages 43442-43455 (enclosed). FDA is required to provide notice to PMA applicants in an approvable letter that their device is

subject to the regulation. Therefore, be advised that under Section 519(e) of the act, FDA has identified the above device as a device which requires tracking. You are required to adopt a method of tracking that follows the devices through the distribution chain and then identifies and follows the patients who receive them. The specific requirements of the regulation are found in 21 CFR 821 as described in the August 16, 1993, FEDERAL REGISTER beginning on page 43447.

If you have questions concerning this approvable letter please contact Doris Terry at (301) 594-2018 or Arnold Alpert, Ph.D., at (301) 594-2186.

Sincerely yours,

Susan Alpert, Ph.D., M.D.

RE: P920015
Medtronic® Transvene® Lead System
Filed: April 1, 1992
Amended: August 27, September 21, October 27 and November 5, 1992,
March 29, June 2, 14, and July 9, 1993

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed its review of your premarket approval application (PMA). The Circulatory System Devices Panel which also reviewed your PMA, recommended to CDRH at the August 2, 1993, panel meeting that the PMA be considered approvable. CDRH is pleased to inform you that the PMA is approvable subject to your submission of the following:

1. The labeling should be modified to include the following directions for use:

   a. diagrams which demonstrate the proper insertion technique and final anatomic position of the intravascular leads and the Sub-Q patch;

   b. defibrillation efficacy data on the different lead configurations, various polarity combinations and sequential versus simultaneous discharges;

   c. information and/or recommendations regarding specific implantation techniques and methods of testing the different configurations. For example, when is it recommended to use a two-lead configuration versus a three-lead configuration, when to implant in the superior vena cava (SVC) versus the coronary sinus (CS), and how the most advantageous position of the Sub-Q patch is determined;

   d. information or recommendations, based on your experience, regarding implantation in patients who do not have at least a 10 Joule safety margin;

   e. information aimed at reducing the incidence of infection;

   f. instructions stressing the importance of pausing between inductions of ventricular fibrillation (VF) at the time of implantation for at least a specified period of time in order to

decrease morbidity and mortality. The comments and the pause duration suggested should be based on the experience of the primary investigators in your study;

g. information regarding the change in defibrillation thresholds that one may expect with time as based on the experience of your investigators in your study;

h. guidance and techniques for separating permanent pacemaker leads from the Transvene® leads to minimize the interaction between the two devices, and diagnostic methods which can be employed at implant or predischarge to confirm the absence of adverse interaction;

i. a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement (x-rays should be done at 3-month intervals for 1 year);

j. information regarding techniques for placing the leads via the cephalic vein when possible; and

k. an explanation regarding the necessity for explant and return of the leads upon the patient's death.

2. The labeling should be modified to include the following warnings:

a. a statement that the Sub-Q patch lead is not for use on the pericardium or epicardium, because it is too inflexible to be used as such;

b. stronger and more specific language regarding the use of dual anchoring sleeves on the right ventricle (RV), SVC, and CS leads. Based on the experience of your investigators, please describe the techniques used to fixate the lead at the insertion into the vein to minimize dislodgment; and

c. information which states that after extensive VF inductions at implant testing with the nonthoracotomy lead system, serious consideration should be given to delaying the thoracotomy for at least 2 days. Please include a statement which states that the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 to 9.3 percent.

3. In addition you should note the following:

a. The indications and contraindications for use of the Medtronic® Transvene® Lead System must be identical (except for certain modifications which pertain to the Transvene® Leads and those described below) to those for the PCD™ Epicardial System. Please change your second indication to read: Poorly tolerated,

sustained ventricular tachycardia and/or fibrillation which recurs spontaneously or can be induced despite the best antiarrhythmic drug therapy. Please also include the following statement in your indications section:

Note: The clinical outcome of hemodynamically stable, sustained VT patients is not fully known. The safety and effectiveness of the PCD® Transvene System in this subgroup of VT patients has not been determined.

b. The technical manuals for the Transvene® Leads must state that the leads are for use together as a system. The labeling (where appropriate) must be consistent in all of the Transvene® Lead manuals. The information regarding the Transvene® Leads in the PCD® Manual must also be included in the Transvene® Lead manuals.

c. There should be an identifying mark on the package label which distinguishes nonthoracotomy leads from thoracotomy leads.

d. The Warnings and Precautions in the labeling must be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991, (a copy of this memorandum was previously sent to you).

4. Provide a copy of the Patient's Manual which includes a reference to use of the non-thoracotomy leads with the PCD® models.

The PMA must be amended to include your concurrence with, or suggested revision of, the enclosed "Conditions of Approval for Implantable Defibrillators and Programmers."

The condition that the sale, distribution and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520(e) of the Federal Food, Drug, and Cosmetic Act (the act) under the authority of section 515(d)(1)(B)(ii) of the act.

The device is further restricted within the meaning of section 520(e) under the authority of section 515(d)(1)(B)(ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

In addition to the above, an FDA inspection must find that the manufacturing facilities, methods and controls comply with applicable device Good Manufacturing Practice Regulations (21 CFR Part 820). If applicable, amend the PMA to include required manufacturing information not previously submitted.

This is to advise you that, following receipt of an approvable letter, an applicant is required by 21 CFR 814.20(e) to update its pending PMA with new safety and effectiveness information learned about the device from ongoing or completed studies that may reasonably affect an evaluation of the safety or effectiveness of the device or that may reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling. This updated reporting is limited to studies sponsored by the applicant or to which the applicant has reasonable access. The update report shall be consistent with the data reporting provisions of the protocol. Any update report shall be submitted in three copies as an amendment to the PMA and shall include the FDA reference number assigned to the PMA.

CDRH will issue an approval order after the requested information has been reviewed and determined to be acceptable. You may not begin commercial distribution of the device until you have received an approval order.

As provided by 21 CFR 814.44(e)(2), you may amend your PMA as requested, or withdraw it, or you may treat this letter as a formal denial of approval. If you choose the latter, you may request administrative review, either through a hearing or review by an independent advisory committee, under section 515(d)(3) and 515(g) of the act by filing a petition with the Food and Drug Administration, Dockets Management Branch (HFA-305), Room 1-23, 12420 Parklawn Drive, Rockville, Maryland 20857, within 30 days of the date you receive this letter. A petition for administrative review must be submitted in accordance with general administrative procedures for submission of documents to the Dockets Management Branch (21 CFR 10.20) and in the form of a petition for reconsideration (21 CFR 10.33). After reviewing the petition, FDA will decide whether to grant or deny the petition and will publish a notice of its decision in the FEDERAL REGISTER. If FDA grants the petition, the notice will state the issues to be reviewed, the form of the review to be used, the persons who may participate in the review, the time and place where the review will occur, and other details.

The above requested information must be submitted in the form of an amendment (3 copies). Unless you amend this PMA to request an extension, and the extension is approved, FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). Any request for an extension must be submitted within the 180-day period, justify the need for the extension, and provide a reasonable estimate as to when the requested information will be submitted.

All amendments to the PMA must be submitted in triplicate to the address below and shall reference the above PMA number to expedite processing.

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

In addition, under Section 522(a) of the act, manufacturers of certain types of devices identified by the act or designated by FDA are required to conduct postmarket surveillance studies. FDA has identified under Section 522(a)(1)(A) the above noted device as requiring postmarket surveillance.

Upon approval and within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce you will be required to submit to FDA certification of the date of introduction into interstate commerce, a detailed protocol which describes the postmarket surveillance study to include the evaluation of the explanted leads for evidence of metal ion oxidation (MIO), and a detailed profile of the study's principal investigator that clearly establishes the qualifications and experience of the individual to conduct the proposed study. For your information, general guidance on preparing a protocol for a postmarket surveillance study is enclosed.

At that time you should submit five (5) copies to:

Postmarket Studies Document Center
Room 408 (HFZ-107)
12720 Twinbrook Parkway
Rockville, Maryland 20852

Within sixty (60) days of receipt of your protocol, FDA will either approve or disapprove it and notify you of the Agency's action in writing. Do not undertake a postmarket surveillance study without an FDA approved protocol.

Failure to certify accurately the date of initial introduction of your device into interstate commerce, to submit timely an acceptable protocol, or to undertake and complete an FDA approved postmarket surveillance study consistent with the protocol, will cause your product to be misbranded and could lead to the imposition of civil money penalties or other regulatory actions. Any distribution of a misbranded device is a violation of the act and may result in a number of FDA enforcement actions, including (but not limited to) withdrawal of your PMA.

If you have questions concerning postmarket surveillance study requirements, contact Postmarket Surveillance Studies Branch at (301) 594-0639.

Finally, on August 16, 1993, the Final Rule for Device Tracking was published in the FEDERAL REGISTER, pages 43442-43455 (enclosed). FDA is required to provide notice to PMA applicants in an approvable letter that their device is

subject to the regulation. Therefore, be advised that under Section 519(e) of the act, FDA has identified the above device as a device which requires tracking. You are required to adopt a method of tracking that follows the devices through the distribution chain and then identifies and follows the patients who receive them. The specific requirements of the regulation are found in 21 CFR 821 as described in the August 16, 1993, FEDERAL REGISTER beginning on page 43447.

If you have questions concerning this approvable letter please contact Doris Terry at (301) 594-2018 or Arnold Alpert, Ph.D., at (301) 594-2186.

Sincerely yours,

Susan Alpert, Ph.D., M.D.

RE: P920015
Transvene™ Lead System
Filed: April 1, 1992
Amended: September 21, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

We recognize the potential public health significance of this device and acknowledge the separate discussions underway to expedite the review. However, because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. To clearly establish the purpose of the clinical data in the PMA application, please provide the following:

   a. the hypothesis and the objectives of your clinical study;

   b. a discussion of (i) how your clinical study addresses the use of a control, which is relevant to all clinical studies, (ii) the appropriateness of the AICD™ as a historical control, and (iii) your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;

   c. the endpoints of your study; and

   d. how the data provided in the PMA application support the specified endpoints.

2. Based on data provided in your PMA application, please prepare table(s) which include a side-by-side comparison of the PCD® Transvene™ and the PCD® Epicardial System and the PCD® Transvene™ and Ventak P AICD™ populations. The table must also include the inclusion and exclusion criteria which were used for each study. You must include a discussion of how these data may or may not represent a valid comparison, and other comments which justify and support the use of these groups as controls.

3. An update of the PMA clinical study population must be provided. The update must include the data as presented in the PMA application, and must include the clinical experience in the use of the new anchoring sleeves, which are aimed at decreasing the incidence of dislodgement, and a summary of the clinical experience (spontaneous treatment efficacy of ventricular tachycardia (VT) and ventricular fibrillation (VF), observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.

4. Please provide a clear description of how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.

5. Of the 214 patients who did not meet the implant criteria and yet were implanted with the device, 170 patients had successful defibrillation with 24 Joules (J). Please provide an update of the clinical experience on these patients, as described in item 3 above. Also, please discuss how your proposed labeling will address this protocol deviation. Will implant criteria be changed?

6. There were 20 patients among the 214 who did not meet the implant criteria and were implanted without the 10 J safety margin. An update of the spontaneous episode experience in the treatment of VT and VF in these patients and the overall survival must be provided.

7. Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not meet the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.

8. Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update must include a summary of the clinical experience as referenced in item 3 above.

9. Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was

categorized as DFT and LED testing must be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.

10. There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. You must document that there were no significant differences between the scheme for performing DFT and LED testing between the Transvene™ and PCD® Epicardial patient populations, if that is the case.

11. Please elaborate on how the comparison of DFTs obtained from the PCD® Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (574 (75.3 percent)) in the Transvene™ study were programmed with the sequential pathway and 178 (23.4 percent) were programmed via the simultaneous pathway. The majority of the patients (496 (65.2 percent)) in the PCD® Epicardial study were programmed with the single pathway. Based on your PCD® Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ System versus the PCD® Epicardial System.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it is determined, and if the patients met the criteria.

14. Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes. What was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes per patient in this group?

15. On page 130, Table IF-4, you report that there were 5362 episodes of VT successfully terminated. On page 131, paragraph 2, you state that 25 patients experienced 45 (0.8 percent) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. You must clarify how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a table which includes a category of ineffective therapies with actual patient numbers and percentages. In addition, what assurance is there that an episode of supraventricular tachycardia or atrial fibrillation is not misinterpreted as VT or VF by the physician and considered a successful therapy?

16. Table IM-6, page 173 must be modified to include a column on inappropriate therapy or therapies delivered as the device was programmed so that the percentages add up to 100 percent.

17. On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8 percent. Please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The tables must include percentages with the representative numerical support.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

19. Please discuss how the 1 year sudden cardiac death survival, as reported in Table IF-2 page 128, was calculated. The numbers and an explanation of patient classification must be included. Was every patient included who had a prior cardiac arrest regardless of the arrhythmia?.

20. On page 177, the number of patients must be provided so that the percentages and calculated p-values can be confirmed.

21. Table IV-C, page 649 of the original submission shows a comparison of patient variables for the three lead systems and provides p-values for the variables tested, but the hypothesis was not clearly stated. Please state the hypothesis and discuss the p-values obtained when reporting by primary indication, and the chi-square test of the data set and how it was computed.

22. For purposes of justification of data pooling and data analysis of Table IV-C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp.162-170).

23. You claim that confidence interval analysis was performed to compare the overall mortality of the PCD® and AICD™ populations. What was the confidence interval?

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

    a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

    b. a chi-square test of primary indication, using the [redacted] (b)(4) computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD® and Ventak P populations are significantly different.

25. Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD® Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment of induced and spontaneous episodes with use of the algorithms must be discussed.

26. Please discuss the "device related" complications reported for the Transvene™ and the PCD® Epicardial System.

27. Please describe in detail the complications reported in the patients followed for a year.

28. There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the procedures for reduction in the number of infections? Please validate these procedures.

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads, and how your labeling assists in the selection of an entry site, must be provided.

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD® and Transvene™ leads) must be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices must be provided. The PMA application must document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD®.

31. Please discuss the circumstances surrounding the death of the patient who died (b)(4) months post implant. What did interrogation of the device reveal?

32. Of the perioperative deaths, how many devices were programmed OFF? Please discuss the circumstances surrounding each death. The number of perioperative deaths must be reported in a table and be identified as sudden cardiac, non-sudden cardiac or non-cardiac. Were there other deaths when the device was programmed OFF?

33. You state that there have been no reported patient deaths in the group with a 1 year sudden cardiac death survival and overall

actuarial survival of 100 percent. Does this include the perioperative deaths and the patients who have been followed out for a year?

34. Please provide an engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent.

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over (b)(4) month period would be sufficient? Describe how the full lead and different segments were flexed. Did you do a finite element stress analysis to validate the flex testing stress?

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.

37. A copy of the Summary of Safety and Effectiveness which includes the updated data must be provided.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA with in the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information (12 copies), voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 6 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

F. Alan Andersen, Ph.D.

RE: P920015
Transvene™ Lead System
Filed: April 1, 1992
Amended: September 21, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

We recognize the potential public health significance of this device and acknowledge the separate discussions underway to expedite the review. However, because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. To clearly establish the purpose of the clinical data in the PMA application, please provide the following:

   a. the hypothesis and the objectives of your clinical study;

   b. a discussion of (i) how your clinical study addresses the use of a control, which is relevant to all clinical studies, (ii) the appropriateness of the AICD™ as a historical control, and (iii) your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;

   c. the endpoints of your study; and

   d. how the data provided in the PMA application support the specified endpoints.

2. Based on data provided in your PMA application, please prepare table(s) which include a side-by-side comparison of the PCD® Transvene™ and the PCD® Epicardial System and the PCD® Transvene™ and Ventak P AICD™ populations. The table must also include the inclusion and exclusion criteria which were used for each study. You must include a discussion of how these data may or may not represent a valid comparison, and other comments which justify and support the use of these groups as controls.

3. An update of the PMA clinical study population must be provided. The update must include the data as presented in the PMA application, and must include the clinical experience in the use of the new anchoring sleeves, which are aimed at decreasing the incidence of dislodgement, and a summary of the clinical experience (spontaneous treatment efficacy of ventricular tachycardia (VT) and ventricular fibrillation (VF), observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.

4. Please provide a clear description of how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.

5. Of the 214 patients who did not meet the implant criteria and yet were implanted with the device, 170 patients had successful defibrillation with 24 Joules (J). Please provide an update of the clinical experience on these patients, as described in item 3 above. Also, please discuss how your proposed labeling will address this protocol deviation. Will implant criteria be changed?

6. There were 20 patients among the 214 who did not meet the implant criteria and were implanted without the 10 J safety margin. An update of the spontaneous episode experience in the treatment of VT and VF in these patients and the overall survival must be provided.

7. Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not meet the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.

8. Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update must include a summary of the clinical experience as referenced in item 3 above.

9. Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was

categorized as DFT and LED testing must be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.

10. There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. You must document that there were no significant differences between the scheme for performing DFT and LED testing between the Transvene™ and PCD® Epicardial patient populations, if that is the case.

11. Please elaborate on how the comparison of DFTs obtained from the PCD® Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (574 (75.3 percent)) in the Transvene™ study were programmed with the sequential pathway and 178 (23.4 percent) were programmed via the simultaneous pathway. The majority of the patients (496 (65.2 percent)) in the PCD® Epicardial study were programmed with the single pathway. Based on your PCD® Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ System versus the PCD® Epicardial System.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it is determined, and if the patients met the criteria.

14. Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes. What was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes per patient in this group?

15. On page 130, Table IF-4, you report that there were 5362 episodes of VT successfully terminated. On page 131, paragraph 2, you state that 25 patients experienced 45 (0.8 percent) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. You must clarify how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a table which includes a category of ineffective therapies with actual patient numbers and percentages. In addition, what assurance is there that an episode of supraventricular tachycardia or atrial fibrillation is not misinterpreted as VT or VF by the physician and considered a successful therapy?

16. Table IM-6, page 173 must be modified to include a column on inappropriate therapy or therapies delivered as the device was programmed so that the percentages add up to 100 percent.

17. On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8 percent. Please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The tables must include percentages with the representative numerical support.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

19. Please discuss how the 1 year sudden cardiac death survival, as reported in Table IF-2 page 128, was calculated. The numbers and an explanation of patient classification must be included. Was every patient included who had a prior cardiac arrest regardless of the arrhythmia?.

20. On page 177, the number of patients must be provided so that the percentages and calculated p-values can be confirmed.

21. Table IV-C, page 649 of the original submission shows a comparison of patient variables for the three lead systems and provides p-values for the variables tested, but the hypothesis was not clearly stated. Please state the hypothesis and discuss the p-values obtained when reporting by primary indication, and the chi-square test of the data set and how it was computed.

22. For purposes of justification of data pooling and data analysis of Table IV-C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp.162-170).

23. You claim that confidence interval analysis was performed to compare the overall mortality of the PCD● and AICD™ populations. What was the confidence interval?

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

    a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

    b. a chi-square test of primary indication, using the (b)(4) computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD● and Ventak P populations are significantly different.

25. Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD® Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment of induced and spontaneous episodes with use of the algorithms must be discussed.

26. Please discuss the "device related" complications reported for the Transvene™ and the PCD® Epicardial System.

27. Please describe in detail the complications reported in the patients followed for a year.

28. There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the procedures for reduction in the number of infections? Please validate these procedures.

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads, and how your labeling assists in the selection of an entry site, must be provided.

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD® and Transvene™ leads) must be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices must be provided. The PMA application must document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD®.

31. Please discuss the circumstances surrounding the death of the patient who died (b)(4) months post implant. What did interrogation of the device reveal?

32. Of the perioperative deaths, how many devices were programmed OFF? Please discuss the circumstances surrounding each death. The number of perioperative deaths must be reported in a table and be identified as sudden cardiac, non-sudden cardiac or non-cardiac. Were there other deaths when the device was programmed OFF?

33. You state that there have been no reported patient deaths in the group with a 1 year sudden cardiac death survival and overall

actuarial survival of 100 percent. Does this include the perioperative deaths and the patients who have been followed out for a year?

34. Please provide an engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent.

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over a (b)(4) month period would be sufficient? Describe how the full lead and different segments were flexed. Did you do a finite element stress analysis to validate the flex testing stress?

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.

37. A copy of the Summary of Safety and Effectiveness which includes the updated data must be provided.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA with in the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information (12 copies), voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 6 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

F. Alan Andersen

Memorandum

Date December 16, 1992

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject Statistical Review of PMA P920015 Amendment, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardvioversion and Defibrillation Electrodes, Medtronic, Inc.

To

Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST MKB for RPC
Through: Chief, Statistics Branch, DBS, OST CSL for HFZ

1. Background

Per our telephone conversation on December 7, 1992, you requested a statistical review of this PMA amendment. This amendment was received at FDA on September 21, 1992. I wasn't notified of any action until December 7. This amendment was sent to me on December 8, 1992. You indicate that you would like to receive my comments before December 18, 1992. With the limited time frame, I can only concentrate on the sponsor's response to the deficiency letter dated August 6 from FDA to the sponsor.

2. Reviewer's Comments

2.1. Item 21. Sponsor provided the p-values for Tables IV-B and IV-C of the original PMA. This reviewer recomputed the p-values and found them identical to those of the sponsor's. However, there is a problem, sample sizes are 18 for 7216A and 739 for 7217B. With such a large difference in sample size, this will cause very low statistical power, then the small difference is very difficult to detect.

2.2. Table IV-C shows comparisons of patient variables for the three lead systems. All the p-values computed by this reviewer is identical to those of the sponsor's. The total numbers of patients of primary indication are 329 for RV/SVC/SQ (of which 187 for SCD, 114 for VT, and 28 for SCDlVT), which are not in agreement with a total sample size of 496 (403 males and 93 females). The sponsor provided p-values for variables tested in Table IV-C. The hypothesis was not clearly stated. After recomputing the p-values listed in the table, all are in agreement except primary indication. The chi-square test of this data set, computed using (b)(4) computer software, yield a p-value of nearly 0, which is also different from that of sponsor's computed p-value of (b)(4)

2.3. The sponsor, for the purpose of justification of data pooling and data analysis of Table IV-C, adjust the multiple statistical significant difference at 0.05 significance level using Hochberg procedure (Dunnett & Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March 1992, 87:162-170). Although this is a published, peer reviewed article, the sponsor's multiple test adjustment procedure is not widely accepted by the biostatistical and clinical community.

2.4. Comparison of Mortality Between One PCD and the AICD

Item 25. The sponsor compared the end points of the two devices. Sponsor claimed that confidence interval analysis was performed but that confidence interval was not given. Confidence interval should be computed by the sponsor to support this claim.

Sponsor provided a table for the comparison of patient characteristics, PCD versus ventak-P. I have two questions about Table XB-1, Page 378, Vol. 2:

(i) The total numbers of patients of primary indication, 291 for Ventak-P (49 for SCD, 169 for VT, and 73 for SCD/VT) are not equal to the total number of patients of Ventak-P of 292.

(ii) A chi-square test of primary indication, using (b)(4) computer software, yield a p-value of nearly 0. This is statistically significant, indicating that PCD and Ventak-P are significantly different.

The inclusion and exclusion criteria for patients of PCD and AICD studies are not discussed by the sponsor.

Conclusion

The sponsor needs to adequately address the issues raised in Section 2 above before the safety and effectiveness of the PCD transvene system can be evaluated from a statistical perspective.

Re: P920015
Transvene™ Lead System
Filed: April 1, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

Because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. Discuss how the use of a silicone adhesive prevents tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of polyurethane and silicone in leads to prevent tissue in-growth.

2. Please provide the results of mutagenicity testing for the (b)(4) and the (b)(4) (anchor sleeve). If the tests have not been done please provide a justification for not doing so.

3. Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.

4. Based on your experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed), and on the Transvene™ leads.

5. Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor when the section is flexed?

6. The Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) electrode coil, and the effects of its failure on the performance of the lead.

7. Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.

8. Please specify the section of each lead assembly that was flexed during life testing. Does this section include the electrode coil? The results of the tests should be included.

9. Provide an update of the (b)(4) month life test.

10. The data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test. Correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

11. Discuss the differences in battery life or energy requirements between the epi-lead system and the Transvene™ system.

12. An update of the chronic animal studies should be provided.

13. An update of the clinical experience of the Transvene™ Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, lead orientations including patch location, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.

14. Please discuss your clinical data which support the claim which states that the Transvene™ Lead System improves both perioperative and long term patient morbidity.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

16. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

17. Please discuss your clinical experience (treatment efficacy, lead orientation, complications and survival rates) of the patients who have been followed for 1 year and more.

18. Provide a detailed discussion of the clinical experience (implant duration, lead orientations, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene™ System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.

19. A breakdown of the different lead orientations within the patient population, and the treatment efficacy reported for each configuration should be included.

20. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead orientations during implant.

21. Please provide the P-values as listed in Table IV B and IV C of the original PMA application for the new patient population.

22. Please discuss the reasons why some patients dropped out of the study, either withdrawn alive or lost to follow-up. There were 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2 month period.

23. For the comparison of complications/observations rates for the PCD™ versus the AICD™, please provide the following:

    a. the number of complications and patients for the PCD™ and AICD™ populations;

    b. the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate Problematic VT/VF Therapy Delivery"; and

    c. a discussion of the pocket infection rate of the PCD™ and the AICD™ and the lead related complications of the PCD™ Transvene™ System versus the PCD™ Epicardial System.

24. Some Transvene™ patients were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these patients to those who did not undergo the hollow can evaluation.

25. Please discuss and/or provide the following regarding the 1 year actuarial survival comparison of mortality between the PCD™ and the AICD™:

    a. the statistical test that was used to compare survival; and

    b. the two survival or life tables by year of follow-up.

26. Please discuss the statistical techniques used to derive the P-values in Table XI G-2, page 862, Vol. 5 and Table J-2, page 54, Vol. 1.

The following additional deficiencies were noted in this initial scientific review and the indicated responses should be provided:

1. Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?

2. Discuss the biostability tests (stress cracking, metal induced oxidation, etc.) performed on the two types of polyurethane. Why was a different polyurethane chosen for the inner coil?

3. Based on the results of the life test, what is the life expectancy of the leads? Please include your assumptions.

4. Provide a side-by-side comparison between the Model 6999 and the epicardial patch lead.

5. Discuss the possible interactions between implanted pacemaker leads and the Transvene™ leads. Also, discuss the effects of the leads on the tricuspid valve and the host vein.

6. The Transvene™ leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Transvene™ leads which support this capability.

7. Are there patients currently implanted with the Model 6895 and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

8. Please list the reasons for not performing pre-hospital discharge testing.

9. The number of spontaneous episodes of the patients followed for 6 months and beyond should be provided.

10. A copy of the Summary of Safety and Effectiveness with the updated clinical data should be submitted.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information 12 copies, voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 8 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Re: P920015
Transvene™ Lead System
Filed: April 1, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

Because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. Discuss how the use of a silicone adhesive prevents tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of polyurethane and silicone in leads to prevent tissue in-growth.

2. Please provide the results of mutagenicity testing for the (b)(4) (b)(4) and the (b)(4) (b)(4) (anchor sleeve). If the tests have not been done please provide a justification for not doing so.

3. Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.

4. Based on your experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed), and on the Transvene™ leads.

5. Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor when the section is flexed?

6. The Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) electrode coil, and the effects of its failure on the performance of the lead.

7. Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.

8. Please specify the section of each lead assembly that was flexed during life testing. Does this section include the electrode coil? The results of the tests should be included.

9. Provide an update of the (b)(4) month life test.

10. The data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test. Correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

11. Discuss the differences in battery life or energy requirements between the epi-lead system and the Transvene™ system.

12. An update of the chronic animal studies should be provided.

13. An update of the clinical experience of the Transvene™ Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, lead orientations including patch location, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.

14. Please discuss your clinical data which support the claim which states that the Transvene™ Lead System improves both perioperative and long term patient morbidity.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

16. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

17. Please discuss your clinical experience (treatment efficacy, lead orientation, complications and survival rates) of the patients who have been followed for 1 year and more.

18. Provide a detailed discussion of the clinical experience (implant duration, lead orientations, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene™ System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.

19. A breakdown of the different lead orientations within the patient population, and the treatment efficacy reported for each configuration should be included.

20. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead orientations during implant.

21. Please provide the P-values as listed in Table IV B and IV C of the original PMA application for the new patient population.

22. Please discuss the reasons why some patients dropped out of the study, either withdrawn alive or lost to follow-up. There were 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2 month period.

23. For the comparison of complications/observations rates for the PCD™ versus the AICD™, please provide the following:

    a. the number of complications and patients for the PCD™ and AICD™ populations;

    b. the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate Problematic VT/VF Therapy Delivery"; and

    c. a discussion of the pocket infection rate of the PCD™ and the AICD™ and the lead related complications of the PCD™ Transvene™ System versus the PCD™ Epicardial System.

24. Some Transvene™ patients were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these patients to those who did not undergo the hollow can evaluation.

25. Please discuss and/or provide the following regarding the 1 year actuarial survival comparison of mortality between the PCD™ and the AICD™:

    a. the statistical test that was used to compare survival; and

    b. the two survival or life tables by year of follow-up.

26. Please discuss the statistical techniques used to derive the P-values in Table XI G-2, page 862, Vol. 5 and Table J-2, page 54, Vol. 1.

The following additional deficiencies were noted in this initial scientific review and the indicated responses should be provided:

1. Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?

2. Discuss the biostability tests (stress cracking, metal induced oxidation, etc.) performed on the two types of polyurethane. Why was a different polyurethane chosen for the inner coil?

3. Based on the results of the life test, what is the life expectancy of the leads? Please include your assumptions.

4. Provide a side-by-side comparison between the Model 6999 and the epicardial patch lead.

5. Discuss the possible interactions between implanted pacemaker leads and the Transvene™ leads. Also, discuss the effects of the leads on the tricuspid valve and the host vein.

6. The Transvene™ leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Transvene™ leads which support this capability.

7. Are there patients currently implanted with the Model 6895 and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

8. Please list the reasons for not performing pre-hospital discharge testing.

9. The number of spontaneous episodes of the patients followed for 6 months and beyond should be provided.

10. A copy of the Summary of Safety and Effectiveness with the updated clinical data should be submitted.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information 12 copies, voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 8 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

for F. Alan Andersen, Ph.D.

JUL 17 1992

Re: P920015
Medtronic® Transvene Lead System
Filed: April 1, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial review of your premarket approval application (PMA). We are pleased to inform you that we have made a threshold determination that the PMA is sufficiently complete to permit a substantive review and is, therefore, suitable for filing. The filing date is April 1, 1992, which is the date of CDRH receipt of the PMA.

Following receipt of a filing letter, an applicant is required by 21 CFR 814.20(e) to update their pending PMA 3 months after the filing date with new safety and effectiveness information learned about the device from ongoing or completed studies when the information may reasonably affect an evaluation of the safety or effectiveness of the device or may reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling.

This updated reporting is limited to studies sponsored by the applicant or to which the applicant has reasonable access. The update report should be consistent with the data reporting provisions of the protocol. Please submit update reports in three copies as an amendment to the PMA and include the above PMA reference number assigned to the PMA.

This letter reflects the current progress of our review of your application. Please be advised that continued review of your application or any response to this letter may result in additional deficiencies.

The PMA cannot be approved until FDA has determined that the manufacturing facilities, methods and controls comply with applicable device Good Manufacturing Practice regulations (21 CFR Part 820). If you have not already done so, please notify CDRH as soon as possible in the form of an amendment to the PMA if there will be a delay in setting up your manufacturing facility for production of the device and provide the expected date that the facility will be prepared for an FDA inspection.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

A meeting of the Circulatory System Devices Panel will be held at which your PMA will be reviewed. You will be notified of the location and date of this meeting. Any additional information to be included in your PMA must be submitted in the form of a PMA supplement amendment and be received by FDA at least 6 weeks in advance of the scheduled advisory committee meeting in order for FDA and the panel members to have adequate time to review the new information. Information received by CDRH less than 6 weeks in advance of a scheduled advisory committee meeting will not be considered or reviewed at the meeting.

For your information, there is an industry representative on this FDA advisory committee whose name, address and telephone number you can obtain by contacting the Committee Management Staff at (301) 443-4016. CDRH believes that the industry representatives will be better prepared to participate in panel discussions if they have been provided with a copy of the Summary of Safety and Effectiveness for review prior to the panel meeting. In accordance with 21 CFR 14.86(b), all panel members are subject to all rules and regulations adopted by FDA and the committee; therefore, even though the industry representatives usually are not given access to trade secret and confidential, commercial information, they are bound to protect the confidentiality of documents that would be sent to them in preparation for panel review of a PMA. If you would like the industry representative to have access to any portion of your PMA, including the Summary of Safety and Effectiveness, please provide a copy for that purpose and notify the executive secretary of the panel at (301) 427-1205. However, review of your PMA will not be prejudiced if you elect not to provide a Summary for industry representative review.

All correspondence regarding this PMA should be submitted in 3 copies in the form of a PMA amendment. Please address all submissions to:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

If you have questions, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

Philip J. Phillips

Re: P920015
PCD Transvene System

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) is continuing to process the above named premarket approval application (PMA). Simultaneously with a review by the Office of Device Evaluation (ODE), the Office of Compliance and Surveillance (OCS) must review the manufacturing information in your PMA to determine that it is sufficiently complete and appropriately organized to permit FDA to determine whether your firm (or your contract manufacturer) has the capability of manufacturing your PMA device in accordance with (1) the conditions specified in the PMA application and (2) the requirements of the medical device GMP regulation.

The Division of Compliance Programs (DCP) of OCS has reviewed the manufacturing section of your PMA and believes that it lacks the information necessary to effectively complete a review and determine whether to initiate a PMA inspection (see enclosed). While the deficiencies outlined in the enclosure do not preclude further review of your PMA, if left uncorrected they may delay or preclude evaluation of your manufacturing process and final approval of your PMA application. We request that you respond as indicated. Please be advised that continued review by ODE of your application (including the manufacturing section) may identify additional deficiencies. Also, the OCS review of your response to this letter may identify additional deficiencies.

For your information a Guidance for Preparation of PMA Manufacturing Information was published on March 22, 1991 (a notice of availability was published in the August 20, 1991 Federal Register). It is also available as part of the PMA Manual Supplement which may be obtained from the Division of Small Manufacturer's Assistance at 1-800-638-2041.

Information supplied in response to the enclosed request should be submitted in the form of an amendment **AND BE CLEARLY IDENTIFIED AS A RESPONSE TO AN OCS REQUEST IN YOUR REFERENCE BLOCK.** FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). You may, however, amend the PMA within the 180 day period to request an extension of time to respond. Any such request is subject to FDA approval and must justify the need

for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180 day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180 day period will be considered a resubmission of the PMA and will be assigned a new number. A resubmission should be complete and self-contained without reference to earlier submissions because of potential difficulties in assembling files from storage.

All correspondence regarding this PMA should be submitted in three (3) copies in the form of a PMA amendment to the address below and reference the above PMA number to expedite processing.

Radiological Health

Deficiency List

The Office of Compliance and Surveillance (OCS) in the Center for Devices and Radiological Health (CDRH) has completed an initial review of your premarket approval application (PMA), P920004, with regard to the Good Manufacturing Practice (GMP) regulations. Please address the following issues and provide the requested documentation:

1. The Design Assurance Plan, Project 6884/6996, dated 2/7/91 for the new helix electrode, part (b)(4) is not representative of the manufacturing operations. The qualification report dated 4/16/91 does not address the effects of the sterilization process on the integrity of the helical electrode. [vol.2, pp.153-156]

2. Provide the locations of the biological indicators used during the sterilization validation and routine production for the 6966 lead. [vol.2, p.207]

3. Provide the product density and configuration pattern for the 6966 sterilization cycle. [vol.2, p.207]

4. Provide the maximum parameter of the humidity specification for the sterilization cycle of the 6966 lead. [vol.2, p.211]

5. The finished device evaluation for the 6966 lead does not adress the effect of sterilization on device performance. [vol.2, p.174]

6. The validation plan for 6963 lead does not address the effects of the sterilization cycle on device performance. [vol.3, p.327]

7. The process qualification report, (b)(4) does not address the effects of the sterilization cycle on the performance of the 6999 lead. [vol.3, p.335]

8. Provide the product location of biological indicator and spore inoculation for the validation and production sterilization cycles of the 6963 and 6999 leads. [vol.3, p.372]

9. Provide the maximum parameter of the (b)(4) exposure for the 6999 lead. [vol.3, p.376]

10. Explain the difference in the sterilization (b)(4) exposure parameters of the 7217B PCD Control Device between the two manufacturing facilities. The (b)(4) exposure parameter at the Rice Creek facility is (b)(4) minutes; the (b)(4) exposure parameter at the Kerkrade facility is (b)(4) minutes minimum. The Kerkrade facility does not specify a maximum (b)(4) exposure. [vol.4, p.415 and p. 432]

11. Provide the manufacturing methods, controls, and evaluation procedures for the facility identified as Medtronic Milaca, 900 6th Ave. N.E. Milaca, MN 56353. [vol.4, p. 437]

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date April 23, 1992

From Mathematical Statistician (T.C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject Statistical Review of PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistical Branch, DBS. OST

1. Background

The Medtronic Pacer-Cardioverter-Defibrillator (PCD) is an implantable, multiprogrammable, automatic tachyarrhythmia control device. This device is used for treatment of patients at risk of sudden cardiac death due to ventricular tachycardia (VT) and/or ventricular fibrillation (VF).

2. Reviewer's Comments

2.1 Pooling

There are a total of 319 implants in 317 patients of the PCD device. A total of 52 investigative centers participated in the clinical trials with 20 centers in the U.S. and 32 in foreign countries. In Vol 5, p 646 - p 650, a section was devoted to the justification for data pooling. Sponsor performed a comparison of U.S. and foreign patients and summarized the variables tested in Table IVA. Sponsor first combined and then compared all the data in U.S. centers and in foreign centers. However, much information was lost in these gross combinations. The initial design with centers nested within countries was reduced to a two-way classification. This is not good statistical practice.

This reviewer recomputed all the p-values listed in Table IVB and IVC; they were all found to be correct, except for the following:

Table IVC

	p-value (sponsor)	p-value (reviewer)
NYHA Classification	(b)(4)	(b)(4)
Congestive Heart Failure		
Cardiomyopathy		

2.2 Patient follow-up

Table E-2, p. 34, vol. 1, shows the follow-up time by type of data form. This is not an adequate presentation of the follow-up data. Sponsor should refer to p. 93, Table 4.6. in "Statistical Methods for Survival Data Analysis" by Elisa Lee for a more proper life-table analysis. Sponsor should also discuss the reason why some patients dropped out of the follow-up study, either withdrawn alive or lost to follow-up. For example, there are 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2-month period.

2.3 PCD transvene system compared to AICD Epicardial System clinical experience

For the comparison of complication/observation rates for PCD vs AICD, as reported in Table IL-1, p634, vol 5, I have the following comments:

2.3.1. Please provide the numbers of complications and patients for PCD and AICD.

2.3.2. Please provide the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate/Problematic VT/VF Therapy Delivery."

2.3.3. I am concerned that pocket infection is 3.5% for PCD as compared to 2.2% of AICD, even though the sponsor argues that the PCD System implant procedure requires multiple lead configurations. There are other "lead related" complications as reported on Table X1 F1 and F2, P857, Vol. 5. PCD Transvene System has more "lead related" complications than PCD Epicardial System.

2.4. One-year actuarial survival comparison of mortality between the PCD and AICD systems was discussed on p. 842, Vol. 5. Sponsor stated "there was a statistical difference in the reported (AICD) perioperative mortality ($p = 0.017$) with the PCD Transvene System having a lower reported perioperative mortality." I have the following comments concerning this statement:

2.4.1. What statistical test was used to compare survival?

2.4.2. Please provide the two survival or life tables by year of follow-up, so that this reviewer can reproduce the statistical test and the derived p-value.

2.5. Comparison to PCD Epicardial System.

P-values for one-year survival comparison of PCD Transvene System vs. PCD Epicardial System for freedom from death by "sudden cardiac", "non-sudden cardiac", "all cardiac" and "noncardiac" causes are provided in Table Xl G-2, p. 862, Vol. 5, also Table J-2, p. 54, Vol. 1. The sponsor should discuss the statistical techniques used to derive the p-values.

2.6. PCD device longevity data.

Sponsor stated in Section M.1. p. 66, Vol. 1: "Thus, the PCD device longevity, which is monitored, utilizing battery voltage and change time obtained via telemetry, was analyzed. The PCD device longevity data collected is consistent with the longevity projection." This reviewer needs to see the data and statistical test used to support the above statement.

3. Reviewer's Conclusion

The sponsor needs to adequately address the issues raised in Section 2 above before the safety and effectiveness of the PCD Transvene System can be evaluated from a statistical perspective.

Memorandum

Date: April 7, 1992

From: Mathematical Statistician (G. Kamer) HFZ-162
Statistics Branch, Division of Biometric Sciences, OST

Subject: PMA Review Statistical Checklist Recommendations for PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To: Donald F. Dahms - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistics Branch, DBS, OST

The Statistics Branch, DBS, OST has received the PMA referenced above and evaluated it against the attached PMA Review Statistical Checklist. The failures to provide justification for sample size or pooling of data over investigational sites were the only non-serious omissions of a statistical nature. Therefore, we recommend this PMA be filed. We will now begin an in-depth statistical review of this PMA. This review should be completed and our comments sent to you within 30 days. If you have any questions, please contact me at 227-8629 or the statistical reviewer, T. C. Lu, at 227-8627. The omissions found are from the Clinical Investigations Section of the checklist and are stated below for your information:

1. This submission does not include any acceptable justification of sample size. Please provide a complete description of your sample-size determination. This should include effect criteria, alpha and beta statistical error tolerances, anticipated variance of the response variables, and any assumptions or statistical formulae with references that are required for sample-size determination.

2. This submission does not include any justification for pooling (combining) the patient data over site. Please review and analyze your prognostic variables to provide a detailed justification why the data may or may not be pooled for evaluation. Note that an analysis by site is always necessary in any case.

Gary L. Kamer

Memorandum

Date 4/3/92

From Chemist
Premarket Approval Staff, ODE, HFZ-402

Subject Request for PMA Filing Review

To DCRND

PMA Application No.: P920015

PMA Applicant: MEDTRONIC, INC.

Device Trade Name: MEDTRONIC® TRANVENE LEAD SYSTEM

Date of Document: 3/31/92

Date Received by DMC: 4/1/92

Date Received by PMA Staff from DMC: 4/2/92

Date letter and checklist due from ODE Division to PMA Staff: 5/11/92

Date Letter Due out of CDRH: 5/16/92

Please review the above referenced PMA for a filing/nonfiling determination. A complete checklist and "filed" or "not filed" letter should be returned to the PMA Staff by the due date specified above.

If the PMA is to be filed, please specify in the checklist special considerations or important aspects of the manufacturing process that should be included in the EDRO inspection of the manufacturing facility. A preliminary determination of whether the device is a "critical device" for purposes of the device Good Manufacturing Practice Regulations should be included (see checklist).

The biostatistics staff (HFZ-116) is notified of every PMA received and will notify the ODE Division as to the identity of the statistical reviewer. The biostatistics staff will review appropriate segments of the PMA and forward a statistical review memo to the reviewing ODE Division before the due date specified above. Please let me know if you need any further assistance.

REMARKS

I spoke to Chuck Swanson about the proposed rewording of the indication; he had no concerns. He also said that "and" will be deleted from the 6963 Manual, last sentence, P.8. Revised Indications will be sent for Changes.

DO NOT use this form as a RECORD of approvals, concurrences, disposals, clearances, and similar actions

RE: TRANSVENE® PMA Submission

Dear Ms. Terry:

This is to confirm our telephone conversation this morning regarding the Summary of Safety and Effectiveness for the TRANSVENE lead and the labeling for the Model 6963 lead. Regarding the Summary of Safety and Effectiveness, Medtronic agrees to the modification as you proposed that the statement regarding the patients with hemodynamically stable VT read as follows:

> "While this patient population was included in the TRANSVENE Lead clinical study, no conclusions were drawn from the data obtained on this specific patient group." The latter part of the sentence reflects a change from the earlier version and we agree to this modification. The relevant pages of our technical manuals have been modified and are attached.

With regard to the labeling for the Model 6963, the last sentence on page 8 does not make sense as written and should be modified by the deletion of the word "and" as indicated on the attachment.

If you have any questions, please call Dennis Connolly immediately at 612-574-4696.

Sincerely,

Charles H. Swanson

6963 Reg (02088dEN/MMC 10/8/93 11:01 AM Page 8

If the electrode is to be placed in the coronary sinus, advance the lead into the right atrium and rotate the curved stylet to manipulate the tip over the tricuspid valve. Move the tip medially and posteriorly to the coronary sinus ostium and advance the lead into the coronary sinus. Continue advancing the lead through the coronary sinus to the desired position.

If the lead goes through the tricuspid valve opening, retract the lead with a gentle posterior rotation and then advance it toward the coronary sinus ostium.

The electrode for the TRANSVENE®-SVC must be as far as possible from other defibrillation electrodes. Also, the cardiac mass between the electrodes should be as large as possible. Insufficient separation between the electrodes may result in reduced defibrillation efficacy.

Proper positioning of the electrode is essential for defibrillation efficacy (Figure 7). Use fluoroscopy (P-A and lateral position) to ensure that the distal end of the electrode is properly positioned in the superior vena cava or is lodged in the coronary sinus with the proximal end of the electrode advanced beyond the coronary sinus ostium.

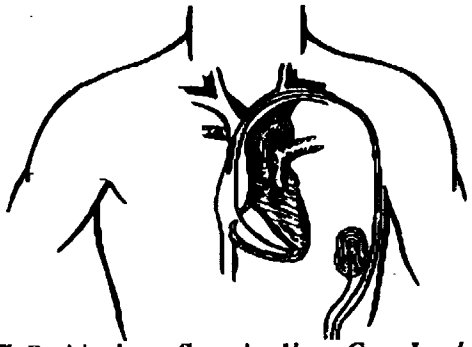

Figure 7. Positioning a Superior Vena Cava Lead

Bradycardia Pacemakers

Previously implanted bradycardia pacemakers, tachyarrhythmia devices and leads should be explanted. The output pulses of an implanted device may adversely affect the tachyarrhythmia detection capabilities of the PCD device. If leads must be abandoned rather than removed they should be capped to ensure they will not become a pathway for currents to or from the heart. If a patient requires a separate atrial or dual chamber pacemaker for hemodynamic reasons, either permanent or temporary, allow adequate space between the pacing lead electrodes and the defibrillation lead electrodes.

DEC 09 '93 12:03PM PACING REG AFFAIRS P.3/6

DESCRIPTION

The Medtronic® TRANSVENE®-SVC Model 6963 Unipolar, Endocardial, Superior Vena Cava or Coronary Sinus Lead is designed for the delivery of cardioversion and defibrillation therapies.

Silicone insulation surrounds the low resistance conductor coil and the coil electrode is a platinum alloy. The lead also has a 6.5 mm connector.

INDICATIONS FOR USE

The Medtronic® TRANSVENE®-SVC Model 6963 is intended for single long-term use in the superior vena cava or coronary sinus and is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the TRANSVENE® system.

Replaced w/

no conclusions were drawn from the data obtained on this specific patient group.

DESCRIPTION

The Medtronic® TRANSVENE®-SQ Model 6999 Unipolar, Subcutaneous, Oval Patch Lead is designed for the delivery of cardioversion and defibrillation therapies.

The lead features a low resistance conductor coil and platinum alloy electrode coils for cardioversion and defibrillation therapies. The outer edge of the lead is used for suturing. The lead also has a 6.5 mm unipolar connector.

There are 3 nodes on one side of the patch, and 2 nodes at the junction of the lead body and patch electrode. These nodes are intended to mark the insulated side of the patch electrode.

INDICATIONS FOR USE

The Medtronic® TRANSVENE®-SQ Model 6999 is intended for single long-term use only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

~~NOTE: The Model 6999 TRANSVENE®-SQ patch lead is not intended for epicardial or pericardial placement.~~

The lead has application for patients in which implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the

designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

The coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses. The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; however, when used with the standard bipolar PCD® pulse generators, pacing occurs between the tip electrode and the coil electrode.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the TRANSVENE® system.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE®-RV lead with two non-radiopaque anchoring sleeves, stylet, and stylet guide
- 2 fixation tools
- 1 vein lifter
- Extra stylets
- End Caps
- Product literature

DISTRICT RECOMMENDATION: Recommend non-concurrence with the PMA approval and that the district send a non-concurrence letter to the firm.

INVESTIGATORS: Karen A. Coleman, ATL-DO
Joseph M. Edwin, MIN-D)

SITUATION: Situation 1 (In accordance with Part V of Compliance Program 7382.830, dated 9-1-91)

CDRH/OCS RECOMMENDATION: PMA Non-Approval

A review of the EIR, FDA 483, and exhibits for Medtronic, Inc. facility indicate that the criteria for a Situation 1 has been met, in accordance with the requirements of Part V of Compliance Program 7382.830, dated 9-1-91. Conditions exist whereby there is a reasonable probability that unsafe or ineffective devices will be produced and distributed.

The following is an evaluation of the EIR, exhibits, and FDA 483. The firm did not respond to the observations made by the investigator on the FDA 483.

21 CFR 820.100(a)(1)

Failure to establish procedures for specification control measures to assure that the design basis for the device is correctly translated into approved specifications, as required by 21 CFR 820.100(a)(1). For example: 1. the firm has not validated critical Tachy Lead Manufacturing Operations currently used in production including but not limited to: Welding, Crimping, and Bonding Operations. Firm does not have data showing they have run a minimum of three consecutive successful runs to provide assurance these processes are validated; 2. a review of sterilization certification (b)(4) reports dated 4/10/85 (adding Permanent Lead Introducer [PLI]) and 3/4/92 (adding 6966 Tachy RV Lead), and 3/30/93 (update certification adding a (b)(4) controller system) revealed: a) D values were determined using the samples in sterilization chambers loaded with (b)(4) (b)(4) do not contain product or simulated product). Firm's documents and SOP's do not define or describe (b)(4) (b)(4). As of 5/13/93 firm did not have a written explanation correlating product load density characteristics of a fully loaded sterilization chamber of product in packages versus a fully loaded chamber of (b)(4) (b)(4) b) Firm does not have a report correlating the results contained in the 4/10/85 and 3/4/92 certificates with conclusions that show the PLI is actually the "worst case" product for this certification group. The PLI is routinely used as the sample for requalifying products or adding new products to this group. c) D value calculations for sterilization certificate (b)(4) dated 3/4/92 and 3/30/93 only shows the D value at confidence intervals calculated at (b)(4) Firm's SOP (b)(4) requires they calculate it at (b)(4) d) Certifications dated 3/4/92 and 3/30/93 do not identify the actual Sterility Assurance Level that will be obtained; 3. Coil Part Number (b)(4) (b)(4) diameter platinum coil sputtering process has not been validated.

This charge is supported by: 1. the discussions on pages 2 & 3 of the EIR; Exhibits F1-3, L1-6, N1-4, M1-6, G1-11, O1-4, J1, K2, F1-3, G1-11, and G8; and FDA 483 #1; 2. the discussion on pages 5-7 of the EIR; Exhibits P1-14, A1-22, E1-43, D1-13, B1-10, and C1-11; and FDA 483 #4; 3. the discussion on page 7 of the EIR, Exhibits Q1-9 and S1-26, and FDA 483 #5.

21 CFR 820.181

Failure to prepare, date, and sign by a designated individual device master records, as required by 21 CFR 820.181. For example, a review of the Plans and Qualification Reports for the New Laser Source; Model 6884 Split Build; and Lead Model 6966 Connector Subassembly revealed the following: a) The plans did not require process validation. b) Sampling plans were not identified. c) Test methods or procedures are not always identified. d) They do not describe how the results will be interpreted and/or analyzed.

This charge is supported by the discussions on pages 3 & 4 of the EIR; Exhibits F1-3, G1-11, L1-6, M1-6, N1-4, and O1-4; and FDA 483 #2.

21 CFR 820.160

Failure to check and, where necessary, test for conformance with device specifications each production run, lot, or batch prior to release or distribution, as required by 21 CFR 820.160. For example, Transvene Leads have not been tested under simulated use conditions.

This charge is supported by the discussion on pages 7 and 8, of the EIR and FDA 483 #6.

21 CFR 820.162

Failure to investigate any failure of a device to meet performance specifications after it has been released for distribution, as required by 21 CFR 820.162. For example, Transvene Lead Model 6884 (b)(4) (b)(4) was returned and found to have cosmetic MIO on both the inner and middle coil insulation. The coils were not analyzed/examined to verify that the platinum sputtering process was done to specification.

This charge is supported by the discussion on page 8 of the EIR; exhibits S1-26, Q1-9, T1-4, and U1-3; and FDA 483 #7.

UNSUPPORTABLE FDA 483 OBSERVATIONS

FDA 483 #3 - There is no GMP requirement for design issues.

Transvene Lead System

We are requesting that your office provide a device expert for a Premarket Approval (PMA) preclearance inspection of the above referenced manufacturer with the Minneapolis district office. We are making this request directly to your office because the subject PMA covers a complex, critical device, and several of t' firm's other sites have violative histories. During the last year and a h[illegible], the Minneapolis district has failed to complete seven of their ten PMA preapproval inspections within two months of the due date because, according to the Inspection Branch management, they do not have a sufficient number of investigators who are qualified to conduct device inspections.

It will be necessary to perform a complete PMA inspection of Medtronic per C.P. 7383.001 to determine if the firm is meeting all of its PMA commitments and GMP requirements. Emphasis should be placed upon determining whether the firm has validated all significant manufacturing processes.

We have requested that the Minneapolis district office contact you to schedule the inspection (see attached assignment). If you need any further information, please do not hesitate to call me at 427-1125.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic Transvene System
Date: October 28, 1993
Office: DCRND/ODE

The manufacturer responded to our approvable letter of September 23, 1993. In addition, the manufacturer mentioned that a follow-up inspection is scheduled for October 18, 1993 (the PMA application might be amended to provide inspection information). The manufacturer also stated that there are no new data from the clinical study of the Medtronic Transvene System which could impact safety and effectiveness.

Deficiency # 1

The manufacturer modified the labeling to include the following: diagrams for proper insertion and the final position of the leads; defibrillation efficacy data for the different lead configurations and polarity combinations (including sequential and simultaneous discharges); information and/or recommendations regarding implantation techniques and testing methods; information regarding implanting in patients who do not have a 10 Joule safety margin; information aimed at reducing the incidence of infection; instructions stressing the importance of pausing between VF inductions; information regarding the expected change in defibrillation thresholds; guidance regarding permanent pacemaker separation from the Transvene leads (RV and SVC/CS); a statement which emphasizes the need for x-rays and pace threshold testing; information regarding techniques for placing the leads via the cephalic vein; and an explanation regarding the necessity for explant and return of the leads upon the patient's death.

The manufacturer provided the requested data. No concerns about how the data are presented in the labeling.

Deficiency # 2

The manufacturer modified the labeling to include warnings which pertain to the following: use of the Sub-Q patch lead on the pericardium or epicardium; language regarding the use of dual anchoring sleeves; and information regarding extensive inductions during implant.

No significant concerns about the warnings as written.

Deficiency # 3

We told the manufacturer that the indications and contraindications for use of the Medtronic Transvene Lead System should be identical to the PCD Epicardial System with certain exceptions. The exact language which states, "The safety and

effectiveness of the PCD...", was not used. However, the proposed language is acceptable. The indications as written are acceptable. It should be noted that the contraindication proposed by the manufacturer, "The Transvene Lead System is contraindicated for use in any system other than a Medtronic implantable tachyarrhythmia control device system for which it has been tested," will not be included in the labeling as a contraindication. The manufacturer was informed of our decision in a phone conversation. They agreed to remove the contraindication, and will send documentation confirming our agreement.

The manufacturer also satisfactorily responded to the requests which consisted of the following: placing an identifying mark to distinguish nonthoracotomy leads from thoracotomy leads; reporting warning and precautions separately and providing a copy of the Patient's Manual.

I also told the manufacturer that the Warnings and Precautions should be included in the labeling according to our Blue Book Memorandum of March, 8. 1991 (manufacturer has a copy). We reviewed the manual and found that caution statements within the context of the manuals should also be included on the list of precautions. They agreed to revise their labeling to include the referenced cautions on the list.

Recommendation

The manufacturer modified the labeling as requested. Formal documentation pertaining to the warnings and precautions and the removal of the requested contraindication will be submitted. In the interim, faxed information will be sent confirming their agreement, as we discussed, regarding those concerns.

Approval of the referenced PMA application.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic® Transvene® Lead System
Date: August 16, 1993
Office: DCRND/ODE

On August 2, 1993, the Circulatory System Devices Panel reviewed the PMA application for the Medtronic® Transvene® Lead System. Specific questions and labeling concerns generated from FDA's review of the PMA application are included in my memoranda of July 9, 1993 (FDA review and panel presentation).

The panel addressed all FDA's questions, and concurred with the labeling recommendations.

The panel recommended approval of the Medtronic® Transvene® PMA with modifications to the labeling. A list of FDA's and the panel's recommendations are listed below.

FDA's and the Panel's Recommendations

The labeling should be modified to include the following:

- diagrams which show proper insertion of the endocardial leads and how the patch lead should be applied to the subcutaneous tissue;
- a caution statement that the patch lead is not for use on the pericardium or epicardium;
- efficacy data of the different lead configurations via the different pathways;
- pictures or diagrams of the various electrode configurations which serve as a guide for selection;
- information and/or recommendations about implanting the leads and testing the different configurations. For example, when to use a two-lead versus a three-lead configuration and when to implant in the superior vena cava (SVC) versus the coronary sinus CS);
- information or recommendations regarding implanting in patients who do not have the 10 Joule safety margin;
- information about how the incidence of infection can be reduced;
- a reference about using 5-minute intervals between ventricular fibrillation (VF) inductions during testing;

- stronger language regarding the use of dual anchoring sleeves on the right ventricle (RV), SVC and CS leads;

- information which states that a thoracotomy after extensive testing with a nonthoracotomy lead system should be delayed at least 2 days (the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 to 9.3 percent);

- guidance regarding separating pacemaker leads from the Transvene leads;

- a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement;

- information regarding placing the leads via the cephalic vein when possible; and

- an explanation regarding the necessity for explant and return of the leads upon the patient's death.

In addition the manufacturer should note the following:

- The indications and contraindications for use of the Medtronic® Transvene® Lead System should be the same (with certain modifications) as those for the PCD™ Epicardial System.

- The technical manuals for the Transvene® Leads should state that the leads are for use together as a system. The labeling (where appropriate) should be consistent in all of the Transvene® Lead manuals. The information regarding the Transvene® Leads in the PCD™ Manual should also be included in the Transvene® Lead manuals.

- There should be an identifying mark on the package label which distinguishes nonthoracotomy leads from thoracotomy leads.

- The Warnings and Precautions in the labeling should be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991 (a copy of this memorandum was previously sent to you).

- Postmarket surveillance will track the explanted leads for evidence of metal ion oxidation (MIO).

The manufacturer should provide a copy of the Patient's Manual which includes a reference to use of the nonthoracotomy leads with the PCD™ models.

Recommendation

The above information will be included in an approvable letter to the manufacturer.

MEMORANDUM

DCRND/AA

DATE: July 19, 1993

FROM: Field Programs Branch CDRH, HFZ-331

SUBJECT: GMP Inspection **NONCLEARANCE**
PMA P920015

TO: Premarket Approval Coordinator
HFZ-402

Mfrs.: Medtronic, Inc.
7000 Central Avenue NE
Fridley, MN 55432

Medtronic B.V.
Wenckebatchstraat 10
Kerkrade, The Netherlands

Applicant: Medtronic, Inc.
7000 Central Avenue NE
Fridley, MN 55432

Product: Transvene Lead System

An inspection of the above referenced manufacturers was accomplished on 5-27-93 and 12-18-92. On the basis of the information reviewed, Medtronic Inc., located in Fridley, MN, has an unacceptable GMP program.

Attached, please find a copy of the review performed by the Manufacturing Quality Assurance Branch which details the GMP deficiencies revealed by the inspection.

On the basis of the information reviewed, Medtronic B.V., located in The Netherlands, has an acceptable GMP program.

PLEASE NOTE THAT NEITHER A COPY OF THIS EVALUATION MAY BE SENT TO THE FIRM, NOR MAY ITS CONTENTS BE DISCUSSED WITH THEM.

A follow-up inspection is being requested for the above manufacturing site. When that inspection has been completed and we have had an opportunity to review the results, you will be advised of the findings of the inspection.

This should complete all of the sites awaiting inspection that are currently outstanding concerning this PMA.

Fridley, MN 55432

CFN: 2182208

PRODUCT: Transvene Lead System

DISTRICT RECOMMENDATION: Recommend non-concurrence with the PMA approval and that the district send a non-concurrence letter to the firm.

INVESTIGATORS: Karen A. Coleman, ATL-DO
Joseph M. Edwin, MIN-D)

SITUATION: Situation 1 (In accordance with Part V of Compliance Program 7382.830, dated 9-1-91)

CDRH/OCS RECOMMENDATION: PMA Non-Approval

A review of the EIR, FDA 483, and exhibits for Medtronic, Inc. facility indicate that the criteria for a Situation 1 has been met, in accordance with the requirements of Part V of Compliance Program 7382.830, dated 9-1-91. Conditions exist whereby there is a reasonable probability that unsafe or ineffective devices will be produced and distributed.

The following is an evaluation of the EIR, exhibits, and FDA 483. The firm did not respond to the observations made by the investigator on the FDA 483.

21 CFR 820.100(a)(1)

Failure to establish procedures for specification control measures to assure that the design basis for the device is correctly translated into approved specifications, as required by 21 CFR 820.100(a)(1). For example: 1. the firm has not validated critical Tachy Lead Manufacturing Operations currently used in production including but not limited to: Welding, Crimping, and Bonding Operations. Firm does not have data showing they have run a minimum of three consecutive successful runs to provide assurance these processes are validated; 2. a review of sterilization certification (b)(4) reports dated 4/10/85 (adding Permanent Lead Introducer [PLI]) and 3/4/92 (adding 6966 Tachy RV Lead), and 3/30/93 (update certification adding a (b)(4) controller system) revealed: a) D values were determined using the samples in sterilization chambers loaded with (b)(4) (b)(4). (b)(4) (b)(4) do not contain product or simulated product). Firm's documents and SOP's do not define or describe (b)(4) (b)(4). As of 5/13/93 firm did not have a written explanation correlating product load density characteristics of a fully loaded sterilization chamber of product in packages versus a fully loaded chamber of (b)(4) (b)(4). b) Firm does not have a report correlating the results contained in the 4/10/85 and 3/4/92 certificates with conclusions that show the PLI is actually the "worst case" product for this certification group. The PLI is routinely used as the sample for requalifying products or adding new products to this group. c) D value calculations for sterilization certificate (b)(4) dated 3/4/92 and 3/30/93 only shows the D value at confidence intervals calculated at (b)(4) Firm's SOP (b)(4) requires they calculate it at (b)(4) d) Certifications dated 3/4/92 and 3/30/93 do not identify the actual Sterility Assurance Level that will be obtained; 3. Coil Part Number (b)(4) (b)(4) diameter platinum coil sputtering process has not been validated.

This charge is supported by: 1. the discussions on pages 2 & 3 of the EIR; Exhibits F1-3, L1-6, N1-4, M1-6, G1-11, O1-4, J1, K2, F1-3, G1-11, and G8; and FDA 483 #1; 2. the discussion on pages 5-7 of the EIR; Exhibits P1-14, A1-22, E1-43, D1-13, B1-10, and C1-11; and FDA 483 #4; 3. the discussion on page 7 of the EIR, Exhibits Q1-9 and S1-26, and FDA 483 #5.

21 CFR 820.181

Failure to prepare, date, and sign by a designated individual device master records, as required by 21 CFR 820.181. For example, a review of the Plans and Qualification Reports for the (b)(4) (b)(4) Model 6884 Split Build; and Lead Model 6966 Connector Subassembly revealed the following: a) The plans did not require process validation. b) Sampling plans were not identified. c) Test methods or procedures are not always identified. d) They do not describe how the results will be interpreted and/or analyzed.

This charge is supported by the discussions on pages 3 & 4 of the EIR; Exhibits F1-3, G1-11, L1-6, M1-6, N1-4, and O1-4; and FDA 483 #2.

21 CFR 820.160

Failure to check and, where necessary, test for conformance with device specifications each production run, lot, or batch prior to release for distribution, as required by 21 CFR 820.160. For example, Transvene Leads have not been tested under simulated use conditions.

This charge is supported by the discussion on pages 7 and 8, of the EIR and FDA 483 #6.

21 CFR 820.162

Failure to investigate any failure of a device to meet performance specifications after it has been released for distribution, as required by 21 CFR 820.162. For example, Transvene Lead Model 6884 (b)(4) (b)(4) was returned and found to have cosmetic MIO on both the inner and middle coil insulation. The coils were not analyzed/examined to verify that the platinum sputtering process was done to specification.

This charge is supported by the discussion on page 8 of the EIR; exhibits S1-26, Q1-9, T1-4, and U1-3; and FDA 483 #7.

UNSUPPORTABLE FDA 483 OBSERVATIONS

FDA 483 #3 - There is no GMP requirement for design issues.

Kent A. Berthold

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Review - Transvene PMA
Date: July 9, 1993
Office: DCRND/ODE

Description of the System

The PCD Transvene System consists of the Model 7217B PCD pulse generator, programmer, external accessories and leads (Model 6966 RV lead, Model 6966 CS/SVC lead and the Model 6999 patch lead, see description of leads and summary of testing in attached memo and in Volume 3, Section A, Bench Testing). The leads may be implanted in 3 configurations: RV/CS/SQ, RV/SVC/SQ and RV/CS/SVC via a single, simultaneous or sequential pathway.

Study Design and Objectives

(b)(4)

(b)(4)

Patient Population

(b)(4)

(b)(4)

(b)(4)

(b)(4)

Clinical Experience

As of February 1, 1993 (the data cutoff), the clinical experience includes data from 762 implants in 757 patients. The data (stratified as described above) were provided in support of the Transvene Lead System. The data included the following: (1) the results of testing at implant and the follow-up intervals; (2) the efficacy of the treatment of VT and VF (spontaneous and induced episodes); (3) complications and observations; (4) patient deaths; and (5) survival. A comparison of the data obtained from the patient population and the different subgroups is also included.

Defibrillation Threshold (DFT) Testing

Three hundred and sixteen patients had DFT testing at implant. The mean DFT was 14.8 Joules (J). The remaining patients had testing which involved the lowest energy to

defibrillate (LED) and/or DFT testing. The mean LED was (b)(4) (b)(4).

Twenty patients were implanted with the Transvene System without a 10 J safety margin (see Volume 2, page 42).

Spontaneous and Induced Episode Experience and Treatment Efficacy of VT and VF - Total Patient Population

- 597 (78.9 percent) patients had a spontaneous VT or VF episode or had VT or VF induced post implant.
- 458 (60.5 percent) patients had a spontaneous episode of either VT and/or VF treated by the PCD Transvene System.
- 141 (60.5 percent) patients had VT only.
- 142 (18.8 percent) patients had VF only.
- 175 patients (23.1 percent) had an episode of VT and VF.
- 90.7 percent of VT episodes were successfully treated with VT therapy # 1.
- 89.1 percent of the VF episodes were successfully treated with VF therapy # 1.
- 60 patients experienced 163 (1.6 percent) spontaneous VT episodes which the PCD Transvene System was ineffective in terminating the arrhythmia (see Volume 2, page 19).
- 16 patients experienced 31 (1.3 percent) spontaneous VF episodes which the PCD Transvene System was ineffective in terminating the arrhythmia (see Volume 2, pages 20 - 21).
- 450 (59.5 percent) patients had induced or spontaneous episodes by the 3 month follow-up.
- 532 (70.3 percent) patients had either a spontaneous or induced episode by the 6 month follow-up.
- 597 (78.9 percent) patients had a spontaneous or induced episode by the 12 month follow-up.

Device Experience - Patients Followed for 6 months or More

- Of 657 patients followed for 6 months or more, 544 (82.8 percent) patients had an induced or spontaneous episode at predischarge or later.

- 113 patients did not have a chronic episode, however pace/sense parameters were measured at the chronic follow-up intervals on all patients except one (see Appendix I).

Summary of Complications and Observations

- 176 complications (required invasive intervention) occurred in 147 patients, included pocket infection (24), lead fracture (9), patch crinkling (7), explants (4) and total lead dislodgement (91). (The 91 cases of lead dislodgement occurred in 86 patients, see Appendix I).

- 212 observations (corrected by reprogramming or antiarrhythmic drug therapy) in 178 patients included inappropriate VT delivery (57), oversensing (52), seroma (17), hematoma (17), patch crinkling (5) and total lead dislodgement (12).

The manufacturer provided tables which report the complications and observations over time (see Table IB3-2 and Table IB3-3, Volume 2, pages 24-25).

The manufacturer stratified the complications and observations by U.S. and foreign patients (see Table IB3-6 Vol. 2, page 28). The complication and observation rates were comparable for the two patient groups. However, more total lead dislodgements (complications) were reported for the U.S. patients and more cases (observations) of inappropriate delivery of VT therapy occurred in the foreign population. There was also a higher incidence of oversensing (observations) in the U.S. population. It should be noted that there should be 7 observations related to loss of capture for the foreign patients instead of 9 (Volume 2, Table IB3-6, page 28).

Because of our concerns about the complications involving lead dislodgement and infection the manufacturer responded as follows: In resolving the concern regarding lead dislodgement, the manufacturer received IDE approval (September 1992) to use dual anchoring sleeves on the Models 6963 and 6966 leads. However, it is unclear if all patients, after IDE approval, are implanted with dual sleeves. The manufacturer confirmed that all patients are receiving dual sleeves. In support of the dual anchoring

sleeves in reducing the rate of lead dislodgement, a report of the clinical experience of additional patients was provided. Data from 439 patients (not a part of the PMA cohort) implanted with dual anchoring sleeves were submitted. Of the 439 patients, 292 were followed for 1 month, 195 were followed for 3 months and 17 were followed for 6 months. Thirteen dislodgements in 10 patients were reported (incidence of dislodgement of 2.3 percent (10/439). Regarding the cases of infection, the manufacturer stated that the incidence of infection in the Transvene study is not significantly different from that reported for the Ventak P Epi study. Therefore, the applicant feels that there is no substantial increase, and that labeling to address this concern is not warranted.

Patient Deaths

There have been 51 deaths (sudden cardiac (5), nonsudden cardiac (31), noncardiac (15). Five perioperative deaths (sudden cardiac (2), nonsudden (2) and noncardiac (1)) are counted within the 51 deaths. None of the deaths were attributed to the PCD Transvene System.

Explants

Sixty-three PCD Transvene Systems were explanted (N=762), patient death (22), infection (22), heart transplant (9), low battery voltage (1), PCD performance issues (4), integrated circuit problem (1) and lead problems (4). The results of analyses on 42 units returned indicated that the devices were performing within specifications.

Of the 42 PCD Transvene Systems returned, 23 lead systems or portions of systems were returned and analyzed. Of these the helix of one Model 6966 lead was damaged. The remaining leads were found to be within specification. The analyses on 19 lead systems are still outstanding. (It should be noted that one of the Model 6884 leads (implanted for 27 months) which was explanted due to heart transplant, exhibited metal ion oxidation (MIO) upon analysis. Metal ion oxidation can cause the polyurethane of the leads to degrade (see Volume 2, Section on Explants, page 296 or Appendix I).

Survival Analysis

The survival analyses encompassed all patients (screened and implanted). The projected one year actuarial survival rates for the PMA cohort (N=757) are as follows: sudden cardiac death (99.5 percent); nonsudden cardiac (96.2 percent); all cardiac (95.8 percent); noncardiac (98.1 percent); and overall (93.3 percent). The perioperative mortality is 0.7 percent.

The survival rates for 854 patients are included in Volume 2, Table IB4-2, page 31. The survival data were updated to include the 897 patients screened for the Transvene System. The one year actuarial survival rates for these patients are as follows: sudden cardiac death (99.5 percent); nonsudden cardiac (96.6 percent); all cardiac (96.1 percent); noncardiac (98.4 percent); and overall (92.9 percent). The perioperative mortality rate is 1.6 percent (see Appendix I).

Comparison Between the Patients Who Met the Implant Criteria and Patients Who Did Not Meet the Implant Criteria

A comparison of the clinical outcome between the patients who met the implant criteria and those patients who did not meet the implant criteria was included. The comparison was made to determine if there was a greater risk of morbidity and mortality among the patients who did not meet the implant criteria and received the Transvene System. The data showed the following: The efficacy of the patient groups in the treatment of spontaneous episodes of VT and VF was similar. There was no significant difference in the one year sudden cardiac death survival and the overall survival reported for the two groups. Ninety-one per cent of the patients who did not met the implant criteria had at least one successful termination of an induced ventricular comparison at 24 joules or less. In addition, there were 170 patients who had successful defibrillation of VF at less than or equal to 24 Joules. As a result the manufacturer requested and received IDE approval for a change in the implant criteria. Instead of 3 of 4 successes at 18 Joules or less, the manufacturer can implant with successful defibrillation at 24 Joules (referenced in Volume 2, page 53).

Labeling

The manufacturer has included information about the Transvene leads in the PCD Manual as well as in the technical manual for each Transvene lead model.

The technical manuals of the Transvene Models 6966, 6963 and 6999 leads should be modified to included additional information. The following modifications are included for the Panel's consideration:

- The indications and contraindications for use of the Transvene lead system should be identical to those of the PCD (with certain modifications).

- The technical manuals for the Models 6966, 6963 and 6999 leads should state that the leads are intended for use together as a system. The labeling (where appropriate) should be consistent throughout the manuals. The

information in the PCD Manual regarding the Transvene leads should also be included in the technical manuals for the leads.

- There should be more explicit diagrams in the technical manuals which show the proper insertion of the endocardial leads and the various positions for placement of the patch lead.

- Efficacy data of the different lead configurations via the different pathways should be included.

- The labeling should recommend and/or provide some direction about implanting the leads and testing the different configurations. For example, when to use a two lead versus a three lead configuration and when to implant in the SVC versus the coronary sinus.

- Information or recommendations regarding implanting in patients who do not have the 10 J safety margin should be addressed.

- There should be stronger language regarding the use of 2 anchoring sleeves.

- The labeling should address how the incidence of infection can be reduced.

Questions

1. One hundred and thirteen patients within the PMA population did not have a spontaneous or induced episode of VT or VF after predischarge. Therefore, the performance of the system in the treatment of VT and VF was not assessed. However, the pace/sense parameters of these patients were measured at the different follow-up intervals. Are these measurements sufficient in assessing the chronic performance and integrity of the lead system in these patients?

2. In light of the differences between the U.S. and foreign patients within the PMA population, are there any concerns about the poolability of the data?

3. A statistically significant decrease in the perioperative mortality was demonstrated for the PCD Transvene System versus the PCD Epicardial System. However, there was a statistically insignificant decrease in perioperative mortality for the PCD Transvene Lead System (when calculated from the intention to treat) as compared to the historical control. Are there specific concerns regarding the perioperative mortality rates reported for the PCD Transvene System versus the historical control?

4. Are there concerns regarding the potential risks of dislodgement of the leads, and the reported incidence of infection?

5. The results of analyses of an explant of the Transvene lead Model 6884 (earlier version of the Model 6966) have raised questions about the lead's chronic structural integrity. Are there significant concerns which could question the reliability of the lead? Do the benefits of the Transvene Lead Model 6966 outweigh the risks which might be associated with its potential for MIO?

In addition, the labeling modifications as referenced on pages 6 and 7 should be considered.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Panel Presentation - Transvene Lead System
Date: July 8, 1993
Office: DCRND/ODE

The manufacturer, Medtronic, Inc. is seeking approval of the PCD Transvene Lead System.

STUDY DESIGN

The primary objectives of the PCD Transvene Lead System study include the following: (1) evaluating and monitoring the system in the detection and treatment of VT and VF; and (2) estimating the survival from sudden cardiac death and the overall survival. These data lend support to the endpoints of the study, conversion efficacy and survival from sudden cardiac death and total death.

The PMA population consists of 757 patients implanted with the Transvene Lead System and either of 2 PCD Models, the 7217B or the 7216A. The performance of the PMA population was compared to the historical control, Ventak P AICD population and a concurrent control, the PCD Epicardial System.

CLINICAL EXPERIENCE

As of February 1, 1993, the clinical experience includes data from 762 implants (447 U.S. and 315 foreign) in 757 patients. Data from the PMA population (stratified according to different subgroups) included the following: (1) results of testing at implant, predischarge and the follow-up intervals; (2) efficacy of the treatment of induced and spontaneous episodes of VT and VF; (3) complications and observations; (4) patient deaths; and (5) survival.

Defibrillation Threshold (DFT) Testing

300 patients had DFT testing at implant. The mean DFT was 14.8 Joules (J).

702 patients had lowest energy to defibrillate (LED) testing at implant. The mean LED was 16 J.

Spontaneous and Induced Treatment Efficacy

- 597 (78.9 percent) patients had a spontaneous VT or VF episode or had VT or VF induced post implant.
- 458 (60.5 percent) patients had a spontaneous episode

of either VT and/or VF.

- 90.7 percent of the VT episodes were successfully treated with VT therapy # 1.

- 89.1 percent of the VF episodes were successfully treated with VF therapy # 1.

- 60 patients experienced 163 (1.6 percent) spontaneous VT episodes which the PCD Transvene System was ineffective in terminating the arrhythmia.

- 16 patients experienced 31 (1.3 percent) spontaneous VF episodes which the PCD Transvene System was ineffective in terminating the arrhythmia.

- Of the 657 patients followed for 6 months or more, 544 (82.8 percent) patients had an induced or spontaneous episode at predischarge or later.

- 113 patients did not have a chronic episode however, pace/sense parameters were measured at the different follow-up intervals.

Complications and Observations

- 176 complications occurred in 147 patients. The complications included pocket infection (24), lead fracture (9), patch crinkling (7), explants (4) and total lead dislodgement (91).

- 212 observations occurred in 178 patients. The observations included inappropriate VT delivery (57), oversensing (52), patch crinkling (5) and total lead dislodgement (12).

Explants

Sixty-three PCD Transvene Systems were explanted: patient death (22), infection (22), heart transplant (9), low battery voltage (1), PCD performance issues (4), integrated circuit problem (1) and lead problems (4). The results of analyses on 42 PCDs returned indicated that the devices were performing within specifications.

Of the 42 PCD Transvene Systems returned, 23 lead systems or portions of lead systems were returned and analyzed. Of these the helix of one Model 6966 lead was damaged. The remaining leads were found to be within specifications. The results of analyses of 19 lead systems are outstanding. It should be noted that one Model 6884 (an earlier version of the Model 6966 lead) implanted for 27 months, which was explanted due to heart transplant, exhibited metal ion oxidation (MIO) upon analysis.

SURVIVAL ANALYSIS

There have been 51 deaths (sudden cardiac (5), nonsudden cardiac (31), noncardiac (15). Five perioperative deaths (sudden cardiac (2), nonsudden (2) and noncardiac (1) are counted within the 51 deaths.

The survival rates for the patients who were implanted with the Transvene leads are as follows: sudden cardiac death (99.5 percent); nonsudden cardiac (96.2 percent); all cardiac (95.8 percent); noncardiac (98.1 percent); and overall (93.3 percent). The perioperative mortality rate is 0.7 percent.

QUESTIONS

1. One hundred and thirteen patients did not have a spontaneous or induced episode of VT or VF after predischarge testing. Therefore, the performance of the system in the treatment of VT and VF was not assessed. However, the pace/sense parameters of these patients were measured at the different follow-up intervals. Are these measurements sufficient in assessing the chronic performance and integrity of the lead system in these patients?

2. In light of the differences between the U.S. and foreign patients within the PMA population, are there any concerns about the poolability of the data?

3. A statistically significant decrease in the perioperative mortality was demonstrated for the PCD Transvene System versus the PCD Epicardial System. However, there was a statistically insignificant decrease in the perioperative mortality for the PCD Transvene System (when calculated from the intention to treat) as compared to the historical control. Are there specific concerns regarding the perioperative mortality rates reported for the PCD Transvene System versus the historical control?

4. Are there concerns regarding the potential risks of dislodgement of the leads and the reported incidence of infection? What are considered as acceptable rates of lead dislodgement and infection as they relate to complications and observations?

5. The results of analyses of an explant of the Transvene lead Model 6884 (an earlier version of the Model 6966) have raised questions about the lead's chronic structural integrity. Are there significant concerns which would question the reliability of the lead? Do the benefits of the Transvene lead Model 6966 outweigh the risks which might be associated with its potential for MIO?

In addition, the labeling modifications as referenced in my review memo should be considered. The modifications include the following: (1) diagrams which show proper insertion of the endocardial leads and the various positions for placing the patch lead; (2) efficacy data of the lead configuration via the different pathways; (3) stronger language regarding the use of dual anchoring sleeves; (4) information about how the incidence of infection might be reduced; and (5) recommendations regarding the use of the different lead configurations.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
To: Dr. Subramanian
Subject: Transvene Lead System - Consulting Review
Date: July 6, 1993
Office: DCRND/ODE

Please review the death summaries included in the referenced file (Volume 2, Section III, Death Summaries). The review should evaluate the accuracy in classifying the deaths. In addition, please look at the causes of death to determine if any of the deaths could be possibly linked to device performance.

Please note the following: A definition of the different death classifications can be found in Volume 2, page 293. Medtronic, Inc. has reported 51 deaths (sudden cardiac (5), nonsudden cardiac (31), noncardiac (15) in the PCD Transvene population (N=757). The perioperative deaths (5) are counted within the following classifications: sudden cardiac (2) nonsudden (2) and noncardiac (1).

Please let me know if you can review the data. If so, when do you think you will be done? Hopefully, by the first of next week? Your assistance is greatly appreciated.

Date: June 3, 1993
Office: DCRND/ODE

The manufacturer submitted the referenced amendment to inform us of a case of "cosmetic" metal ion oxidation (MIO). The MIO was found on the Model 6884 (comparable to Model 6966) Transvene RV lead explanted from a patient who underwent a heart transplant.

According to the manufacturer, the presence of MIO on the middle insulation is not entirely unexpected. It was stated that if the middle insulation completely degrades (shorting the sensing ring), then an integrated bipolar sensing system would result (sensing would occur between the unipolar pacing tip and the common defibrillation electrode instead of true bipolar (sensing between the pace/sense tip and the ring electrodes). However, if the innermost insulation degrades and the pacing tip electrode is shorted, intermittent sensing could result. This type of behavior such as intermittent sensing, oversensing, undersensing, etc. could be detected at the follow-up intervals.

Consultation and the review of the issue in the referenced amendment, as well as previous IDE supplements, have taken place with (b)(6) Due to the failure of the Medtronic, Inc. brady leads which employ the platinum sputtering process as the Model 6966 and 6884 leads, she is very concerned. In past reviews, we have requested that the manufacturer institute long term testing to asses the MIO problem.

The monthly report of all observations and complications, as referenced in our letter regarding the IDE expansion, was requested. In addition, the following concerns were conveyed to the manufacturer:

1. The differences between the Model 6884 and the Model 6966 Transvene leads. (The Model 6884 (3.2 connector size and the Model 6966 - 6.5 connector size). The number of leads explanted to date and the MIO and environmental stress cracking (ESC) noted. (As of 150 explants, there was no evidence of MIO).

2. To date, how many patients have received the Transvene lead System? How many patients have been implanted for 2 years and greater? (at least 50) What is the compliance to follow-up of these patients. (Compliance to follow-up 98 to 99 percent). Update on clinical experience: lead related complications, first shock VT/VF efficacy, survival rates,

etc. Are there patients with a dilated RV counted in the group followed for 2 years or more? At what intervals were the complications noted?

3. A description of the expected failure mechanism of the leads. In the referenced case, evidence of MIO was noted at 2 years (MIO visible on the innermost insulation and the middle insulation). What is considered the life expectancy of the leads void of signs of MIO? What is the projected rate of progression. Are their studies to confirm these speculations?

4. Based upon the review of the requested data, the protocol and testing at follow-up might need to be modified to include the following: x-rays or fluoroscopy when there are recurring and/or suspect lead complications or observations and periodically at preset intervals.

5. Regarding the patient whose lead was explanted:

   a. When were the 6 spontaneous VT/VF shocks delivered? Was the system interrogated after explant? [This was the implant history].

   b. Was there more damage noted on the innermost or middle insulation?

   c. What were the lead impedance and threshold measurements?

   d. Explain how the patient's dilated RV contributed to the MIO noted.

The occurrence of MIO noted upon explant of the Model 6966 leads and its significance will be brought to the attention of the Panel.

The manufacturer agreed to provide answers to the above questions and additional supporting data in the Panel volumes.

DOCU#: P920015/A **DATE:** 6/93
TO: Record, PEDB
FROM: Albert E. Moyal, PEDB **COMP:** Medtronic, Inc.
DEVICE: Transvene NTL System
SUBJECT: Phone MEMO, re: Questions on Amendment

I phoned and spoke with Ms. Jennifer Marrone, Regulatory Affairs Manager, regarding several questions that I had concerning the file P920015/A.

The first question concerned the use of a two-lead Transvene system. The amendment stated the use of an RV/SQ or RV/SVC configurations. Ms. Marrone stated that there were several of these configurations present within the group of patients implanted in the non-standard configuration. A total of 37 patients were implanted in this group. Most of the implant population, about 80-90% were implanted with a three-lead configuration.

I asked if these configurations would be included in the final labeling. Ms. Marrone responded by stating that they would be included in the final labeling under "Alternate Configurations". Data on those implanted with a two-lead configuration will be needed before the final review is completed on this device.

Regarding question 1b, the disparity was explained as being 24 couldn't be induced into VF/VFlutter and those patients who couldn't get an LED were also excluded.

Regarding question two, the peri-operative deaths are not included in the overall death calculations. They are stated to be reflected in the duration.

Concerning question number three, the entry sites for the SQ patch are between the first and fifth intercostal muscles.

DOCU#: P920015 DATE: 5/17/93

TO: Record, PEDB

FROM: Biomedical Engineer, PEDB
Albert E. Moyal

COMP: Medtronic, Inc.

DEVICE: Transvene NTL System

SUBJECT: Review of Amendment: Response to FDA Questions.

Medtronic has responded to the questions asked in the FDA Letter March 17, 1993. They have responded to the various concerns raised in the evaluation of the Transvene Non-Thoracotomy Lead System.

A total of 1330 patient have been implanted with the Transvene NTL System. The PMA total number of Transvene patients followed up until February 1993 is 757 patients. Out of this number, 657 have been followed for greater than six months, with 393 patients followed for greater than one year.

The one year survival rate for SCD is 99.3%. There were 458 spontaneous episodes of VT that occurred. Sixty (60) patients experienced 163 episodes that were ineffectively treated terminated. This represents a company claim of 1.6%, although 60 patients out of 757 represents 7.9% of the population.

Other information provided included patients meeting, and not meeting implant criteria, clinical experience, survival rates, clinical complications and observations, and comparisons between the PCD Transvene with the PCD Epicardial and AICD Ventak P historical data.

The concerns that I have with this amendment are as follows:

1. On page S12, the company describes the lead configurations that may be done with the leads making up the transvene system. In the first paragraph, they mentioned a three lead system that includes the RV/CS/SQ, RV/SVC/SQ, RV/SQ, and RV/SVC.

   Does Medtronic plan on including the use of a one lead/patch (RV/SQ) and/or a two lead (RV/SVC, RV/CS) system as a recommended implant technique? Have they tested this type of two lead system? Does the use of the RV/CS/SVC configuration in only 37 out of 702 lead system preclude the use of this configuration, in comparison the configurations using the SQ patch?

   It is stated on page S21, table IF-3, the breakdown of the of the lead systems used. The total is 702, yet, there are 757 patients implanted with the PCD Transvene system. Please explain the disparity, and describe what, if any, other implant configurations used with the Transvene Leads.

2. Table IK-5 on page S45 lists the Survival Analysis for patients not meeting the implant criteria for the PCD Transvene System and the patients not meeting the implant criteria for the PCD Epicardial System.

   Please explain the breakdown of survival rates for those patients not meeting the PCD Epicardial Implant Criteria when there is a total of 92 patients, of which there are 17 patient deaths (18.5%).

3. On page 105 of the amendment, the response to question 26, listed in tabular form is the breakdown of venous entry sites for the RV and CS/SVC leads. What about a breakdown of the entry sites for the SQ lead? Please provide.

These are initial concerns that I have with this amendment, that I am submitting to comply with the May 17,18 Panel decision date. I will submit further concerns if and when they arise.

SUMMARY: The company has provided the responses to the questions asked in the FDA letter sent to them regarding the review of this Non-Thoracotomy Lead System. The data provided appears to be satisfactory, although several concerns have arisen regarding the presentation of this data. The course of action to be taken is to explore any and all concerns questions that may arise from the review of the amendment prior to the panel taking place.

The recommendation for this application is to submit this to the panel at the earliest time possible.

Albert Moyal MD

Albert Moyal.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Transvene Lead System
Date: April 19, 1993
Office: DCRND/ODE

The manufacturer responded to the deficiencies listed in our letter of March 17, 1993. The data provided in the referenced amendment includes the experience of the PMA population (757 patients) as of a data cutoff of February 1, 1993. The letter contains deficiencies from a team of reviewers. The team consists of a medical officer, 3 scientific reviewers (including myself) and a statistician. The memos from the other reviewers will address specific requests.

Request # 1

We told the company to state the hypothesis and the objectives of the study. The hypothesis of the PCD Transvene clinical study is to demonstrate that the PCD Transvene System is safe and effective in treating VT and VF. We also asked the manufacturer to: (1) address the use of a control and the rationale for not using a concurrent control during the study; (2) randomization; (3) endpoints of the study; and (4) how the data will support the specified endpoints.

Objectives of the Study

The objectives are to determine the safety and effectiveness of the Transvene Lead System by:

- evaluating the sensitivity and specificity of the PCD with the Transvene lead system in detecting episodes of VT and VF. To evaluate the ability of the system to appropriately discriminate between VT and VF and other potentially nonmalignant rhythms;
- monitoring the efficacy of the PCD with the Transvene leads in treating VT and VF episodes;
- evaluating the performance of the Transvene leads;
- estimating one year sudden cardiac death survival and overall survival; and
- evaluating the safety and performance of the Model 9710 Programmer and the Model 9788 (b)(4) software cartridge in terms of effective programming.

Use of a Control

In addressing the use of a control, the PCD Epicardial (Epi)

system which is used as a control is similar to the PCD Transvene system with the exception of the lead system used. The manufacturer considers the PCD Epi group as the most closely matched population to the PCD Transvene population. This is because there is concurrent enrollment of the patients in the studies. In addition, the primary indications, implant criteria and clinical data requirements are identical for the two groups. A comparison between the PCD Transvene and Ventak P Epicardial lead system was also made. This was done essentially for comparison of the desired endpoints (overall survival and sudden cardiac death survival).

Randomization

In addressing the issue of randomization, the manufacturer identified patients who may not be able to withstand a thoracotomy. Therefore, randomization would not be feasible or clinically appropriate for these patients. These patients include: (1) those where there is no indication for concomitant surgery at the time of ICD implant; (2) those with pulmonary disease; (3) those with severe congestive heart failure; and (4) those who may require open chest procedures for treatment of their CAD or cardiac transplant. In these cases, the non-thoracotomy lead system is considered as the only therapy available for the ICD candidates.

Randomization was not employed, nor considered during the design of this study. This was due to: the investigators' preference; the known risks to the patient which are associated with a thoracotomy; and the urgency regarding the public health need for the product. A study such as the PCD Transvene will aid in determining, and/or making a case for or against a randomized trial involving nonthoracotomy and thoracotomy leads. The study could generate certain questions or concerns which could be answered through a randomized trial.

Endpoints of the Study

- freedom from sudden cardiac death and all causes of mortality shown through the 1 year survival; and

- treatment efficacy of spontaneous episodes of VT and VF episodes.

The data which will be used in the support of the endpoints will include data from the following: (1) patient deaths (sudden cardiac death survival and overall survival at 1 year); (2) complications and observations; (3) patient indications; (4) VT and VF detection and therapy performance; and (4) PCD Transvene System performance.

Request # 2

We asked that the manufacturer provide a side-by-side comparison between the PCD Transvene and the PCD Epi populations, and the PCD Transvene and the Ventak P AICD populations. The comparison between the named groups included: patient demographics; implant data (DFTs); programmed parameters; spontaneous VT and VF efficacy; complications an observations; and 1 year actuarial survival.

Comparison - PCD Transvene and Ventak P Epi

There were more patients with the indication of sudden cardiac death in the PCD Transvene group than in the Ventak P Epi group. The results of the Cox regression analysis showed that primary indication had no influence on the probability of survival. Therefore, it was considered that the two groups could be compared. Basically, the two groups were found to be comparable. The sudden cardiac death survival rates for the two patient groups were also comparable (99.7 percent for the PCD Transvene and 98.6% for the Ventak P Epi.

Comparison - PCD Transvene and PCD Epi

It was noted that there are more patients with the primary indication of sudden cardiac death in the PCD Transvene than in the PCD Epi population. As with the Ventak P analysis, the results showed that primary indication did not have an impact on patient outcome. The spontaneous VT episode efficacy for the PCD Transvene System was 98.4% which is comparable to that of the PCD Epi System of 98.3 percent. The spontaneous VF episode efficacy for the PCD Transvene System was 98.4 percent which is comparable to 98.7 percent reported for the PCD Epi System. The incidence of lead related complications is somewhat higher in the PCD Transvene population versus the PCD Epi population (15.1 percent versus 2.8 percent). The incidence of observations was statistically lower in the PCD Transvene group. The sudden cardiac death survival rate for the PCD Transvene was 99.5 percent and 98.9% for the PCD Epi group. The overall one year actuarial survival (including death from all causes for patients receiving the PCD Transvene System was 93.3 percent. A marked improvement of the overall one year survival for the PCD Epi of 88.6 percent. It is believed that the improvement is primarily due to the improvement in perioperative mortality of the PCD Transvene System (0.7 percent for the Transvene and 5.3 percent for the PCD Epi).

The implant pace/sense parameters (pacing threshold, R wave amplitude, slew rate and resistance) were found to be statistically significant. The mean implant DFT for the PCD Transvene System and PCD Epi System was 14.8 Joules (J) and 9.8 J respectively.

The majority (574 (75.3 percent)) of the patients in the PCD Transvene study had defibrillation programmed in the sequential pathway. Two hundred and fifty-one (33 percent) patients in the PCD Epi study were programmed in the sequential pathway. Four hundred and ninety-six (65.2 percent of the PCD Epi population were programmed with single defibrillation with only 10 (1.3 percent) patients in the PCD Transvene group with single.

Overall, the two groups were considered as closely matched as possible. The inherent difference being the design of the lead system.

Request # 3

The manufacturer provided an update of the PMA population (757 patients with a mean implant duration of 11.7 months) as of February 1, 1993.

Experience of Patients with the Dual Anchoring Sleeves

Two hundred and thirty-four patients (not included in the PMA population of 757 patients) were implanted with two anchoring sleeves. These patients received an additional sleeve due to the reported cases of lead dislodgement. This group of patients was similar to the PMA population with a slightly higher percentage of VT patients. Of the 234 patients, 186 have been followed for one month and 49 patients have been followed for 3 months. Only one lead dislodgement was reported in these patients.

Clinical Experience - Patients Followed for One Year or Greater

- 393 patients followed for one year or greater
- mean follow-up time 16.3 months
- primary indication: SCD - 150 (38.2 percent), VT - 191 (48.6 percent) and SCD/VT (52 (13.2 percent)
- defibrillation pathway: sequential - 296 (74.9 percent), simultaneous - 93 (23.6 percent) and single - 6 (1.5 percent)
- mean LED - 15.6 J (N= 365), mean DFT - 14.3 J (N=184)
- spontaneous VT success (99.0 percent)
- spontaneous VF success (98.6 percent)
- patient deaths - 7 (0 sudden cardiac, 4 nonsudden cardiac and 3 (noncardiac)

- complications - 89 in 76 patients (19.3 percent)

- observations - 122 in 99 patients (25.2 percent), forty of the observations involved inappropriate VT therapy delivery and 29 observations associated with oversensing

- none of the complications and observations resulted in patient death

Lead Dislodgements

Twenty-nine lead dislodgements occurred at greater than 30 days. None of these dislodgements resulted in ineffective therapy for the treatment of spontaneous episodes of VT or VF or patient death. The dislodgements were found during fluoroscopy at EP evaluation, chest x-ray or during pacing/sensing threshold evaluation during follow-up testing. In 29 cases, reoperation was necessary to reposition the lead.

Request # 4

A discussion of the implant criteria and how the implant testing attempted to satisfy the protocol requirements was provided.

The manufacturer described the patients who did not meet the implant criteria. These patients are among those patients referenced above who are at risk with a thoracotomy procedure. In these cases the investigators felt that if the patients had a lowest energy to defibrillate (LED) of 24 J, then they could be implanted with a 10 J safety margin (34 J max output of the device).

Request # 5

We requested that an update of the clinical experience of the patients who did not meet the implant criteria be provided. Also, a discussion regarding how the proposed labeling will address the deviation was requested.

One hundred and seventy patients did not meet the implant criteria, but had successful defibrillation at 24 J, were implanted with the PCD Transvene System. In determining if the patient's not meeting the implant criteria had a higher risk for morbidity and mortality, a comparison of their survival was made. There were no statistically or clinically significant differences in outcome between the patients who met the implant criteria and those who did not (one year survival - overall 93.8 percent for the patients not meeting the implant criteria and 93.2 percent for the patients who met the criteria).

Of the 170 patients, 41 complications were reported in 33 (19.4 percent) patients and 34 observations were reported in 31 (18.2 percent) patients. None of the complications and observations resulted in patient death.

Lead Dislodgements - Patients who did not Meet the Implant Criteria

There have been 14 lead dislodgements which occurred at greater than 30 days. The dislodgements were discovered and documented as described in the PMA application. In all 14 cases reoperation was required to reposition the lead.

There were no clinically significant differences in the characteristics and patient outcome of the patients who did not meet the implant criteria versus those who did. Based on these data, the manufacturer plans to recommend revising the defibrillation efficacy requirements to include the following: (1) two consecutive successful defibrillations with the final lead configuration with a stored output energy of 24 J or less; or (2) three successful defibrillations in four attempts with the final configuration at a stored output energy of 24 J or less.

Request # 6

Twenty patients who did not meet the implant criteria were implanted without the 10 J safety margin. We asked that an update of the clinical experience of these patients be provided. The mean ejection fraction of these patients was 26.9 percent. It is believed that the patient's condition was responsible for the termination of the implant procedure which resulted in the patients not meeting the implant criteria. Of these 20 patients, VT was induced at chronic follow-up in 16 patients and in all cases successful treatment was documented. The overall spontaneous VT episode efficacy was 98.9 percent. The spontaneous VF efficacy was 96 percent. There have been 2 deaths, both classified as nonsudden cardiac secondary to end stage heart failure. The one year sudden cardiac death survival in this population is 100 percent. The overall one year survival was 85.5 percent.

Request # 7

The manufacturer provided a table with percentages and the numerical support where appropriate.

Request # 8

An update of the patients who were implanted with the Transvene Lead system and were not counted in the PMA population was provided. The data covers a total of 1335 implants in 1330 patients with the PCD Transvene Lead System (757 patients in the PMA population and 573 additional patients). Of the 1330

patients, the primary indication was VT in 725 (54.5 percent). The spontaneous efficacy for VT and VF was 98.1 percent and 98.1 percent respectively. The overall survival was reported as 93 percent.

As of February 1, 1993, there have been 225 complications reported in 195 patients and 275 observations reported in 228 patients implanted with the PCD Transvene Lead System. How many of the complications and observations were from the additional 573 patients? According to the manufacturer, the percentage of patients with a complication or observation has decreased compared to the original PMA population of 757. Also, according to the applicant, the percentage of patients with lead dislodgements was reported to have also decreased from 12 percent of the population with a complication to 8.8 percent, and from 1.60 percent of the population with an observation to 0.9 percent.

Of the 1330 patients, there have been 30 (2.3 percent) complications involving pocket infection, and a total of 117 (8.8 percent) lead dislodgements. Included in the lead dislodgements, there were 36 cases which involved the SVC lead. (The manufacturer should discuss this information to clarify that every attempt has been made to address the complications. There should be evidence that the frequency of the complications has decreased.) There have been a total of 68 deaths (10 sudden cardiac, 37 nonsudden cardiac and 21 noncardiac) of the population of 1330 patients. The patients in whom the PCD was programmed OFF were included in the survival analysis. The perioperative death rate was 0.8% (10/1330). The one year actuarial survival rates were reported as follows: sudden cardiac death - 99.3 percent; nonsudden cardiac - 96.3 percent; all cardiac - 95.6 percent; noncardiac - 98.1 percent; perioperative - 0.8%; and overall - 93 percent.

Request # 9

We asked that the manufacturer differentiate between DFT testing and lowest energy to defibrillate (LED) testing. Also, we asked that samples of patient report forms which show the scheme of testing which was used in determining DFT and LED be provided. DFT testing was described as 3 out of 4 successes at 18 Joules. The protocol which included step down testing was included. The investigators were allowed to waive the step down testing if the patients could not tolerate the additional VF inductions. In these cases, the LED which is the lowest energy that successfully defibrillated the heart was programmed.

Request # 10

There was a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and other configurations. We asked the manufacturer to discuss the difference and the intended ramifications. The manufacturer

stated that the tests demonstrated that the RV-CS-SQ configuration had a lower DFT than the other configurations. This was simply due to the energy being better distributed throughout the myocardium with this configuration. It was pointed out that the intent of the study was not to show that lower DFTs result in better patient outcome. The primary emphasis was to demonstrate that the patient could be reliably defibrillated over time, and that there is a high probability of survival from sudden cardiac death regardless of the lead configuration or pathway chosen.

In terms of comparison of the PCD Transvene and PCD Epi groups, it was stated that the defibrillation efficacy protocol was identical for both groups.

Request # 11

The manufacturer provided a discussion of the DFTs or energy requirements obtained with the use of the single versus the sequential and simultaneous pathways. Essentially, even though the majority of the patients in both PCD populations were programmed with different defibrillation pathways, the DFTs were comparable (single - mean DFT 10.5 J and for sequential/simultaneous - mean DFT 8.8 J). It was reported that there was no difference in outcome for the patients with either of the systems.

Request # 12

According to the manufacturer, the time between detection and delivery of therapy of the PCD Transvene System is dependent upon the programmable VT and VF detection parameters. (The manufacturer should respond to the effect that an increase in lead impedance could have on the time from detection to delivery of therapy). In both of the PCD populations (Transvene and Epi), the majority (90 percent) of the spontaneous episodes of VT and VF were converted with the first shock. The most frequently programmed VT detection and therapy parameters were: VT number of intervals to detect (NID) (b)(4) VT tachycardia detection interval (TDI) (b)(4) VT therapy # 1 type - (b)(4) VT therapy # 1 parameters (b)(4) percent rate adaption, (b)(4) (b)(4) sequences, (b)(4) ms decrements; VT therapy # 2 type - cardioversion; and VT therapy # 2 parameters (b)(4) The most frequently programmed parameters for VF detection and therapy included: VF number of intervals to detect (NID) (b)(4) VF tachycardia detection interval (TDI) (b)(4) VF therapy #1 type/parameter - defibrillation/(b)(4) J; charge time for VF therapy # 1 -(b)(4) seconds; VF therapy # 2 type/parameter - defibrillation/(b)(4) and charge time for VF therapy # 2 -(b)(4) seconds.

Request # 13

In response to the deficiency regarding the 2:1 VF sensing margin, the manufacturer provided the following information. The

recommendations for programming include a programmed sensitivity value of 0.3 mV for the PCD. During defibrillation testing, the ETCD is programmed with a nominal sensitivity value of 1.2 mV which is four times the nominal sensitivity setting (0.3 mV) of the PCD. When the PCD is programmed at 0.3 mV, it provides a four step safety margin (because sensing was evaluated at a value four times less sensitive than the programmed value). When the device is programmed at 0.6 mV, there would be a 2:1 VF sensing margin. It was stated that all of the patients who received the PCD Transvene System had a 2:1 VF sensing margin. At the last known follow-up, the manufacturer mentioned that 76.6 percent of the patients were programmed to 0.3 mV and 22.3 percent were programmed to 0.6 mV. There have been no reports of undersensing during induced VF episodes and no deaths due to the nondetection of a spontaneous VF episode.

Request # 14

As of the June 24, 1992 data cutoff, 130 of the 329 patients followed for 6 months or greater had a spontaneous VT episode with a mean of 28.9 (3752/130) episodes per patient. One hundred and twenty patients had a spontaneous VF episode with a mean of 5.6 (667/120) episodes per patient. A total of 179 patients had either spontaneous VT or VF episodes with a mean of 24.7 (4419/179) episodes per patient.

Of the 115 patients followed for 12 months or greater, 60 patients had a spontaneous VT episode with a mean of 29.5 (1770/60) episodes per patient. Thirty-seven patients had a spontaneous VF episode with a mean of 6.7 (248/37) episodes per patient. A total of 67 patients had either spontaneous VT or VF episodes with a mean of 30.1 (2018/67) spontaneous episodes per patient (will be updated).

Request # 15

We asked that clarifications be provided regarding how the treated episodes, designated as success or failure, were categorized. The manufacturer reiterated that spontaneous episodes (VT and VF) are defined as those which satisfy the detection criteria for VT and VF. A table which included the spontaneous VT and VF experience was provided. The table clearly outlined the experience which included a breakdown of the number of episodes and patients and the ineffective episode experience.

It was noted that 60 patients had 163 VT episodes in which the PCD was ineffective in terminating the spontaneous episode of VT despite the delivery of all four therapies. No patient deaths occurred as a result of the ineffective VT therapy. Reprogramming and an adjustment of the patient's drug regimen resolved the problems. There are no concerns regarding the data as presented.

Sixteen patients experienced 31 episodes of VF in which the PCD

was ineffective in terminating the episodes despite the delivery of all four programmed VF therapies. Three of the patients experienced ineffective therapy of a spontaneous VF episode due to lead performance or "secondary to a terminal event." One patient had an episode of ineffective VF therapy due to lead dislodgement. A second patient had an episode of ineffective VF therapy due to lead fracture which generated "noise" which was detected as VF by the PCD. The third patient had two episodes of ineffective therapy at the time of his "monitored" death. Pharmacologic intervention and reprogramming was used in resolving the events associated with the majority of the 16 patients.

Request # 16

The Table IM-6 was modified to include the episodes which were unsuccessfully terminated due to atrial fibrillation or sinus tachycardia. The percent of unsuccessful termination (ineffective in terminating the arrhythmias despite the delivery of all four therapies) is also included for VT and VF. There was a higher incidence (0.9 - Epi and 0.4 Transvene) of unsuccessful termination of VT with the PCD Epi System versus the PCD Transvene System. The information in the Table is as of the June 24, 1992 cutoff date. It is unclear if the data on the proceeding pages are as of the updated cutoff (February 1, 1993). These data state that 30 patients out of 757 had 68 spontaneous VT episodes where the PCD was ineffective in terminating the episode despite delivery of all four therapies. Twenty-five of the patients experienced 45 (0.9%) episodes which were due to sinus tachycardia or atrial fibrillation/flutter with a rapid ventricular response which were detected as VT. Five patients in the Transvene population had 9 spontaneous VF episodes where the device was ineffective in terminating the episode despite the delivery of all four VF therapies. This was due to the detection of sinus tachycardia and atrial fibrillation with a rapid for The device responded appropriately as programmed. However, the rhythms were not VF as seen by the device. Reprogramming and pharmacologic intervention resolved these problems and those mentioned regarding the detection of the spontaneous episodes of VT.

Request # 17

We asked for a clarification regarding the category "Failure to Cardiovert/Defibrillate" and how an episode of an inappropriate therapy is categorized. The manufacturer reported that the incidence of "Fail to Cardiovert/Defibrillate" was 0.8 percent is now 1.2 percent due to the increased follow-up time. The manufacturer stated that the instances of failure to cardiovert and/or defibrillate were due to increased defibrillation requirements during induced episodes of VF. It was stated that the failures reported in the article by Winkle, et. al, (AICD patient population used for comparison to the PCD Transvene population) were associated with patch dislodgement, patch

crinkling, lead conductor fracture and elevated defibrillation thresholds due to changing patient condition. The comparison between the complications/observations of the PCD Transvene and the AICD showed a somewhat greater incidence of pocket infection within the PCD Transvene population.

Request # 18

We asked the manufacturer to differentiate between the 38 inactive patients reported in Table IH-1 (previous amendment) and the 34 patients who were reported as no longer active. The manufacturer stated that the amendment contained an error. According to the manufacturer, the text preceding the Table should have read, "there are a total of 38 patients who had received a PCD System and are no longer active in the study as of 6/24/92." As of the data cutoff, it was reported that 82 patients (patient deaths - 51, infection (explant) - 22 and heart transplant - 9) who received a PCD system are no longer active in the study.

Request # 19

This request had to do with how the sudden cardiac death survival was calculated and if all patients who had a prior cardiac arrest were included in the analysis. The manufacturer adequately responded to the request. It was mentioned that additional data regarding the statistics would be available upon request if there was a need to verify the survival probability. It was mentioned that all patients in the Transvene study were included in the analysis regardless of the indication or prior cardiac arrest status.

Request # 20

At our request the manufacturer included the number of patients in the referenced Table with the percentage and calculated p-values. It was again referenced that verification of the percentages and p-values are available upon request.

Request # 21

As requested, the manufacturer stated that the null hypothesis was that the patient characteristics are equivalent for the three lead configurations: RV/SVC/SQ, RV/CS/SQ and RV/CS/SVC. The Chi-Square test was used to test for association between variables (the Pearson chi-square statistic was used). The commercial statistical software package was used in calculating the statistical information presented in Table IV-C. The validity of the statistical analyses performed along with statistical methods employed will be reviewed by FDA's statistician.

Request # 22

In order to justify data pooling and data analysis, the FDA

statistician questioned the statistical procedure which was used. The manufacturer responded by saying that there is no reason to adjust the significance level below 0.05 to eliminate type 1 errors because none of the comparisons are significant at a 0.05 significance level. However, the adequacy of the response will be addressed by the statistician.

Request # 23

The manufacturer discussed how the confidence interval was calculated. According to the manufacturer, the interval was calculated by taking the survival probability (b)(4) the (b)(4) (survival standard error). It was stated that the survival standard error was (b)(4) therefore the confidence interval for Transvene survival at 1 year was 95.3 ± 2.2 or [93.1, 97.5]. The statistician should review this response. provided.

Request # 24

Clarifications regarding the information presented in Table XB-1, page 378 of Volume 2 were requested. The response involved the use of the (b)(4) computer software in analyzing whether there were significant differences between the PCD and Ventak P populations. The FDA statistician should also address the adequacy of this response.

Request # 25

The manufacturer discussed the instances of inappropriate therapies. The majority of the cases involved atrial fibrillation with a rapid ventricular response or sinus tachycardia. In these cases the rhythms overlapped the programmed detection criteria. In cases like these, the investigator either reprogram the device or modifies the patient's drug regimen. The manufacturer stated that the labeling for the PCD contains programming recommendations and warnings for potential programming problems.

The Manual also contains explicit recommendations for programming the Onset Criterion and the Stability Criterion. It was reported that as of February 1, 1993, 33 of the 757 Transvene patients had the Onset Criterion enabled and 55 patients had the Stability Criterion enabled. Eleven of the patients had both the Onset and the Stability algorithms enabled. The majority of the patients with the Onset and Stability enabled had the algorithms programmed ON within 30 days of implant. However, many patients had the algorithms programmed ON for the first time very late in the follow-up period. The efficacies for the treatment of VT and VF (induced and spontaneous episodes) when the algorithms are programmed ON were provided. In the cases of induced episodes, it was reported that the PCD performed appropriately. Specifically, the spontaneous experience includes the following:

The efficacies for VT and VF of the patients with the Stability Criterion programmed ON was 94.8 percent and 100 percent respectively. The efficacy for VT and VF in patients with the Onset Criterion programmed ON was 97 percent and 100 percent respectively.

Request # 26

We asked the manufacturer to provide a discussion of the "device related" complications reported for the Transvene and the PCD epicardial populations. The manufacturer stated that "device related" complications have reference to the complications which resulted in explantation of the device for reasons other than death, infection or transplant.

There were 4 patients within the Transvene population who were explanted due to reasons other than those named above. Reasons for explant included: (1) low battery voltage due to leakage at the input of one of the integrated circuits; (2) failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode; (3) Power on Reset condition which was not related to the delivery of external defibrillation or cautery; and (4) inappropriate delivery of VF therapy during manual capacitor charge time. In all cases, it was reported that the devices were safely replaced with no adverse consequences to the patient.

There were 7 patients in the PCD Epi population in whom the PCD was explanted due to reasons other than death. The reason for explant in all 7 cases was because of lower than expected battery voltage. The causes for low battery voltage included the following: (1) failure of the integrated circuit; (2) leakage at the input of one of the integrated circuits; and (3) tantalum capacitor leakage. In all of these cases, the devices were also safely removed with no adverse effects on the patients.

There were 4 patients in whom the PCD was explanted due to reasons other than those mentioned above. In these cases the events were classified as complications. These cases involved: low battery voltage (1); inappropriate VF therapy (1); failure to synchronize and delivery therapy (1);and Power On Reset condition due to electrocautery or external defibrillation (1). (The results of all pending analyses should be provided.

Request # 27

The manufacturer discussed complications reported in the patients followed for one year or greater. As of February 1, 1993, there have been 393 patients implanted for one year or greater. There have been 89 complications reported in 76 patients and 122 observations reported in 99 patients. Therefore, 19.3 percent (76/393) of the patients had an event categorized as a

complication and 25.2 percent (99/393) had an event categorized as an observation. The observations included 40 cases of inappropriate VT therapy and 29 cases of oversensing.

The complications included 5 cases of pocket infection, 6 cases of lead fracture and 56 cases of total lead dislodgement. Of these there were 29 dislodgements which occurred at greater than 30 days. Reoperation was required in all cases to reposition the lead.

None of the complications and observations have resulted in a patient death.

Request # 28

We questioned the infection rate reported for the Transvene study. The manufacturer stated that the incidence of infection in the Transvene study is not significantly different form that reported for the Ventak P epicardial lead system (2.3 percent for the Transvene and 2.4 for the Ventak P). The manufacturer feels that there is no substantial increase in the infection rate. Therefore, the current labeling is appropriate.

Request # 29

The manufacturer discussed the experience in the use of the different entry sites. We wanted to know whether the labeling would aid in the selection of an entry site. The manufacturer stated that the left subclavian vein was the most frequently used entry site regardless of the lead and location. It was stated that the physician makes the decision about the specific entry site. However, the technical manuals contain information about the selection of a entry site, and cautions regarding the different entry sites. There are no specific concerns regarding this information.

Request # 30

This deficiency asked about the Transvene Systems that were explanted, returned and analyzed. Of the 762 implants in 757 patients, 41 units were explanted. Fifteen systems were explanted due to patient death, infection (17), cardiac transplant (5) low battery voltage measurement (1) and PCD performance issues (3). Fifteen systems of the 22 deaths were explanted and returned to the company for analysis (five systems were interred with the patients). Of the 15 systems which were returned, ten were analyzed and found to be performing to specifications. Of the 41 devices explanted, final analysis on 19 systems showed that the systems were performing to specifications. It was reported that final analysis is pending on 17 units. The report of the analyses of these units should be provided. The manufacturer mentioned that of the 41 lead

systems, 21 lead systems or portions of the systems were returned. Of these 21 lead systems, the helix of one 6966 lead was damaged (explant data will be updated in requested volumes).

Request # 31

The manufacturing discussed the death of the patient who died 22.5 months post implant. The manufacturer stated that the patients was admitted to the hospital for heart failure and increased episodes of VT and VF. In addition, the patient was reported to have digitalis toxicity. The patients later expired, described as secondary to heart failure due to LV dysfunction. The death was categorized as nonsudden cardiac and not related tot e PCD Transvene System. Interrogation of the device at the explant revealed a normal battery voltage and charge time. Therefore, the patient had experienced no new episodes of VT or VF since the last follow-up visit. The analysis showed that the PCD was performing to specifications. Were the leads returned and analyzed?

The manufacturer provided all relevant data (implant and follow-up data, programmed status of the PCD, etc.) pertaining to the patient (PCD Serial Number (b)(4) implanted for 22.5 months.

Request # 32

We asked about the number of perioperative deaths, and if in these cases there were devices programmed OFF. As of February 1, 1993, there have been 51 deaths in the Transvene PMA population. Five (0.7 percent) of the deaths were perioperative (sudden cardiac (2, nonsudden cardiac (2) and noncardiac (1)). The patient death in which the PCD was programmed OFF, was classified as non-sudden cardiac not related to the tachyarrhythmia episode. A copy of the death summaries was provided for our review.

Request # 33

This deficiency deals with the 1 year sudden cardiac death survival and overall actuarial survival of the patients followed for a year. According to the manufacturer, the survival calculations took in to account the following: all of the patients were alive at one year post implant so their survival from all causes of death was 100 percent. Patients who died within 30 days are not counted within this group. There are no concerns about how the manufacturer addressed this deficiency.

Data (treatment efficacy, lead orientation, complications and survival rates, etc.) of the patients who have been followed for 1 year or more were provided. Of the 115 patients followed for one year or more, the majority (94.7 percent), the primary indication was recurrent, sustained VT without an episode of sudden cardiac death. The treatment efficacy for the patient

population was 98.9 percent for spontaneous VT and 98.8 percent for VF. The treatment efficacy is equivalent to the overall patient population. Twenty-four of the patients followed for 1 year or more had a complication. There are no specific concerns regarding the data submitted.

Request # 34

The manufacturer provided an engineering drawing of the Transvene lead models and a description of the testing of each segment and the full lead body. These data have been reviewed in the IDE application. However the adequacy of the response will be assessed by one of the reviewers on the team.

Request # 35

We asked that the manufacturer discuss the adequacy of the flexing procedures employed (b)(4) cycles at a bend radius of (b)(4) inch per lead model over a (b)(4) month period). The manufacturer discussed the life testing protocol and how the leads were tested. These data were also reviewed in the IDE application. We asked that the manufacturer document, for clarity, all relevant testing of the Transvene leads. The response will be reviewed further by one of the reviewers on the team.

Request # 36

The manufacturer provided documentation regarding the potential for failure of the platinum sputtered Transvene Model 6966. A side-by-side comparison of the Model 6966 and the 4,000 series bradycardia leads (platinum sputtered leads where failure was noted) was included. The review of other team members will specifically address the specifics of the response.

Request # 37

The manufacturer provided a copy of the Summary of Safety and Effectiveness with the updated clinical data.

The manufacturer submitted copies of the technical manuals for our review. Data as referenced in the review will be considered for incorporation into the labeling. At this time there are no specific concerns. The Transvene Lead System will be labeled for use with the pulse generator with which it has been tested. Namely the Medtronic Model 7217B PCD.

It should be noted that as a condition for approval of expansion (allotment of 200 patients per month), the manufacturer has agreed to submit monthly reports. The reports should include a

trend analysis of the observations and complications, returned devices and deaths. These data will be a beneficial adjunct to the data contained within the PMA application. These data will lend support and help to alleviate any concerns which might be related to the incidence of complications and observations reported for the PCD Transvene System.

Discussion of the Review of the PMA Application for the PCD Transvene System

The manufacturer has responded satisfactorily to the deficiencies listed in our letter of March 17, 1993. Several issues which are noted in the teleconference memo (attached) were discussed with the manufacturer. Namely, presentation of the data for Panel review, questions pertaining to the performance of the PCD Transvene and the reported observations and complications. The manufacturer adequately responded to our questions and/or agreed to include specific data in the Panel PMA volumes.

Teleconference

Between: Medtronic Representatives
And: Doris Terry (HFZ-450)
Date: April 29 - May 17, 1993

We discussed and/or requested the following:

1. Updated information on patients with non-standard Transvene configurations should be provided. It was stated that twenty-four patients received the Transvene leads initially (not counted in the 757). Need data on this group. Four of the patients with non-standard configurations received the leads after implant and are counted. Data are not separated out. The manufacturer will provide a "patient tree" which includes all patients.

2. Updated data on the 97 patients who were screened for the Transvene and went on to receive the Epi system should be provided.

3. How many of the patients followed for a year or greater did not meet the implant criteria? Need to know the experience of these patients.

4. The PMA Data should be arranged to include the following sections for panel review:

   Preclinical Tests (Bench, Animal, Life)

   Investigational plan (protocol, hypothesis, objectives of the study, patient report forms)

   Updated clinical report

      Patients who did not meet the implant criteria.
      Patients in the non-standard lead configuration
      Patient followed for one year and greater
      patient followed for 6 months and greater
      (spontaneous experience)
      experience by primary arrhythmia
      Foreign patients

   Observations and Complications

   Additional Transvene patients

   Pertinent Data from June 24, 1993
   Clinical Report

   Comparison Data

Explants

Deaths

Labeling

Summary of Safety and Effectiveness

Survival curves (statistics)

Pertinent Articles (when referring to an article, please include)

Patient Manual

Responses to FDA Concerns (Reviewers and Statisticians). All questions will be included an addressed. If data are incorporated into other sections of the volumes, the section and page number will be referenced.

4. A comparison table of mortality and survival data for the PCD Epi and PCD Transvene and the Ventak P should be provided.

5. Number of patients followed for one year or greater who had spontaneous episodes or were induced after 6 months. Update of Table, page 73.

6. Update of table (complications and observations by follow-up interval) as presented in Volume 2, September 21, 1992 amendment. Complications and observations for the two patient populations (PMA cohort and additional Transvene patients) should be reported separately.

7. Update on foreign experience, namely complications and observations.

8. Trend analysis of the incidence of complications observations and complications within the patient groups (patients followed for 1 year and more, patients implanted with nonstandard lead configuration, etc.) and by primary indication (VT, VF, and VT/VF). These data should be updated. Statistical methods employed should be identified.

9. The complications and observations of the 573 additional Transvene patients should be reported separately. How many have dual sleeves?

Update on experience with dual anchoring sleeves. Update on

573 patients, complications and observation by follow-up.

10. There should be a section which includes ineffective therapies. The Section should report the circumstances surrounding these patients.

11. There should be an update on the reprogrammings (Table VIIF-5, September amendment).

12. Incidence of ineffective therapies with the PCD Epi and PCD Transvene. Updated data as reported in Table IM6, page 78 of the March amendment should be provided.

13. Data obtained from interrogation of the device upon the patient's death should be provided. The data should be referenced as explant data.

14. On Page 338, it was stated that all 58 devices were returned. A Table which contains these data should be prepared.

Continued - May 12, 1993

15. Evidence to support the claim that gender, primary indication and the system implanted (PCD Epi or PCD Transvene) had no impact on survival outcome. The evidence would consist of a description of the computer program used, data input and output, and the decision criteria.

26. A statistically significant difference between the PCD Transvene and the AICD Epicardial System using the confidence interval analysis was found. How was the confidence interval computed?

27. The table on page 24 shows the actuarial survival of PCD Transvene versus PCD Epi. The statistician would like to see a Table which includes mortality data according to monthly intervals, e.g., number dead/number at risk for the Transvene and Epi systems. Then the Mantel Haenszel Chi square test should be used to compute the p-values. The manufacturer should also discuss how the p-values in Table 2-16, page 24 were derived.

28. Based on the clinical experience, will include addition to the labeling: different positions for patch placement. Majority (75 percent) of patients had patch leads placed at the mid axillary line or fourth or fifth intercostal space. Data will be provided about surgical approach.

29. In support of the chronic performance and integrity of the lead system, We asked the manufacturer to provide data regarding the induced and spontaneous activity of the

patients followed for 6 months and beyond. We reiterated that they should be able to account for the experience of each patient. Each of the patients should have been tested or should have had spontaneous episodes. The data can be presented at 90 days and beyond, 6 months and beyond, 12 months and beyond, etc.

30. Results of remaining analyses on all device explants. should be provided. Note: There was a total of 58 explants.

31. Update of the observations and complications as per the time interval. The data in Table XII-E-2 in the September amendment will be updated.

32. In response to Albert Moyal's review, I asked the company about the use of a two lead configuration. The manufacturer stated that the patients who were implanted with a two lead configuration are counted within the group of patients (43) with a non-standard configuration. Among these, 6 patients have a RV-SVC or RV-SQ; and 10 patients have three leads, programmed in a two lead configuration.

    The 702 patients counted in the table on page 289, March Amendment, include only those patients who had LED and/or DFT testing. Other concerns included in the reviewer's memo will be documented in a phone conversation by the reviewer.

The manufacturer agreed to provide the requested information.

Response to Statistician's Review

Items # 2.1 and 2.2

The statistician stated that the p-values for sex and primary indication rendered the two groups (PCD Transvene and PCD Epi) significantly different. Therefore, the statistician contends that the two groups are not "compatible." According to the manufacturer, primary indication and gender did not impact survival. However, the implanted system did influence the probability of survival. The manufacturer used the Cox Regression Analysis to support this position. The statistician asked that the manufacturer provide evidence (description of the computer program, the data input and output and the decision criteria which were used) to support the claim. The request was discussed with the manufacturer. Appropriate data will be submitted in the Panel Volumes to address this issue.

Item # 2.3

The manufacturer was asked to provide data regarding how the confidence interval (as referenced on pages 13 and 256, March Amendment) for the one year overall survival data was computed. The response will be included in the Panel volumes.

Item # 2.4

The manufacturer was asked to prepare a table which depicts the number of patients dead versus the number at risk or total patient population at the different monthly intervals, e.g. 0-3, 3-6, 6-9 and 9-12. In addition, the manufacturer was asked to use a specific Chi square test to compute the p-value for the "association" between the Transvene and Epi survival. It was unclear how the p-values were derived. The requested data will be submitted in the Panel volumes.

Item # 2.5

The similarities and differences between Table 2-12 and Table 3-3 essentially involve data presented for the entire population versus patients followed for one year.

Item # 2.6

The data set and a description of the computation procedure for calculating the survival probabilities were requested. These

data are necessary for verification purposes. A response will be included in Panel volumes. The manufacturer mentioned that the requested data consists of reams of raw data. However, a response which includes a description of the statistical procedure utilized and how the probabilities were calculated will be provided.

Item # 2.7

The similarites and differences between the one year actuarial survival in Table 1K-4, page 43 and Table 8-5, page 451 should be discussed. The numerators and denominators used to derive the one year actuarial survival shown in Table 8.5 should be provided in the requested volumes.

Item # 2.8

The data set and the computation procedure (as referenced on page 83) used in the calculation of the survival probability should be provided for verification. Same as in Item # 2.6. However, the requested data will be condensed, and included in the Panel volumes.

Item # 2.9

The manufacturer should provide the data set and the SAS procedure (statistical software package) used to derive the p-values for the data provided in Table 1M-10, page 84. Information will be included in the Panel volumes.

Item # 2.10

The manufacturer reported a p-value of (b)(4) The statistician calculated a p-value of (b)(4) The manufacturer should discuss how the p-value was calculated. The manufacturer will address the difference in the calculations.

Item # 2.11

We requested that the results of the analyses pending on the devices that underwent early explant should be provided. Data will be included in the requested volumes.

Item # 2.12

The choice of 30 days (in reporting lead dislodgement) can be justified because of its use historically on an acute basis. Acute is described as within the first 6 weeks.

Item # 2.13

The concern deals with justifying pooling the data from all 78 centers which participated in the PCD Transvene clinical trial. It should be noted that all centers used the same protocol or investigational plan (patient selection criteria, follow-up plan, data collection procedures, etc.) for the PCD Transvene study. The manufacturer will also address this issue in the data which will be submitted.

Item # 2.14

The statistician stated that Table E-2, page 215 does not provide an adequate presentation of the follow-up data. The statistician directed the manufacturer to Table 4.6 as published in Lee, Elisha, "Statistical Methods for Survival Data Analysis", page 93 to see how the data could be best presented. This was considered as a good reference for preparing a life table analysis. It was pointed out that the manufacturer should also discuss the reasons why some of the patients were not represented in the follow-up data. It should be noted if the patients were withdrawn alive or lost to follow-up. The statistician's request was relayed to the manufacturer. The response will be provided in the Panel volumes.

Item # 2.15

The statistician would like to see the survival table (page 231) stratified monthly as referenced in Item # 2.4. How the projected one year survival calculations were done should be explained. The manufacturer agreed to provide the data for our review.

Item # 2.16

The numerators and the denominators for the percent success (Table I-1, page 233; Table IF-2, page 287 ; and Table IF-4, page 290) for the treatments of spontaneous episodes should be provided. These data will be included in the Panel volumes.

Item # 2.17

The data collected at the designated follow-up intervals will be included in the updated report and reflected throughout the Panel volumes.

Item # 2.18

The manufacturer was asked to address the calculation of the p-values reported in Table 2.16, page 24. FDA's statistician calculated the p-values and obtained different values than those reported by the manufacturer. This will be addressed in the

Panel volumes.

Note: These data are for clarification and verification purposes. The data do not significantly impact upon the safety and effectiveness of the PCD Transvene System. Therefore, the request for these data are being made via a telephone conversation to the manufacturer.

MEMO

To: Doris Terry
From: Quynh Hoang
Date: 1/27/93

Regarding: Review of the Medtronic PCD Transvene System - P920015 amendment dated 9/18/92

SUMMARY

This amendment contains the response to the deficiencies of the original PMA. It also contains a clinical update on the PCD Transvene System.

Response to Deficiencies

The amendment have fully addressed a majority of the deficiencies. There remain, however, a few items which were not fully answered. Please refer to the Questions section below.

Clinical update

The clinical update covers 757 Transvene patients (447 US) in 78 investigational centers (35 US), as of 6/24/92. For the 757 patients, 762 Transvene systems were used since 5 systems were explanted and replaced due to infection. The 762 lead systems included 762 RV leads, 801 CS/SVC leads, and 723 SQ patches.

By indication: 37.1% of the implants were due to SCD (281/757), 49.8 % for VT (377/757), and 13.1% for SCD/VT (99/757). Coronary artery disease existed in 74.1% (561/757). The mean ejection fraction was 35.6% (688/757). Only 1.5% were of NYHA class IV (11/757). The patients were primarily male (80.6%, 610/757) with a mean age of 59.4 years.

At implant: 71.7% (543/757) met criteria, 97.4% (737/757) had at least a 10 J margin safety, and 2.6% (20/757) failed to finish the implant evaluation due to poor conditions. The most chosen Transvene configuration included: left subclavian as the entry site, RV-SVC-SQ as the lead system (65.6%, 500/762), and sequential as the shock pathway (75.3%, 574/762). The RV always served as the common (-) defibrillation electrode. The mean DFT at implant was 14.8J (316/757), and mean LED was 16.0J (702/757). Sixteen patients also have each a concomitant pacemaker.

Follow-up at one year have been performed on 113 patients, and six month follow-up on 329. Spontaneous VT occurred in 226 patients for a total of 5430 episodes. There were 68 episodes (1.3%, 68/5430) in 30 patients where all four VT therapies were unsuccessful

in terminating the problem; none resulted in a patient death. Spontaneous VF occurred in 198 patients for a total of 973 episodes. Nine episodes (0.9%, 9/973) in 2 patients could not be terminated by the four VF therapies; no patient died. At 3 month, the mean DFT was 15.9 J (54 patients), and mean LED was 19.3 J (88 patients).

There were 138 complications occurred in 138 patients (18.2%, 138/757) and 157 observations occurred in 157 patients (20.8%, 157/757). The majority of the complications were because of lead dislodgement (77 cases) and pocket related (26 cases). Most of the observations were due to inappropriate therapies (62 cases), pocket related (37 cases), and pace/sense related (31 cases). Of the 295 complications and observations, 48.1% (142/295) occurred during the perioperative period. There were 22 patient deaths with 5 in the perioperative period. Thirty-eight patients are no longer active in the study (22 deaths, 11 explants due to infection, and 5 heart transplants). Forty-one systems were explanted.

As of 6/24/92, there are also 548 patients who received the Transvene after the cutoff for the study population. These patients and the 43 who received non-standard lead systems were not included in this clinical update.

Please refer to the Questions section below, for the clarifications required of this update.

QUESTIONS

1. Please describe the similarities and differences between the 6966 and 6968 to justify the use of the 6968 lifetest results in supporting the reliability of the 6966.

2. Given their respective defibrillation thresholds, discuss the differences in battery or energy requirement of the Transvene and Epicardial systems.

3. Clearly identify the objectives, endpoints, and indicators which show that the endpoints have been met. Also, discuss the control in this study.

4. Provide data to show that the new anchoring sleeve does reduce the number of lead dislodgement.

5. Please give the time between Detection and Delivery of therapy. Compare the data from the Transvene and the patch leads.

6. Please provide a breakdown of the electrodes' polarities (cathode or anode) and pathways.

7. Provide the number of patients who died when their devices were turned off. Please breakdown the number by follow-up period.

8. Provide an update analysis of the explanted devices.

9. Provide a profile of the explanted system: how long were the leads implanted; what was found with the leads; and, explanting due to lead or device failure.

10. Document the comparability of the PCD Transvene and the PCD epicardial systems.

12. Provide the status (complications, observations, and death rate) of the "Other" patients who were not in the study population, and of the patients with the non-standard lead systems.

PHONE MEMO

On 1/26/93, Medtronic is contacted. Jennifer Marrone and colleagues responded.

1. Please explain the discoloration of the 6999 lead which occurred during lifetesting. Was it also observed in the explanted leads from human implants?

   Response: The discoloration was an anomaly induced by the lifetest procedure, because the lead was in and out of the saline solution for flexing. They attempted to dry the lead before flexing, but were not entirely successful. Analysis showed that the discoloration was not due to corrosion and there were no electrical problem. It is not expected that the lead would discolor while implanted, since the lead would not be moved in and out of the liquid environment.

2. Please identify the sections on the leads where flex testing was performed. Describe the comparability of the Transvene lead and the 6907 lead, such that the flexing criterion derived from the 6907 data may be applied to the Transvene.

   Response: A section of the defibrillation coil and a section of the cable body were flexed. The whole lead was not flexed since the flex equipment can handle a small section at a time. It is assumed that the cable body is homogeneous so that one section is identical to another. No testing on the distal tip of any of the lead was performed because that part is stiff and not expected to flex.

   There does not exist a model to predict the reliability of a lead; thus, data on the Model 6907 pacing lead were used because the lead has the worst performance of any Medtronic leads. The only determining factor for the choice is the fact that the

Model 6907 is an endocardial lead, and so are the Transvene. The Model 6907 is a silicone lead; however, this should not be a factor where the functional specification is concerned.

During benchtesting, the minimum of flex cycle to failure was (b)(4) for 6966 where (b)(4) leads were tested. Only (b)(4) 6966 underwent lifetesting because the 6968 is considered equivalent to the 6966 lead, and (b)(4) 6968 were used in the lifetest.

3. In this study, is the RV coil always serves as the common electrode.

   Response: No.

4. Please verify these tables:

   a. Tables E-2 and E-3, the number of patients followed at 6M does not match.

      Resp: 329 is the correct number.

   b. Table E-7, switch the numbers under the "attempts" and "successes" headings.

      Resp: will modify accordingly.

   c. Explain why the numbers in Table F-2 do not add up to the 18.2% rate of complications and 20.7% rate of observations.

      Resp: some data are not included. Will be more complete in the next summary

   d. Include <u>all</u> lead-related complications in Table F-3 (and not just those beyond the perioperative period), since it is intended to be a <u>summary</u> of clinical experience.

      Resp: will modify accordingly.

5. Discuss how the screening requirements (Transvene leads or epicardial patches) are different from the implant requirements. If they are the same, explain the Transvene subset that did not meet implant criteria.

   Resp: All study subjects undergo the Transvene implant evaluation (3 out of 4 at 18 J or less). Those who didn't have a 10J safety margin were screened out to receive

the epicardial patches. Of the remaining, they were divided into two groups: one which meets the implant criteria and one which didn't meet the implant criteria. The ones designated to have the epicardial patches would then undergo the patch lead implant evaluation.

6. In the cases where inappropriate VT therapy was delivered, was ONSET programmed On? If so, please explain why this algorithm fails to detect.

Resp: Refer to page 417 of the 9/18/92 submission. Out of 49 instances of inappropriate VT therapy, 21 was resolved by reprogramming, 26 by drugs, 1 with no action, and 1 by AV node ablation. In 2 patients with sinus tachycardia, the ONSET algorithm was enabled and was successful in resolving the problem. In 3 patients with atrial fib, the STABILITY algorithm was enabled and resolved the problem.

7. How are those dropped from the study (due to infection or heart transplant) classified in the survival analysis?

Those patients who were alive when they received heart transplants, a new PCD system, etc. were included in the analysis up to the day where the changes took place. After which, they were censored out of the data. Those receiving the new PCD system will be considered as new patients in the survival curve.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P9110015
Subject: Medtronic Transvene Lead System
Date: December, 8, 1992
Office: DCRND/ODE

The sponsor has responded to our deficiency letter dated August 6, 1992.

Update of Patient Population

The update of the clinical experience of the Model 7217B and Transvene System is as of June 24, 1992. The Medtronic Models 7216A and 7217B PCD with epicardial leads underwent panel approval in February, 1992. The System presented for review in the referenced file is the Models 7216A and 7217B with non thoracotomy leads (Transvene™ System). The review will concentrate on the study of the Transvene leads in conjunction with the PCD models.

The patient population consists of 757 patients, three hundred and twenty-nine patients have implant durations greater than or equal to 6 months. Identical data pertaining to the spontaneous VT and VF efficacy, overall success rate, complications and observations and deaths were reviewed in the expansion request (IDE supplement G870102/S87). To reiterate there were 22 deaths (sudden cardiac - 3, non-sudden cardiac - 15 and noncardiac - 4).

A total of 854 patients were evaluated for the Transvene System. The patients were divided into the following groups: (1) patients who received a Transvene System (757) and (2) patients screened for a Transvene System and received an epicardial lead system (97). Of the 757 patients who received the Transvene System, 543 patients (71.1%) met the implant criteria and 214 patients (28.3%) did not. Of these 214 patients, 170 had an LED of less than or equal to 24 J and 194/214 had at least one successful termination of an induced ventricular tachyarrhythmia at 24 Joules or less. In 20 patients, their condition precluded further testing. Of the 97 patients who received the epicardial system, 81 patients met the implant criteria for the epicardial system and 16 patients did not. The overall survival for patients who met the implant criteria for the Transvene System was 94.9% and for the patients who did not was 97.4%. For the patients who received the epicardial system who met the criteria, the overall survival was 92.9% and for those who did not meet the implant criteria for the epicardial system was 80.7%.

It was stated that 737/757 (97.4%) received the Transvene System with at least a 10 Joule safety margin. The cardiovascular condition of 20 patients (2.6%) precluded an adequate definition of the safety margin. The investigators in these cases felt that the benefit of the Transvene System outweighed the risks of

further inductions and a thoracotomy. In most cases, the venous entry site for the placement of the Transvene Leads was the left subclavian vein. The majority of the investigators placed the SQ patch subcutaneously and laterally near the mid axillary line. The choice of the lead system was at the physician's discretion. The RV-SVC-SQ configuration was the selection in most cases.

A comparison between the PCD Transvene Study and the PCD Epicardial Lead System and Ventak P AICD studies was made. The comparison entailed looking at patient demographics, clinical performance (DFTs, incidence of spontaneous VT and VF episodes, incidence of complications) and one year survival. Overall there were no issues that rendered the groups significantly different and could be of concern in the evaluation of the data.

The pace/sense performance of the PCD Transvene versus the PCD Epicardial System was compared. In both systems sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria are as follows: pacing threshold - less than or equal to 1.5V at 0.5 ms; R-wave amplitude - greater than or equal to 5 mv; slew rate - greater than or equal to 0.75 volt/sec; and resistance - 200-880 ohms. There was a statistically significant difference in all of the pace/sense parameters of the Transvene versus the epicardial lead system. This was anticipated due to reportedly better endocardial pace/sense parameters. However, it was stated that the difference had no impact on the pacing and sensing performance of the PCD Transvene System. The PCD Transvene System reported a higher mean implant DFT (14.8J versus 9.8J for the PCD Epicardial System). There was a statistically significant difference between the mean DFT obtained with the RV-CS-SQ System and the mean DFT obtained with the other lead systems (RV-CS-SVC and RV-SVC-SQ).

There was also a higher incidence of lead related complications in the PCD Transvene System (6.6% versus 2.8% in the epicardial population). Observations of interest included: inappropriate therapy - 8.2% for the Transvene - 10.6% for the Epicardial System; pace/sense related - 4.1% for the Transvene and 10.2% for the epicardial.

Statistical Analysis

The applicant provided a justification for pooling the U.S. and foreign data. The patient selection criteria, investigational protocol procedures and indications for implant of the Transvene System were identical in all of the studies. Even though there were statistically significant differences in the patient groups (U.S. and foreign), they were not considered to be clinically sitgnificant enough to require stratification of the U.S. and foreign populations. This issue will be left to the discretion of the reviewing statistician.

Patient Data

The applicant provided a list of the primary indications for use which are identical to those for the PCD Epicardial System. The patient demographics of the PCD Transvene Lead System were presented and discussed in detail. A description of the implant and follow-up procedures and a discussion of the data obtained at each interval were provided. The procedures performed at implant and follow-up were identical to those for the PCD Epicardial System.

Response to Deficiencies

The deficiencies relating to the leads were adequately addressed, as per the consulting review. I have the following concerns about the life testing. I have repeatedly questioned the sequence of testing flexing - soaking - high energy pulsing - soaking - electrical and visual inspection. The testing should have involved more than (b)(4) cycles per lead. (b)(4) leads (b)(4) Model 6963, (b)(4) Model 6966 and (b)(4) Model 6968 (tined version of the Model 6966 which is not a subject of the PMA). I question the use of only (b)(4) Model 6966 leads during the life testing. How many Model 6966 leads were used during the course of bench testing and life testing? The data obtained from testing only (b)(4) leads during life testing appears to be inadequate. It was stated that the leads were placed back onto the test and flexed until failure, and that the data would be used only for improvement of the leads. It seems as if only the defibrillation segment of the leads were flexed to failure. Data from the defibrillation electrode segment of each lead model flexed at (b)(4) inch radius was reported as follows for the Model 6963 lead, the median was greater than (b)(4) cycles, for the Model 6966, the median was greater than (b)(4) cycles and for the Model 6999, median greater than (b)(4) cycles. A justification for the use of (b)(4) inch radius for flexing should be discussed. It is unclear how each segment (other than the defibrillation coil) of the Model 6966 lead was tested. The Model 6963 which has a polyurethane platinum sputtered lead body has the job of both pacing and sensing and defibrillation. In light of the recent failure of platinum sputtered brady leads, alot of concentration should be placed on how each of the segments of the Model 6966 were tested. Some background about the failure and mechanism of the failure of the brady platinum leads should be provided for our review.

An update of the animal studies which addressed the tumorigenesis issue was included. These findings were reviewed during the IDE study. There are no new findings to report.

The results of chronic animal studies which assessed chronic performance of the lead system were provided. Data, such as defibrillation thresholds, pacing thresholds, slew rates and R-wave amplitudes, the amount of energy delivered through the lead system for each shock delivered and the amount of current and

voltage across the lead system for each delivered shock were used in the chronic assessment of the Transvene Lead System. According to the manufacturer, the results of testing demonstrated the acceptable stability and performance for its intended use.

The manufacturer provided information regarding the improvement of perioperative and long term patient morbidity with use of the Transvene Lead System. The perioperative mortality of the patients implanted with the Transvene and the epicardial leads were compared and discussed. Undoubtedly, there is a decrease in perioperative mortality with use of the Transvene System. For as it was discussed, the majority of ICD patients are patients in which a thoracotomy poses an additional risk. The study has shown that the use of the Transvene Lead System which is implanted via a non-thoracotomy approach results in a decrease of perioperative death.

Treatment efficacy, complications and survival analysis on the patients followed for 6 months were provided for our review. There were 329 patients followed for 6 months. The primary indication for this group was recurrent sustained VT without an episode of sudden cardiac death. Sixty-six percent of the patients were implanted with the RV-SQ-SVC lead orientation. The mean LED was 15.4J (n=306) and the mean DFT was 13.9J (n=155). Percent success of VT spontaneous episodes was 99.0% and % success of spontaneous VF episodes was 98.7% The one year overall survival for patients followed for 6 months was 99.4% and the one year survival from sudden cardiac death was reported to be 100.0%.

There were 115 patients followed for one year. The primary indication was VT in 56 patients (48.7%). The mean LED and DFT were 15.2 J (n=105) and 13.8J (n=62) respectively. The treatment efficacy was 98.9% for spontaneous VT and 98.8% for spontaneous VF episodes. The overall and sudden cardiac death at one year was reported as 100%. It was stated that one death which was classified as non-sudden occurred 22.5 months post implant. It was reported that 24 of the 115 patients followed for a year had as complication. Specific information will be requested regarding the patient deaths.

Complications and Observations

Complications were reported in 138 patients and 157 patients experienced clinical observations. The incidence of complications was 18.2% (18/757) and 20.8% (157/757) for the observations.

Complications included: increased defibrillation requirements - 0.8%; pace/sense performance related - 0.8%; infection related-explant required - 2.0%; infection related - 1.5%; lead related 12.4%; and device related - 0.5%. The observations were increased defibrillation requirements 0.5%, inappropriate

therapy delivery- 8.2%, pace/sense performance related- 4.1%, infection related - 4.9% and lead related 2.6%. Of the observations related to inappropriate therapy delivery, there were 49 observations which involved inappropriate VT therapy delivery
and 13 observations of inappropriate VF therapy delivery. The manufacturer made a comparison of the Transvene complications and observations to those reported for the PCD Epicardial System. Of interest, the comparison showed that the lead related complications for the Transvene were 6.6% versus 2.8% for the PCD epi and pace/sense related complication which were considerably less (0.9%) for the Transvene and 3.5% for the epi. there were more infection related observations with the Transvene (5.3%) versus 2.2% for the epi and more lead related observations with the Transvene (2.2%) than with the epi (1.2%).

Lead dislodgement which has been a problem in the study, has been addressed in earlier IDE supplements. IDE approval was granted for the use of new anchoring sleeves. It was requested that the results of the experience of at least 50 patients with the new sleeves implanted for 30 days be provided in the PMA for our review According to the manufacturer the lead dislodements have occurred within the first 30 days of implant. However, the frequency of dislodgement greater than 30 days is also of interest. The majority of the dislodgements were reported as complications since reoperation was necessary.Most of the dislodgements involved the Model 6881/6963 CS/SVC lead.

Patient Deaths

As of 6/24/92, there have been 22 deaths (15 U.S. and 7 foreign). Three of the deaths were sudden cardiac, non-sudden cardiac 16 and noncardiac 3. The PCD Transvene sudden cardiac death survival at one year is 99.8% which is comparable to that of the PCD Epicardial System (98.7%) and the commercially available AICD (98.6%). There were 5 perioperative deaths out of the total deaths with a resultant perioperative mortality of 0.7% (sudden cardiac 2, non-sudden 2 and non-cardiac 1). A Table which included the clinical characteristics of the patients who expired was submitted for our review. Death classifications were also provided by primary indication. There was no difference in patient survival based on the Transvene configuration or the indication for implant. The PCD Transvene one year actuarial survival is as follows: sudden cardiac 99.8%; non-sudden cardiac 96.8%; all cardiac 96.6%; noncardiac 99.4%; and overall 95.3% (includes perioperative deaths).

My concerns regarding the referenced will be relayed in the form of deficiencies which should be fully addressed and documented in a PMA Amendment for our review.

Questions and Concerns

1. For documentation and purposes of the PMA application, please reiterate and outline the following:

    a. the hypothesis and the objectives of the study;

    b. a discussion of the use of the AICD™ as a historical control, and how your study addressed the concept of a control which is pertinent in clinical trials, and the practicality, at this time, of the use of a concurrent control during an implantable defibrillator study (ICD);

    c. the endpoints of the study; and

    d. and how the data provided in the PMA application support the specified endpoints.

2. Based on data provided in your PMA application, please prepare Tables which will include a side-by-side comparison of the PCD™ Transvene™ and the PCD™ Epicardial System and the PCD™ Transvene™ and Ventak P AICD™ populations. The data should also include inclusion and exclusion criteria which were used in each study. A discussion of how these data may or not represent a valid comparison and other comments which justify, and support the use of these groups as controls should be included.

3. An update of the PMA population should be provided. The update should include the data as presented in the PMA application. Your update should also include the clinical experience in the use of the new anchoring sleeves which are aimed at decreasing the incidence of dislodgement, and a summary of the clinical experience (spontaneous treatment efficacy of VT and VF, observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.

4. For purposes of documentation in the PMA, please clarify and reiterate how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.

5. Of the 214 patients who did not meet the implant criteria, 170 patients had successful defibrillation with 24 Joules (J). Please provide a updated summary of the clinical experience (as referenced in item # 2) on these patients.

6. There were 20 patients among the 214 who did not meet the implant criteria who were implanted without the 10 J safety margin. An update of the spontaneous episode experience in

the treatment of VT and VF in these patients and the overall survival should be provided.

7. Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not met the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.

8. Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update should include a summary of the clinical experience as referenced in item # 2.

9. Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms, of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was categorized as DFT and LED testing should be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.

10. There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. It should be documented that there were no significant differences between the scheme for performing DFT and LED testing between the PCD Transvene™ and PCD Epicardial patient populations.

11. Please elaborate on how the comparison of DFTs obtained from the PCD™ Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (574 (75.3%)) in the Transvene™ study were programmed with the sequential pathway and 178 (23.4%) were programmed via the simultaneous pathway. The majority of the patients (496 (65.2%)) in the PCD™ Epicardial study were programmed with the single pathway. Based on your PCD™ Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ PCD™ System versus the PCD™ Epicardial System.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it

is determined and if the patients met the criteria.

14. Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes, what was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes per patient in this group?

15. On page 130, Table IF-4, it was reported that there were 5362 episodes of VT successfully terminated. On page 131, paragraph 2, it was stated that 25 patients experienced 45 (0.8%) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. It should be clarified how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a Table which includes a category of ineffective therapies with actual patient numbers and percentages.

16. Table IM-6, page 173 should be modified to include a column on inappropriate therapy or therapies delivered as device was programmed so that the percentage can add up to 100%.

17. On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8%, please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The Tables should include percentages with the representative numerical support.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

19. Please discuss how the one year sudden cardiac death survival, as reported in Table IF-2 page 128, was calculated. The numbers and an explanation of patient classification should be included. Was every patient who had a prior cardiac arrest regardless of the arrhythmia included?

20. On page 177, the number of patients should be provided so that the percentages an calculated p-values can be confirmed.

21. Table IV-C shows a comparison of patient variables for the three lead systems. Please state the hypothesis of the study. The p-values obtained when reporting by primary indication should be discussed. The chi-square test of the data set and how it was computed should be discussed.

22. For purposes of justification of data pooling and data analysis of Table IV -C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp.162-170).

23. A comparison was made between the mortality between the PCD™ and AICD™ populations. What was the confidence interval?

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

    a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

    b. a chi-square test of primary indication, using the (b)(4) computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD™ and Ventak P populations are significantly different.

25. Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD™ Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment induced and spontaneous episodes with use the algorithms should be discussed.

26. Please discuses the "device related" complications reported for the Transvene™ and the PCD™ epicardial System.

27. Please describe in detail the complications reported in the patients followed for a year.

28. There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the reduction in the number of infections?

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads and how your labeling assist in the selection of an entry site should be provided.

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD™ and Transvene™ leads should be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices should be provided. The PMA application should document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD™.

31. Please discuss the circumstances surrounding the death in the patient who died 22.5 months post implant. What did interrogation of the device reveal?

32. Of the perioperative deaths, how many devices were programmed OFF. Please discuss the circumstances surrounding each death. The number of perioperative deaths should be reported in a Table. The deaths should also be reported as sudden cardiac, non-sudden cardiac and cardiac non-cardiac. Were there other deaths when the device was programmed OFF?

33. It was stated that there have been no reported patient deaths in the group with a one year sudden cardiac death survival and overall actuarial survival of 100%. Does this include the patients who have been followed out for a year and the perioperative deaths?

34. An engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent should be provided.

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over a (b)(4) month period would be sufficient. Describe how the lead and different segments were flexed.

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads. Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads should be provided. The comparison should include material,

design, dimensions, function, tests performed and a schematic drawing.

The deficiencies also include the concerns as per the consulting reviews. See memos.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # G870102/S87
Subject: Medtronic Transvene System
Date: December 7, 1992
Office: DCRND/ODE

The sponsor is requesting expansion of the Transvene study to include an additional 150 patients.

The following is an overview of the clinical data as of June 24, 1992:

- Patient population of 757, 329 patients have implant durations equal to or greater than 6 months
- 744 PCD implants and 18 7216A implants, of these 444 Model 7217B in U.S. and 300 Model 7217B implants internationally)
- Mean implant duration - 5.6 months
- Defibrillation pathway: sequential - 574 (75.3%); simultaneous - 178 (23.4%); and single - 10 (1.3%)
- Mean DFT - 14.8J (n=316)
- Mean LED 16.0J (n=702)
- Spontaneous VT: 226 patients, 5430 episodes % success = 98.7%
- Spontaneous VF: 198 patients, 973 episodes, % success = 99.1%
- One year survival 99.8%

Of the 757 patients who received the PCD Transvene System, 443 patients (58.5%- 443/757) have either experienced a spontaneous VT or VF episode or had VT or VF induced during a post implant EP study.

There have been 138 complications identified in 138 patients (77 U.S.) and 157 observations identified in 157 patients (68 U.S.) in the Transvene patient population. None of the complications and observations resulted in patient death. Included among the complications were 33 lead dislodgements reported in 33 patients at greater than 30 days. The dislodgements were identified through fluoroscopic examinations during EP evaluation and chest x-rays and pacing/sensing threshold evaluations during routine follow-up. In all cases reoperation was performed and the leads were repositioned. Approval was obtained under IDE in September,

1992 for the use of new anchoring sleeves which will aid in eliminating lead dislodgement. In the last expansion request, we requested one month follow-up experience on at least 50 patients implanted with the new anchoring sleeves to be reported in the PMA application.

Recommendation: Approval to add 150 patients to the study. At this time, no specific plan of expansion which will allow a certain number of patients per month to be added to the study is being approved.

DEPARTMENT OF HEALTH & HUMAN SERVICES — Public Health Service

Memorandum

Date DEC 9 1992

From Engineer, DCRND, ICDB

Subject Platinum-Iridium Mesh Leads

To Doris Terry, DCRND, PEDB

This memorandum is a formal response to your question regarding the possibility that platinum-iridium could be a contributing factor in the observation of tumor growth in canines in which epicardial patch defibrillation leads were implanted. It should be noted that my comments are purely speculative and are not based upon a review of the leads in question or any data associated with such.

The toxicity of elements contained in alloys is related to the solubility of their corrosion products and the levels of the element present. Tumors can result because of one or several of the following factors:

1. Presence of a chemical carcinogen.
2. Generation of a carcinogenic chemical(s) through degradation of the material or through a chemical reaction of an ingredient in the material.
3. Cancer through physical effects (referred to as a solid state cancer).

With the defibrillation patch leads, solid-state carcinogenicity is a definite possibility. The use of platinum-iridium in the lead (versus another material) could influence this phenomenon since the mechanical/physical properties of the patch will be influenced by the materials of construction, i.e., stiffness, thickness, etc.

With respect to the presence of a chemical carcinogen in the (b)(4) (b)(4) it is doubtful that the metal itself would produce a toxic effect. However, the use of platinum-iridium in defibrillation leads could present new safety concerns. One obvious problem would be the fatigue resistance of the (b)(4) (b)(4) This material is not used as a coil material in permanent pacing leads so I am unsure of its fatigue properties for this application. Given the large amount of current used in defibrillation leads, (b)(4) (b)(4) could be the cause of the burning/degradation observed in some studies. Also if (b)(4) (b)(4) (b)(4) (b)(4) the metal is subject to accelerated corrosive attack. Products of corrosion will diffuse out and local tissues can suffer from both metallic toxicity and electrochemical changes at the implant surface.

The issue of electrochemical reaction at the stimulation electrode-physiological saline interface is significant and the possibility of dangerous electrochemical reactions should be eliminated. A conservative requirement

for any "safe" electrical stimulation is the absence of chemical changes adjacent to the stimulating electrode. In electrochemical terms, this means that charge transfer processes producing dissolved species or gaseous products must be avoided. Possible dissolved species resulting from reactions at the Pt/saline interface include (b)(4) (b)(4) (b)(4) (b)(4) and (b)(4) Little information is available about the body's tolerance for the species produced at the Pt/saline interface and I cannot provide any estimate of a "safe level". Possible damage resulting from the flow of electric current through the physiologic solution produced at the interface presents another layer of complexity which may need to be considered.

In summary then, it may be advisable to have the manufacturers of these devices explore these areas in more detail to ensure safety and effectiveness, particularly long-term. If you have any questions please let me know.

Applicant: Medtronic, Inc.
7000 Central Avenue, N.E.
Minneapolis, MN 55432

Product: PVD Transvene System

A Premarket Approval application is still pending for the above referenced product due to the previous violative inspection completed on 1-9-92 for the manufacturer identified above. Our records indicate that the firm is currently on Automatic Detention.

Please arrange to have a follow-up inspection conducted which should be scheduled as soon as possible after the manufacturer has indicated that the necessary corrections have been made and a satisfactory response to the Warning Letter has been received.

Please have the finished report (EIR) submitted to HFZ-331 and mark the coversheet **"PMA PRE-APPROVAL FOLLOW-UP INSPECTION"**.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic Transvene System
Date: June 5, 1992
Office: DCRND/ODE

On the basis of a further review of the referenced file, the following concerns have been identified. These deficiencies should be included in a major amendment letter for the manufacturer's response.

Questions and Concerns

1. An update of the clinical experience of the Transvene Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.

2. What is the mean time of device activation for the patient population?

3. Please discuss your clinical data which support the claim which states that the Transvene Lead System improves both perioperative and long term patient morbidity.

4. A discussion of the data or past performance of similar marketed leads which support the adequacy of (b)(4) flex cycles in support of lead performance should be provided.

5. Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.

6. Please specify the section of each lead assembly that was flexed during life testing. the results of the tests should be included.

7. Please provide a detailed discussion of all cases of crinkling and curling of the patch leads and dislodgement of the coronary sinus lead.

8. An update of the chronic animal studies should be provided.

9. Are there patients currently implanted with the Model 6895

and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

10. A side-by-side comparison of the Model 6897 epicardial patch lead and the Model 6999 patch lead should be provided.

11. Please discuss the results of tests performed with the Transvene System and the Model 2394.

12. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

13. Please list the reasons for not performing pre-hospital discharge testing.

14. The number of spontaneous episodes of the patients followed for six months and beyond should be provided.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

16. Provide a detailed discussion of the clinical experience (implant duration, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.

17. Please discuss your clinical experience (treatment efficacy, complications and survival rates) of the patients who have been followed for one year and more.

18. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead configurations during implant.

19. A breakdown of the different lead configurations within the patient population, and the treatment efficacy reported for each configuration should be included.

20. An update of the life tests on the leads should be provided.

21. A discussion of the energy requirements of the Transvene versus the epicardial lead system should be provided.

22. A copy of the Summary of Safety and Effectiveness with the updated clinical data should be submitted.

RE: Questions concerning the benchtest/prior investigations performed on the Transvene leads from Medtronic - P920015

DA: 6/5/92

SUMMARY

Medtronic requests market approval for the Transvene lead system. The Transvene leads are used with the Model 7217B PCD for pacing, sensing, cardioversion, and defibrillation of the heart. They require non-thoracotomy means for implantation. For a detailed summary of the prior investigations, please refer to the 5/7/92 memo.

Based on my review and the comments given at the working group and filing meetings, the questions for Medtronic include:

1. Discuss the use of a silicone adhesive to prevent tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of polyurethane and silicone in leads to prevent tissue in-growth.

2. Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.

3. From experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed).

4. Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor, when the section is flexed?

5. Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) electrode coil, and the effects of its failure on the performance of the lead.

6. Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?

7. Discuss the biostability tests (stress cracking, MIO, etc.) performed on the two types of polyurethane. Why chose a

different polyurethane for the inner coil?

8. Discuss why the (b)(4) and the (b)(4) (b)(4) (anchor sleeve) have not undergone the mutagenicity test.

9. Based on the results of the lifetest, what is the life expectancy of the leads. Please include your assumptions.

10. What section of each lead was flexed in the lifetest? Does this section include the electrode coil?

11. Provide an update of the (b)(4) month lifetest.

12. The Transvene leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Tranvene leads which take them better.

13. The provided data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test, correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

14. Compare the 6999 against the epicardial patch leads.

15. Discuss any differences in battery life, between the epi-lead

system and the Transvene system.

16. Some Transvene subjects were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these subjects to the ones who did not undergo the hollow can evaluation.

17. Discuss any possible interaction between the pacemaker leads and the Transvene leads. Also, discuss the effects of these leads on the tricuspic valve and the host vein.

RE: Review of the benchtest/prior investigations performed on the Transvene leads from Medtronic - P920015
DA: 5/7/92

SUMMARY

Medtronic requests market approval for the Transvene lead system. The Transvene leads are used with the Model 7217B PCD for pacing, sensing, cardioversion, and defibrillation of the heart. They require non-thoracotomy means for implantation.

Device Descriptions

The Transvene lead system consists of three leads, Models 6963, 6966, and 6999. The leads contain conductor coils made of a (b)(4) (b)(4) and a (b)(4) (b)(4) shell. Their electrodes are made of a (b)(4) (b)(4)

Model 6963 is a unipolar, transvenous, coronary sinus/superior vena cava (CS/SVC) lead. It serves as an anode for cardioversion and defibrillation. It consists of a (b)(4) connector (b)(4) (b)(4) connector pin and (b)(4) (b)(4) sleeve); a conductor coil insulated by (b)(4) (b)(4) and, a coil electrode of (b)(4) inches in length (b)(4) (b)(4). To prevent tissue in-growth, a silicone adhesive is used with the lead.

Model 6966 is a tripolar, transvenous, right ventricular (RV), screw-in lead. It serves as the pacing/sensing, as well as a cathode (common) for cardioversion and defibrillation. It consists of a bipolar (b)(4) connector (b)(4) (b)(4) connector ring and rotatable pin, and (b)(4) (b)(4) for the ring and helix electrodes; an unipolar (b)(4) connector (b)(4) (b)(4) connector pin and (b)(4) (b)(4) sleeve) for the coil electrode; a tri-layer conductor coil coated with (b)(4) (b)(4) and insulated by (b)(4) (b)(4) rubber; a coil electrode of (b)(4) inches in length (b)(4) (b)(4); a ring electrode with (b)(4) surface area; and, a helix electrode of (b)(4) surface area. Correlating the functions of the lead and its three electrodes: pacing takes place between the coil and helix electrodes; sensing takes place between the ring and helix electrodes; and, cardioversion/defibrillation takes place between the coil electrode and the other leads. (b)(4) (b)(4) tubing prevents tissue in-growth in the lead.

Model 6999 is a unipolar, sub-cutaneous (SQ), patch lead. It serves as an anode for cardioversion and defibrillation. It consists of a (b)(4) (b)(4) connector (b)(4) (b)(4) pin and (b)(4) (b)(4) sleeve); a conductor coil insulated by (b)(4) (b)(4) rubber; and a (b)(4) (b)(4) rubber patch embedded with a (b)(4) (b)(4) and (b)(4) electrode coils. The

inside of the electrode coils is filled with (b)(4) rubber to prevent tissue in-growth in the patch.

Components for use with the leads are: a (b)(4) anchoring sleeve for stationing the lead body at the insertion site; a (b)(4) for stiffening the lead during insertion; and, an (b)(4) tool for entrenching the helix. Descriptions of the (b)(4) tool have not been provided.

RECOMMENDATION

Based on the above review of the Transvene lead system, filing is recommended. A major amendment, regarding the concerns raised here, is expected.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic Transvene System
Date: April 13, 1992
Office: ODE/DCRND

The applicant seeks approval of its non-thoracotomy leads, the PCD Transvene System. The system is composed of the Model 6963 Unipolar Coronary Sinus or Superior Vena Cava lead for cardioversion and defibrillation; the Model 6966 Tripolar, Endocardial, Screw-In Lead for pacing, sensing and cardioversion and defibrillation and the Model 6999 unipolar, subcutaneous patch lead for cardioversion and defibrillation.

The indications for use of the Transvene System are similar to those of the Medtronic PCD models. The applicant contends that due to the less invasive nature of the non-thoracotomy leads, the system can be implanted in patients who may not be able to undergo a thoracotomy.

Description of the System

The Model 6963 is a silicone, unipolar, coronary sinus or superior vena cava lead with (b)(4) connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies.

The Model 6966 is a (b)(4) tripolar extendable/retractable, screw-in lead with a (b)(4) connector and platinum alloy electrode for cardioversion and defibrillation. The lead also has a (b)(4) connector for pacing and sensing.

The Model 6999 is a (b)(4) unipolar, oval subcutaneous patch with a (b)(4) connector and platinum alloy electrode coils embedded in the (b)(4) patch. The lead is intended for cardioversion and defibrillation.

Recommendation: There are no concerns regarding the data as submitted. Based on our review, to date. the determination has been made that the application is suitable for filing.

Medical Officer

MEMORANDUM TO THE RECORD

From: R. Subramanian, M.D., DCRND

Subj: Addendum to review of death summaries, Medtronic Transvene Lead - P920015

Date: October 1, 1993

::

The death summaries were rereviewed to determine if the infections noted:
a) were related to the device, and to
b) obtain further details regarding time and sites of infection.
This rereview does not include "pocket infections" which have been listed separately in the submission and have been addressed previously (see memo from Dr. J. Jones).

1. A total of 68 deaths were reported in the PCD Transvene System population of 1330.

2. Eleven (11) of these patients had clinical evidence of (or were clinically suspected to have had) infections as follows:

#	Patient #	Infection	Autopsy
1.	(b)(6)	Staph sepsis, ? prosthetic valve infection.	No
2.		Sputum and blood positive for enterobacteriaceae	NA
3.		Pneumonia	NA
4.		Pneumonia, sepsis (83 year old with metastatic lung CA)	NA
5.	(b)(6)	"pt. diagnosed with sepsis"	NA
6.		? Pneumonia, pleural effusion of unknown cause	NA
7.		Pneumonia vs. amiodarone toxicity	No
8.		Sepsis, no source noted	No
9.		"Pneumonia with subsequent sepsis"	NA
10.		Sepsis due intestinal perforation	No
11.		Sepsis secondary to pneumonia	NA

NA = Not available

Conclusion: Although the information provided in the death summaries is limited, there does not appear to be any evidence of device related infection causing death in this group of patients.

CC Ms. Doris Terry, reviewer, DCRND

MEMORANDUM

To: Doris Terry, DCRND

From: R. Subramanian, DCRND

Subj: Review of death summaries, Medtronic Transvene lead - P920015

Date: August 4, 1993

==========

I have reviewed the death summaries provide with the amendment to the above application. As we have discussed previously:

1. The classification of deaths appears to be reasonable.

2. It is not possible, with the information provided in the death summaries, to state categorically, whether or not any of the deaths could be possibly linked to device performance.

3. As indicated by the sponsor, there appears to be only one death (Patient (b)(6) vol 2, page 134) that is clearly device related.

Recommendation: In future studies, instances where the cause of death is considered unknown, and no autopsy is performed, such death should classified as device related.

Memorandum

June 11, 1993

To: Doris Terry, B.S., M.S., Medical Reviewer, DCRND

From: Jeffrey D. Jones, M.D., F.A.C.C., Medical Officer, DCRND

RE: Medtronic PCD Transvene Lead System, PMA Amendment P920015

At your request I have reviewed the relevant clinical aspects of the Medtronic PCD Transvene PMA amendment. The clinical study involved 757 patients followed for a mean of 11.7 months. 657 patients were followed for 6 months or greater and 393 patients were followed for 1 year or greater. Inclusion criteria were as follows:

1. Those patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction.

2. Those patients who have recurrent sustained ventricular tachycardia that remains inducible via programmed electrical stimuli or exercise, or occurs spontaneously despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

The 757 patient population was compared to three (3) different historical controls in a retrospective fashion. The three historical controls were 1) the Ventak-P Epicardial system PMA (which was obtained through the freedom of information act), the published AICD clinical experience published from Winkle et al, in the May 1989 JACC (copy attached to this consult for reasons described below) and the PCD Epicardial System clinical experience.

This retrospective picking and choosing of historical controls is not only **not** scientifically sound but it gives the impression that Medtronic is attempting to maximize any demonstrable benefit or minimize less desirable qualities by inappropriate manipulation of historical data. For example, the JACC article by Winkle which was referenced by Medtronic was conducted over a seven (7) year period. It is inappropriate to use these total complication rates as a comparison. To do so markedly minimizes the "complication and observation" rates presented in this study of lesser duration than the control. Specifically, it minimizes the significance of the incidence to failure to cardiovert or defibrillate, of inappropriate VT/VF therapy delivery, pocket

infection (explant) and erosion rates. Approximately half of the infection in the control was due to generator replacement at end of life. It clearly is misleading to compare this to the incidence of primary infection in the study population. In addition, I was unable to determine how the 4.1% failure to cardiovert or defibrillate that is presented by Medtronic was calculated from this article.

Regardless of their flawed scientific approach and manipulation of the historical data several important clinically relevant statements can be made based on the data provided by the company.

1. The patient population of the Ventak-P is likely similar enough to the PCD Transvene study population to allow the comparison of carefully selected endpoints.

2. The one year actuarial survival from SCD in probably comparable between the PCD Transvene and the Ventak-P Epicardial system. Regardless of the fact that survival distributions were not compared by an acceptable statistical method (eg: Mentel-Haenszel), the conclusion is probably a reasonable one.

3. The perioperative mortality of the PCD Transvene is **comparable** to the Ventak-P patient population but **not** statistically lower. When all patients screened for a PCD Transvene are included into the study group (as is clinically appropriate) the perioperative mortality increases from 0.7% to 1.6% and is no longer statistically significantly different than the 2.7% in the Ventak-P population which Medtronic chose as their comparison.

4. The PCD Transvene and the PCD Epicardial patient populations are likely similar enough to allow the comparison of carefully selected endpoints.

5. The one year actuarial survival from SCD is probably comparable between the PCD Transvene and the PCD Epicardial system. Again however, survival distributions were not compared.

The comparison of spontaneous VT/VF episode efficacy is so inconsistently performed and contradictory that no definite conclusions can be drawn from this analysis in my opinion. In addition, R-R interval analysis is not accurate enough to make the bold claims of the high success rates of appropriate therapy that are made by the company. My overall impression is that this device delivers inappropriate therapy much more frequently than the 9.6% that the current method of analysis suggests. In other words, the device is over sensitive to avoid under detection. Medtronic recognizes this and states that "the philosophy behind Medtronic's labeling recommendations and the practice of PCD

investigators is to accept some over detection of non-VT/VF rather than risk under detection of a life threatening tachycardia." At this stage in the development of these devices this is a very reasonable approach. Therefore, the PCD Transvene is probably no more oversensitive than currently available devices but this has not been clearly established from the data in the PMA.

Of continued concern is the very high incidence of lead dislodgment (15.7% total, 9.7% for SVC, 10% for CS) with a reported lead related complication rate of 15.1%. Recall that Medtronic defines complications as requiring invasive interventions to correct. This explains the 5.3% infection rate in the PCD Transvene patient population compared to the 2.5% in the PCD Epicardial system population. Re-operation and repositioning of the lead contributes to the iatrogenic infection rate. This absolute difference is even more alarming when one considers that the mean follow-up in the epicardial group was 16.3 months compared to the lesser 11.7 months is the Transvene. The infection related explant was 2.9% in the PCD Transvene patient population compared to 2.3% in the PCD Epicardial study and 2.4% in the Ventak-P study. No statistical analysis was provided by Medtronic between these comparisons.

In response to FDA's deficiency letter, Medtronic has submitted data in an additional 234 patients which have been implanted with two (2) separate anchoring sleeves. These patients were not included in the 757 patients in the study population. 186 patients completed their one (1) month follow-up and 49 completed a 3 month follow-up. Reportedly, there has been only a single documented dislodgment. Additional follow-up on these patients is needed. If prior to panel review, the follow-up data appears favorable, changing the labeling to emphasize the need for the use of 2 anchoring sleeves should be adequate. FDA should inquire as to the recruitment method used to obtain these additional 234 patients. It could be phrased in the following question:

In reference to the 234 patients who received 2 anchoring sleeves, please explain how these patients were chosen. For example, were they consecutive patients from selected institutions or were consecutive patients from all institutions represented? Are all patients currently undergoing implantation implanted with 2 anchoring sleeves? If not, why not and how are you assured that alternative methods are as effective as the two anchoring sleeve method?

In summary, this collection of clinical data presented by Medtronic in support of their PMA has demonstrated the following:

1. In a similar patient population the PCD Transvene had an equivalent 1 year SCD survivorship when compared to the PCD epicardial system and the Ventak-P systems.

2. A higher incidence of lead dislodgment and infection and probably infection related explant is present in the PCD Transvene PMA patient population when compared to controls.

3. No definite improvement in perioperative mortality has been demonstrated in the PMA population when compared to the Ventak-P study population.

4. No definite conclusions can be drawn about the appropriateness or "efficacy" of spontaneously delivered VT or VF therapy.

The above conclusions can be summarized in the following question which can be posed to the panel:

Has Medtronic demonstrated in its clinical study that the increased risk of lead dislodgment and potential iatrogenic infection justifies a small but statistically insignificant decrease in perioperative mortality?

Lastly, I have a continued concern regarding the perioperative death of patient (b)(6) This death was classified as Sudden Cardiac and rightfully so; however, even though the device was interrogated, we have not been told of the results of that interrogation. This information was to be provided to us with this submission but as with the last update Medtronic states, "The results of this analysis are not available as of this submission but will be provided to the FDA." I suggest we require this information before the device is allowed to be reviewed by the panel.

If I may be of further assistance please do not hesitate to ask.

Memorandum

January 25, 1993

To: Doris Terry, Reviewer, DCRND

From: Jeffrey D. Jones, M.D., F.A.C.C., Medical Officer

RE: Medtronic PCD Transvene, Clinical Review

At your request I have reviewed the clinical data found in the PMA Amendment to the Medtronic PCD Transvene System. I will first answer your specific questions but will then expand to a more general evaluation with specific comments.

In response to your questions regarding the data presented by the company concerning the patients that did not met the recommended defibrillation implant criteria but who received a device anyway. Apparently each individual investigator who implanted such a device was given the latitude to make such a decision if he/she felt it was clinically appropriate. Reportedly, when the implant criteria could not be met but the patient was felt to be at increased risk for an arrhythmic death the device was subsequently implanted. Medtronic claims that regardless of the implant criteria that almost all of the patients had a 10 j safety margin. This "safety margin" has not been established in the literature by a well controlled prospective study. The reference sited by Medtronic on page 145 of the PMA does not discuss safety margins at all. It was however discussed in a subsequent reference of theirs. In addition, 20 patients had no DFT trial performed because they were judged to be in "poor condition". One could argue that if their general medical status was so poor that they could not undergo testing of the device then perhaps their short term survival was such that they should not have received the device at all. However, with such a high risk group of patients with a high likelihood of cardiac death perhaps it is acceptable to proceed in this fashion. It does unfortunately give the impression that Medtronic has little control over its investigators. Regardless, the reported overall survival in this group is 97.4% This is presented on pg. 153. We are not informed as to the average time of follow-up and maximum time of follow-up in these patients.

Therefore, my recommendations are as follows. We insist that Medtronic restrain investigators from implanting devices in patients that do not meet the implant criteria. This is not only bad science but it will decrease the actual patient population cohort that will be available and potentially prolong their study and subsequent approval. If Medtronic wishes to change their implant criteria they should provide data to support their position. I spoke to (b)(6) (b)(6) M.D. who was recently appointed Chief of Cardiovascular Electrophysiology at Baylor College of Medicine in Houston. He claims that no standard for defibrillation threshold exists but that the recommendations that he

recently presented at the NASPE Board Review Course in Cardiac Electrophysiology are based on his experience in electrophysiology. We need a more scientific approach. This burden should be placed on the manufacturer. I would also like to see up to date data on the overall survival between those meeting implant criteria and those patients not meeting implant criteria along with statistical analysis of those data. They should include the average and total time of follow-up.

Medtronic uses three historical control study populations in evaluating the safety and effectiveness of the PCD Transvene. They utilize the Ventak-P data, obtained through the freedom of information act, for comparison of patient characterists, clinical performance, and survival analysis (to include perioperative death).

The comparison is acceptable and favors the PCD Transvene in several ways. 92% of VT's were successfully treated with anti-tachycardia pacing and did not require further therapy. This represents an advantage with translates into better tolerance by the patient. My concern as explained below is that this figure may be artificially inflated. It requires that we assume that the attending physician is correct 100% of the time when he reports the device functioned properly after treatment. All that is available to the physician is the R-R interval and it would be relatively easy to misinterpret SVT as VT. For this reason we should refrain Medtronic from boldly proclaiming 99+% success rate (also see #4 and #5 below).

Perioperative mortality was lower in the PCD Transvene population at 0.7% compared to 2.7% with P = (b)(4) DFT's were reported as similar although we are not told how Ventex-P determined the DFT's, this is necessary to make an accurate comparison.

In addition to the specific questions you asked I would like to take this opportunity to comment in general on the presentation of the clinical data. A recurring difficulty I encountered was the presentation in table form of percentages when comparing two or more variables. It is very frequently unclear how these percentages are calculated. For example, in the table on pg. 128 it is unclear how the "One Year SCD Survival" percentages presented are calculated. They repeatedly place the burden on us to manipulate the numbers to achieve their percentages. In addition, an accompanying P value is often presented and again, it is unclear how this number is calculated. Frequently the number of patients is very small and representing this information as a percentage is misleading (eg; the number of patients in several categories followed for one year). In future submissions, all data presented as percentages should be accompanied by the number of patients so that the numbers can be easily verified and all P values can be easily confirmed by our statisticians. This would also allow us to easily add up all patients at a glance to confirm that all patients are accounted for and appropriately classified.

The general presentation of the data is also disorganized and very often redundant. I would suggest that for future submissions we insist on a clinical study mainframe for presentation of their data. For example, all the clinical data is presented in a section called "Clinical Data" in

table form where all the information can be easily review and compared and all calculations confirmed. They should save their comments and conclusions for those specific sections. This would greatly reduce our review time. There were also several occasions in which I came upon a term that had not yet been defined and I had to "stumble" through the data until I eventually came upon a definition (eg: DFT and LED). A section entitled, "Definitions" would have been helpful. We should insist on the same standards that a peer review journal would insist upon prior to publishing a manuscript.

In addition, when a manufacturer sites a specific reference and/or author to support their position they should not only provide a copy of the reference but also highlight the pertinent portion of the document. This would greatly reduce our reviewing time and speed up the review process in general. I spent approximately 6 hours looking up references cited by the authors in this current clinical section. The librarian had to call several other libraries to find one particular reference which was subsequently faxxed to me.

To continue, I have several additional recommendations to make and specific questions to pose.

1) Pg. 125, #2 near the bottom of the page. It is unclear to me what "a 2:1 VF sensing safety margin" is. This is not defined. How is it determined and did the patients meet the criteria.

2) Pg. 128, at the bottom of the table. How was "One year SCD Survival" calculated ? We need the specific numbers and an explanation of patient classification. Was every patient that had a prior cardiac arrest regardless of the arrhythmia included ?

3) Pg. 129, end of paragraph 2. Do we know what the manufactures recommendations are that they reportedly give to institutions "that prefer to obtain DFT,s during the implant procedure ?"

4) Pg. 130, table. The manufacturer claims that there were 5362 successful episodes of VT termination. On pg. 131, paragraph 2, they claim that 25 patients experienced 45 (0.8%) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category. They should not only clarify this but restructure the table to include a category of ineffective therapy with actual patient numbers and percentages.

5) As in #4 above, 964 successful episodes of VF are reported but on pg. 131 at the bottom they claim that 75 episodes were not VF. It appears to me that they count these episodes as successes when they should place them in the category of ineffective therapy. I would also like to know how they definitively confirm that an episode of VT or VF was definitely an episode. Is there a blinded third party interpreter of the interrogated retrieved events or is this based solely on the opinion of the attending physician ?

6) Pg. 136, Table H. There are a total of 38 patients who are inactive according to the chart but this does not correlate with the 34

patients as listed in the paragraph above the table.

7) There should be a similar table for periopeative deaths as the one shown on pg. 138. Perioperative deaths should be classified in chart form with numbers and percentages into sudden cardiac, non-sudden cardiac and non-cardiac deaths. I realize this is done in sentence form on page 451 but it would lend itself to more efficient review and comparison if it was present with the rest of the clinical data.

8) Pg. 139, The table at the top of the page relates a value for overall one year actuarial survival and again it is unclear how many patients actually were followed for a year. As I mentioned previously, every percentage should have an associated number of patients so we may verify the calculations immediately and not spend unnecessary time trying to confirm their calculations.

9) Pg. 151, The table compares the patients meeting and those not meeting implant criteria but again many percentages are presented without numerical support.

10) Pg. 156, They claim that there have been no reported patients deaths in the patient group with a resultant one year sudden cardiac death survival and overall actuarial survival of 100%. The real important data is the number of patients followed out this far. Does this also include perioperative deaths ?

11) Pg. 160, The DFT of the Ventak-P is compared to the DFT of the Transvene but we are never told how the DFT of the Ventak-P is determined. This is a worthless comparison without that knowledge. This mistake is repeated when the PCD-Transvene is compared to the PCD Epicardial device in chart form on pg. 171.

12) Pg. 162, The chart lists a "Fail to Cardiovert/Defibrillate" as 0.8% but for the reasons I provided above this is a gross misrepresentation. If a patient survives an episode of inappropriate therapy it should not be classified as a success. Again, tables of percentages are not acceptable without the numbers of patients in an adjacent column.

13) Pg. 173, The chart lists efficacy of termination of spontaneous episodes of VT and VF. The chart should be modified to include the total number of episodes out of the total and a column on inappropriate therapy so that the percentages all add up to 100% in each column.

14) Pg 177, Again, the number of patients should be provided so that the percentages and calculated P-Value can be confirmed.

In general, the comparison of the Transvene clinical data to data collected from three different historical sources gives the impression of manipulation to selectively compare in a manner aimed at maximizing the advantage of the Transvene. In the future, a single historical source should be used unless the manufacturer can convincingly argue to the contrary. Lastly, I would suggest that you obtain statistical input from our statistician in those areas that I have suggested above.

Memorandum

Date October 29, 1993

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistics Branch, Division of Biometric Sciences, OSB

Subject Statistical Review of PMA P920015 Panel Package, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To

Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices, ODE
Through: Director, Division of Biometric Sciences, OSB
Through: Chief, Statistics Branch, DBS, OSB

In my July 9, 1993 memo to you, I asked for the numerators and denominators used for the percent success (Table I-1, page 233, Table 1F-2, page 287 and Table 1F-4, page 290, PMA Amendment, March 26, 1993) for the treatment of spontaneous episodes. After thorough investigation, I have the following results:

Spontaneous VT % success 98.4% of Table I-1, p. 233 can be obtained from Table 8-1, p. 110, June 11, 1993. (9864/10027 = 98.4%)

Spontaneous VF % success 98.4% of Table I-1, p. 233 can be obtained from Table ID2-6, p.98, June 11, 1993. (1951/1982 = 98.4%)

Spontaneous VT % success 99.0% after 12 months of follow-up of Table 1F-2, p. 287 can be obtained from Table ID3-1, p.78, Vol. 2, June 11, 1993. (6273/6338 = 99.0%)

Spontaneous VF % success 98.6% after 12 months of follow-up of Table IF-2, p. 287 can be obtained from ID3-1, p. 78, Vol. 2, June 11, 1993. (1090/1105 = 98.6%)

I couldn't locate the section or table to address 6 months of follow-up for spontaneous VT and VF % success.

Table IF-4, p. 290, March 26, 1993 agrees with the table in the June 11, 1993 panel package.

If you have any questions concerning this memorandum, please contact me at 594-0627.

Public Health Service

Memorandum

Date .July 9, 1993

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistics Branch, Division of Biometric Sciences, OSB

Subject Statistical Review of PMA P920015 Panel Package, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices, ODE
Through: Director, Division of Biometric Sciences, OSB
Through: Chief, Statistical Branch, DBS, OSB

1. Background

The original PMA was submitted in April 1992. Amendment two was submitted for review in March 1993. The purpose of this memo is to review the response from the sponsor to the deficiencies stated in the FDA letter and in the telephone conference call held on July 7, 1993. Information provided in this panel package includes clinical experience of 757 patients through February 1, 1993.

2. Reviewer's Comments

2.1. Cox Regression

This reviewer wants the sponsor to provide a description of the computer program, including data input and output, and the decision criteria used to support the sponsor's claim that primary indication and gender do not impact survival. Sponsor stated that "Appropriate data will be submitted in the panel volumes to address this issue" in response to statistician's review. In the telephone conversation, the sponsor stated that (b)(4) was used for survival curve comparison, but the (b)(4) test was used for testing the equality of survival curves. (Table 1D2-10, page 76).

2.2. Actuarial Survival

In my March 10, 1993 memo to you, I asked for the number of deaths, number at risk for transvene and epicardial by month intervals (0-3, 3-6, 6-9 and 9-12). Sponsor claims that Table 1B1-5, page 17 "Patient Compliance" will serve this purpose. The compliance rate is very high, according to this table. However, to use this patient compliance table for survival analysis would be misleading, because it does not give survival probability. Sponsor said they will fax a copy of their survival curve graphical comparison.

2.3. Percentage Success

This reviewer needs to review the numerators and the denominators used for the percent success (Table I-1, page 233, Table 1F-2, page 287 and Table IF-4, page 290) for the treatment of spontaneous episodes. Sponsor pointed out that those numbers are located in other sections of the panel package.

2.4. P-values

The sponsor was asked to address the calculation of the p-values reported in Table 2.165, page 24. I calculated the p-values and obtained different values than those reported by the sponsor. Sponsor claimed that (b)(4) Life-test was used for the calculation. Subsequently, a computer output was faxed to me by the sponsor for review.

3. Conclusion

In my previous memos to you, I raised questions about the safety and effectiveness of the device. My telephone conversation with the sponsor certainly helped to answer some of these questions. The safety and effectiveness of the device should be evaluated from a clinical perspective.

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date May 10, 1993

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject Statistical Review of PMA P920015 Amendment, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices, ODE
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistical Branch, DBS, OST

1. Background

The Medtronic Pacer-Cardioverter-Defibrillator (PCD) is an implantable, multiprogrammable, automatic tachyarrhythmia control device. This device is used for treatment of patients at risk of sudden cardiac death due to ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The original PMA was submitted in April 1992. Amendment One was submitted in September 1992. Amendment Two was submitted for review in March 1993. The purpose of this memo is to review the response from the sponsor for the deficiencies stated in the FDA letter. Information provided in this amendment includes clinical experience of 757 patients through February 1, 1993.

2. Reviewer's Comments

2.1. Historical Control

Sponsor compared the PCD transvene system (treatment group) clinical experience to the reported PCD epicardial system (control group) clinical experience. Sponsor argued that patients were enrolled in the two studies concurrently and patients' indications, implant criteria and clinical data requirements were identical for the two patient groups. But, in Table 2-7, comparison of patient characteristics, PCD transvene system versus PCD epicardial system, as of February 1, 1993, page 19, gives different information. The p-values for sex and primary indication, (b)(4) and (b)(4) respectively, are statistically significantly different. Therefore, the sponsor's argument that the two groups are compatible is not correct.

2.2. Cox Regression

Sponsor stated, on pages 12 and 90, that: "Cox regression analysis was performed to see what effect gender, primary indication and system implanted (PCD transvene or PCD epicardial) had on survival outcome. This analysis showed that for overall survival at one year, the system implanted had an influence on the probability of survival but gender and primary indication had no influence". This reviewer would like to see the detailed evidence to support this claim, including the computer program, input, output and decision criteria.

2.3. Confidence Interval Analysis

Sponsor compared the PCD transvene system and Ventak-P epicardial system and claimed a statistically significant difference in one-year overall survival between the PCD transvene and AICD epicardial system, using confidence interval analysis, pages 13 and 256. This reviewer asked for this information in my December 16, 1992 memo to you and I would like to ask again for the computation of this confidence interval.

2.4. Actuarial Survival Comparison I

Table 2-16, page 24, depicts the actuarial survival of PCD transvene vs. PCD epicardial. This reviewer would like to see a more detailed Table such as this:

Month	Transvene	Epicardial
0-3	No.dead/No.at risk	No.dead/No.at risk
3-6	No.dead/No.at risk	No.dead/No.at risk
6-9	No.dead/No.at risk	No.dead/No.at risk
9-12	No.dead/No.at risk	No.dead/No.at risk

Then use the Mantel-Haenszel Chi-square test to compute the p-value for association between transvene and epicardial survival. Sponsor didn't discuss how the p-values in Table 2-16 were derived; it looks as if the binomial distribution was used for the computation. Sponsor should address this issue.

2.5. Please discuss the similarities/differences between Table 2-12 (page 22) and Table 3-3 (page 27).

2.6. Survival Probability I

Sponsor stated, on page 43, that the survival probabilities are calculated using a life-table survival analysis. For verification of survival probabilities, the data necessary to do calculations are available upon request. This reviewer would like to see this data set and the computation procedure.

2.7. Please discuss the similarities/differences between "one-year actuarial survival" of Table 1K-4 (page 43) and Table 8-5 (page 51). This reviewer would like to see the numerators and denominators actually used to derive the one-year actuarial survival shown in Table 8.5.

2.8. Survival Probability II

Sponsor stated, on page 83, that: "Presentation of the number of patients does not allow calculation of the survival probability. Therefore, a data set will be available upon request if you desire to verify the survival probability". This reviewer would like to see this data set and the computation procedure.

2.9. Actuarial Survival Comparison II

Table 1M-10 (page 84) depicts the comparison of actuarial survival: transvene vs epicardial as of June 24, 1992. Again, this reviewer would like to see the data set and the (b)(4) procedure actually used to derive the p-values.

2.10. NYHA Classification

The p-value for the NYHA classification in Table IV-C (page 88) is (b)(4), as computed by the sponsor. Based on the data provided in this table, the reviewer calculated a p-value of (b)(4) Sponsor should address this difference in p-values.

2.11. Early Device Explant

There were four patients in whom the PCD device was explanted due to reasons other than death, infection or heart transplant. Analysis of one explanted PCD device indicated a random device failure in the microprocessor and low power hybrid. Another patient experienced a power on reset (POR) condition, see page 100. Please submit the other two results for review as soon as the results are available.

2.12. Lead Dislodgement

Lead dislodgements are reported as complications/observations in Table 27-2 (page 103). The sponsor should justify his choice of thirty (30) days as a cutoff.

2.13. Pooling

There are seventy eight (78) investigative centers participating in the clinical trial with thirty five (35) domestic centers and forty three (43) foreign centers. Please justify pooling all seventy eight centers together.

2.14. Follow-up Presentation

Table E-2, page 215, depicts the PCD transvene system follow-up. This is not an adequate presentation of the follow-up data. As I requested in my April 23, 1992 memo, the sponsor should refer to page 93, Table 4.6, in "Statistical Methods for Survival Data Analysis" by Elisa Lee for a more proper life-table analysis. Sponsor should also discuss the reasons why some patients dropped out of the follow-up study, i.e., either withdrawn alive or lost to follow-up.

2.15. Actuarial Survival Comparison III

Table 11-2 (page 231) depicts the PCD transvene system one-year actuarial survival as of 2/1/93. Again, this reviewer would like to see the actuarial survival table stratified by every month, similar to that in Section 2.4 above. Sponsor also stated "this table included the projected one year survival calculations for patients who ultimately received a PCD transvene system....". Please explain in detail the projected one-year survival calculations.

2.16. Data Summary by Primary Indication

Sponsor provided PCD transvene system data summary by primary indication as of 2/1/93 in Table I-1 (page 233). This reviewer would like to see the numerators and denominators for percent success from treating spontaneous VT and spontaneous VF. Sponsor provided similar information in Table IF-2 (page 287) and Table IF-4 (page 290).

2.17. Follow-up Evaluations

Sponsor indicated, on page 284, that clinical data were collected for follow-up evaluations at 1 and 3 months post-implant and at 3-month intervals. Please provide all of this information

2.18. P-values for Actuarial Survival

This reviewer calculated the p-values in Table 2-16 (page 24) as follows:

Cause of Death	P-Values Sponsor	Reviewer
Sudden Cardiac	(b)(4)	(b)(4)
Non-Sudden Cardiac		
All Cardiac		
Non-Cardiac		
Overall		

3. Conclusion

The sponsor needs to adequately address all issues raised in Section 2 above, mainly actuarial survival and follow-up, before the safety or effectiveness of the PCD transvene system relative to the PCD epicardial system can be evaluated from a statistical perspective.

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date December 16, 1992

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject Statistical Review of PMA P920015 Amendment, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardvioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST MKB for RPC
Through: Chief, Statistics Branch, DBS, OST CSL for HFB

1. Background

Per our telephone conversation on December 7, 1992, you requested a statistical review of this PMA amendment. This amendment was received at FDA on September 21, 1992. I wasn't notified of any action until December 7. This amendment was sent to me on December 8, 1992. You indicate that you would like to receive my comments before December 18, 1992. With the limited time frame, I can only concentrate on the sponsor's response to the deficiency letter dated August 6 from FDA to the sponsor.

2. Reviewer's Comments

2.1. Item 21. Sponsor provided the p-values for Tables IV-B and IV-C of the original PMA. This reviewer recomputed the p-values and found them identical to those of the sponsor's. However, there is a problem, sample sizes are (b)(4) for 7216A and (b)(4) for 7217B. With such a large difference in sample size, this will cause very low statistical power, then the small difference is very difficult to detect.

2.2. Table IV-C shows comparisons of patient variables for the three lead systems. All the p-values computed by this reviewer is identical to those of the sponsor's. The total numbers of patients of primary indication are 329 for RV/SVC/SQ (of which 187 for SCD, 114 for VT, and 28 for SCDlVT), which are not in agreement with a total sample size of (b)(4) (b)(4) The sponsor provided p-values for variables tested in Table IV-C. The hypothesis was not clearly stated. After recomputing the p-values listed in the table, all are in agreement except primary indication. The chi-square test of this data set, computed using (b)(4) computer software, yield a p-value of nearly 0, which is also different from that of sponsor's computed p-value of (b)(4)

2.3. The sponsor, for the purpose of justification of data pooling and data analysis of Table IV-C, adjust the multiple statistical significant difference at 0.05 significance level using Hochberg procedure (Dunnett & Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March 1992, 87:162-170). Although this is a published, peer reviewed article, the sponsor's multiple test adjustment procedure is not widely accepted by the biostatistical and clinical community.

2.4. Comparison of Mortality Between One PCD and the AICD

Item 25. The sponsor compared the end points of the two devices. Sponsor claimed that confidence interval analysis was performed but that confidence interval was not given. Confidence interval should be computed by the sponsor to support this claim.

Sponsor provided a table for the comparison of patient characteristics, PCD versus ventak-P. I have two questions about Table XB-1, Page 378, Vol. 2:

(i) The total numbers of patients of primary indication, 291 for Ventak-P (49 for SCD, 169 for VT, and 73 for SCD/VT) are not equal to the total number of patients of Ventak-P of 292.

(ii) A chi-square test of primary indication, using (b)(4) computer software, yield a p-value of nearly 0. This is statistically significant, indicating that PCD and Ventak-P are significantly different.

The inclusion and exclusion criteria for patients of PCD and AICD studies are not discussed by the sponsor.

Conclusion

The sponsor needs to adequately address the issues raised in Section 2 above before the safety and effectiveness of the PCD transvene system can be evaluated from a statistical perspective.

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date: April 23, 1992

From: Mathematical Statistician (T.C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject: Statistical Review of PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To: Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistical Branch, DBS, OST

1. Background

The Medtronic Pacer-Cardioverter-Defibrillator (PCD) is an implantable. multiprogrammable, automatic tachyarrhythmia control device. This device is used for treatment of patients at risk of sudden cardiac death due to ventricular tachycardia (VT) and/or ventricular fibrillation (VF).

2. Reviewer's Comments

2.1 Pooling

There are a total of 319 implants in 317 patients of the PCD device. A total of 52 investigative centers participated in the clinical trials with 20 centers in the U.S. and 32 in foreign countries. In Vol 5, p 646 - p 650, a section was devoted to the justification for data pooling. Sponsor performed a comparison of U.S. and foreign patients and summarized the variables tested in Table IVA. Sponsor first combined and then compared all the data in U.S. centers and in foreign centers. However, much information was lost in these gross combinations. The initial design with centers nested within countries was reduced to a two-way classification. This is not good statistical practice.

This reviewer recomputed all the p-values listed in Table IVB and IVC; they were all found to be correct, except for the following:

Table IVC

	p-value (sponsor)	p-value (reviewer)
NYHA Classification	(b)(4) (b)(4)	(b)(4) (b)(4)
Congestive Heart Failure		
Cardiomyopathy		

2.2 Patient follow-up

Table E-2, p. 34, vol. 1, shows the follow-up time by type of data form. This is not an adequate presentation of the follow-up data. Sponsor should refer to p. 93, Table 4.6. in "Statistical Methods for Survival Data Analysis" by Elisa Lee for a more proper life-table analysis. Sponsor should also discuss the reason why some patients dropped out of the follow-up study, either withdrawn alive or lost to follow-up. For example, there are 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2-month period.

2.3 PCD transvene system compared to AICD Epicardial System clinical experience

For the comparison of complication/observation rates for PCD vs AICD, as reported in Table IL-1, p634, vol 5, I have the following comments:

2.3.1. Please provide the numbers of complications and patients for PCD and AICD.

2.3.2. Please provide the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate/Problematic VT/VF Therapy Delivery."

2.3.3. I am concerned that pocket infection is 3.5% for PCD as compared to 2.2% of AICD, even though the sponsor argues that the PCD System implant procedure requires multiple lead configurations. There are other "lead related" complications as reported on Table X1 F1 and F2, P857, Vol. 5. PCD Transvene System has more "lead related" complications than PCD Epicardial System.

2.4. One-year actuarial survival comparison of mortality between the PCD and AICD systems was discussed on p. 842, Vol. 5. Sponsor stated "there was a statistical difference in the reported (AICD) perioperative mortality (p = (b)(4) with the PCD Transvene System having a lower reported perioperative mortality." I have the following comments concerning this statement:

2.4.1. What statistical test was used to compare survival?

2.4.2. Please provide the two survival or life tables by year of follow-up, so that this reviewer can reproduce the statistical test and the derived p-value.

2.5. Comparison to PCD Epicardial System.

P-values for one-year survival comparison of PCD Transvene System vs. PCD Epicardial System for freedom from death by "sudden cardiac", "non-sudden cardiac", "all cardiac" and "noncardiac" causes are provided in Table X1 G-2, p. 862, Vol. 5, also Table J-2, p. 54, Vol. 1. The sponsor should discuss the statistical techniques used to derive the p-values.

2.6. PCD device longevity data.

Sponsor stated in Section M.1. p. 66, Vol. 1: "Thus, the PCD device longevity, which is monitored, utilizing battery voltage and change time obtained via telemetry, was analyzed. The PCD device longevity data collected is consistent with the longevity projection." This reviewer needs to see the data and statistical test used to support the above statement.

3. Reviewer's Conclusion

The sponsor needs to adequately address the issues raised in Section 2 above before the safety and effectiveness of the PCD Transvene System can be evaluated from a statistical perspective.

Memorandum

Date: April 7, 1992

From: Mathematical Statistician (G. Kamer) HFZ-162
Statistics Branch, Division of Biometric Sciences, OST

Subject: PMA Review Statistical Checklist Recommendations for PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To: Donald F. Dahms - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistics Branch, DBS, OST

The Statistics Branch, DBS, OST has received the PMA referenced above and evaluated it against the attached PMA Review Statistical Checklist. The failures to provide justification for sample size or pooling of data over investigational sites were the only non-serious omissions of a statistical nature. Therefore, we recommend this PMA be filed. We will now begin an in-depth statistical review of this PMA. This review should be completed and our comments sent to you within 30 days. If you have any questions, please contact me at 227-8629 or the statistical reviewer, T. C. Lu, at 227-8627. The omissions found are from the Clinical Investigations Section of the checklist and are stated below for your information:

1. This submission does not include any acceptable justification of sample size. Please provide a complete description of your sample-size determination. This should include effect criteria, alpha and beta statistical error tolerances, anticipated variance of the response variables, and any assumptions or statistical formulae with references that are required for sample-size determination.

2. This submission does not include any justification for pooling (combining) the patient data over site. Please review and analyze your prognostic variables to provide a detailed justification why the data may or may not be pooled for evaluation. Note that an analysis by site is always necessary in any case.

RE: P920015
Medtronic® Transvene® Lead System
Filed: April 1, 1992
Amended: August 27, September 21, October 27 and November 5, 1992, March 29, June 2, 14, and July 9, 1993

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed its review of your premarket approval application (PMA). The Circulatory System Devices Panel which also reviewed your PMA, recommended to CDRH at the August 2, 1993, panel meeting that the PMA be considered approvable. CDRH is pleased to inform you that the PMA is approvable subject to your submission of the following:

1. The labeling should be modified to include the following directions for use:

   a. diagrams which demonstrate the proper insertion technique and final anatomic position of the intravascular leads and the Sub-Q patch;

   b. defibrillation efficacy data on the different lead configurations, various polarity combinations and sequential versus simultaneous discharges;

   c. information and/or recommendations regarding specific implantation techniques and methods of testing the different configurations. For example, when is it recommended to use a two-lead configuration versus a three-lead configuration, when to implant in the superior vena cava (SVC) versus the coronary sinus (CS), and how the most advantageous position of the Sub-Q patch is determined;

   d. information or recommendations, based on your experience, regarding implantation in patients who do not have at least a 10 Joule safety margin;

   e. information aimed at reducing the incidence of infection;

   f. instructions stressing the importance of pausing between inductions of ventricular fibrillation (VF) at the time of implantation for at least a specified period of time in order to

decrease morbidity and mortality. The comments and the pause duration suggested should be based on the experience of the primary investigators in your study;

g. information regarding the change in defibrillation thresholds that one may expect with time as based on the experience of your investigators in your study;

h. guidance and techniques for separating permanent pacemaker leads from the Transvene® leads to minimize the interaction between the two devices, and diagnostic methods which can be employed at implant or predischarge to confirm the absence of adverse interaction;

i. a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement (x-rays should be done at 3-month intervals for 1 year);

j. information regarding techniques for placing the leads via the cephalic vein when possible; and

k. an explanation regarding the necessity for explant and return of the leads upon the patient's death.

2. The labeling should be modified to include the following warnings:

a. a statement that the Sub-Q patch lead is not for use on the pericardium or epicardium, because it is too inflexible to be used as such;

b. stronger and more specific language regarding the use of dual anchoring sleeves on the right ventricle (RV), SVC, and CS leads. Based on the experience of your investigators, please describe the techniques used to fixate the lead at the insertion into the vein to minimize dislodgment; and

c. information which states that after extensive VF inductions at implant testing with the nonthoracotomy lead system, serious consideration should be given to delaying the thoracotomy for at least 2 days. Please include a statement which states that the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 to 9.3 percent.

3. In addition you should note the following:

a. The indications and contraindications for use of the Medtronic® Transvene® Lead System must be identical (except for certain modifications which pertain to the Transvene® Leads and those described below) to those for the PCD™ Epicardial System. Please change your second indication to read: Poorly tolerated,

sustained ventricular tachycardia and/or fibrillation which recurs spontaneously or can be induced despite the best antiarrhythmic drug therapy. Please also include the following statement in your indications section:

Note: The clinical outcome of hemodynamically stable, sustained VT patients is not fully known. The safety and effectiveness of the PCD® Transvene System in this subgroup of VT patients has not been determined.

b. The technical manuals for the Transvene® Leads must state that the leads are for use together as a system. The labeling (where appropriate) must be consistent in all of the Transvene® Lead manuals. The information regarding the Transvene® Leads in the PCD® Manual must also be included in the Transvene® Lead manuals.

c. There should be an identifying mark on the package label which distinguishes nonthoracotomy leads from thoracotomy leads.

d. The Warnings and Precautions in the labeling must be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991, (a copy of this memorandum was previously sent to you).

4. Provide a copy of the Patient's Manual which includes a reference to use of the non-thoracotomy leads with the PCD® models.

The PMA must be amended to include your concurrence with, or suggested revision of, the enclosed "Conditions of Approval for Implantable Defibrillators and Programmers."

The condition that the sale, distribution and use of this device are restricted to prescription use in accordance with 21 CFR 801.109 within the meaning of section 520(e) of the Federal Food, Drug, and Cosmetic Act (the act) under the authority of section 515(d)(1)(B)(ii) of the act.

The device is further restricted within the meaning of section 520(e) under the authority of section 515(d)(1)(B)(ii) insofar as the approved labeling specifies the requirements that apply to the training of physicians who may use the device.

In addition to the above, an FDA inspection must find that the manufacturing facilities, methods and controls comply with applicable device Good Manufacturing Practice Regulations (21 CFR Part 820). If applicable, amend the PMA to include required manufacturing information not previously submitted.

This is to advise you that, following receipt of an approvable letter, an applicant is required by 21 CFR 814.20(e) to update its pending PMA with new safety and effectiveness information learned about the device from ongoing or completed studies that may reasonably affect an evaluation of the safety or effectiveness of the device or that may reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling. This updated reporting is limited to studies sponsored by the applicant or to which the applicant has reasonable access. The update report shall be consistent with the data reporting provisions of the protocol. Any update report shall be submitted in three copies as an amendment to the PMA and shall include the FDA reference number assigned to the PMA.

CDRH will issue an approval order after the requested information has been reviewed and determined to be acceptable. You may not begin commercial distribution of the device until you have received an approval order.

As provided by 21 CFR 814.44(e)(2), you may amend your PMA as requested, or withdraw it, or you may treat this letter as a formal denial of approval. If you choose the latter, you may request administrative review, either through a hearing or review by an independent advisory committee, under section 515(d)(3) and 515(g) of the act by filing a petition with the Food and Drug Administration, Dockets Management Branch (HFA-305), Room 1-23, 12420 Parklawn Drive, Rockville, Maryland 20857, within 30 days of the date you receive this letter. A petition for administrative review must be submitted in accordance with general administrative procedures for submission of documents to the Dockets Management Branch (21 CFR 10.20) and in the form of a petition for reconsideration (21 CFR 10.33). After reviewing the petition, FDA will decide whether to grant or deny the petition and will publish a notice of its decision in the FEDERAL REGISTER. If FDA grants the petition, the notice will state the issues to be reviewed, the form of the review to be used, the persons who may participate in the review, the time and place where the review will occur, and other details.

The above requested information must be submitted in the form of an amendment (3 copies). Unless you amend this PMA to request an extension, and the extension is approved, FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). Any request for an extension must be submitted within the 180-day period, justify the need for the extension, and provide a reasonable estimate as to when the requested information will be submitted.

All amendments to the PMA must be submitted in triplicate to the address below and shall reference the above PMA number to expedite processing.

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

In addition, under Section 522(a) of the act, manufacturers of certain types of devices identified by the act or designated by FDA are required to conduct postmarket surveillance studies. FDA has identified under Section 522(a)(1)(A) the above noted device as requiring postmarket surveillance.

Upon approval and within thirty (30) days of first introduction or delivery for introduction of this device into interstate commerce you will be required to submit to FDA certification of the date of introduction into interstate commerce, a detailed protocol which describes the postmarket surveillance study to include the evaluation of the explanted leads for evidence of metal ion oxidation (MIO), and a detailed profile of the study's principal investigator that clearly establishes the qualifications and experience of the individual to conduct the proposed study. For your information, general guidance on preparing a protocol for a postmarket surveillance study is enclosed.

At that time you should submit five (5) copies to:

Postmarket Studies Document Center
Room 408 (HFZ-107)
12720 Twinbrook Parkway
Rockville, Maryland 20852

Within sixty (60) days of receipt of your protocol, FDA will either approve or disapprove it and notify you of the Agency's action in writing. Do not undertake a postmarket surveillance study without an FDA approved protocol.

Failure to certify accurately the date of initial introduction of your device into interstate commerce, to submit timely an acceptable protocol, or to undertake and complete an FDA approved postmarket surveillance study consistent with the protocol, will cause your product to be misbranded and could lead to the imposition of civil money penalties or other regulatory actions. Any distribution of a misbranded device is a violation of the act and may result in a number of FDA enforcement actions, including (but not limited to) withdrawal of your PMA.

If you have questions concerning postmarket surveillance study requirements, contact Postmarket Surveillance Studies Branch at (301) 594-0639.

Finally, on August 16, 1993, the Final Rule for Device Tracking was published in the FEDERAL REGISTER, pages 43442-43455 (enclosed). FDA is required to provide notice to PMA applicants in an approvable letter that their device is

subject to the regulation. Therefore, be advised that under Section 519(e) of the act, FDA has identified the above device as a device which requires tracking. You are required to adopt a method of tracking that follows the devices through the distribution chain and then identifies and follows the patients who receive them. The specific requirements of the regulation are found in 21 CFR 821 as described in the August 16, 1993, FEDERAL REGISTER beginning on page 43447.

If you have questions concerning this approvable letter please contact Doris Terry at (301) 594-2018 or Arnold Alpert, Ph.D., at (301) 594-2186.

Sincerely yours,

Susan Alpert, Ph.D., M.D.

RE: P920015
Transvene™ Lead System
Filed: April 1, 1992
Amended: September 21, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

We recognize the potential public health significance of this device and acknowledge the separate discussions underway to expedite the review. However, because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. To clearly establish the purpose of the clinical data in the PMA application, please provide the following:

   a. the hypothesis and the objectives of your clinical study;

   b. a discussion of (i) how your clinical study addresses the use of a control, which is relevant to all clinical studies, (ii) the appropriateness of the AICD™ as a historical control, and (iii) your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;

   c. the endpoints of your study; and

   d. how the data provided in the PMA application support the specified endpoints.

2. Based on data provided in your PMA application, please prepare table(s) which include a side-by-side comparison of the PCD® Transvene™ and the PCD® Epicardial System and the PCD® Transvene™ and Ventak P AICD™ populations. The table must also include the inclusion and exclusion criteria which were used for each study. You must include a discussion of how these data may or may not represent a valid comparison, and other comments which justify and support the use of these groups as controls.

3. An update of the PMA clinical study population must be provided. The update must include the data as presented in the PMA application, and must include the clinical experience in the use of the new anchoring sleeves, which are aimed at decreasing the incidence of dislodgement, and a summary of the clinical experience (spontaneous treatment efficacy of ventricular tachycardia (VT) and ventricular fibrillation (VF), observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.

4. Please provide a clear description of how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.

5. Of the 214 patients who did not meet the implant criteria and yet were implanted with the device, 170 patients had successful defibrillation with 24 Joules (J). Please provide an update of the clinical experience on these patients, as described in item 3 above. Also, please discuss how your proposed labeling will address this protocol deviation. Will implant criteria be changed?

6. There were 20 patients among the 214 who did not meet the implant criteria and were implanted without the 10 J safety margin. An update of the spontaneous episode experience in the treatment of VT and VF in these patients and the overall survival must be provided.

7. Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not meet the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.

8. Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update must include a summary of the clinical experience as referenced in item 3 above.

9. Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was

categorized as DFT and LED testing must be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.

10. There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. You must document that there were no significant differences between the scheme for performing DFT and LED testing between the Transvene™ and PCD® Epicardial patient populations, if that is the case.

11. Please elaborate on how the comparison of DFTs obtained from the PCD® Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (b)(4) (75.3 percent)) in the Transvene™ study were programmed with the sequential pathway an(b)(4) 23.4 percent) were programmed via the simultaneous pathway. The majority of the patients (b)(4) (65.2 percent)) in the PCD® Epicardial study were programmed with the single pathway. Based on your PCD® Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ System versus the PCD® Epicardial System.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it is determined, and if the patients met the criteria.

14. Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes. What was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes per patient in this group?

15. On page 130, Table IF-4, you report that there were 5362 episodes of VT successfully terminated. On page 131, paragraph 2, you state that (b)(4) (b)(4) (0.8 percent) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. You must clarify how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a table which includes a category of ineffective therapies with actual patient numbers and percentages. In addition, what assurance is there that an episode of supraventricular tachycardia or atrial fibrillation is not misinterpreted as VT or VF by the physician and considered a successful therapy?

16. Table IM-6, page 173 must be modified to include a column on inappropriate therapy or therapies delivered as the device was programmed so that the percentages add up to 100 percent.

17. On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8 percent. Please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The tables must include percentages with the representative numerical support.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

19. Please discuss how the 1 year sudden cardiac death survival, as reported in Table IF-2 page 128, was calculated. The numbers and an explanation of patient classification must be included. Was every patient included who had a prior cardiac arrest regardless of the arrhythmia?.

20. On page 177, the number of patients must be provided so that the percentages and calculated p-values can be confirmed.

21. Table IV-C, page 649 of the original submission shows a comparison of patient variables for the three lead systems and provides p-values for the variables tested, but the hypothesis was not clearly stated. Please state the hypothesis and discuss the p-values obtained when reporting by primary indication, and the chi-square test of the data set and how it was computed.

22. For purposes of justification of data pooling and data analysis of Table IV-C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp.162-170).

23. You claim that confidence interval analysis was performed to compare the overall mortality of the PCD® and AICD™ populations. What was the confidence interval?

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

    a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

    b. a chi-square test of primary indication, using the (b)(4) computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD® and Ventak P populations are significantly different.

25. Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD® Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment of induced and spontaneous episodes with use of the algorithms must be discussed.

26. Please discuss the "device related" complications reported for the Transvene™ and the PCD® Epicardial System.

27. Please describe in detail the complications reported in the patients followed for a year.

28. There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the procedures for reduction in the number of infections? Please validate these procedures.

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads, and how your labeling assists in the selection of an entry site, must be provided.

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD® and Transvene™ leads) must be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices must be provided. The PMA application must document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD®.

31. Please discuss the circumstances surrounding the death of the patient who died 22.5 months post implant. What did interrogation of the device reveal?

32. Of the perioperative deaths, how many devices were programmed OFF? Please discuss the circumstances surrounding each death. The number of perioperative deaths must be reported in a table and be identified as sudden cardiac, non-sudden cardiac or non-cardiac. Were there other deaths when the device was programmed OFF?

33. You state that there have been no reported patient deaths in the group with a 1 year sudden cardiac death survival and overall

actuarial survival of 100 percent. Does this include the perioperative deaths and the patients who have been followed out for a year?

34. Please provide an engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent.

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over (b)(4) month period would be sufficient? Describe how the full lead and different segments were flexed. Did you do a finite element stress analysis to validate the flex testing stress?

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.

37. A copy of the Summary of Safety and Effectiveness which includes the updated data must be provided.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA with in the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information (12 copies), voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 6 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

F. Alan Andersen

Re: P920015
Transvene™ Lead System
Filed: April 1, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

Because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. Discuss how the use of a (b)(4) prevents tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of polyurethane and silicone in leads to prevent tissue in-growth.

2. Please provide the results of mutagenicity testing for the (b)(4) and the (b)(4) (anchor sleeve). If the tests have not been done please provide a justification for not doing so.

3. Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.

4. Based on your experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed), and on the Transvene™ leads.

5. Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor when the section is flexed?

6. The Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) electrode coil, and the effects of its failure on the performance of the lead.

7. Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.

8. Please specify the section of each lead assembly that was flexed during life testing. Does this section include the electrode coil? The results of the tests should be included.

9. Provide an update of the (b)(4) month life test.

10. The data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test. Correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

11. Discuss the differences in battery life or energy requirements between the epi-lead system and the Transvene™ system.

12. An update of the chronic animal studies should be provided.

13. An update of the clinical experience of the Transvene™ Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, lead orientations including patch location, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.

14. Please discuss your clinical data which support the claim which states that the Transvene™ Lead System improves both perioperative and long term patient morbidity.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

16. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

17. Please discuss your clinical experience (treatment efficacy, lead orientation, complications and survival rates) of the patients who have been followed for 1 year and more.

18. Provide a detailed discussion of the clinical experience (implant duration, lead orientations, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene™ System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.

19. A breakdown of the different lead orientations within the patient population, and the treatment efficacy reported for each configuration should be included.

20. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead orientations during implant.

21. Please provide the P-values as listed in Table IV B and IV C of the original PMA application for the new patient population.

22. Please discuss the reasons why some patients dropped out of the study, either withdrawn alive or lost to follow-up. There were 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2 month period.

23. For the comparison of complications/observations rates for the PCD™ versus the AICD™, please provide the following:

    a. the number of complications and patients for the PCD™ and AICD™ populations;

    b. the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate Problematic VT/VF Therapy Delivery"; and

    c. a discussion of the pocket infection rate of the PCD™ and the AICD™ and the lead related complications of the PCD™ Transvene™ System versus the PCD™ Epicardial System.

24. Some Transvene™ patients were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these patients to those who did not undergo the hollow can evaluation.

25. Please discuss and/or provide the following regarding the 1 year actuarial survival comparison of mortality between the PCD™ and the AICD™:

    a. the statistical test that was used to compare survival; and

    b. the two survival or life tables by year of follow-up.

26. Please discuss the statistical techniques used to derive the P-values in Table XI G-2, page 862, Vol. 5 and Table J-2, page 54, Vol. 1.

The following additional deficiencies were noted in this initial scientific review and the indicated responses should be provided:

1. Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?

2. Discuss the biostability tests (stress cracking, metal induced oxidation, etc.) performed on the two types of polyurethane. Why was a different polyurethane chosen for the inner coil?

3. Based on the results of the life test, what is the life expectancy of the leads? Please include your assumptions.

4. Provide a side-by-side comparison between the Model 6999 and the epicardial patch lead.

5. Discuss the possible interactions between implanted pacemaker leads and the Transvene™ leads. Also, discuss the effects of the leads on the tricuspid valve and the host vein.

6. The Transvene™ leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Transvene™ leads which support this capability.

7. Are there patients currently implanted with the Model 6895 and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

8. Please list the reasons for not performing pre-hospital discharge testing.

9. The number of spontaneous episodes of the patients followed for 6 months and beyond should be provided.

10. A copy of the Summary of Safety and Effectiveness with the updated clinical data should be submitted.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information 12 copies, voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 8 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

for F. Alan Andersen, Ph.D.

Re: P920015
Medtronic® Transvene Lead System
Filed: April 1, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial review of your premarket approval application (PMA). We are pleased to inform you that we have made a threshold determination that the PMA is sufficiently complete to permit a substantive review and is, therefore, suitable for filing. The filing date is April 1, 1992, which is the date of CDRH receipt of the PMA.

Following receipt of a filing letter, an applicant is required by 21 CFR 814.20(e) to update their pending PMA 3 months after the filing date with new safety and effectiveness information learned about the device from ongoing or completed studies when the information may reasonably affect an evaluation of the safety or effectiveness of the device or may reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling.

This updated reporting is limited to studies sponsored by the applicant or to which the applicant has reasonable access. The update report should be consistent with the data reporting provisions of the protocol. Please submit update reports in three copies as an amendment to the PMA and include the above PMA reference number assigned to the PMA.

This letter reflects the current progress of our review of your application. Please be advised that continued review of your application or any response to this letter may result in additional deficiencies.

The PMA cannot be approved until FDA has determined that the manufacturing facilities, methods and controls comply with applicable device Good Manufacturing Practice regulations (21 CFR Part 820). If you have not already done so, please notify CDRH as soon as possible in the form of an amendment to the PMA if there will be a delay in setting up your manufacturing facility for production of the device and provide the expected date that the facility will be prepared for an FDA inspection.

A meeting of the Circulatory System Devices Panel will be held at which your PMA will be reviewed. You will be notified of the location and date of this meeting. Any additional information to be included in your PMA must be submitted in the form of a PMA supplement amendment and be received by FDA at least 6 weeks in advance of the scheduled advisory committee meeting in order for FDA and the panel members to have adequate time to review the new information. Information received by CDRH less than 6 weeks in advance of a scheduled advisory committee meeting will not be considered or reviewed at the meeting.

For your information, there is an industry representative on this FDA advisory committee whose name, address and telephone number you can obtain by contacting the Committee Management Staff at (301) 443-4016. CDRH believes that the industry representatives will be better prepared to participate in panel discussions if they have been provided with a copy of the Summary of Safety and Effectiveness for review prior to the panel meeting. In accordance with 21 CFR 14.86(b), all panel members are subject to all rules and regulations adopted by FDA and the committee; therefore, even though the industry representatives usually are not given access to trade secret and confidential, commercial information, they are bound to protect the confidentiality of documents that would be sent to them in preparation for panel review of a PMA. If you would like the industry representative to have access to any portion of your PMA, including the Summary of Safety and Effectiveness, please provide a copy for that purpose and notify the executive secretary of the panel at (301) 427-1205. However, review of your PMA will not be prejudiced if you elect not to provide a Summary for industry representative review.

All correspondence regarding this PMA should be submitted in 3 copies in the form of a PMA amendment. Please address all submissions to:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

If you have questions, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

Debra Y. Lewis

Re: P920015
PCD Transvene System

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) is continuing to process the above named premarket approval application (PMA). Simultaneously with a review by the Office of Device Evaluation (ODE), the Office of Compliance and Surveillance (OCS) must review the manufacturing information in your PMA to determine that it is sufficiently complete and appropriately organized to permit FDA to determine whether your firm (or your contract manufacturer) has the capability of manufacturing your PMA device in accordance with (1) the conditions specified in the PMA application and (2) the requirements of the medical device GMP regulation.

The Division of Compliance Programs (DCP) of OCS has reviewed the manufacturing section of your PMA and believes that it lacks the information necessary to effectively complete a review and determine whether to initiate a PMA inspection (see enclosed). While the deficiencies outlined in the enclosure do not preclude further review of your PMA, if left uncorrected they may delay or preclude evaluation of your manufacturing process and final approval of your PMA application. We request that you respond as indicated. Please be advised that continued review by ODE of your application (including the manufacturing section) may identify additional deficiencies. Also, the OCS review of your response to this letter may identify additional deficiencies.

For your information a Guidance for Preparation of PMA Manufacturing Information was published on March 22, 1991 (a notice of availability was published in the August 20, 1991 Federal Register). It is also available as part of the PMA Manual Supplement which may be obtained from the Division of Small Manufacturer's Assistance at 1-800-638-2041.

Information supplied in response to the enclosed request should be submitted in the form of an amendment AND BE CLEARLY IDENTIFIED AS A RESPONSE TO AN OCS REQUEST IN YOUR REFERENCE BLOCK. FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). You may, however, amend the PMA within the 180 day period to request an extension of time to respond. Any such request is subject to FDA approval and must justify the need

for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180 day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180 day period will be considered a resubmission of the PMA and will be assigned a new number. A resubmission should be complete and self-contained without reference to earlier submissions because of potential difficulties in assembling files from storage.

All correspondence regarding this PMA should be submitted in three (3) copies in the form of a PMA amendment to the address below and reference the above PMA number to expedite processing.

Radiological Health

Deficiency List

The Office of Compliance and Surveillance (OCS) in the Center for Devices and Radiological Health (CDRH) has completed an initial review of your premarket approval application (PMA), P920004, with regard to the Good Manufacturing Practice (GMP) regulations. Please address the following issues and provide the requested documentation:

1. The Design Assurance Plan, Project 6884/6996, dated 2/7/91 for the new helix electrode, part (b)(4) is not representative of the manufacturing operations. The qualification report dated 4/16/91 does not address the effects of the sterilization process on the integrity of the helical electrode. [vol.2, pp.153-156]

2. Provide the locations of the biological indicators used during the sterilization validation and routine production for the 6966 lead. [vol.2, p.207]

3. Provide the product density and configuration pattern for the 6966 sterilization cycle. [vol.2, p.207]

4. Provide the maximum parameter of the humidity specification for the sterilization cycle of the 6966 lead. [vol.2, p.211]

5. The finished device evaluation for the 6966 lead does not adress the effect of sterilization on device performance. [vol.2, p.174]

6. The validation plan for 6963 lead does not address the effects of the sterilization cycle on device performance. [vol.3, p.327]

7. The process qualification report, (b)(4) does not address the effects of the sterilization cycle on the performance of the 6999 lead. [vol.3, p.335]

8. Provide the product location of biological indicator and spore inoculation for the validation and production sterilization cycles of the 6963 and 6999 leads. [vol.3, p.372]

9. Provide the maximum parameter of the (b)(4) exposure for the 6999 lead. [vol.3, p.376]

10. Explain the difference in the sterilization (b)(4) exposure parameters of the 7217B PCD Control Device between the two manufacturing facilities. The (b)(4) exposure parameter at the Rice Creek facility is (b)(4) minutes; the (b)(4) exposure parameter at the Kerkrade facility is (b)(4) minutes minimum. The Kerkrade facility does not specify a maximum (b)(4) exposure. [vol.4, p.415 and p. 432]

11. Provide the manufacturing methods, controls, and evaluation procedures for the facility identified as Medtronic Milaca, 900 6th Ave. N.E. Milaca, MN 56353. [vol.4, p. 437]

P R O C E E D I N G S

DR. BRINKER: It's now 8:30. I'd like to call this session of the Circulatory Systems Device Panel to order. My name is Jeff Brinker, and I am acting chairperson for this session. I'm from Johns Hopkins University, and I suppose that one of the reasons that we've waited until the last minute is that a number of our panelists haven't made it in. Presumably they are at the Hubert Humphrey Building, or some other area along the Beltway. But I think we can go ahead now.

To start, we'll just have the panel who is here introduce themselves, and then allow Wolf to read the opening sermon. Mike, do you want to start?

DR. DOMANSKI: I'm Mike Domanski, National Heart, Lung and Blood Institute. I'm a cardiologist.

DR. SAPIRSTEIN: Wolf Sapirstein. I'm the executive secretary of this panel, and the chief medical officer at the Office of Device Regulation, Division of Cardiovascular, Respiratory and Neurological Devices.

DR. ECHT: Debra Echt, a cardiologist from Vanderbilt University.

DR. GREGORATOS: Gabe Gregoratos, University of California at Davis.

DR. AZIZ: Salim Aziz from the University of Washington in Seattle, cardiac surgeon.

DR. SIMMONS: Tony Simmons, cardiologist, Wake Forest University.

DR. STEVENS: My name is Larry Stevens. I'm the industry representative on the panel.

DR. BRINKER: Fine. Now Wolf will read the conflict of interest statement.

DR. SAPIRSTEIN: The following announcement addresses conflict of interest issues associated with this meeting, and is made a part of the record to preclude even the appearance of a conflict.

To determine if any conflict existed, the agency reviewed the submitted agenda and all financial experiments reported by the committee participants. The conflict of interest statutes prohibit special government employees from participating in matters that could affect their or their employers' financial interests. However, the agency has determined that the participation of certain consultants with financial interests are not so substantial as to be deemed likely to affect the integrity of a service which a government might expect from such employees, and the need for certain members whose service outweighs the potential conflict of interest created by the financial interests involved is in the best interests of the government.

Therefore, waivers have been granted to the following employees. Dr. Debra Echt is an unpaid principal

investigator for a product that competes with an application that will be discussed today for an implantable cardio defibrillator. A waiver has been granted for her participation in this matter. She is also an unpaid clinical investigator for an application that will be discussed today for a non-thoracotomy defibrillation lead system. A limited waiver has been granted for her participation in the discussions, but she will not vote on this application.

Dr. Jeffrey Brinker is an unpaid investigator for an application that will be discussed today for a balloon catheter for percutaneous transveneous mitral commiseratomy. A limited waiver has been granted for his participation and discussions, and as chairman, but he will not vote on this application in the event there is a tie. He will however be permitted to vote on the other two applications if there is a tie.

Dr. Tony Simmons is an unpaid investigator for a closely related product to one of the applications to be discussed today. Since there is no funding to Dr. Simmons or his employer, a full waiver has been granted for him to participate in this matter.

A copy of these waiver statements may be obtained from the agency's Freedom of Information office. We would also like to note for the record that the agency took into

consideration other matters regarding Dr. Brinker, Dr. Simmons and Dr. Echt, and found that they have other involvements with companies that could potentially be affected by the committee's deliberations. However, since these matters are not directly related to the specific matters before the panel, the agency has determined that these employees may participate fully in the panel discussions, except for those limitations that have already been mentioned.

We also would like to disclose that Dr. Gulshan Sethi, Dr. Michael Domanski, Dr. Ronald Weintraub have involvements with firms that could be affected by the committee's deliberations. These matters are not directly related to the specific matters before the panel. Therefore, the agency has determine that they may participate fully in the panel discussions today.

In the event that the discussions involve any other products or firms not already on the agenda for which an FDA participant has a financial interest, the participants are aware of the need to exclude themselves from such involvement, and the exclusion will be noted for the record.

With respect to all other participants, we ask in the interest of fairness that all persons making statements or presentations to disclose any current or previous

financial involvement with any firm with products they may wish to comment upon. We generally classify these financial interests as compensation for time and services of clinical investigators and their staff, a direct stake in a product under review, such as the patent holder or owner shares of stock, and thirdly as owner or part owner of a company.

At this time, for the benefit of the panel members, their vote on recommendations should be in the nature of an approval, an approval with conditions, or non-approval of the PMA application, and recommendations are to be based on submissions made available with this PMA, which should stand on its own data and not be related to any other similar device available. Reasons for non-approval may also be added by members so voting, and can be for lack of safety, lack of efficacy or false or misleading labelling.

With the summer doldrums, we are short of some members. Under the terms of the panel advisory committee, we have taken this opportunity of making Dr. Tony Simmons and Dr. Salim Aziz voting members for this panel's session, if they are agreeable.

Dr. Brinker, can I have a few moments for another housekeeping procedure? Dr. Gregoratos has served this panel since 1988 as a consultant, voting member and chairman. Prior to that, he had appeared in 1977 as a panel member for four years. During this time, we have used his

expertise and knowledge which he has provided unstintingly. He has been associated with efforts to change the way this panel has been run. He has been able to develop consensus of a body of physicians, which is extremely difficult to accomplish. In appreciation of all his work over these many years, and his agreement to stay on as a consultant, the Commissioner has presented Dr. Gregoratos with this certificate and this letter of approval. Thank you. Dr. Gregoratos.

The other situation, Dr. Chakir has resigned from the FDA and is now present on the other side of the table, and Dr. Tom Callahan is acting director, sitting over there.

DR. BRINKER: I'd like to offer my congratulations to you, Gabe, also for the job that he has done over the last year, and hope that the panel with his assistance will continue to do such an admirable job.

Is there any old business to be undertaken? Any new business prior to the open committee discussion? Then I think we should launch into the first application, which is premarket application P920015, a transvene lead system from Medtronic. I would like the people from Medtronic and their physician investigators to identify themselves, please, also, for the non-employees of the company to give their classification as to their involvement with the company and the device. Class one compensation for time and services,

class two, a direct stake in the product or stock in the company, and class three, owner or part owner of the company. I dont think any of those exist, but I would like the company representatives to identity he or she and start the presentations.

MS. MARRONE: I'm Jennifer Marrone, manager of regulatory affairs.

DR. SCHABER: I'm Dan Schaber, manager of clinical evaluation and product planning.

DR. NORENBERG: Sue Norenberg, senior clinical evaluation manager

DR. SAKUN: Valerie Sakun, senior clinical evaluation manager.

DR. ZIPES: Doug Zipes, cardiologist from Indiana University, consultant, class one.

DR. STEINHAUS: I'm David Steinhaus, cardiologist for the Heart Institute in Kansas City, class one consultant.

DR. BARDY: Gus Bardy, investigator, University of Washington, class two.

DR. BRINKER: Fine. Would you like to start?

DR. SCHABER: Good morning. My name is Dan Schaber. I'm the manager of clinical evaluation and product planning for the Medtronic tachyarrhythmia division. Medtronic has been involved in the research, design and

development of products to treat tachyarrhythmias for nearly two decades now. In the next few minutes, I will be describing the transvene lead system and providing an overview of the clinical results.

In February of 1992, the FDA's circulatory devices panel unanimously recommended for approval the PCD epicardial system. In February of '93, the system was market released. Extensive data that had been collected worldwide continues to demonstrate the safe and effective performance of the PCD epicardial system. During this presentation, I will give an overview of the transvene lead system, its components and how they operate together, and of the clinical results.

As you will see from the data, sudden cardiac death survival is not statistically different between the two groups. Ninety-nine point five percent were transvened versus 98.9 percent with the epicardial system. Overall survival is statistically better for transvene, 93.3 percent for transvene versus 88.6 for the epicardial system. Hopsital stays have been significantly reduced, seven days for transvene versus ten days for the epicardial system.

The transvene system includes the transvenous leads, models number 6963 superior vena cava coronary sinus lead, the 6966 right ventricular lead and the 6999 subcutaneous patch. The only difference between the

approved epicardial system and the transvene system is the inclusion of the transveneous leads which are here highlighted in yellow.

The transvene system offers the clinician another therapeutic option. His performance has been as good as or better than the PCD epicardial system. The lead on the far left is the right ventricular lead. In the center is the superior vena cava coronary sinus lead, and on the right is the subcutaneous patch.

As with our epicardial system, the transvene system employed bipolar sensing. Sensing occurs between the tip and the ring electrode in the standard bipolar configuration. Pacing occurs between the tip and the common defibrillation electrode. Except for patients with a prosthetic heart valve, any patient who is a candidate for the epicardial system is also a candidate for the PCD transvene system. There are people, however, who are candidates for the transvene system and not for the epicardial system. For example, people who have previous open chest surgery, where their risk for surgery is greater.

The PCD device was designed to treat both sudden cardiac death and sustained ventricular tachycardia. Specifically, the transvene indications are identical to those recently approved for the PCD epicardial system.

The system allows for greater versatility in lead

placement. It also can accommodate a wide variety of patients with differing anatomical and physiological conditions. A variety of lead configurations has been used successfully during an investigation of the transvene system. The three that are shown here were the predominant ones used in the study. With these three three-lead systems, energy can be delivered simultaneously or sequentially. In approximately 66 percent of the cases, this configuration, RV SVC sub-Q was used. In an additional 29 percent of the cases, RV CS sub-Q was used. These two configurations comprise 95 percent of the cases in the clinical data to be presented today. There were 95 percent of the cases that totally transvenous, RV CS SVC configuration was used.

Of the 897 patients who were screened for and ultimately implanted with a PCD system, 757 patients received a three lead transvene system, representing 84.4 percent of the population. After trial with the transvene system, it was determined that 97 patients, 10.8 percent of the population, should receive the epicardial system because of high defibrillation thresholds. Forty-three patients, or 4.8 percent of the population, received other transvene systems, including combinations of transvene and epicardial leads. The 757 patients who received the three-lead transvene system formed the basis of the data that I will b`

sharing with you today.

Now let me proceed to a brief overview of the clinical results. The PCD transvene trial began in October, 1989. The 757 implants occurred under a common worldwide protocol that was conducted to evaluate the safety and efficacy of the transvene lead system. The recently approved epicardial system was studied concurrently under an identical protocol at the same centers. The 742 patient data cohort followed for a mean of 16.3 months has been used as a comparison throughout this study.

The 757 transvene devices had a mean implant follow-up time of 11.7 months, and the longest follow-up time now exceeds three years. For this group, as you can see, the most frequent indication was sustained ventricular tachycardia. Sudden cardiac death was the indication in 37.1 percent of the patients, and the combination of sudden cardiac death and ventricular tachycardia was the indication in 13.1 percent of the patients. The distribution of indications between the transvene and epicardial systems is similar. Our analysis indicates that primary indication does not affect sudden cardiac death survival.

An evaluation of other patient care characteristics shows that except for gender, the PCD epicardial and transvene systems are not statistically different. There were more female patients who received the

transvene system. Our analysis indicates that this difference in gender does not affect the study outcomes. As you can see by the mean rejection fraction and New York Heart Association classifications, the majority of patients exhibited moderately depressed left ventricular function.

Now let's look at spontaneous episode efficacy. Episode efficacy is defined as the number of episodes that were converted divided by the total number of episodes treated. As you can see for the two populations, VT episode efficacy was identical, 98.4 percent. You can also see that 88.1 percent of the time, cardia pacing was successful in terminating the episodes of VT in the epicardial population and 91.4 percent of the time in the transvene population. The remaining episodes were treated by cardioversion.

For spontaneous VF efficacy, the two populations were not statistically different, 98.4 percent for transvene versus 98.7 percent for the epicardial system. In the transvene population, 89.1 percent of the VF facilities were treated with the first VF therapy.

For the purposes of the epicardial and transvene trials, a complication was defined as a medical event that had to had surgical intervention for resolution. Because of the differences between the two lead systems, the complications associated with each lead system are different. For example, dislodgement is a complication

inherent in the transvenous system, whereas it is not an issue with an epicardial lead system. For the purposes of the presentation, I will be comparing complications that may be affected by the lead system. Except for pace sense, there is no statistical difference in the incidence of complication rates between the transvene and epicardial groups. There were more pace sense complications -- 3.5 percent with epicardial versus 0.8 percent with the transvene system. Infection, 2.9 percent in the transvene group versus 2.3 in the epicardial group -- was not statistically different.

We were initially concerned with the incidence of lead dislodgment that we observed in the transvene trial. Because of this, we instituted a program of increased education of our clinical investigators and added a second anchoring sleeve to the leads. The incidence of lead dislodgement has steadily declined throughout the study. As you can see, the acute dislodgement rate was 5.3 percent, and now with the additional patients reported in the PMA, it is down to 1.6 percent. The chronic dislodgement rate was 6.1 percent, and it's now 0.7 percent.

As I said, all of the 757 patients in the populations had the single anchoring sleeve. We have an additional 439 patients reported in the PMA that had two anchoring sleeves. Our analysis shows that 80 percent of

the dislodgements occur within three months of implant. As you can see from this graph, the dislodgement free survival, the probability of having a dislodgement with two anchoring sleeves is 3.3 percent at three months, versus 9.2 percent with a single anchoring sleeve. We believe that our program of increased education and the addition of a second anchoring sleeve has significantly reduced our dislodgement rate.

Extensive survival analyses have been performed on the transvene and epicardial populations. Overall survival includes peri-operative mortality. Peri-operative mortality is defined as those deaths that occur within 30 days postoperatively. There have been 51 deaths in the 757 transvene patients, and 113 deaths in the 742 epicardial patients. Our survival analysis shows that sudden cardiac death survival probability at one year is not statistically different for the two groups, 99.5 percent for transvene versus 98.9 percent for the epicardial system. It also shows that the transvene system is statistically better in enhancing overall survival, 93.3 percent and 88.6 percent for the epicardial.

In summary then, the transvene system has been shown to be equal to the epicardial system in enhancing sudden cardiac death survival. It has been shown to be better than the epicardial system for overall survival, 93.3

percent with transvene versus 88.6 percent with the epicardial system.

Finally, the benefit of the transvene system is that it allows placement of an IUCD without opening the patient's chest, and therefore reduces hospital stay to seven days and ten days.

Medtronic has established a large and thorough training and comprehensive support capability for clinicians who treat tachyarrhythmias, including the use of our transvenous lead system. We will continue to provide this service for new users of the system. In the nearly four years of clinical trials with this system involving 69 investigators worldwide, we have conducted a thorough and extensive evaluation of the system. Our clinical investigators have reviewed this data and unanimously support our application to the FDA for PMA approval. It is with their support that we bring you the transvene lead system for review today.

DR. BRINKER: Thank you. Does that conclude your presentation?

DR. SCHABER: It does.

DR. BRINKER: We can have lights up, please, and have the FDA reviewer, Doris Terry, present her summary and concerns.

DR. TERRY: Good morning. The manufacturer,

Medtronic Incorporated, is seeking approval of the PCD transvene lead system. The primary objective of the study of the PCD transvene lead system include to evaluate and monitor the system in the detection and treatment of VT and VF, and to estimate the survival from sudden cardiac death and the overall survival. These data intend to lend support to the end points of the study, conversion, efficacy and survival from sudden cardiac death and total death. The PMA population consists of 757 patients implanted with the transvene non-thoracotomy leads in either of two PCD models, the 7217 B or the 7216 A. The performance of the PMA population was compared to the historical control, the ventach PICD population and a concurrent control, the PCD epicardial population.

As of February 1, 1993, the clinical experience includes data from 762 implants, 447 U.S. and 315 foreign, in 757 patients. Data from the PMA population stratified according to different sub-groups include the following: results of testing at implant, pre-discharge and the follow-up intervals, efficacy of the treatment of induced and spontaneous episodes of VT and VF, complications and observations, patient deaths and survival data. Three hundred patients had DFT testing at implant. The mean DFT was 14.8 jewels, 702 patients had lowest energy to defibrillate, or LED testing at implant. The mean LED was

16 jewels.

Regarding the spontaneous and induced treatment efficacy, 597, 79.9 percent of the patients, had a spontaneous VT or VF episode, or had VT or VF induced post implant. Four hundred and fifty-eight, 60.5 percent of the patients, had a spontaneous episode of either VT and/or VF. Ninety point seven percent of the VT episodes were successfully treated with VT therapy number one; 89.1 percent of the VF episodes were successfully treated with VF therapy number one. Sixty patients experienced 163 -- 1.6 percent -- spontaneous VT episodes when the PCD transvene system was ineffective in determining the arrhythmia. Sixteen patients experienced 31 -- 1.3 percent -- spontaneous VF episodes, when the PCD transvene system was ineffective in terminating the arrhythmia. Of the 657 patients followed for six months or more, 544 -- 82.8 percent of the patients, had an induced or spontaneous episode at pre-discharge or later. One hundred and 13 patients did not have a chronic episode, however, pace sense parameters were measured at the different follow-up intervals.

One hundred and 76 complications occurred in 147 patients. The complications included pocket infections, 24, lead fracture, nine, patch crinkling, seven, explants, four, and total lead dislodgement, 91. Two hundred and twelve

observations occurred in 178 patients. The observations included an appropriate VT therapy, 57, over sensing, 52, patch crinkling, five and total dislodgement, 12. Sixty-three PCD transvene systems were explanted, patient death, 22, infection, 22, heart transplant, nine, low battery voltage, one, PCD performance issues, four, integrated circuit problems, one, and lead problems, four.

The results of analyses on 42 PCDs returned indicated that the devices were performing within specification. Of the 42 PCD transvene systems returned, 23 lead systems or portions of lead systems were returned and analyzed. Of these, the helix of one model, 6966 lead, was damaged. The remaining leads were found to be within specification. The results of analysis of 19 lead systems are pending. It should be noted that one model, 6884, an earlier version of model 6966 lead implanted for 27 months, which was explanted due to heart transplant, exhibited metal ion oxidation upon analysis.

There have been 51 deaths, sudden cardiac, five, non-sudden cardiac, 31, non-cardiac, 15. Five peri-operative deaths, sudden cardiac, two, non-sudden, two and non-cardiac, one, are counted within the 51 deaths. The survival rates for the patients who were implanted with the transvene leads are as follows: sudden cardiac death, 99.5 percent, non-sudden cardia, 96.2 percent, all cardiac, 95.8

percent, non-cardiac, 98.1 percent, and overall survival, 93.3 percent. The peri-operative mortality rate is .7 percent.

The questions for the panel include the following. Number one, 113 patients did not have a spontaneous or induced episode of VT or VF after pre-discharge testing. Therefore, the performance of the system in the treatment of VT and VF was not assessed. However, the pace sense parameters of these patients were measured at the different follow-up intervals. Are these measurements sufficient in assessing the chronic performance and integrity of the lead system in these patients.

Number two. In light of the differences between the U.S. and foreign patients within the PMA population, are there any concerns about the poolability of the data.

Number three. A statistically significant decrease in the peri-operative mortality was demonstrated for the PCD transvene system versus the PCD epicardial system. However, there was a statistically insignificant decrease in the peri-operative mortality for the PCD transvene system when calculated from the intention to treat, as compared to the historical control. Are there specific concerns regarding the peri-operative mortality rates reported for the PCD transvene system versus the historical control.

Number four. Are there concerns regarding the potential risks for dislodgement of the lead and the reported incidence of infection. What are considered as acceptable rates of lead dislodgement and infection as they relate to complications and observations.

Number five. The results of analysis of an explant of a transvene lead model 6884, an earlier version of the model 6966, have raised questions about the lead's chronic structural integrity. Are there significant concerns which would question the reliability of the lead. Do the benefits of the transvene lead model 6966 outweigh the risk which might be associated with this potential for MIO.

In addition, the labelling modification as referenced in my review memo should be considered. The modifications include but are not limited to the following: diagrams which show proper insertion of the endocardial leads, and the various positions for placing the patch lead, efficacy data of the lead configurations via the different pathways, stronger language regarding the use of dual anchoring sleeves, information about how the incidence of infection might be reduced, and number five, recommendations regarding the use of the different lead configurations.

DR. BRINKER: Thank you. The panel discussion will be led by myself. I would like to start by saying that

I think the panel has some basic understanding of the potential benefits of a transvene lead system, since we did approve one in the not-too-distant past. Most of the questions will not be aimed at discussing whether a transvenous system is as good as an epicardial system or better, but rather, this particular transvenous system and its efficacy.

I would like to first start by asking for information on patients with concomitant dual chamber pacemakers. I think there is some reference in here that patients with pacemakers should have them removed or something toads that end, and I want to know, what is the experience with dual chamber pacemakers and the amount of hardware that is in the heart.

DR. BARDY: I don't have a whole lot of experience with dual chamber pacemakers and transvene lead systems combined, but of the two patients that I do have, I can comment on that. I have put in 140 transvene systems, so it's an infrequent event to have that need for having both.

Usually, if there is an episodic heart block, I will just rely on the device itself to pace the patient for VVI mode for backup needs. On occasion, we will use a single AAI or AAIR pacing mode for a pseudo dual chamber system, where we will use the PCD for backup, should the AV node fail, but the AAI unit primarily to maintain antigrade

conduction through the AV node and to supply chronotropic competence.

But in two patients, we have had experience with a dual chamber transvene system combined with a transvene PCD, and in both of those people, they came to me on referral after they had the transvene pacemaker inserted, and in both cases, the transvene ventricular lead was placed fortuitously about two or three centimeters away from the RV apex, which is where I place the endocardial defibrillation lead, higher up in the septum. In those cases, there is no problem with sensing. Because of the pacemaker spike, there was no under sensing of ventricular fibrillation.

I think that might be an issue had those leads been closer to the pace sense leads of the PCD. But if I were to have the need to insert both of those simultaneously, I think I would do the same thing, that is, place one, screw an electrode up into the septum, and another down by the apex, and that should be sufficiently far apart to avoid pacemaker spikes from the dual chamber unit from inhibiting of VF detection.

But I just haven't seen it in those two people. I specifically put a magnet over their pacemakers at the time of the epiduction. I think that has to do with the bipolar sensing of the PCD system, and it's pretty good with respect to that.

DR. ZIPES: We have two patients with the dual chambered devices, both of whom received the device because they needed atrial kick because of reduced cardiac function. Both are bipolar, and with care we were able to place the electrodes such that the size of the spike was sufficiently small in terms of what was sensed by the PCD, that it was not a problem, and that the spikes did not inhibit PCD function in the event of ventricular tachycardia fibrillation, which were induced in the patient during pacing to be certain that that didn't happen.

I think a unipolar pacing should be precluded, and is a potential danger in the concomitant hardware. It would be preferable not to have a second pacing system if one could avoid it, but the PCD at the stage that it's at now, without providing dual chamber pacing in some patients who need it, I think you are forced on occasion to have combined hardware in a patient.

DR. STEINHAUS: I was just going to add two other caveats that I have thought about in this regard. One is that you have to be careful you don't choose a pacemaker that is going to have a power on reset. There are some pacemakers out there which -- that's not different to the transvene system versus an epicardial system, but there are pacemakers which will power on reset after a shock, which you don't want that to do.

I think the other issue would be how many leads you have across the tricuspid valve. We have experience with multiple leads across the tricuspid value in our older pacemaker patients, and it does not seem to be a particular problem.

DR. BRINKER: Thank you. There is one patient who had considerable pain with cardioversion shocks, and actually asked for his device to be turned off, and let to a DNR state. The question I have is, do you have any sense of the amount of sensation a patient feels from a sub-Q patch placed over the muscle as opposed to a epicardial patch?

DR. ZIPES: The patient whose device was turned off and subsequently removed was my patient. There was a major problem with him, in that he has significantly reduced left ventricular function, would run a chronic sinus tachycardia and had a slow ventricular tachycardia, such that there was overlap between the two rhythms. The device would sometimes sense the sinus tachycardia as a ventricular tachycardia, pacing into the ventricular tachycardia in an attempt to terminate what it thought was a VT but was a sinus tachycardia, and then attempt to pace him out of that, and if that didn't work, end up giving him a shock. Despite manipulation of the device settings, drugs, et cetera, we could never adequately resolve this problem.

He eventually asked us to turn it off, and

subsequently surgically we removed the pulse generator. Presently he has long episodes, days on end of chronic ventricular tachycardia, sits in a chair at home, and when he gets sufficiently short of breath, he comes in and gets cardioverted and then goes home again.

It wasn't so much the pain per se, though the shock in the awake state was uncomfortable. But it was a chronic problem of the device putting him into the VT. It just got too much psychologically for him.

DR. BRINKER: But getting back to the point, is there a difference, do you feel, in your experience between the sensation from a sub-Q patch as compared to an epicardial patch?

DR. ZIPES: I don't think so. I think if we go back a number of years when we were first working with just a single lead cardioversion device to terminate ventricular tachycardia, our perception was, once one got above a half jewel or so, that you could then go from there to 20 jewels, and there wasn't a significant difference in pain perception. I think it represented a contraction of the intercostal muscles as a large contributor to that. My sense is that the patch really doesn't seem to change that perception very much from the single lead cardioversion alone.

DR. STEINHAUS: I think I can speak to that. I

actually test all of my patients afterwards, both the epicardial leads in patients and the transvene lead system patients. I test them awake, because I want them to feel what a shock is like. I've done this hundreds of times, and I would say there is absolutely no difference in the way they're felt. In fact, I had the experience of a patient who had a device taken out, an epicardial system, for the same reason that your patient did, multiple shocks and just couldn't stand the discomfort. I really, truly don't think there is any difference in the way they're felt.

DR. BRINKER: Thank you. There is a recommendation in here, establishing an effective defibrillatory lead system that perhaps a cutaneous patch can be used to examine whether a subcutaneous patch would be appropriate. Do you have the feeling that the cutaneous patch is a realistic mimic of the subcutaneous patch?

DR. STEINHAUS: I'd be happy to take a stab at that, too. That is the way I do my implants. I do them all with -- I use a paddle. I take the paddle off the old defibrillator and hook it up. The advantage of that is, it allows me to move it around the chest, so I can try to find the best position. In fact, it's truly amazing how well it does mimic. It mimics closely also the resistances, which is sort of surprising. I would think the resistance would change when you use the subcutaneous patch versus the trans-

thoracic paddle, and it's actually not all that much different. So we found it a very good correlation. What I typically do is, I test it with the trans-thoracic paddle first with most of my shocks, and then I'll go and confirm that using the patch, and they are very similar.

DR. BRINKER: If I remember the data correctly, there were only about five percent of the patients that had a totally transvene defibrillatory system. Is that a function of a decreased efficacy of that configuration, or is that a function of vascular access, or what, in your feeling? I just point it up, because it's quite different from the other transvene system that we had to evaluate.

DR. BARDY: I think a lot of that is historically based on what lead systems were initially used and what you see in the database reflects initial recommendations for this particular lead system. My experience is that the flexibility of the system allows you to choose whatever you want, totally transveneous or mixed with a patch or a two-lead system. I have patients in all categories.

More lately, my experience has been to use simply two leads, and break away from older habits that work fine and use three leads when it doesn't. So I think that three-lead configuration with a patch is in large measure what we started out with in the early investigations, and as we've gotten more experience, we use two leads as well as three,

sometimes three totally transveneous lead systems. It's a matter of patient preference.

DR. BRINKER: Clearly it would be nice to have some logic behind -- if you can get away with two, why would you put three leads, especially an intravascular lead that has a high incidence of dislodgement, albeit steps have been made to improve that. One easy answer to this is that each patient is individual, and you would like to have the benefit to pick and choose. But is there a difference in defibrillatory efficacy between the configurations as a whole?

DR. BARDY: Sure. I've done plenty of studies to demonstrate that. But I guess from a practical perspective of an everyday user, one can easily make a series of recommendations on how to proceed through the implant procedure in a logical way without a lot of variations starting with that, with a high SVC to RV lead system, two leads, very efficient in defibrillation, because the vector is an appropriate vector, and if that doesn't work, to add a high subcutaneous patch through that same incision. That would be my recommendation for the initial approach to implantation.

DR. BRINKER: That kind of thinking, I think, is not clear in the labelling. I think there needs to be some recommendations along those lines to physicians, albeit they

can have the option of doing what they think is best in the individual case. I think that it would be good to have some real instruction as to what a logical course to take is, based a little bit more than on whether you want to put in a CS lead or not.

DR. BARDY: I wasn't even talking about a CS lead, unless there was trouble in defibrillation.

DR. BRINKER: I understand.

DR. STEINHAUS: To answer that question a little bit differently, why weren't there more -- I think the system was built as a three-lead system. To me, and the reason why I implanted the protocol is, it was billed as a subcutaneous patch. I'm not perhaps as creative as Dr. Bardy in trying to figure out different ways -- and I mean it seriously -- of using the device. But the reason why I think most of the implants were done that way is because that's the way the protocol was written, to be using a subcutaneous patch the two other leads.

The system is a three-lead system. I don't think it's -- I think it can be modified to a two-lead system. I think whatever works, works. But I think basically what we were asked to utilize in the protocol is --

DR. ZIPES: That is true, but there is a practical issue. At our institution, the surgeon implants the device with one of the electrophysiology people in attendance.

This is done in the OR. The surgeon -- not to be disparaging -- has not got a lot of experience finding the coronary sinus with a catheter, certainly nowhere near as much as we electrophysiologists do. Also, we have portable fleura, which is not as good as the fleura in our lab. He would make a few passes, give up, and then we would end up with an SVC RV apex and patch lead in the vast majority of our patients. It was a sheer practical decision, based on how it was being pt in.

In our labelling there are recommendations, and the recommendation is to start with RV SVC sub-Q. That has to do with the practical issues that Dr. Zipes is talking about, and with the fact that the majority of the data in the application is with that lead configuration. That is why we recommend that as the starting point.

DR. BRINKER: I think that's important from another point of view. There is a suggestion that the more times you fibrillate a patient to determine the efficacy of a system, the worse the prognosis might be for that patient, especially if you turn out after multiple manipulations with the transvene system, that the patient has to go onto an epicardial system. While you carefully say that these things should be kept to a minimum before you decide to go an epicardial system, is there any guidance that you can give -- and I guess it's patient dependent, but how many

times do you think it's reasonable to fibrillate a patient using different variations of the schema?

DR. BARDY: This is an interesting topic, because I don't think it relates to the number of times as much as it relates to the pause between inductions. I routinely do a great number of VF inductions on my patients, and I have no operative deaths out of 140, and I have a 98 percent implant success rate. But I do routinely 14 VF inductions in the operating room.

The key here is to instruct pausing between inductions rather than limiting the number of inductions. Waiting five minutes between a VF induction I think is the crucial issue, and a prompt rescue. One can go logically through a sequence of recommendations, lead system A, lead system B, lead system C and D, and that is four inductions before you can go through four steps and know yes or no, whether you've had an adequate defibrillation. Pick a number, 24 jewels, 20 jewels, 18 jewels, test configuration A. Does it work or not. If it works, you're probably there. If it doesn't work, move on to the next logical step and do so in the labelling very easily. I don't see that as a problem.

DR. BRINKER: You don't have to convince me, but I think there should be this guidance. Maybe if it's a general consensus about the interval between

defibrillations, but I think it would be helpful for people to get some better insight. I think that these things are going to be used because they are easier than putting in epicardial systems. I think many more patients are going to get these kinds of devices than previously had them. In many cases, it's going to be -- unlike your situation, Dr. Zipes, I know many of our EP people are putting in skin to skin systems of this sort. So I think the check and balance of having somebody else put in the system if you say the patient needs it is going to be a single operator. I think these kinds of guidelines will be helpful.

The next question has to do with the right ventricular lead. I notice that the inner and middle installation is (b)(4) (b)(4) That polyurethane has a mixed history associated with it. Can you tell me why you chose to use this instead of either the (b)(4) or (b)(4) for this lead?

MS. MARRONE: The design of that RV lead was based on a very similar Brady lead, screw-in lead. We have extensive history on that Brady pacing lead. Due to the similarities in design and wanting a screw-in lead for our RV lead, it was the most timely design that we had, and we also felt we had adequate chronic performance on that type of design, our Brady history.

DR. SCHABER: In addition to that, it has to do

with the size of the lead. Silicon increases the size of the lead, and in order to keep the lead a more manageable size and to have good handling, that was the reason for the selection of the polyurethane.

DR. BARDY: That size issue is not a minor one. The choice of (b)(4) over (b)(4) interdigitates with two other issues, true bipolar sensing versus integrated bipolar sensing, and crush injury. I think trying to have true bipolar sensing and a bipolar lead, if you were into (b)(4) you would probably end up with many more crush injuries between the clavicle and the first rib, where most people are going to pt this in. I think that alone outweighs the use of (b)(4) Plus the need for bipolar sensing which I favor strongly over integrated sensing because I think it enhances post-shock detection of ventricular fibrillation. I think those are other issues that might outweigh any concerns about (b)(4)

DR. BRINKER: I'm not sure that there is a difference between (b)(4) and (b)(4) in terms of the thickness of the material that you would use, if size was the primary concern. I am concerned with the MIO that has b been noted already in these leads, and the difference between a cosmetic problem and a failure of the lead may be only microns.

If the middle installation fails, can you get

make-break signals that would interfere with the functioning of the device?

DR. SCHABER: You could get make-break functions which could lead to over sensing and false positive therapies. But we have not seen that.

DR. BRINKER: Okay. This is an area of concern, I think. Obviously, you follow these for the longest duration leads you have, or what?

DR. SCHABER: Over three years now.

DR. BRINKER: Right, but from our past experience with other leads like this, you really don't see a big dropoff for four or five years, do you?

DR. SCHABER: That is correct. As Jennifer was saying earlier, this is patterned after one of our Brady leads that has longer duration.

MS. MARRONE: And actuarial survival on that similar design is --

DR. SCHABER: It's 99.7 percent at three years.

DR. BRINKER: The subclavian crush business. You advise physicians to use a lateral insertion site, but any subclavian stick is going to result in a medial placement of the leads, no matter what you do. It's not very easy to put these leads, all of them, especially if you use a three-lead system, through a cephalic vein, unless you use an introducer technique. Do we have any idea -- I guess you

do, since I saw the numbers, but how many three-lead systems have been placed through a cephalic vein?

DR. SCHABER: In general, two-thirds of the patients we implanted have used subclavian versus a cephalic vein approach. In terms of the three-lead totally transveneous, I don't think we have it broken out that way.

MS. MARRONE: In the patients that received a totally transveneous system, a cephalic vein cutdown was used for RV placement, and then a subclavian stick was either used for the CS and the SEC position. They are not all through the subclavian. They're using two vein accesses.

DR. BRINKER: But if you use an introducer technique, you could probably put as many of these things -- because we all have to go through the same vein, after all. They all go through the subclavian, and the cephalic is usually sacrificed once you put in more than one lead through it, anyway. So basically, you just have a more lateral access to the cephalic system.

I noticed with some glee that you only had four episodes of subclavian axillary thrombosis, which is kind of unique with this, I would imagine, especially if you put in three leads. Nothing more along those lines has surfaced. You're not getting any more than you reported.

DR. SCHABER: No.

MS. MARRONE: In fact, none of the subclavian vein thrombosis was reported in the patients with totally transveneous systems. There has been none of that reported in the totally three-lead transvened patient group.

DR. BRINKER: The next question I have concerns lead dislodgement, which is all too common with this system. Perhaps it has been fixed by a double anchor, and if it has, I think that it should be formally suggested in the labelling that physicians should use a double anchor.

But my real question is, why is the dislodgement for an SVC lead, for instance, so common, since there is really nothing pushing against it. The only thing is the pull of the device, I would imagine. Is this a major factor in epicardial systems that use a SVC lead as part of their system?

DR. STEINHAUS: I think much has been made of that, and I think a lot of it is a learning curve and experience. I know the engineers think they fixed it by putting a second sleeve on there. I don't really believe that's what fixed it. I think what fixed it is two things. One is, the sleeve is better, it holds the lead a little bit better, and the second thing is, people now know how you have to do this.

Remember, a lot of the people who started putting these things in were EP docs, and they weren't used to doing

a lot of pacemakers. The pacemaker doctors had a lower rate of lead dislodgement, because thy were used to putting the hub of the sleeve that holds it right up next to the subclavian vein, and using multiple sutures to hold it in place.

I think if one does that, that really does solve the problem of lead dislodgement. We have had a very low rate of lead dislodgement, and I only use the one connector, and always have. I really don't think it's the second sleeve that does it; I think it's the fact that you've got to get that first sleeve right up next to the vein. You've got to be careful how you tie it down, and I think also the sleeve itself is slightly different, so it ties down a little bit better. I think those are the three issues. I think it's a learning curve issue more than it is an issue of dislodgement. My lead dislodgement rate is very low.

DR. BARDY: I'll echo that, especially the anchoring design. It was not very good initially. It was quite loose, and one had to apply a great deal of pressure to make it approximate the lead. Once that was redesigned and we learned that the tension on these leads from body torsion and flexion was high, once those two issues were brought in focus, I think dislodgements dropped dramatically across the board. I know they did in my experience, because I had quite a few early on which I attributed to a

combination of the sleeve and ignorance in anchoring.

DR. BRINKER: The subcutaneous patch, that cannot be used in the epicardium, is that correct?

DR. SCHABER: Our labelling indicates that it should only be used for subcutaneous.

DR. BRINKER: I think that in a description of the three nodes that are on the side of the patch and how to position the patch, it would be nice if there was a picture showing what the three nodes looked like and how the patch should be applied to the subcutaneous tissue, because I found it a little bit difficult to envision that as I was reading this.

You add to the indications for use patients undergoing replacement of a previously implanted cardioverted defibrillator system. I would assume that this should not be done if the leads through the previous system are efficacious. In other words, this should only be done if the lead system is no longer functioning.

DR. SCHABER: The indication is that I think PCD manual is for use both with our epicardial and transveneous systems. So that is to cover -- if an epicardial system is in place, the device reaches end of life and you need to replace it with another PCD, that is an appropriate use of the system. What it is not to do is to say, if you have a functioning epicardial system and replace it with a

transvene system, that is not the intent.

DR. BRINKER: Let's say that you have a pre-existing epicardial system, and nobody wants to take out the -- it doesn't function well for whatever reason -- nobody wants to take out the epicardial patch electrodes. Some decision is made to put in a transveneous electrode system. Assuming that the epicardial patches are capped, would there be interference with the way the energy is delivered between a sub-Q system and the pre-existing epicardial systems?

DR. BARDY: I can talk about that directly, because I have a pig model of a field distribution across the thorax. Although much has been made of the epicardial defibrillation patch interfering with tarns-thoracic rescues or in this case, transveneous defibrillation, the problem really is non-existent. When you measure the field across the myocardium, it's almost totally uniform. The real field dropoff is not because of insulation from a patch around the epicardium, but rather the electrode-tissue interface from the shocking electrode. So I think that's a theoretical issue, but not one that can be measured.

DR. SCHABER: If you were to replace the system, our labelling addresses the fact that you should go through the standard implant testing, to show that you can meet the implant criteria and have a safety margin.

DR. BRINKER: I think I have reached a point where

I can pass the questions on to some of the other panel members. I guess we'll start with my right, Dr. Sethi.

DR. SETHI: About your subcutaneous patch electrode, during testing, could you tell us more about it, how you use it? In the labelling, it's not very clear how you use your subcutaneous patch electrode.

DR. STEINHAUS: Sure. What I will do is, I'll put the two intercardiac leads inside. I'll put the RV lead in first, and then get measurements on that lead. I'll then put the lead in the coronary sinus. I do like the coronary sinus positioning. It gives me a chance, while people are checking the lead, to go ahead and put the coronary sinus lead in. Then what we'll do is, we'll take a standard defibrillation paddle from a standard defibrillation device, which is almost the same size as the patch, and that will plug in -- there's a cable where all those leads plug into to mimic the device. We'll plug that into the cable as well. I usually start right at the apex, is where I like to go, underneath the left breast. If that works the first time, then I'll do several more defibrillations there to prove it's going to work there. If that does not work, then I'll either change the configuration, or I'll move my paddle either more laterally or more interiorly, or more superiorly. I'll just try to move it in a lightly different position.

The beauty of that is, I can do all of my testing non-invasively. I've made one incision up here, but I haven't yet committed myself to where I'm going to make my incision for the cutaneous electrode placement. Once I have found a good position, then I know where I want my patch to be. Then I can make my incision where I want to make it, and make a pacemaker patch pocket and just lay it right in there.

It's worked very well for me conveniently. It's been nice to be able to move that kind of electrode around. It's surprising how well they match.

DR. SETHI: How about Dr. Bardy? Do you use the same thing?

DR. BARDY: No. I used to do it that way, but I prefer -- my bias is to use a single incision for the pacemaker patch up high. I will resort to other methods if that doesn't work. I'll simply put the sub-Q patch up through the same incision that I used to get the transvenous leads in, if I'm going to use a sub-Q patch. That vector tends to be reliable in over 80 percent of people for defibrillation. It's a rare time for me to move it down anymore. I'll tend to move the SPC lead instead into the coronary sinus rather than move the sub-Q patch. One can make a pocket easily up here that usually goes down to the aureolus and to the lateral margin of the pectoralis, and

I'll place the patch over top of the fascia. That's the way I do it. I don't use the paddle testing technique anymore, because it's a pretty rare event to have a failure.

DR. SETHI: How about you, Doctor?

DR. ZIPES: We use pretty much what Dr. Steinhaus has indicated.

DR. SETHI: Is there any data available regarding use of the patch in the pectoral region?

DR. BARDY: I've done no randomized comparisons to the two. My techniques evolved over the years. Obviously, down here, if one uses the coronary sinus as your common electrode and you're pulsing out from the coronary sinus, you have a much better vector across the myocardium. But my interests lately have been towards speed and efficiency of implantation, minimization of incisions, and trying to translate all those more complicated implant methods down to a method that a general electrophysiologist can use easily.

So much of my work has been trying to test simpler things, so that it can be translated out into the community with ease, rather than coronary sinus systems, which are very effective, especially in difficult to defibrillate patients. But it's more complicated and convoluted to people that may not have a lot of experience. So by a two incision system, one for the pulse generator, one for the patch, high patch position, high SVC position, that works

very easily 80 percent of the time. It doesn't take a lot of expertise to implant.

DR. SETHI: Thank you. You had quite a few patients who had good DFTs at the initial implantation. When they were tested before discharge, the DFTs weren't markedly increased. Some of course are because of the lead displacement. Do you have any idea why other patients had high DFTs?

DR. BARDY: Actually, I've done a study and I've excluded all the lead dislodgements and drug superimpositions on the patient, and all the other things that can affect the defibrillation threshold, and just looked at change of DFT over time, when no other changes were present in the patient. This phenomenon is an interesting one to me, where you do get a rise in the defibrillation threshold in the first week to six weeks, maybe as long as three months.

I'm learning as we progress, and I think I can speculate the cause. That is thrombosis around the coil, clot formation, will give a marked rise and a dropoff of the field in the first few millimeters, not the first few centimeters. That clot is enough to raise the impedance at the electrode-tissue interface many times. It's after the clot dissolves or turns into a fiber sheath that that field then approaches what it was at the time of implantation.

In fact, you can see that rise in defibrillation efficacy if it's a long case. If you're in there for a few hours, you'll see your defibrillation threshold rise by the end of the case. I think it's because of the clot. In the days when we were putting these transvene lead systems in and then pulling them out before they were approved for implantation, if the leads were in for a half an hour to an hour, you would see this platelet slime cover the coil. As that builds up, I think that's what causes your rise in defibrillation requirements, but as soon as it shrinks back down, it returns to normal, as I have seen in a year follow-up.

DR. SCHABER: One thing I might comment about in addition to that is that we have seen the same phenomenon with the epicardial system, that is, the thresholds tend to rise in the immediate post-operative period and go back down. But there is a very rare circumstances where the thresholds rise enough where they have to do something with the lead system. The reason for a ten jewel safety margin is that that will allow for rises in the threshold. Usually when the thresholds do rise, they rise by a few jewels, so you can maintain the same lead system. Then after three months or so, they go back down to what they were initially.

DR. ZIPES: I think the acute changes also may be modulated at least to some degree by the autonomic nervous

system. Catecholamines have been reported to reduce defibrillation thresholds, and they are going to be very high intra-operatively, and might indeed be significantly lower during a pre-discharge test. That may play some role.

DR. SETHI: One of the concerns which have been discussed is about thrombosis of the subclavian vein. It's a pretty bad complication when a patient has it. Any thought been given regarding anticoagulation or something like that by the company?

DR. BARDY: I've had four patients out of 140, three of which I picked up on routine visits, just slight swelling in the left hand, and one that was more symptomatic with more marked swelling. My concern by making a recommendation of anticoagulation would be pocket hematomas, which I think would be much more of a problem than a left clavian vein thrombosis. I think the incidence of a two or three percent left subclavian vein thrombosis is probably going to be unchanged by anything other than really aggressive anticoagulation, which will probably get you in more trouble.

DR. STEINHAUS: I think that's an issue. Probably subclavian vein thrombosis is under reported in all the literature. If you look at studies that have been done in the pacemaker literature, it happens more frequently than we ever know clinically. I suspect that's a function of time.

If it develops over a long period of time, collaterals can form and you never see it.

I have not seen it with this system in any patient. That's not to say it hasn't happened. I suspect it has happened. I just suspect it's slow enough that we get collaterals.

DR. ZIPES: If you were to do a venous angiogram or fibrinogen labelling, I think you would find a much higher incidence than is clinically apparent. Most of the patients do very well, even though it may be a thrombosis.

DR. SETHI: I agree with you. I think the complication of coagulation would be very high, and I wanted to see what you all thought about it. One question I've got. I'm not an EP cardiologist, I'm just a surgeon. I'm concerned about the VT and V-fib therapy in your report here. I think there are 77 or 80 patients. Is that expected or accepted? Is that too high or too low?

DR. ZIPES: No, I think that's the state of the art with the present systems. In looking at primary cycle length, the system can easily be deceived by atrial fibrillation or other SVTs. I think the advances will come with better tachyarrhythmia identification. Measuring cycle length is done easily and with exquisite accuracy, but ultimately, the devices will look for AV disassociation, will have a measure of the duration of the electrogram to

distinguish a normal QRS from a wide QRS. There are a number of refinements. But I think that's the state of the art at the present time.

DR. BARDY: I think it also represents a degree of trigger-happiness on the part of programmers. That is that they tend to want to treat every little VT that comes by, instead of ignoring them. I would think a lot of those inappropriate therapies would be resolved if one simply programmed the tachycardia detection interval so aggressively low. It's a rare event for me to program a TDI greater than 400 milliseconds. I think that is where you get into trouble with these inappropriate therapies, when you start getting TDIs of 500 milliseconds.

If I were recommending labelling, I would put flags up at 400 and above.

DR. SETHI: One final question. There were significant incidents of lead dislodgement. There is not a single death during that period. Is that a function of luck? Could you explain that to me, how that happens?

DR. SCHABER: I think much of the reason is that half of the dislodgements are caught before the patient even leaves the hospital. So they are under medical supervision for this entire time. The majority of the risk is while they are in the hospital and there is other protection available. But the other ones occur between implant in the

first month, and it's a matter of the incidence of arrhythmias. There aren't that many patients who have an arrhythmia in the first 30 days post-operatively, so there is a short exposure time if there is a dislodgement at that time.

DR. SETHI: How about the late dislodgements? Two or three percent of the patients had late dislodgement. How do you follow those patients?

DR. SCHABER: The way we follow the patients is standard follow-up things, doing pacing and sensing thresholds and evaluating an X-ray to evaluate the position of the leads. The most frequent cause for a late dislodgement is a traumatic event in the case where someone is tumbling down a hill and reaches to grab a tree, so that they don't fall down the hill, and the extensive stretching pulled the leads out. But the vast majority of the lead dislodgements are associated with some event like that.

DR. ZIPES: I think you are right, luck has to play a role. A patient who has a late lead dislodgement and develops ventricular fibrillation may well die at that point, and fortunately it's not happened. I don't disagree with any of the things that have been elaborated, but luck does play a role.

DR. SETHI: I think some of the sudden deaths which the investigators and your committee have said they

are not the causes of the device could be because of lead dislodgement.

MS. MARRONE: I think you raise an interesting point, but all those patients when they were seen at follow-up prior to the death, there was no indication that there was a problem with the position of the lead system. Again, in getting intensive information from these patients' death by the physician or the referring physician with documentation of X-rays showed no dislodgement of the lead system. As you noted, we had a clinical event review committee review all these deaths, and felt there was no relation back to a dislodgement of the lead system.

You raise a point, but there is no data that would indicate that was the case in these patients.

DR. SETHI: Thank you.

DR. DOMANSKI: I have just a couple of questions for you. There was no change in peri-operative mortality. Can you discuss that?

MS. MARRONE: I'd like to comment on that. There is a difference in intention to treat peri-operative mortality. If you take the patients who were screened for a transvene system and you look at their peri-operative mortality, the incidence is 1.6 percent. If you compare that to the patients who were screened for an epicardial system, and their peri-operative mortality is 4.5 percent.

Looking at the statistical analysis, there is a statistical difference in that peri-operative mortality.

DR. DOMANSKI: Do you think that accounts for the overall lower mortality of the transvene system then? If there was no difference, then it would be interesting to know why the overall mortality was lower. But it sounds like that explains it.

MS. MARRONE: Exactly. We looked at the epicardial patients, and that data is provided in the panel package. We looked at the overall patient survival for the transvene system. I think what the reviewer may have been indicating is when you take the patients that have received the transvene system, their peri-operative mortality was 0.7 percent. If you take the patients that were screened for a transvene system, it was 1.6 percent. There is no difference there. But when you compare it to the epicardial group, there is a difference.

DR. DOMANSKI: Does that answer your concern about it?

DR. TERRY: It was a concern about this comparison of 1.6 percent versus a 2.2 or so that you would get from the historical control. Our statistician somehow felt that that was --

MS. MARRONE: We're making our comparison to our own PCD epicardial system. Because we don't have all the

data available from any of the historical controls to be able to do it without comparison, we're looking at our two systems. There is a difference.

DR. DOMANSKI: That answers my concern. That's the only question I have now.

DR. ECHT: I'll also start with a concern that was mentioned by the FDA review. That is a pooling of data from U.S. and international populations, which showed that the U.S. population was older, had a lower ejection fraction, more incidence of coronary disease, more incidence of cardiomyopathy. You state that this is statistically different, but probably not clinically significantly different. So I just wondered if you could explain what you mean by that.

DR. SCHABER: I think what we've done is, we've gone back and looked at the data in terms of the patients that were enrolled concurrently. Because of the way the system operates, what happens is that we do the evaluation concurrently worldwide. Once Medtronic is satisfied that the system is suitable for market release, then we market release it in areas where there is not a regulatory issue with doing that. At that time, we don't enter any further patients in from outside the U.S.

So if you look at the patients who are enrolled outside the U.S. up to the point of market release and the

patients that were enrolled in the U.S. up to the point of market release, and compare those patient populations -- that is what we did in our September submission -- those indeed are the same. The only differences is a couple of years' difference in age, but all of those other factors are the same.

It's our belief that as the study progressed, the patients with which the physician would try to implant the system changed. Early on, it was thought that patients with a low ejection fraction wouldn't do as well, so the system because of the limited supply of them were put more in patients who had a higher ejection fraction. As the study has progressed, that has changed now, so that the opposite is happening. They believe that patients who are sicker should get the transvene first and not the epicardial system.

DR. SAKUN: One point before I let the physicians speak, those points that you raised, do they make an impact on outcome. Doing that analysis showed that it did not. So we felt that based on statistical comparison and the initial analysis that it was appropriate to pool those patients.

DR. STEINHAUS: I don't like commenting on a pool data because I'm not a great statistician. But I looked at all the U.S. data alone. For a study that we're doing, it's U.S. and one Canadian center, and it turns out to be exactly

the same numbers. It's surprisingly close. So to me, it doesn't make a whole lot of difference whether you pool or not pool. It looks very similar, both in terms of ejection fraction and in terms of mortality statistics. That same mortality difference holds up. It was .6 percent in our study for the non-thoracotomy system and 3.4 percent at a PO of one level.

DR. ZIPES: There probably is some difference. I think the selection of patients in Europe for a device, depending upon the country, may be different from ours. Where budget crunches affect England so dramatically, they would probably tend to go with younger patients with better EFs, and possibly stay away from cardiomyopathies. So there may be some differences, but I think you need to ask outside of a statistically significant difference, does this have any clinical relevance in terms of the device function. I think there, the answer is no. I think these patients have sudden death, and the device works in them as well as it works in the American population. I think from that standpoint, it's perfectly reasonable to pool the data.

DR. ECHT: The Europeans used the exact same protocol and the same exclusion and inclusion criteria we used, right?

DR. SAKUN: Yes, identical protocol, same follow-up.

DR. ECHT: I personally have no problem with it, either, but it was brought up and I thought it was worth discussing. But as long as the exclusion-inclusion criteria are used and the protocol is exactly the same, and the target patients for marketing are receiving the device, I think it's clinically relevant myself.

To comment in terms of efficacy, I think the VP-VF determination efficacy and survival is excellent with this device. There are some safety issues, though, that I would like to talk to, some of which were already alluded to or mentioned, but I really want to get into this dislodgement thing a little bit more in detail.

My understanding from data in Appendix I is that of the 11 or 12 percent dislodgement rate, 3.2 percent were RV lead, 8.4 percent were CS lead and 8.4 percent were SVC lead. I would like to go through lead by lead and talk about how they're dislodging and how the anchors are going to help. As regards the SVC lead, I was wondering, how many of these were leads that were retracting, how many were leads that were falling down in the IVC, to start?

DR. SAKUN: I think that's a good question. We went back and polled each of the physicians to give us that information. Almost 70 percent are being pulled back. The remaining 30 percent are falling forward.

DR. ECHT: We luckily haven't had that much

problem with this, but with the old spring patch epicardial systems, it seemed that adding more anchors and putting a loop in and all those sorts of things really didn't help this retraction problem so much as it helped the falling down problem. So I'm not sure how having two anchors or the stronger anchor is going to necessarily prevent it from pulling out.

DR. SCHABER: In order for the anchoring sleeve to be effective, you really have to anchor the sleeve to the lead itself, and then anchor that to the vein. Initially, our first anchoring sleeve didn't anchor as tightly to the lead, so the lead could move back and forth within the sleeve. The new anchoring sleeve has tabs on it. In terms of pull strength, it's significantly better. So that does make a difference, that it's harder to pull through. With the addition of the two, and our increased education, talking about adding a loop or some other sort of redundancy, I think that really has addressed the pull-back.

DR. ECHT: The CS lead I think has two problems. I don't think any of them actually drift down farther into the CS, but they could either just flop out of the CS or be pulled out of the CS. I wondered what proportion of each you had seen.

DR. SAKUN: Interestingly enough, a great number of the CS leads that dislodge actually dislodge to an SC

position. Then the physician elected to repeat defibrillation efficacy testing and found that the system worked. So I think in the range of 60 to 70 percent came in in the SPC position. The remaining were still anchored in the os, but the coil was now sitting in the right atrium. So it kind of flopped out.

DR. ECHT: What you mean by flopping out, it's not pulled back at all, it flips and now it's hanging in the RV? That doesn't happen?

DR. SAKUN: We had none.

DR. BARDY: I think flopping out is almost -- dependent on the diameter of the coronary sinus. I've had two flop out, both big vessels. That lead being a (b)(4) lead, it's less rigid than the (b)(4) lead and more likely to do that. But there are ways around it, and the ways around it are selection of electrode polarity to guard against that, should it happen, and another is where it's positioned in the coronary sinus. The way I put it in, it's up to the point where it's wedged into the coronary sinus. That typically holds it into place without any sequelae from closing off this CS.

DR. ECHT: So in terms of polarity, would you guard against that by making the RV and CS the same polarity, so that if it would flop out and touch each other -- okay, that's what I thought you meant. So if

retraction is the main problem with the CS lead, you think anchors should help that a lot? Okay.

Then the last lead is the RV lead, the incidence being 3.2 percent, which is a lot lower than the other two leads. But 3.2 percent still seems to be maybe double what I would like to see. It surprises me some, because it's an active fixation lead.

One of the questions I have that is not exactly clear to me is whether or not these RV leads are also retracting, in which case this anchor might work, or whether or not something about the stiffness down there -- because there is that RV thing with that contracting ventricle might just pop it, because it's screwed in. So I was wondering whether those dislodgements are retractions or whether they're just unscrewing and still have the same length.

DR. SAKUN: I'll let Dr. Bardy describe some of his patients in detail, but all of the RV leads that dislodged were still in the RV. So they had not gone back across the valve.

DR. ECHT: So this is a different problem, then. It's not a --

DR. BARDY: I think it is a pull-back problem, but it's --

DR. ECHT: But it's pulled back out.

DR. SCHABER: Enough to lose pacing. The

incidence was 3.2 percent with a single anchoring sleeve, and with dual it's less than one percent in 400 and some patients. So we think between the education and this anchoring, that that really has addressed that.

DR. BARDY: Yes, I think it is mostly pull-back. Certainly all the ones that I've had with RVs have pulled back and have straightened up in the right ventricle, more than come out. The screws probably help keep them in place.

The other reason I think this dislodgement rate may be higher than what we would have liked is that the size of the leads are small, and they're not gripped by the first rib clavicular space. In a way, it's a kind of a paradox. The bigger the lead, the less likely you are to get dislodgement, because the first rib clavicle grip adds some active fixation. The smaller size leads dont' have that kind of limitation there, and they are going to be subjected to that incredible torsion and flexion, because of their length.

DR. ECHT: To follow up on what you said, Dan, subsequent to the 757 patients, found two pieces of data, one on 439 additional patients and one on 573. Was the 439 a subset of the added 573?

DR. SAKUN: Some of the 439 patients are in that new subset.

DR. ECHT: I read 439 patients, most recent

patients, had a 2.3 percent dislodgement, and then for the 573 patients, the dislodgement was stated to be 4.5 percent.

DR. SCHABER: Some of the 500 have a single anchoring sleeve, and the 439 were the ones --

DR. ECHT: Those were purely -- they all have two, okay. So in this group of patients who all have two anchors with the 2.3 percent --

DR. SCHABER: And that includes all leads, RV, SVC, CS.

DR. ECHT: What is the follow-up time on those? What is the mean follow-up in that group of 439 patients?

DR. SCHABER: It's over three months, and 80 percent of our dislodgements --

DR. ECHT: Were in the first three months, yes. Half were in the first month, and then the other half --

DR. SCHABER: The other half occurred between the one month and the three month interval.

DR. ECHT: You said that of that group -- was that the group said only had a one percent RV dislodgement?

DR. SCHABER: Right, less than one percent.

DR. ECHT: I just have another Valerie question. On the infection rates, because there were a couple of numbers, in one part of the PMA Volume two clinical report, page 74, it said as Dan showed in his presentation, there

was a 2.9 percent infection rate, and a 5.3 quote observation of infection. On page 52, Volume one summary, they list pocket infection as 3.2 percent complication, 1.3 percent observation. So my questions are, those are slightly different. Maybe you can just break it down in terms of infection -- I don't know what an observation versus a complication is. Does that mean whether or not it was explanted? Which ones needed explant, which ones were treated with observation, and which ones were treated with antibiotics and no explant? Could you clarify that?

DR. SAKUN: The clinical study as was stated in the presentation. A complication is a medical event that requires intervention. So when you talk about infection, there are going to be some patients who are explanted, and we would also count patients who had a pocket debrided and the device placed back in the pocket. So there were 24 patients where surgical intervention was required, 22 of those, the devices was explanted. That is where you get the 2.9 percent. So when we did the comparison of epi versus transvene, we wanted to compare apples to apples, how many resulted in explant. When you look at the total number of infections that required invasive intervention, that's 24. So that's 3.2 percent. The patients that are in the observation column, those are all patients that were treated with antibiotic therapy and the infection resolved.

DR. ECHT: Those were limited to the pocket?

DR. SAKUN: Exactly, they were all pocket infections. They had not seeded to a sub-Q patch, so there was no evidence of infection other than in the pocket.

DR. ECHT: I have a question regarding peri-operative mortality, which was extremely good in the transvene population. But I seem to remember seeing some data on patients who underwent testing for transvene, the DFT was too high and they went ahead and had an epicardial system, and it seemed like their peri-operative mortality is much higher. So I was interested in what their peri-operative mortality is. How many VF inductions they had as compared to the other patients, and whether or not they had thoracotomies performed at the same setting versus on a later date, and all that.

DR. SAKUN: What I would like to do is give you those numbers and then I would like to have some physician input on how they may manage those patients. There were 97 patients who were initially screened for a transvene system and went on to an epi. In that group, there were nine peri-operative deaths, which gives us a peri-operative mortality of 9.3 percent in that patient group. They are included back in when we do the intention to treat.

DR. ECHT: Right, but they're not separated out.

DR. SAKUN: Right. Your next question was, were

their implant procedures any different than the patients who did get a transvene system. Interestingly enough, the number of configurations tested is different, the mean number of configurations, from those who got the transvene, but the number of inductions is not.

Looking at them, seven died on same-day procedures, two died doing the implants on separate days.

DR. BARDY: I think when we reviewed those deaths, it was clear that the patients were being put through too much, too soon. The recommendation was to delay the epicardial for at least two days before proceeding, because they had been through a lot with their failed transvenous.

The other thing that came out of looking at those deaths was that many of those people were allowed to fibrillate too long. I think their deaths are in large measure related to prolonged episodes of VF, more so than difficulty in getting a system to work. It was being unprepared to rescue the patient. That is what struck me about several of those deaths, was the lack of preparation in the operating room.

DR. ZIPES: I don't think it should be mandatory that it be a two-day procedure if the transvene system is found to fail. I think if one decides early on after just a few inductions that the transvene system is not going to work, and then immediately go to a thoracotomy or a sub-

costal or sub-xiphoid or whatever for the patch, I think i's very reasonable to do it at the same time. I think it ought to be a clinical judgment.

I agree with Gus that prolonged episodes of VF -- and I disagree with him a little bit that the numbers have got to play a role, maybe 14 with a five-minute rest period in between is okay, but 20 with little rest period -- VF is harmful to your heart. I think those prolonged episodes, unquestionably, you ought to stop at that point and come back several days later. But I don't think it should be an obligatory statement.

DR. ECHT: Do you think there should be a recommendation in the physician's manual --

DR. ZIPES: Yes, and interestingly, I think some of the poor practices in the OR stem from some of the early dog studies, where it was said that you get the same numbers with a preposterously short interval between VF inductions, that that was part of some of the animal protocols, 30 seconds or a minute, or something very short between two VF inductions. It's ridiculous.

DR. STEINHAUS: I feel the same way Doug does, but I disagree a little bit with what Gus had to say, not in huge proportion. But I think after you have had a patient who has had multiple inductions and multiple configurations, you are now getting into two hours or so of anesthesia time.

There are patients who have VFs of 20 percent, and the anesthesiologist is now putting dopamine on the patient to boost up their blood pressures. I think that is the time not to do a thoracotomy. It's time to stop and reassess and let them recover.

DR. ECHT: My opinion is that there is a huge difference between 0.7 percent and 9.3 percent, so maybe we ought to be a little bit stronger about informing that this really is associated with a high peri-operative mortality. Even though there may be individual patients in whom it's perfectly safe, I think people should be aware of this 9.3 number.

DR. SAKUN: That particular percentage is not put into the labelling, but there is a specific note that says patients who failed to meet implant criteria and went on to epicardial, that there is an increased risk for peri-operative --

DR. ECHT: Yes. This is like more than a ten times risk. This is not a small-time difference.

DR. SAKUN: Right. If the panel feels we should actually put the percentage on, I don't think we would have any issue with that.

DR. ECHT: Next on my list are devices and leads out of service. I comment just that out of service percentage was very low, excellent, but I don't know what

(b)(4) -- what is it?

DR. SCHABER: (b)(4) is the name of an integrated circuit. That was the same issue that was reported on the epi system, where there was early on an issue with integrated circuit.

DR. ECHT: Because it was an FDA concern, we need to talk about this one case of metal ion oxidation. It seems to me it's just a really oddball case, in that there was damage 20 centimeters from the tip, but 20 centimeters from the tip was inside the RV. This patient must have had a strangely huge right heart. I would personally not want to make any extrapolations, but maybe we should talk about it anyway, because it was something that came up. Do you want to talk about that case a little bit?

DR. SCHABER: That was a case with, as you said, an extremely large boot-shaped heart. The reason that the lead was explanted was because their heart function was so bad, they had to have a heart transplant.

DR. ECHT: It was a functional lead?

DR. SCHABER: It was a functional lead, correct.

DR. ECHT: Had that patient received therapies?

DR. SCHABER: Right, that patient had received successful therapies. There had been no issues up to the time of explant with pacing sensing or detection or defibrillation. So the lead was explanted and returned as

part of our -- we asked for all of the investigational leads back when we do a transplant, and it was only upon microscopic evaluation that we found a cosmetic MIO.

DR. ECHT: VF re-detection after shock was never seen, which is wonderful. But what do you attribute to the absence of any post-shock signal attenuation with this system?

DR. BARDY: The detection algorithm I think is great, and it's based upon bipolar sensing, and the years of work Walter Olssen put in making sure that it doesn't fail following shock when amplitudes may fluctuate more or be smaller, or the spacing on it avoids polarization effects. It's been stressed a lot and hasn't really failed in that regard. The way it's defined, the decay of the sensing amplifier, it's an issue as well. Also, the sensitivity -- the fact that VF detection is 75 percent rather than a hundred percent requirement for detection, that helps. I think those are the main issues.

DR. SAKUN: We spent a lot of time going through the strips to insure that there weren't any reports of under sensing, either in sinus or under sensing that then related to delayed detection. We've had delayed re-detection, but we've had no reports of anything, because of the reasons that Dr. Bardy has outlined.

DR. ECHT: I think it's still hocus-pocus. I'm

still looking for the answer.

DR. SCHABER: It works, though.

DR. ECHT: I just have a couple of clinical kind of questions. As regards following patients, since half of the lead dislodgements occur after the first month, so even though a lot of them occur acutely, still more than half of them occur after the patient goes home. How should we be working for these things? What would we be doing? Chest X-rays, pacing thresholds, how often? Any other thoughts?

DR. SAKUN: What I'll do is outline what is in the labelling and then have physicians offer any additional recommendations to that. The patients are seen every few months because of the need to reform the capacitors and do measurements. That will remain unchanged. Labelling for the transvene system will recommend that X-rays be obtained in those follow-up visits to evaluate for the possibility of dislodgement. You do do the same routine kinds of measurements which are the pace sense threshold evaluation to look at capture threshold and sensing threshold, as well as in looking at the device and in looking at if any of this has occurred, are they appropriately being treated, is there any indication that there may have been an improvement. Those are the kinds of things that we have in the current labelling.

DR. ECHT: At what time, though? What about two

weeks, two months? When should they be seen at discharge to try to catch those?

DR. SAKUN: X-rays are required at the pre-hospital discharge. Whether or not one is done at the one month, we've left that to the -- the strong recommendation is that it be done, and the long-term is that at every follow-up from there on in, each three-month follow-up, that X-rays be done at that point in time.

DR. STEINHAUS: We have all looked at the insert, and I think those are reasonable recommendations. You've got to walk between overdoing things and carrying a lot of expense versus what seems reasonable. I think those are reasonable assessments.

DR. ECHT: Just one more, and then I'll stop. That is where to put the sub-Q patch. It seems like there are still a number of schools. In the physician's manual, it suggests that to do the mid-axillary line, which is a little different from Gus' anterior and John's posterior. We personally have found that to be the best position as well, and I wondered, is this a consensus.

The other is, the field clinical engineer that comes to our institution made a point of saying that not only should it be mid-axillary, but it's best if it's perpendicular either this way or this way, not this way.

PARTICIPANT: That's hocus-pocus.

DR. ECHT: All right. But we have had good luck with that. So I agree with the idea in the recommendation of starting at axillary. But what if that doesn't work? There are two different schools about the front and the back. Unless you do a cutaneous patch like David does, and a lot of people don't because you have to do a lot more testing to do it that way, most of us go to the front or the back at that point, and that means making more incisions in the patient. Once you have made the one, you would like to not have to make too many more extended anterior. So what are you going to suggest if the mid-axillary doesn't work, the interior-posterior?

DR. SCHABER: I might go back to say that with our data with RV SVC sub-Q in a mid-axillary position, that approximately 60 to 70 percent of the patients meet the implant criteria with that first configuration.

DR. ECHT: But what would be if you were in the other third? What do you suggest next? How do you guide physicians in that?

DR. NORBERG: As opposed to telling them to move the patch, we would do some recommendations on moving the electrical first, and possibly change the RV common to the sub-Q common, and change vectors and see if that would increase your probability for effective --

DR. SAKUN: And the second thing you could do is

that we recommend you start off sequential. If you can't meet the implant criteria, to reprogram to simultaneous. So there are things you can do both by reconnection and reprogramming before, and then pick up a good percentage of those patients who haven't met implant criteria, before you'd have to move on to the point of another incision and reposition the sub-Q patch.

DR. SCHABER: The flow chart in the PCD tech manual indicates, start with RVS VC sub-Q, and either sequential or simultaneous, and then first try that. Then try changing the common. That would be our recommendation, rather than moving the patch around a lot first. That is a simpler change.

DR. ECHT: My personal feeling is the sequential simultaneous is a little bit hocus-pocus, too. I think sequential works a lot better, because we're told to try it first.

DR. SCHABER: We do have paired data in a number of patients. You can see that having options allows you to get patients you can't get with one or the other. There's a fair amount of overlap.

DR. ECHT: I know that data. They always try sequential first, too, so it wasn't randomized, so I don't think that data is really great. But anyway, you've done all those things, and you want to move the patch. You don't

have any advice as to which direction to go?

DR. BARDY: I wouldn't use the approaches that you're doing. My labelling would be a two incision rather than a three incision. I would label a very high SPC, not one that most people use. I would put a patch up very high. If that didn't work, I'd move into the coronary sinus. I wouldn't move the patch, because I would try to avoid a third incision. I think that's a big deal for my practice, and moving into the coronary sinus isn't.

DR. ZIPES: I think we're hearing reflected here not only your comments, but the comments from this side. It's that this is an evolving state of the art, and we don't know exactly what is the best approach. I think Gus has suggested one that seems to work, and the others have as well. So I think the labelling needs to reflect that, that there isn't necessarily a hard and fast way that it should be done, but offer these as possibilities in the patient with a high DFT. Labelling may change in a year or two when we have more knowledge about it.

DR. STEINHAUS: I agree with you. We have all had the experience where what should work doesn't seem to. Then you try something that doesn't seem like it ought to have good field lines or whatever, and then it does. I think there is still a lot we don't know about this, and I think you just have to try to do your best. I think the bottom

line is, if you get a 24-jewel DFT, no matter how you did it, you're going to be okay.

DR. ECHT: It's gratifying to know I'm not the only one who doesn't know everything. I think I'll stop here.

DR. GREGORATOS: Paraphrasing Dr. Sethi, I'm not an electrophysiolgist, I'm only a clinician, so I don't have many questions. It seems to me that there has been ample demonstration that the device is effective for what it is supposed to do. I think the results of therapy are very gratifying.

So my questions will be few and related mainly to safety issues. First of all, I was a bit disappointed to find out that the mean hospital stay was only three days less for the transvenous system than the thoracotomy system. I would have thought that avoiding thoracotomy might lower the hospital stay a little bit more. Would you care to comment on that?

DR. SCHABER: In brief, that calculation is based on the first 757 patients entered into the population. That is what we are looking at. That was when physicians were more conservative about the testing that they were going to perform and how long to keep a patient in the hospital. Then I would like the physicians to talk about what their practice is now, after they have been up that learning path.

DR. STEINHAUS: I agree with you entirely. One of the major benefits is the decreased discomfort it is to the patient not to have a thoracotomy. Thoracotomies are not entirely benign procedures as we've learned, not only in terms of mortality, but also in terms of morbidity to the patient. It's a rare patient who is up doing all the things he wants to do after a thoracotomy before six weeks, whereas with this device, people can be up doing what they want to do very quickly. In fact, I send patients home now routinely at two days, so I will put it in on a Monday, they will get tested on a Wednesday, and they will go home the day they are tested, and that's it.

So I think you can achieve a significant decrease in hospital stay, and I think for the purposes of the study we're being pretty conservative. I think we will see that.

DR. GREGORATOS: Is that everybody's experience?

DR. ZIPES: I think that's absolutely right. If you know that this is the device for that patient, you don't have to do a lot of fumbling up front in terms of EP testing and whatever. They're in and they're out very quickly.

DR. GREGORATOS: Thank you. If I read the material correctly, the only thrombotic complications that were seen were subclavian. There was no coronary sinus thrombosis reported with CS leads, is that correct?

DR. SCHABER: That's correct. We've done a study

on that, on the patients that have died or have been transplanted, and have looked at their coronary sinus. I think we have about seven or eight. Our pathologist that we have worked with is here, and you don't see it. You do see a thin fiber sheath adhering to the endothelium on the coronary sinus, but no evidence of thrombosis.

DR. GREGORATOS: For my own edification, how far out do you insert the lead, in the sinus or in the great cardiac vein like the diagram up there seems to imply?

DR. BARDY: In large measure, it depends on where you have your other electrodes. One tries to triangulate the left ventricle, but with the other electrodes. So choice of cathode or anode affects where you put it.

Lately in my practice, I tend to put it more proximal into the coronary sinus rather than the great vein, because I use -- the patch here is common, and the vector is better if it's more proximal. But if I use the right ventricular electrode, it's common, or cathode, then I'll put it out in the great cardiac vein and wedge it in the vein. It works fine there, and doesn't cause any mechanical problems.

DR. GREGORATOS: Thank you. What type of training is Medtronic planning to give, if and when the device is marketed?

DR. SCHABER: We have an extensive program of

training, where we would go through an overview of the clinical results and what has been successful and what has not been successful, and go through the implant procedure, et cetera, with the implanting staff, meaning the electrophysiologist, the surgeon who is going to be in attendance, if that is the case, and the nursing staff that would be involved. The amount of education is tailored to the experience of the implanting group.

DR. GREGORATOS: Or lack thereof.

DR. SCHABER: Or lack thereof, correct. So if they have had experience with an epicardial system and another manufacturer's transvenous system, they would need less education than if this was their first experience with a transvenous system.

DR. GREGORATOS: Going back to Dr. Brinker's early question about the interaction with the DDT type of pacemaker and the response that was given, is there anything in the labelling about maintaining distance between the standard patient lead and the transvene lead? Or if there isn't, do you think that will be something to introduce into the labelling?

DR. SAKUN: The recommendations that are currently included in the labelling talk about the issues that the physicians brought up, which is the unipolar pacemaker, that those should be explanted. Though there are not specific

distance recommendations that are in the labelling, that was something the advisory panel would like to see included. We do recommend that the leads be separated as far as possible while still maintaining appropriate function of the pacemaker as well as appropriate function of the PCD.

DR. GREGORATOS: It seems to me that would be a useful sentence to include in the labelling.

DR. BRINKER: Doesn't the PCD labelling have something about, if there's the presence of a pacemaker, you have to test sensing with the pacing on?

DR. SAKUN: Yes, the labelling states that you should have sensing of the PCD with the pacer program to its full output, and then during defibrillation testing with VF being induced to make sure that there is no inappropriate non-detection.

DR. BRINKER: So that would cover that issue.

DR. GREGORATOS: Looking at the inappropriate therapies, it seems to me that the major culprit obviously is rapid atrial fib. I counted ten or 14 appropriate VT were due to A fib and 29 of 57 VFs were due to A fib. Obviously, everybody knows that, or at least I would hope everybody knows it, and would try to prevent it happening as much as possible. Is there a caution in the labelling related to that?

DR. SAKUN: One of the features available in the

PCD device is that there is a detection algorithm which we have labelled stability. In the section that talks about programming recommendations, we give programming recommendations for how that algorithm should be enabled and when it should be used, specifically, if the patient does have a history of atrial fibrillation, the physician may wish to consider enabling the algorithm. If there is then an appropriate therapy due to what the physician believes is atrial fibrillation, to go ahead and enable that algorithm. So we do have those kinds of recommendations about how do you use the other detection parameters within the PCD device.

In our warnings and cautions section, there is a discussion that there is a possibility of inappropriate therapies due to A fib or sinus tachycardia.

DR. GREGORATOS: Was this algorithm enabled in the episodes of A fib that resulted in inappropriate therapy?

DR. SAKUN: All the patients who had the inappropriate therapy did not have the algorithm enabled. In a percentage of patients it was enabled and no further inappropriate therapies were delivered.

DR. BARDY: I use the stability algorithm a lot, and will program fairly tight intervals on it, sometimes 30 milliseconds. It's a rare patient that continues to fool the device if we use that.

DR. GREGORATOS: So if I understood you then, the majority of the patients where the device was fooled did not have the stability algorithm?

DR. BARDY: Right.

DR. GREGORATOS: Good. That's all I have.

DR. AZIZ: I have one comment, although I think the questions have been well addressed. At the time of explanation, patients who have this device are a pleasure to have compared to the AICD older systems, where we couldn't get the patches off, particularly attached to the pericardium, and parts of the heart were left behind. So I think this is an advancement in those sorts of patients.

The other thing, addressing the subclavian vein thrombosis issue, this subset of patients who do transplantation are on anticoagulants. I think we probably will be seeing an increasing number of these patients. From my recollection, I don't think that they have had any increased incidence of hematomas, and Gus may be able to address that.

DR. BARDY: We do see pocket hematomas on the ones that are anticoagulated, who have valves, for example. Those are the patients where we're struggling to balance surgical bleeding against valve clotting. We often end up with pocket hematomas on them because of our reluctance to stop their anticoagulants completely. So I think it is an

issue. That concerns me more because of dehiscence, clots that favor infection early on. We've seen a patient get a pocket hematoma and then an infection. So I would still argue against anticoagulation in those patients.

DR. STEINHAUS: But that's early on you're talking about, not later.

DR. BARDY: That's right.

DR. AZIZ: The second issue, of crinkling of the subcutaneous patch. Does that tend to occur early, or is it that once they get over the socking-in stage, it doesn't occur?

DR. BARDY: I think that's a late phenomenon, and related to activity levels and anchoring technique.

DR. SIMMONS: Quite frankly, most of the questions have been asked by now. But a couple of issues, just for interest's sake. A lot of patients now get referred in our lab for extraction of these lead systems from pacemakers. Have you extracted very many of these leads from the CS for infection, and how late are you willing to pull these leads out, and is that going to make a difference in the type of patients you might chose to put one of these lead systems in?

DR. BARDY: I've had to pull two out for infection, put them in on the left side and then subsequently put them in on the right side after their

infection cleared. In both of those people, the infections were sub-acute, and in the three to six month time period. At that time, there was no difficulty pulling them out at all. Whether they would be more difficult four, five, six years down the road, I don't know; I would imagine they would be. But the lack of tines and the durability of that right ventricular lead I think makes it easier to pull it out.

The SPC lead, because I put them up high, is very simple to get out. I can't comment about four or five years. I would assume it would be harder, but probably not as hard as a tined --

DR. SIMMONS: You have pulled them out of the coronary sinus as well? Okay. I've gotten a lot of questions about the kinds of ablations we're doing with regular frequency, and whether or not doing them inside the CS is really -- is it dangerous. Seven patients that you have looked at for damage to the coronary sinus or coronary artery, or damage inside the CS really enough to make any kind of comment?

DR. BARDY: I happen to have a lot of experience in catheter ablation of the coronary sinus. I'm probably one of the people who influenced going away from the coronary sinus in the days when you used to use DC ablation, and exposed a great number of problems with doing that. But

that is a totally different therapy and a different energy technique, and much more traumatic than what we're doing now.

We would distribute 2,000 or 3,000 volts across two millimeters of electrode in the ablation base, and now we're talking 700 volts across five centimeters of electrode, a much different result from that doesn't create the problems.

DR. SIMMONS: But dont' you think still, just in these five or six hearts that you've had the opportunity to examine, the story isn't in on what may happen after several discharges from this device in the CS?

DR. BARDY: Well, I don't think that's an issue. The reason is, when you damage the coronary sinus with an electrical pulse, you will know it immediately, because the effect is an effect of trauma and burning, not an effect of an electric field that is not burning the tissue. If it's burning the tissue, you will know immediately because you'll see your voltage wave form change. That change is apparent on the oscilloscope. If you are burning, you will get a big rise in resistance and you will see your voltage wave form change immediately. You don't see that with this like you do see it presently with radio frequency ablation techniques.

DR. ZIPES: Whether those seven patients are

representative or not, I think my feeling would be they probably are, because clinically it's not a problem. Indeed, when we were still operating on WPW patients, the surgeon got into a CS tear, for example, they would often ligate the coronary sinus with impunity, and the patients did perfectly fine. I realize that surgeons don't tear the coronary sinus too often. And clinically, coronary sinus obstruction is not a problem. So I would tend to believe the data.

DR. SIMMONS: Probably also from the early days of pacing, all the coronary sinus leads were placed in for atrial pacing. So there is some body of evidence that says we're probably going to be able to get away with this. But still, I'm not going to be surprised the first time something comes up like --

DR. STEINHAUS: I don't think anybody is. We're probably going to be able to get away with this, but still, I'm not going to be surprised the first time something comes up like --

DR. STEINHAUS: I don't think anybody is.

DR. BARDY: Two issues. Art Moss put the first coronary sinus pacing unit in 25 years ago. He still has some of those patients in his practice. He has done long-term coronary angiograms with coronary sinus phases, showing they're patent 20 years later. That makes me sanguine. To

build upon Doug's comment on the surgical approach, George Guiridone when he did his epicardial WPW dissections, used to intentionally ligate the coronary sinus. So I don't see that as an issue.

DR. SIMMONS: There wee a couple of instances which sparked something in me. I always get these devices that I send back to the company, and then always come back, in spec. But there were two instances of these power on resets, two patient who had problems with that. Both of those devices came back as in spec. Do you have any comment on that?

DR. SCHABER: Other than there weren't reports of it being used around electrocautery. But there could have been electrocautery at the time of explant that would have caused it to do that, or some other strong electric field.

DR. SIMMONS: I guess I don't have anything else to say, other than to reiterate what other people have said. I think the majority of the lead fractures look like they have been in subclavian veins. I think the labelling should be very strong to suggest that all the leads should be placed through a cephalic vein when at all possible. The labelling has to be very strong about the follow-up. I don't think it should be left out that these patients need X-rays. There are a lot of people looking over our shoulders right now about the cost of these devices, and

their efficacy in the five-year long follow-ups and things like that. If we're ending up with one percent fracture rates and even three percent dislodgements and we're not taking care of those, those patients are going to end up as deaths on our overall nationwide statistics.

So I think the labelling should be very strong that the robustness of this design is not as strong as some of the others, and it needs a little more tinkering and a little more care. I think the labelling should be very strong, in my opinion.

DR. SAPIRSTEIN: Just one informational question. Can you dispense with the subcutaneous patch?

DR. SCHABER: Yes, you can. In this population, the majority of the patients had a subcutaneous patch, but there are a number of patients who had RV SVC without a patch, or RV CS SVC without a patch.

DR. SAPIRSTEIN: But they all had patches in this group of patients?

DR. SCHABER: Ninety-five percent of the 757 had a patch; five percent did not.

DR. SAPIRSTEIN: And all the infections had to have the device removed, did they?

DR. SCHABER: There were 3.4 percent of the patients who had an infection where the pocket had to be entered, 2.9 percent of the patients had the device

explanted. But there were other infections that were treated with antibiotics.

DR. BRINKER: I think we can have an expedited second round here. I just have a couple of questions. One is that you carefully label the devices to be used only with Medtronic PCV. It's unfortunate, I think, that these leads haven't reached a state of evolution between and betwixt and manufacturers that the pacemaker leads have. Why not have unified lead adapters for these devices?

DR. SCHABER: We are moving towards that. There's a DF-1 standard defibrillation standard, so that the leads could be interchangeable. It's our position right now that before we can recommend that any lead be used with any one of our pulse generators, or any one of our leads be used with anyone else's pulse generators, that we need to have data showing that that indeed is safe and effective.

DR. BRINKER: Do you make adapters, or are you thinking of making adapters?

DR. SCHABER: We're in the process of making adapters and making all of our leads available with the DF-1 connector, so that once all the manufacturers adopt that standard, they will be able to be used interchangeably. But it is still our position that that shouldn't be done until clinical data shows that it's safe and effective.

DR. BRINKER: On the complication review, there

are a number of patients that had perforations, which is a little bit higher than you would expect. These were serious perforations, tamponade or LV/RV. Do you think that this is due to the intrinsic stiffness of the lead, or perhaps due to the fact that when you deliver therapy, as part of the therapy, the lead shoots axially against the apex or against where it's positioned?

DR. SCHABER: It's our belief that it's implant technique, and the stiffness of the lead that is doing it. If you look at the lead in a patient's heart during defibrillation, it doesn't move.

DR. BRINKER: Does the heart move? The lead stays where it is, and the heart --

DR. SCHABER: The lead stays where it is relative to the heart.

DR. BRINKER: Some of these were not acutely obvious, which is what you would normally see with a technique problem, especially those leading to tamponade.

DR. BARDY: I've had it happen to me once. It was acutely obvious. It was technique.

DR. ZIPES: We see it with ablations. It's not that rare, unfortunately. We have learned, for example, that the little old lady, their hearts are very thin walled and it's so easy to perforate that heart, even when you go in knowing that they are at risk for tamponade. So I think

it's technique.

DR. BRINKER: But it has to do with the device, too, because this incidence of perforation, be it as small as it is, isn't seen with endocardial sensing leads, for instance, with the old devices, to the best of my knowledge.

One final comment from me. I wouldn't be so cavalier as Debby was about MIO, especially since most of these leads are going to continue to be placed in the subclavian access. We know that MIO is facilitated by stress or strain, even though this particular case was unusual, to have it at a spot in the right ventricle. I think when you're up against the subclavian site, there are two recent publications suggesting that installation problems can occur in this area, and that MIO plays a part in that.

MS. MARRONE: I would just like to note that there have been in the last few years a number of process changes, a net effect clinically, that has demonstrated that the incidence of MIO in that area relative to that position up in the subclavian is significantly reduced, due to some of these process changes.

DR. BRINKER: But MIO is peculiar to (b)(4) installation. I think that's the gist of my comments. If there was other installation, MIO would not be a consideration. I think as part of the overall post-

marketing surveillance anyway, this thing ought to be kept in view, because this usually isn't obvious for five years.

DR. SETHI: Have you seen any cases of -- insufficiency? This lead is pretty stiff.

PARTICIPANT: (Remarks off mike.)

DR. SETHI: The last question is about endocarditis. When the system gets infected, have you seen any case of endocarditis?

DR. SCHABER: It's a concern. But we haven't had endocarditis reported to us. We've had systems where they explained the explanted the pulse generators and the lead themselves, but not yet a report of endocarditis, although that is a concern.

DR. SETHI: Suppose the lead is infected. Do you treat this patient as a potential endocarditis patient?

DR. ZIPES: We recommend antibiotic prophylaxis for dental work and so on. I don't know that that's the right way to do it, but that's what we recommend.

DR. ECHT: I just had a couple of labelling comments. I agree with virtually all the labelling suggestions by the FDA.

DR. BRINKER: Do you want to hold those until after the meeting?

DR. ECHT: Yes, that's all I need to talk about.

DR. BRINKER: I want to just ask Doris whether

most of her queries have been answered during this debate.

DR. TERRY: Yes.

DR. BRINKER: Okay, I'd like to entertain proposals to recommend approval or disapproval of this device.

DR. SAPIRSTEIN: Jeff, could I just clarify the voting status? Dr. Gregoratos, Dr. Domanski were made voting members, and that was done prior to this meeting. At this meeting, Dr. Simmons and Dr. Zipes were made voting members temporarily. Dr. Echt is not permitted to vote on this PMA.

DR. DOMANSKI: I move approval.

DR. SIMMONS: Second.

DR. BRINKER: Can we have some discussion on that before we vote? I assume we would want to make a vote for approval with recommendations for labelling changes. Debby, why don't you now put in your recommended labelling changes, and then we'll have a motion as to whether we should vote on that?

DR. ECHT: I recommend that there be more specific recommendation to use two anchoring sleeves for each of the three types of -- not each of the three, but the RV and the SVC CS leads. I suggest that there should be a caution added to the sub-Q lead that says not to use it on the pericardium or epicardium, because it's too stiff. I

think that as the FDA suggested, it might be helpful to -- although this is very much of an evolving process, it might be helpful to add some of the results of testing of the various electrode configurations to serve as some sort of guide to physicians, and put it right in the physician's manual.

I also agree with the FDA that it would really be helpful that pictures of the various electrode configurations, including shoeing various polarity combinations, to help guide them in selecting. I suggest there be a little bit stronger recommendation about considering not doing a thoracotomy if you have done extensive testing with a non-thoracotomy system, and find that the defibrillation efficacy is too low. Perhaps even adding the .7 versus the 9.3 percent peri-operative data, which I think would be helpful to physicians.

I also suggest that there be a little bit more explicit recommendation regarding as Tony suggested to follow-up recommendations for getting chest X-rays and doing pace sense threshold testing in terms of timing. It's just a recommendation, but I think it would be helpful.

Then the only other one, there are all these electrode configuration recommendations and guidelines that are all in the pulse generator physician manual, and they're not in the lead manuals. I wonder, since you don't actually

open up the box for the pulse generator until you've retested all the leads, it doesn't seem like it's as helpful as to have that same information in each of the lead packages.

DR. SCHABER: We can do that. The rationale for not putting it in there is that in the future when there's different sorts of pulse generators available, the experience may be different with the different pulse generators. For example, in biphasic, the recommendation will likely be RV SVC as the starting point. But that doesn't preclude us from putting it in.

MS. MARRONE: Other things might be referring to that, the PCV tech manual and providing that at the same time you're providing leads, even though they may be reconnecting to the same pulse generator, as opposed to reproducing it once more in the tech manuals.

DR. ECHT: I think that would be acceptable. It just seems that after you do all this stuff, you open it up and say, oh, look what I should have done.

MS. MARRONE: Right now, it does refer you to the ICD tech manual for specifics.

DR. ECHT: That was one thing I really didn't feel particularly strongly about, but thought I would bring up.

DR. BRINKER: Are there any other labelling changes being proposed?

DR. SIMMONS: Should we consider something about suggesting the pre-discharge EPT testing is not -- many institutions consider pre-discharge EPT testing of devices to be optional, and that probably shouldn't be optional. Maybe they should be encouraged to be brought back for late EPT testing.

MS. MARRONE: In the current PCD manual, pre-hospital discharge testing is a requirement.

DR. SIMMONS: Maybe an encouragement should be made to bring these patients back at a later point for a three to six month check for defibrillation.

MS. MARRONE: It is requested at the six-month follow-up.

DR. STEINHAUS: I don't think that's necessary. I think first of all, patients really don't like to be tested an awful lot, as you undoubtedly are aware. Second of all, the data suggest that once it's --

DR. SIMMONS: I do mine when they're asleep.

DR. STEINHAUS: But I think even asleep, they don't like it. I think the system has been shown to be effective in the long term, provided you get a good short-term result. I don't think there have been enough problems with the system to justify asking everybody to go through another defibrillation test at six months, in my mind. It seems like that's a little bit overkill, I think.

DR. GREGORATOS: I would like the panel to consider whether we should ask, this issue of distance between standard pacing lead in the RV lead be mentioned in the labelling.

DR. SAKUN: There are specific recommendations in the manual already, that talk about the requirement to test the device during sinus rhythm, to make sure of appropriate interaction, and then during VF. Then based on that testing, repositioning of the leads may be required.

DR. GREGORATOS: That's in the PCD?

DR. SAKUN: That's in the PCD.

DR. BRINKER: I think Gabe would be happy if -- and I think you allude to this in your current recommendations, but in the leads, it's mostly the RV lead, that there is just a reminder that the likelihood of interaction between pacemaking leads is greater if the leads are juxtaposed as opposed to separated. I don't think there is any minimal distance that gives you any feeling better than another.

DR. GREGORATOS: Right, it's just a generic statement that function might --

MS. MARRONE: We can introduce that into what is already in for the PCD and add that to the lead tech manuals as well.

DR. GREGORATOS: Fine.

DR. BRINKER: We did this a little bit out of the rules of order here. If Mike would agree to accept these labelling amendments as Wolf will read them, rather than to vote on his blanket approval, is that okay?

DR. DOMANSKI: Sure, I'll move that we amend them as they are about to be read.

DR. SAPIRSTEIN: The amendments to the labelling were that specific anchoring of individual electrodes be incorporated, that caution -- that the subcutaneous patch should not be used as an epicardial patch, a guide to configuration and polarity with illustrations be provided in the manual, stronger recommendations to delay any needed thoracotomy after a prolonged period of EP testing, specific recommendations for post-operative X-ray and follow-up to determine lead displacement, and informational literature available apart from the packaging, and that a separation of implanted pacer leads from the device electrode leads should be noted as a precaution.

DR. GREGORATOS: A comment. My understanding from the investigators' discussion was that the importance of the fixation of the lead above and beyond the sleeve is an issue. Maybe in the labelling that should be emphasized.

DR. BRINKER: You mean above and beyond the double anchor?

DR. GREGORATOS: The double anchor, yes, the

double sleeve, right.

DR. BARDY: (Remarks off mike.)

DR. GREGORATOS: No, you specifically said that you think the double sleeve was as important as fixating the lead up against the vein to minimize migration either forward or a retraction. I think that statement should be incorporated.

DR. SAPIRSTEIN: So specific anchoring of individual electrodes and fixation to the vein.

DR. BRINKER: Yes, we can work out the specific wording with the FDA.

DR. ECHT: A tiny thing. In addition to chest X-rays, to follow up with special testing. I think it's a good way to pick up RV lead dislodgement.

MS. MARRONE: I've got that here in the notes.

DR. BRINKER: Any other comments? The motion is for approval with these amendments as Wolf mentioned. Can we have a vote of those in favor of this? Those opposed? It's approved with those recommendations. Thank you.

What I would like to do is, since we're about an hour early, I wonder if we could start the next one at noon rather than at 1 o'clock.

DR. STEINHAUS: I would just make one plea from an investigator standpoint and a doctor standpoint, with patients. I consider this a major advance, major difference

in the way we do things. Hospitalization now is going to be two days. Patients don't have to have a thoracotomy. They have a much lower mortality rate. This is better than the epicardial systems that we're all used to using. Is there any way this can be done in some reasonably quick way once it's approved? Can that be done by the FDA people in a semi-expedited way? I feel so strongly that this is a major difference for my patients that I wish I could convey that so it could get done.

DR. BRINKER: The exact same plea was made when we approved the first transvenous set of electrodes. I think that the FDA understands that particular thing, and I'm sure they will do it as expeditiously as possible.

DR. GREGORATOS: I think there is a lot of emphasis on streamlining and moving faster than previously, so maybe we'll see how it works.

DR. BRINKER: So we're going to start with the CPI device at noon. Thank you.

(The meeting was adjourned for lunch at 11:11 a.m., to reconvene at 12:00 p.m.)

Memorandum

Date 4/3/92

From Chemist
Premarket Approval Staff, ODE, HFZ-402

Subject Request for PMA Filing Review

To DCRND

PMA Application No.: P920015

PMA Applicant: MEDTRONIC, INC

Device Trade Name: MEDTRONIC® TRANVENE LEAD SYSTEM

Date of Document: 3/31/92

Date Received by DMC: 4/1/92

Date Received by PMA Staff from DMC: 4/2/92

Date letter and checklist due from ODE Division to PMA Staff: 5/11/92

Date Letter Due out of CDRH: 5/16/92

Please review the above referenced PMA for a filing/nonfiling determination. A complete checklist and "filed" or "not filed" letter should be returned to the PMA Staff by the due date specified above.

If the PMA is to be filed, please specify in the checklist special considerations or important aspects of the manufacturing process that should be included in the EDRO inspection of the manufacturing facility. A preliminary determination of whether the device is a "critical device" for purposes of the device Good Manufacturing Practice Regulations should be included (see checklist).

The biostatistics staff (HFZ-116) is notified of every PMA received and will notify the ODE Division as to the identity of the statistical reviewer. The biostatistics staff will review appropriate segments of the PMA and forward a statistical review memo to the reviewing ODE Division before the due date specified above. Please let me know if you need any further assistance.

The Transvene/PCD System clinical study (IDE G870102) includes 319 Transvene lead implants with a mean implant duration of 4.5 months and a total of 1426 device months experience. There are 116 patients with lead system implant duration equal to or greater than six months. The data included in this submission is all data that was received by Medtronic and entered onto the clinical database as of November 27, 1991. The results from the clinical study are provided in Volume 5 of this application.

Market approval is not being sought for use of the Transvene/PCD System with other manufacturers' implantable-cardioverter-defibrillators, nor is it sought for use of the PCD device with other manufacturers' transvenous defibrillation lead systems.

Two manufacturing facilities are to be used in the assembly, sterilization and packaging of the Transvene leads. These are:

1. Medtronic, Inc.
   Rice Creek Facility
   7000 Central Avenue N.E.
   Minneapolis, MN 55432
   Tel: 612-574-4000
   Establishment Registration Number: 2182208
   Is presently prepared for inspection.
   Most recent FDA inspection: January 21-February 8, 1992.

2. Medtronic, B.V.
   Wenckebachstraat 10
   6466 NC Kerkrade West
   The Netherlands
   Tel: 31-45-43-85-85
   Is presently prepared for inspection.
   Most recent FDA inspection: January 6-9, 1992.

The existence of this PMA application and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date April 23, 1992

From Mathematical Statistician (T.C. Lu) HFZ-162
Statistical Branch, Division of Biometric Sciences, OST

Subject Statistical Review of PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST MKB for RFC
Through: Chief, Statistical Branch, DBS, OST TCL

1. Background

The Medtronic Pacer-Cardioverter-Defibrillator (PCD) is an implantable, multiprogrammable, automatic tachyarrhythmia control device. This device is used for treatment of patients at risk of sudden cardiac death due to ventricular tachycardia (VT) and/or ventricular fibrillation (VF).

2. Reviewer's Comments

2.1 Pooling

There are a total of 319 implants in 317 patients of the PCD device. A total of 52 investigative centers participated in the clinical trials with 20 centers in the U.S. and 32 in foreign countries. In Vol 5, p 646 - p 650, a section was devoted to the justification for data pooling. Sponsor performed a comparison of U.S. and foreign patients and summarized the variables tested in Table IVA. Sponsor first combined and then compared all the data in U.S. centers and in foreign centers. However, much information was lost in these gross combinations. The initial design with centers nested within countries was reduced to a two-way classification. This is not good statistical practice.

This reviewer recomputed all the p-values listed in Table IVB and IVC; they were all found to be correct, except for the following:

Table IVC

NYHA Classification	p-value (sponsor)	p-value (reviewer)
Congestive Heart Failure	(b)(4)	(b)(4)
Cardiomyopathy		

2.2 Patient follow-up

Table E-2, p. 34, vol. 1, shows the follow-up time by type of data form. This is not an adequate presentation of the follow-up data. Sponsor should refer to p. 93, Table 4.6. in "Statistical Methods for Survival Data Analysis" by Elisa Lee for a more proper life-table analysis. Sponsor should also discuss the reason why some patients dropped out of the follow-up study, either withdrawn alive or lost to follow-up. For example, there are 224 patients at 1 month and only 154 patients at 3 months. Please explain the difference of 70 patients during this 2-month period.

2.3 PCD transvene system compared to AICD Epicardial System clinical experience

For the comparison of complication/observation rates for PCD vs AICD, as reported in Table IL-1, p634, vol 5, I have the following comments:

2.3.1. Please provide the numbers of complications and patients for PCD and AICD.

2.3.2. Please provide the clinical success/failure criteria used for "Failure to Cardiovert/Defibrillate and Inappropriate/Problematic VT/VF Therapy Delivery."

2.3.3. I am concerned that pocket infection is 3.5% for PCD as compared to 2.2% of AICD, even though the sponsor argues that the PCD System implant procedure requires multiple lead configurations. There are other "lead related" complications as reported on Table X1 F1 and F2, P857, Vol. 5. PCD Transvene System has more "lead related" complications than PCD Epicardial System.

2.4. One-year actuarial survival comparison of mortality between the PCD and AICD systems was discussed on p. 842, Vol. 5. Sponsor stated "there was a statistical difference in the reported (AICD) perioperative mortality ($p = 0.017$) with the PCD Transvene System having a lower reported perioperative mortality." I have the following comments concerning this statement:

2.4.1. What statistical test was used to compare survival?

2.4.2. Please provide the two survival or life tables by year of follow-up, so that this reviewer can reproduce the statistical test and the derived p-value.

2.5. Comparison to PCD Epicardial System.

P-values for one-year survival comparison of PCD Transvene System vs. PCD Epicardial System for freedom from death by "sudden cardiac", "non-sudden cardiac", "all cardiac" and "noncardiac" causes are provided in Table X1 G-2, p. 862, Vol. 5, also Table J-2, p. 54, Vol. 1. The sponsor should discuss the statistical techniques used to derive the p-values.

2.6. PCD device longevity data.

Sponsor stated in Section M.1. p. 66, Vol. 1: "Thus, the PCD device longevity, which is monitored, utilizing battery voltage and change time obtained via telemetry, was analyzed. The PCD device longevity data collected is consistent with the longevity projection." This reviewer needs to see the data and statistical test used to support the above statement.

3. Reviewer's Conclusion

The sponsor needs to adequately address the issues raised in Section 2 above before the safety and effectiveness of the PCD Transvene System can be evaluated from a statistical perspective.

From

Subject Filing Review of PMA # P920015

To Premarket Approval Coordinator
Through: (Division Director) _____

Applicant: Medtronic, Inc

Device Trade Name: Medtronic Transvenous Lead System

1. Organizational and Administrative Elements (I and II in the PMA Guideline):

a.	adequate number of copies (check with DCC)	Yes ___ No ___
b.	copy provided with all confidential information deleted	Yes ___ No ___
c.	pages properly numbered	Yes ✓ No ___
d.	table of contents included	Yes ✓ No ___
e.	PMA is signed by applicant or representative in this country	Yes ✓ No ___
f.	complete English translation of PMA	Yes ___ No ✓
g.	Is there currently a pending 510(k) or reclassification petition for this device?	Yes ___ No ✓
h.	Could this device be found substantially equivalent to a Class I or Class II device?	Yes ___ No ✓

2. Summary of Safety and Effectiveness Data (III in Guideline):

a.	description of disease(s) or condition(s) for which the device is used	Adequate ___ Inadequate ___
b.	description of the device	Adequate ___ Inadequate ___
c.	description of alternative practices for the indicated use of the device	Adequate ___ Inadequate ___
d.	potential adverse effects of the device	Adequate ___ Inadequate ___
e.	summary of all studies on the device	Adequate ___ Inadequate ___
f.	conclusions from studies	Adequate ___ Inadequate ___

3. Laboratory Data for Each Investigation (IV in Guideline):

a.	statement of compliance with GLPs	Adequate ✓ Inadequate ___ N/A ___
b.	protocol	Adequate ✓ Inadequate ___ N/A ___
c.	results	Adequate ✓ Inadequate ___ N/A ___
d.	analysis	Adequate ✓ Inadequate ___ N/A ___
e.	conclusions	Adequate ✓ Inadequate ___ N/A ___
f.	Does laboratory data appear to be inadequate, i.e., any obvious studies not conducted?	Yes ___ No ✓

If yes, briefly specify: _____

4. Animal data (V in Guideline):

a.	statement of compliance with GLPs	Adequate	✓	Inadequate	___	N/A	___
b.	protocol	Adequate	✓	Inadequate	___	N/A	___
c.	results	Adequate	✓	Inadequate	___	N/A	___
d.	analysis	Adequate	✓	Inadequate	___	N/A	___
e.	conclusions	Adequate	✓	Inadequate	___	N/A	___

f. Does animal data appear to be inadequate, i.e., were any obvious studies not conducted? Yes ___ No ___

If yes, briefly specify: _____

_____

5. Clinical Data (Item VI, A and B in Guideline):

a. statement of compliance with applicable IDE or other applicable requirements or explanation for non-compliance Yes ✓ No ___ N/A ___

b. If the clinical investigation is ongoing, does this continuing study appear to be in compliance with IDE requirements? Yes ✓ No ___ N/A ___

If no, briefly explain: _____

_____

c. State number of independent clinical investigations. App. 50
If only one clinical investigator has participated in the investigation, is there an adequate justification that this is adequate? Yes ✓ No ___

d. complete description of each clinical study as in VI(A) of Guideline Adequate ✓ Inadequate ___

If not, briefly describe information needed: _____

_____

e. overall results and conclusion as in VI(B) of Guideline Adequate ✓ Inadequate ___

If not, briefly describe information needed: _____

_____

6. Device Characteristics (VII in Guideline):

a.	detailed description of device function	Adequate	✓	Inadequate	___	N/A	___
b.	if applicable, reliability testing provided	Adequate	✓	Inadequate	___	N/A	___

7. Performance Standards (VIII in Guideline):

reference to performance standard or statement of justification for deviation from standard — Adequate ✓ Inadequate ___ N/A ___

8. Labeling (IX in Guideline):

a. labeling in proper format — Adequate ___ Inadequate ___
b. Should patient labeling be required? — Yes ___ No ___ Included in PMA ___
c. Should promotional material be requested? — Yes ___ No ___ Included in PMA ___

9. Bibliography (X in Guideline):

a. bibliography provided — Yes ___ No ___
b. significant articles included — Yes ___ No ___

10. Manufacturing Data (XI in Guideline):

a. copy of labeling and items A-J in a separate volume for EDRO — Yes ___ No ___
b. location of all manufacturing facilities included — Yes ___ No ___
c. organization of firm included — Yes ___ No ___
d. description of physical plant included — Yes ___ No ___
environmental assessment or impact statement included — Yes ___ No ___
e. description of manufacturing equipment — Adequate ___ Inadequate ___ N/A ___
f. description of control system for components — Adequate ___ Inadequate ___ N/A ___
g. description of manufacturing process and flow chart of process — N/A___ Adequate ___ Inadequate ___
h. description of packaging, sterilization and labeling controls — Adequate ___ Inadequate ___ N/A ___

If sterile device, does the PMA include description of method of sterilization, validation data, and pyrogenicity testing and results? — Adequate ___ Inadequate ___ N/A ___

i. description of holding, distribution and installation controls — Adequate ___ Inadequate ___ N/A ___
j. description of finished device inspection — Adequate ___ Inadequate ___ N/A ___
k. description and location of device records — Adequate ___ Inadequate ___

11. Patient Report Forms (XIII in Guideline):

a. patient report forms included — Yes ___ No ___
b. Will additional PRFs be required? — Yes ___ No ___

12. Samples (XIV in Guideline):

Should FDA request a sample of the device? — Yes ___ No ___

Recommendation: Filed _____ Not Filed _____

Comments: _____

_____

_____

If the PMA is to be filed, please specify special considerations or important aspects of the manufacturing process that should be included in the EDRO inspection of the manufacturing facility. _____

_____

_____

Does the device meet the definition of a critical device? _____ Yes _____ No

Note: "Critical device" means a device that is intended for surgical implant into the body or to support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user.

Provide a brief rationale why this device meets the above definition for a "critical device": _____

_____

_____

Is a color additive under section 706 of the act included in this device?
_____ Yes _____ No

Will a statistical review of the PMA be required? _____ Yes _____ No

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date: April 7, 1992

From: Mathematical Statistician (G. Kamer) HFZ-162
Statistics Branch, Division of Biometric Sciences, OST

Subject: PMA Review Statistical Checklist Recommendations for PMA P920015, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To: Donald F. Dahms - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices
Through: Director, Division of Biometric Sciences, OST
Through: Chief, Statistics Branch, DBS, OST

The Statistics Branch, DBS, OST has received the PMA referenced above and evaluated it against the attached PMA Review Statistical Checklist. The failures to provide justification for sample size or pooling of data over investigational sites were the only non-serious omissions of a statistical nature. Therefore, we recommend this PMA be filed. We will now begin an in-depth statistical review of this PMA. This review should be completed and our comments sent to you within 30 days. If you have any questions, please contact me at 227-8629 or the statistical reviewer, T. C. Lu, at 227-8627. The omissions found are from the Clinical Investigations Section of the checklist and are stated below for your information:

1. This submission does not include any acceptable justification of sample size. Please provide a complete description of your sample-size determination. This should include effect criteria, alpha and beta statistical error tolerances, anticipated variance of the response variables, and any assumptions or statistical formulae with references that are required for sample-size determination.

2. This submission does not include any justification for pooling (combining) the patient data over site. Please review and analyze your prognostic variables to provide a detailed justification why the data may or may not be pooled for evaluation. Note that an analysis by site is always necessary in any case.

Gary L. Kamer

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic Transvene System
Date: June 5, 1992
Office: DCRND/ODE

On the basis of a further review of the referenced file, the following concerns have been identified. These deficiencies should be included in a major amendment letter for the manufacturer's response.

Questions and Concerns

1. An update of the clinical experience of the Transvene Lead System should be provided. The update should include all additional patients and the clinical experience to date. The data should be presented as done in your original PMA application, and should include, e.g., implant and follow-up data, spontaneous episode experience, analyses by different groups, complications/observations, and survival analysis. All remaining deficiencies listed below which pertain to your patient population should be addressed using the updated patient group.

2. What is the mean time of device activation for the patient population?

3. Please discuss your clinical data which support the claim which states that the Transvene Lead System improves both perioperative and long term patient morbidity.

4. A discussion of the data or past performance of similar marketed leads which support the adequacy of (b)(4) flex cycles in support of lead performance should be provided.

5. Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.

6. Please specify the section of each lead assembly that was flexed during life testing. the results of the tests should be included.

7. Please provide a detailed discussion of all cases of crinkling and curling of the patch leads and dislodgement of the coronary sinus lead.

8. An update of the chronic animal studies should be provided.

9. Are there patients currently implanted with the Model 6895

and 10317 patch leads? If so, please provide a breakdown of the clinical data, e.g., complications, survival, etc. for each lead.

10. A side-by-side comparison of the Model 6897 epicardial patch lead and the Model 6999 patch lead should be provided.

11. Please discuss the results of tests performed with the Transvene System and the Model 2394.

12. Data such as treatment efficacy, complications and survival analysis on the patients followed for 6 months should be provided.

13. Please list the reasons for not performing pre-hospital discharge testing.

14. The number of spontaneous episodes of the patients followed for six months and beyond should be provided.

15. Based on your experience and on the data as reported in the literature, what is the percentage of patients who have been found unable to withstand a thoracotomy?

16. Provide a detailed discussion of the clinical experience (implant duration, spontaneous episodes, treatment efficacy, survival analysis, complications, etc.) of the patients who did not meet the implant criteria and were implanted with the Transvene System. Also discuss the experience of the patients who were implanted without the 10 Joule safety margin.

17. Please discuss your clinical experience (treatment efficacy, complications and survival rates) of the patients who have been followed for one year and more.

18. Based upon your clinical experience, the Physician's Manual should recommend the sequence of testing with the different lead configurations during implant.

19. A breakdown of the different lead configurations within the patient population, and the treatment efficacy reported for each configuration should be included.

20. An update of the life tests on the leads should be provided.

21. A discussion of the energy requirements of the Transvene versus the epicardial lead system should be provided.

22. A copy of the Summary of Safety and Effectiveness with the updated clinical data should be submitted.

MEMO

TO: Doris Terry

FR: Quynh Hoang

RE: Questions concerning the benchtest/prior investigations performed on the Transvene leads from Medtronic - P920015

DA: 6/5/92

SUMMARY

Medtronic requests market approval for the Transvene lead system. The Transvene leads are used with the Model 7217B PCD for pacing, sensing, cardioversion, and defibrillation of the heart. They require non-thoracotomy means for implantation. For a detailed summary of the prior investigations, please refer to the 5/7/92 memo.

Based on my review and the comments given at the working group and filing meetings, the questions for Medtronic include:

1. Discuss the use of a (b)(4) adhesive to prevent tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of (b)(4) and (b)(4) in leads to prevent tissue in-growth.

2. Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.

3. From experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed).

4. Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor, when the section is flexed?

5. Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) electrode coil, and the effects of its failure on the performance of the lead.

6. Discuss the properties of polyurethane which make it the ideal insulation material for the 6966 lead. Why was silicone not chosen?

7. Discuss the biostability tests (stress cracking, MIO, etc.) performed on the two types of polyurethane. Why chose a

different polyurethane for the inner coil?

8. Discuss why the (b)(4) (b)(4) and the (b)(4) (b)(4) (b)(4) (b)(4) (anchor sleeve) have not undergone the mutagenicity test.

9. Based on the results of the lifetest, what is the life expectancy of the leads. Please include your assumptions.

10. What section of each lead was flexed in the lifetest? Does this section include the electrode coil?

11. Provide an update of the (b)(4) month lifetest.

12. The Transvene leads seem to tolerate crush testing better than the pacing leads. Please discuss the properties of the Tranvene leads which take them better.

13. The provided data indicate that a new lead is used for each (temperature tolerance, crush load, or life) test, correlate the results from those tests to the worst case condition where the same lead has to face temperature differences, crushing, and flexing. Why was sequential testing not performed?

14. Compare the 6999 against the epicardial patch leads.

15. Discuss any differences in battery life, between the epi-lead

system and the Transvene system.

16. Some Transvene subjects were also evaluated with the Model 10388 hollow can electrode. Please compare the infection rate of these subjects to the ones who did not undergo the hollow can evaluation.

17. Discuss any possible interaction between the pacemaker leads and the Transvene leads. Also, discuss the effects of these leads on the tricuspic valve and the host vein.

Re: P920015
PCD Transvene System

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) is continuing to process the above named premarket approval application (PMA). Simultaneously with a review by the Office of Device Evaluation (ODE), the Office of Compliance and Surveillance (OCS) must review the manufacturing information in your PMA to determine that it is sufficiently complete and appropriately organized to permit FDA to determine whether your firm (or your contract manufacturer) has the capability of manufacturing your PMA device in accordance with (1) the conditions specified in the PMA application and (2) the requirements of the medical device GMP regulation.

The Division of Compliance Programs (DCP) of OCS has reviewed the manufacturing section of your PMA and believes that it lacks the information necessary to effectively complete a review and determine whether to initiate a PMA inspection (see enclosed). While the deficiencies outlined in the enclosure do not preclude further review of your PMA, if left uncorrected they may delay or preclude evaluation of your manufacturing process and final approval of your PMA application. We request that you respond as indicated. Please be advised that continued review by ODE of your application (including the manufacturing section) may identify additional deficiencies. Also, the OCS review of your response to this letter may identify additional deficiencies.

For your information a Guidance for Preparation of PMA Manufacturing Information was published on March 22, 1991 (a notice of availability was published in the August 20, 1991 Federal Register). It is also available as part of the PMA Manual Supplement which may be obtained from the Division of Small Manufacturer's Assistance at 1-800-638-2041.

Information supplied in response to the enclosed request should be submitted in the form of an amendment **AND BE CLEARLY IDENTIFIED AS A RESPONSE TO AN OCS REQUEST IN YOUR REFERENCE BLOCK.** FDA will consider the PMA to have been withdrawn voluntarily if you fail to respond in writing to this request for an amendment within 180 days of the date of this letter as provided under 21 CFR 814.44(g). You may, however, amend the PMA within the 180 day period to request an extension of time to respond. Any such request is subject to FDA approval and must justify the need

for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA within the 180 day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180 day period will be considered a resubmission of the PMA and will be assigned a new number. A resubmission should be complete and self-contained without reference to earlier submissions because of potential difficulties in assembling files from storage.

All correspondence regarding this PMA should be submitted in three (3) copies in the form of a PMA amendment to the address below and reference the above PMA number to expedite processing.

Deficiency List

The Office of Compliance and Surveillance (OCS) in the Center for Devices and Radiological Health (CDRH) has completed an initial review of your premarket approval application (PMA), P920004, with regard to the Good Manufacturing Practice (GMP) regulations. Please address the following issues and provide the requested documentation:

1. The Design Assurance Plan, (b)(4) (b)(4) dated 2/7/91 for the new helix electrode, part 136250-001, is not representative of the manufacturing operations. The qualification report dated 4/16/91 does not address the effects of the sterilization process on the integrity of the helical electrode. [vol.2, pp.153-156]

2. Provide the locations of the biological indicators used during the sterilization validation and routine production for the 6966 lead. [vol.2, p.207]

3. Provide the product density and configuration pattern for the 6966 sterilization cycle. [vol.2, p.207]

4. Provide the maximum parameter of the humidity specification for the sterilization cycle of the 6966 lead. [vol.2, p.211]

5. The finished device evaluation for the 6966 lead does not adress the effect of sterilization on device performance. [vol.2, p.174]

6. The validation plan for 6963 lead does not address the effects of the sterilization cycle on device performance. [vol.3, p.327]

7. The process qualification report, (b)(4) (b)(4) does not address the effects of the sterilization cycle on the performance of the 6999 lead. [vol.3, p.335]

8. Provide the product location of biological indicator and spore inoculation for the validation and production sterilization cycles of the 6963 and 6999 leads. [vol.3, p.372]

9. Provide the maximum parameter of the (b)(4) (b)(4) exposure for the 6999 lead. [vol.3, p.376]

10. Explain the difference in the sterilization (b)(4) exposure parameters of the 7217B PCD Control Device between the two manufacturing facilities. The (b)(4) exposure parameter at the Rice Creek facility is (b)(4) minutes; the (b)(4) exposure parameter at the Kerkrade facility is (b)(4) minutes minimum. The Kerkrade facility does not specify a maximum (b)(4) exposure. [vol.4, p.415 and p. 432]

11. Provide the manufacturing methods, controls, and evaluation procedures for the facility identified as Medtronic Milaca, 900 6th Ave. N.E. Milaca, MN 56353. [vol.4, p. 437]

MEMO

TO: Doris Terry
FR: Quynh Hoang
RE: Review of the benchtest/prior investigations performed on the Transvene leads from Medtronic - P920015
DA: 5/7/92

SUMMARY

Medtronic requests market approval for the Transvene lead system. The Transvene leads are used with the Model 7217B PCD for pacing, sensing, cardioversion, and defibrillation of the heart. They require non-thoracotomy means for implantation.

Device Descriptions

The Transvene lead system consists of three leads, Models 6963, 6966, and 6999. The leads contain conductor coils made of a (b)(4) core and a (b)(4) shell. Their electrodes are made of a platinum/iridium alloy.

Model 6963 is a unipolar, transvenous, coronary sinus/superior vena cava (CS/SVC) lead. It serves as an anode for cardioversion and defibrillation. It consists of a (b)(4) connector (b)(4) connector pin and (b)(4) rubber sleeve); a conductor coil insulated by (b)(4) rubber; and, a coil electrode of (b)(4) inches in length (b)(4) To prevent tissue in-growth, a (b)(4) adhesive is used with the lead.

Model 6966 is a tripolar, transvenous, right ventricular (RV), screw-in lead. It serves as the pacing/sensing, as well as a cathode (common) for cardioversion and defibrillation. It consists of a bipolar (b)(4) connector (b)(4) connector ring and rotatable pin, and (b)(4) rubber sleeve) for the ring and helix electrodes: an unipolar (b)(4) connector (b)(4) connector pin and (b)(4) rubber sleeve) for the coil electrode: a tri-layer conductor coil coated with (b)(4) and insulated by (b)(4) rubber; a coil electrode of (b)(4) inches in length (b)(4) a ring electrode with (b)(4) surface area; and, a helix electrode of (b)(4) surface area. Correlating the functions of the lead and its three electrodes: pacing takes place between the coil and helix electrodes; sensing takes place between the ring and helix electrodes; and, cardioversion/defibrillation takes place between the coil electrode and the other leads. (b)(4) tubing prevents tissue in-growth in the lead.

Model 6999 is a unipolar, sub-cutaneous (SQ), patch lead. It serves as an anode for cardioversion and defibrillation. It consists of a (b)(4) connector (b)(4) pin and (b)(4) rubber sleeve); a conductor coil insulated by (b)(4) rubber; and a (b)(4) rubber patch embedded with a (b)(4) and (b)(4) electrode coils. The

inside of the electrode coils is filled with (b)(4) rubber to prevent tissue in-growth in the patch.

Components for use with the leads are: a (b)(4) anchoring sleeve for stationing the lead body at the insertion site; a (b)(4) for stiffening the lead during insertion; and, an active fixation tool for entrenching the helix. Descriptions of the fixation tool have not been provided.

MEMORANDUM TO FILE FOR P920015

From: Associate Director
Pacing and Neurological Devices
DCRND

Through: Chief
Pacing and Electrophysiology Devices Branch
DCRND

Subject: Request for Expedited Review Status for Non-Thoracotomy Leads

On February 11, 1992, Medtronic submitted a letter (copy attached) requesting that FDA consider Expedited Review Status for their yet to be submitted PMA for an implantable non-thoracotomy lead to be used with their implantable pacer cardioverter defibrillator (PCD) device. At a meeting held with Medtronic on March 13, 1992, we discussed the advantages and disadvantages of tagging the PMA for expedited review. The comments expressed at this meeting were excerpted from a review memo dated March 5, 1992 (copy attached). After some discussion, Medtronic agreed not to pursue "expedited review".

A response to Medtronic's February 11,1992 letter will not be sent and the PMA will be reviewed in the normal fashion.

Rockville, MD 20850

Dear Doctor Acharya:

With this letter. I am requesting a meeting with you and members of your staff regarding the PMA for our Non-Thoracotomy Lead (NTL) System for use with our PCD™ device. I am aware of your recent meeting with Bill Hogan and your discussion regarding the potential for expedited review. Naturally, we are very interested and believe the NTL System is an appropriate candidate.

The purpose of the meeting would be to understand the process for expedited review and what we need to do to obtain expedited review for the NTL PMA. In addition, we would like FDA feedback on the structure and content of the PMA. A proposed agenda for the meeting is attached. Your participation in the meeting is critical based on your previous discussions on this subject.

I had hoped to discuss this subject with you last week. At your suggestion, I followed up with Lynne Reamer. She was receptive to a meeting. She also recommended that we put the basis for expedited review in writing which is attached.

We will follow up in a few days to schedule a meeting time. In the meantime, if you have any questions, please call me.

Sincerely,

MEDTRONIC, INC.

EXPEDITED REVIEW FOR THE USE OF NON-THORACOTOMY LEADS WITH PCD™

In recent discussions between Medtronic and FDA, the concept of "Expedited PMA Review" has been raised. We are requesting a meeting with FDA to discuss its applicability to the Non-Thoracotomy Lead (NTL) System for use with our Implantable Pacer Cardioverter Defibrillator (PCD). This system is currently under clinical evaluation and we expect to submit a PMA or PMA Supplement in the near future. This paper presents Medtronic's view on why expedited review is warranted as a basis for further discussion.

It is our understanding that devices should receive expedited review if they meet either of the following criteria:

- Applies to a life-threatening or severely debilitating illness.
- Makes therapy available to patients who could not otherwise receive adequate therapy.
- Represents a major advancement in therapy that provides significant patient and/or public health benefits.

We believe that the NTL System meets these criteria. The data cited below is based on our clinical experience with the NTL System. These data were the basis for approval by Medtronic's Executive Committee for market release of the NTL System outside the U.S. These data will of course be included in FDA submissions as well.

Life-Threatening Disease

The PCD is indicated for patients who have experienced an episode of sudden cardiac death or who have recurrent sustained ventricular tachycardia that cannot be controlled effectively with drugs. The prognosis for these VT and VF patients is very poor (34-73% survival at one year when treated with drugs alone).

Patients With No Alternative Therapy

There is a class of patients who cannot tolerate the thoracotomy required for utilization of the patch lead system and who are at high risk of sudden death. For these patients, the NTL System is the only therapy available.

Current implantable cardioversion/defibrillation therapies use epicardial patch systems which require major procedures such as a sternotomy to introduce the lead systems. Because of the surgical risks and postsurgical complications, this critical life-saving therapy is not available to certain patient categories. These include:

- Patients that pose high surgical risk because of their state of health
- Potential heart transplant candidates
- Patients who for varying reasons refuse to submit to the major surgical procedure required

The NTL System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is not a need to open the chest of these patients, options for future therapy remain available; e.g., CABG is associated with a decreased morbidity and mortality if there has been no prior open chest surgery.

Significant Patient and Public Health Benefits

In simplifying surgical procedures and reducing their attendant risks, the NTL System provides significant benefits to patients both in terms of safety and quality of life.

The benefits are clear in reduced mortality and morbidity. As reported in our current PCD/Patch Lead PMA application (N=434), perioperative mortality is 5.5% and overall mortality is 14.4%. With the NTL System (N=319), perioperative mortality is 0.4% and overall mortality is 3.6%.

The NTL System is also associated with a reduction in postoperative complications, faster recovery and shorter hospitalization, which mean an improved patient quality of life. These clear benefits are obtained for all patients without any change in effectiveness of VT/VF therapies versus PCD/Patch Systems.

Finally, the NTL System also offers clear public health benefits in this era of concern about increasing health care costs. The ease of introduction of the NTL System reduces surgical costs and the reduction in surgical trauma decreases hospitalization time (average 8 days for patients with NTL Systems versus 12 days for patients with patch systems).

Time factor? MD comments?

We believe all these factors clearly establish the patient and public health benefits of the NTL System and justify expedited review and PMA approval by FDA.

MEMORANDUM

Date: March 5, 1992

To: Director, DCRND, ODE (HFZ-450)

From: ADPN, DCRND (HFZ-450)

Subject: Request for Expedited Review

Background

On February 11, 1992, Medtronic submitted a letter requesting that FDA consider expedited review status for an implantable (non-thoracotomy) lead to be used with their Pacer Cardioverter Defibrillator (PCD). The new lead would be in addition to the one (thoracotomy) presently being used with the PCD. The PCD and its attendant thoracotomy lead system was recently presented to the Circulatory System Devices Panel (February 3, 1992) and was recommended for approval. An approvable letter is currently being prepared for the PMA application.

The new implantable lead designed to be used with the PCD as an alternate lead system is a non-thoracotomy lead (NTL), i.e., the chest does not have to be opened to insert the lead. The NTL is being studied clinically under G870102. Currently, implantable defibrillators are used with leads that must be inserted by thoracotomy.

Medtronic's Position

Medtronic claims that there are significant patient and public health benefits using an NTL because the insertion procedure is simplified and shortened, the surgical risks are reduced, postoperative complications are reduced, hospitilization time is shortened, costs are reduced and mortality is reduced.

Medtronic also claims that use of the implantable defibrillator with its current thoracotomy lead system is not available to patients who fall into the following three categories: (1) patients who pose high surgical risk because of their state of health; (2) potential heart transplant candidates; and, (3) patients who for varying reasons refuse to submit to the major surgical procedure required.

FDA Concerns

The indications for use of a PCD are: (1) patients who have survived at least one episode of cardiac arrest due to ventricular arrhythmia not caused by an acute myocardial infarction; or (2) patients with recurrent sustained, ventricular tachycardia that remains inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most

efficacious antiarrhthymic drug therapy that can be tolerated by the patient chronically; and (3) patients who are undergoing a replacement of a previously implanted cardioverter defibrillator. Alternate therapies to treat ventricular tachyarrhythmias include antiarrhythmic drug therapy, ventricular tachycardia surgery, and transthoracic defibrillation.

According to General Program Memorandum #G89-2, expedited review is available for a new device use to treat "a life-threatening or severely debilitating illness for which there is no alternate diagnosis, therapy, or prevention modality." In the case of the PCD, patients are at risk of sudden cardiac death due to ventricular tachyarrhythmias. Estimates report that 450,000 people experience sudden cardiac death annually. Medtronic does not document how many patients cannot receive a PCD because thoracotomy leads are used. The second part of the definition of qualification for expedited review requires that there be no alternate diagnosis, therapy of treatment modality. There are in fact alternate treatment modalities as mentioned above.

However, at issue is not whether the PCD is of benefit or not, but whether the current lead system which must be inserted by thoracotomy poses more risk to the patient than the new NTL lead system. Medtronic did not mention expedited review when they originally proposed their clinical trial of the NTL. The IDE was approved on October 4, 1990, and was handled in a normal fashion with no emphasis on a feasibility study. To date, according to Medtronic, 319 patients have been implanted with the NTL. No special meetings have been requested by, or held with Medtronic to guide them in their clinical study. Because we have not closely worked with Medtronic during the clinical trial, we have no idea whether the clinical data support the premise that there is less morbidity and mortality with the NTL.

At issue is also the fact that we have under review an original PMA from a competitor for a non-thoracotomy lead system for their automatic implantable cardioverter defibrillator. When this PMA was submitted expedited review was not requested. Unlike the Medtronic PCD, which was just recommended for approval by the Circulatory System Devices panel, the competitor's defibrillator is on the market. If expedited review is to be granted for NTLs at all, it should be granted to the competitor's device first because their defibrillator is on the market and when their NTL is approved, their system will be the first available. Let's follow this scenario. The reviewer assigned to the competitor's NTL is the same reviewer who is working on the approval package for the Medtronic PCD. If expedited review status is granted for NTLs, the competitor's NTL moves to the top of the review pile and may delay the approval of the Medtronic PMA for their PCD. Since the Medtronic NTL can only be used with the Medtronic PCD, Medtronic has to have their PCD approved before the NTL can be used. If we follow this scenario, Medtronic's argument for expedited review falls apart, because there will be an alternate lead system available - the competitor's system, not Medtronic's.

FDA Position

There is an alternate implantable lead available to use with the Medtronic PCD. In addition, Medtronic did not approach us early on at the IDE stage regarding expedited review, we believe it is inappropriate to consider expedited review at the PMA stage. We did not work closely with them to design the clinical study and have not frequently monitored the data through progress reports. The IDE has been handled as a regular IDE and the number of patients entered in the study indicate that Medtronic was in no great hurry to get this over with. They had various opportunities to request expedited review when they submitted supplements to the IDE to request study expansion. But they did not. Only after the PMA for their PCD was recommended for approval did they approach us with the expedited review request.

(b)(4) did not request expedited review and were in a far better position to succeed if they had because they already have an approved automatic implantable cardioverter defibrillator on the market. If anyone should receive expedited review status, it should be (b)(4)

Based on the above, our recommendation is to deny Medtronic's request based on the fact that there is an alternate implantable lead available for use with Medtronic's PCD which is part of the recent PCD PMA, and on the language in Guidance Memorandum G 89-2, in that Medtronic did not fulfill the IDE requirements.

Action

Draft a letter to Medtronic explaining our position and denying their request.

Lynne Reamer

Lynne Reamer

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic Transvene System
Date: April 13, 1992
Office: ODE/DCRND

The applicant seeks approval of its non-thoracotomy leads, the PCD Transvene System. The system is composed of the Model 6963 Unipolar Coronary Sinus or Superior Vena Cava lead for cardioversion and defibrillation; the Model 6966 Tripolar, Endocardial, Screw-In Lead for pacing, sensing and cardioversion and defibrillation and the Model 6999 unipolar, subcutaneous patch lead for cardioversion and defibrillation.

The indications for use of the Transvene System are similar to those of the Medtronic PCD models. The applicant contends that due to the less invasive nature of the non-thoracotomy leads, the system can be implanted in patients who may not be able to undergo a thoracotomy.

Description of the System

The Model 6963 is a (b)(4) unipolar, coronary sinus or superior vena cava lead with (b)(4) connector and (b)(4) electrode for delivery of cardioversion and defibrillation therapies.

The Model 6966 is a (b)(4) tripolar extendable/retractable, screw-in lead with a (b)(4) connector and (b)(4) electrode for cardioversion and defibrillation. The lead also has a (b)(4) connector for pacing and sensing.

The Model 6999 is a (b)(4) unipolar, oval subcutaneous patch with a (b)(4) connector and (b)(4) electrode coils embedded in the (b)(4) patch. The lead is intended for cardioversion and defibrillation.

Re: Premarket Approval Application (PMA) for the Medtronic® Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, i.e., the PCD™ Transvene System, Lead Models 6963, 6966 and 6999.

This submission is a PMA application for the Medtronic Transvene Lead System used in conjunction with the Model 7217B pacer-cardioverter-defibrillator (PCD), Model 5355 external tachyarrhythmia control device (ETCD) and Model 9788 MemoryMod Software Module.

The PCD and ETCD devices as used with an epicardial lead system were recommended for approval by the FDA Advisory Panel on February 3, 1992 (P900061). The purpose of this PMA application is to obtain approval for the use of the non-thoracotomy lead system for use with the Medtronic PCD and ETCD. The terms non-thoracotomy leads (NTL), transvenous leads and Transvene Lead System are synonymous and may be used interchangeably throughout this application.

The Transvene System, in conjunction with the PCD device, is intended to treat patients at risk of sudden cardiac death due to ventricular arrhythmias. Like the epicardial electrodes/PCD System, the primary benefits from the use of the Transvene/PCD System center on the detection and termination of these life-threatening ventricular arrhythmias. The incorporation of a non-thoracotomy lead system allows for a safer and effective implantation procedure, and improving both perioperative and long-term patient morbidity and mortality.

The Transvene/PCD System clinical study (IDE G870102) includes 319 Transvene lead implants with a mean implant duration of 4.5 months and a total of 1426 device months experience. There are 116 patients with lead system implant duration equal to or greater than six months. The data included in this submission is all data that was received by Medtronic and entered onto the clinical database as of November 27, 1991. The results from the clinical study are provided in Volume 5 of this application.

Market approval is not being sought for use of the Transvene/PCD System with other manufacturers' implantable-cardioverter-defibrillators, nor is it sought for use of the PCD device with other manufacturers' transvenous defibrillation lead systems.

Two manufacturing facilities are to be used in the assembly, sterilization and packaging of the Transvene leads. These are:

1. Medtronic, Inc.
   Rice Creek Facility

III. Summary of Safety and Effectiveness

A. Indications For Use

The Medtronic PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System with Nonthoracotomy Cardioversion and Defibrillation Electrodes (hereafter referred to as the PCD Transvene System) is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias. Indications for use include:

- Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
- Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.
- Patients undergoing replacement of a previously implanted implantable cardioverter defibrillator.

The patients who meet the above patient selection criteria should have also undergone a complete cardiological evaluation that includes electrophysiological testing. Electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the PCD Transvene System.

The PCD Transvene System components, except for the defibrillation lead system, are identical to the PCD Epicardial System which was unanimously recommended for approval by the FDA Advisory Panel on February 3, 1992.

Market approval **is not** being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems. In addition, market approval **is not** being sought for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

B. Description of the Transvene Lead/PCD System

The Medtronic Tachyarrhythmia Control System consists of two fundamental configurations: (1) the implantable configuration and (2) the external configuration. Both configurations use the Transvene lead system. See Figure III B-1

The implantable configuration is composed of a Pacer-Cardioverter-Defibrillator (PCD) device, implantable leads, and a programmer. The PCD device is an implantable, multiprogrammable, automatic tachyarrhythmia control device.

The external configuration is composed of an External Tachyarrhythmia Control Device (ETCD), a patient cable, implantable leads, and a programmer. The ETCD is an externally-operated, multiprogrammable, tachyarrhythmia control device.

Intended Uses - Transvene Leads

Model 6963 Lead

The Medtronic Transvene Model 6963 Unipolar, Coronary Sinus or Superior Vena Cava, Transvenous Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use in the coronary sinus or superior vena cava and is designed to be used with an implantable tachyarrhythmia control device along with at least one other lead, such as the Model 6966 Tripolar, Right Ventricular, Transvenous Lead.

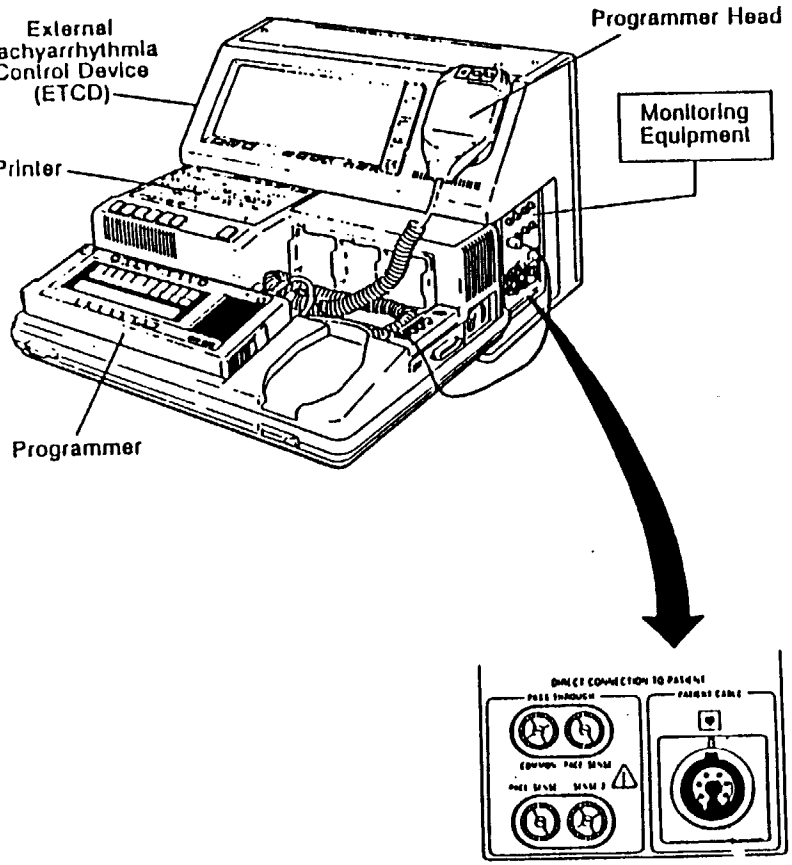
The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

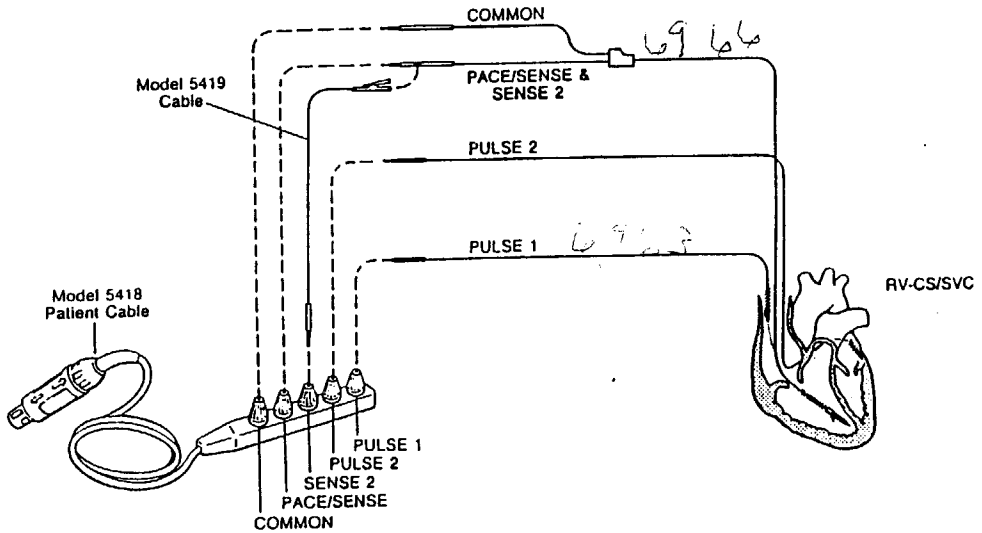
Model 6966 Lead

The Medtronic Transvene Model 6966 Tripolar, Endocardial, Screw-In Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. The lead has application where implantable tachyarrhythmia control systems are indicated.

The Model 6966 lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool.

FIGURE III B-1





Connections to Model 5418 Patient Cable for
Typical Simultaneous or Sequential Pathway (RV-CS/SVC).

Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be potential a problem.

The three electrodes of this lead are the coil, ring, and helix:

The defibrillating **coil electrode** is most proximal to the pulse generator and connects electrically to the connector pin of the unipolar leg of the bifurcation. This unipolar leg will not accept a stylet.

The **ring electrode** is proximal to the helix and connects electrically to the connector ring of the bipolar leg of the bifurcation.

The **helix tip electrode** is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector pin with a special fixation tool. The helix electrode connects electrically to the connector PIN of the bipolar leg of the bifurcation. This bipolar leg is the only one that will accept a stylet.

The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; the coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6999 Lead

The Medtronic Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use and is designed to be used with an implantable tachyarrhythmia control device along with at least one complementary defibrillating electrode and a pacing/sensing lead; a third defibrillating electrode may also be used.

The lead has application for patients in whom implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Intended Uses - PCD Device

The Model 7217B PCD device is intended for use in patients who are at high risk of sudden death due to ventricular tachyarrhythmia.

Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or
- in the absence of a prior cardiac arrest, have recurrent, sustained ventricular tachycardia that occur spontaneously or can be induced, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically.

Extensive electrophysiologic evaluation and testing of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Model 7217B PCD device. Before permanently programming the PCD device to the automatic detection and delivery of the VT and/or VF therapies, the patient should have demonstrated a satisfactory response to the proposed therapy.

Intended Uses - ETCD

The Model 5355 External Tachyarrhythmia Control Device is intended for use in conjunction with an antitachycardia/defibrillation lead system during diagnostic studies for implanting the Model 7217B PCD device.

Indications for use of the ETCD include:

- Patients experiencing recurrent episodes of ventricular tachyarrhythmia,
- Patients who survived a cardiac arrest due to a ventricular tachyarrhythmia and are at risk for repeated episodes,
- Patients who are undergoing an assessment of the efficacy of antitachycardia pacing, cardioversion, or defibrillation therapies in anticipation of an implantable cardioverter-defibrillator.

Components of the System

A list of components used in the system is given below. It is separated into a listing of those components for which market approval is sought and those components that are now commercially available. Market approval is not being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems or for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

Seeking Approval:

Transvene Leads
- Model 6963
- Model 6966
- Model 6999

Pacer-Cardioverter-Defibrillator (PCD) Device*
- Model 7217B

External Tachyarrhythmia Control Device (ETCD)*
- Model 5355 ETCD
- Model 5418 Patient Cable

Commercially Available:

Programmers Model 9710 and accessories

Printers Model 9751/9712

* Indicates devices pending FDA approval, P900061

Components Used in the Implantable Configuration

The implantable configuration is composed of a PCD Device, lead system, and a 9710 Programmer with applicable software cartridge. The implantable device is a Model 7217B PCD Device. The PCD device requires an appropriate lead system consisting of up to three cardioversion/defibrillation electrodes. See Figure III B-2. The Transvene leads used with the Model 7217B PCD Device are the Models 6963, 6966, and 6999.

The Model 9710 Programmer is commercially available. Two printers are also commercially available. When higher printing speeds are desired, it is recommended that the programmer be used with the faster printer, the Model 9751. If slower printing speeds are acceptable, as may be the case in some follow-up situations, the Model 9710 Programmer can be used with the battery-powered Model 9712 Printer.

Components used in the External Configuration

The external tachyarrhythmia control system is composed of the Model 5355 ETCD, a Model 5418 Patient Cable, a Model 5419 cable, lead system, and a Model 9710 Programmer with applicable software cartridge, see Figures IV-A-3, 4. The ETCD uses replaceable batteries as its power source. The Model 5418 Patient Cable and Model 5419 Cable are designed to connect the Transvene leads to the ETCD. Like the implantable system, the ETCD uses the same Transvene leads (Models 6963, 6966, and 6999).

MEDTRONIC CONFIDENTIAL

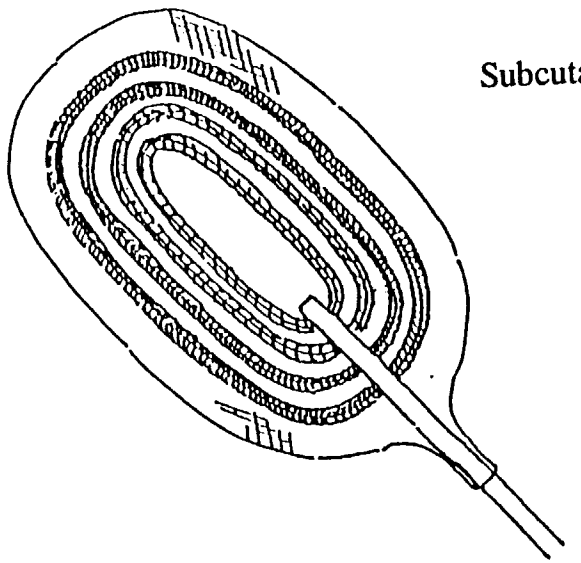
Model 6966 Right Ventricle



Subcutaneous Patch

Model 6999

Purpose of the System

PCD System Configuration

The PCD Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or a progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation. The PCD Device also has bradycardia pacing capability. The Transvene leads allow the PCD device to deliver these therapies to the heart.

ETCD System Configuration

The ETCD is an external tachyarrhythmia control device designed to deliver overdrive pacing, cardioversion, defibrillation, and bradycardia therapies in the same fashion as the PCD device. The ETCD can be programmed to automatically deliver overdrive pacing therapy upon detection of VT. When used as a component of a system that includes the appropriate Medtronic programmer and applicable software cartridge, the ETCD can deliver manually-initiated VT pacing, cardioversion, and defibrillation therapies. The ETCD allows the assessment of the Transvene lead system characteristics and aids in the assessment of lead system pacing and sensing characteristics.

Overview of System Features

General

The PCD device is designed to automatically detect episodes of VT or VF and, upon detection, deliver the appropriate programmed pacing, cardioversion, or defibrillation therapies. The device has two independently programmable detection and therapy procedures, one for VT and a second for VF.

When used as a component of a system that includes the appropriate Medtronic programmer and dedicated software, the ETCD is designed to deliver manually initiated cardioversion and defibrillation therapies. The ETCD is also designed to detect episodes of VT and VF. It can automatically deliver VT overdrive therapies (burst and ramp) upon detection of a VT.

VT Detection and Therapy

Both the PCD device and ETCD use a VT detection algorithm which can use up to three separately programmable criteria as it monitors the cardiac cycle length to identify the presence of a tachycardia. Upon detection, the devices deliver their first programmed VT therapy. If the VT episode persists and is again detected, up to three additional independently programmable VT therapies may be delivered to restore the patient's normal cardiac rhythm. This progression of four VT therapies can be tailored to each patient's need. For the PCD device the therapies may be selected from two methods of overdrive pacing (burst and ramp) and synchronized cardioversion.

For the ETCD the same overdrive pacing therapies can be automatically delivered, with cardioversion therapy being available as a manual therapy.

VF Detection and Therapy

The VF Detection algorithm monitors the cardiac cycle length to identify a VF episode. Upon detection, the PCD device provides a programmable high energy defibrillation pulse for VF therapy. Up to a maximum of four VF therapies may be delivered for ongoing detected VF episodes. Each defibrillation therapy consists of one (single pulse) or two (simultaneous or sequential) high voltage pulses designed to restore the normal cardiac rhythm.

For the ETCD, each cardioversion or defibrillation therapy, which must be initiated manually via the programmer, also consists of one high-voltage pulse or two (simultaneous or sequential) high-voltage pulses in the same fashion as the PCD devices.

Bradycardia Therapy

For both the ETCD and PCD devices, bradycardia pacing is delivered in the VVI mode. Asynchronous, (VOO), pacing is not available, and is avoided even with magnet application since this type of pacing has increased potential to initiate ventricular arrhythmias in patients receiving this system.

Lead Systems

The PCD Device and the ETCD perform pacing, sensing, cardioversion, and defibrillation through multiple electrodes in the lead system. Listed below are the electrodes and their function:

- The PACE/SENSE electrodes are incorporated in the right ventricular defibrillation lead. These electrodes function as the sensing circuit and deliver pacing pulses. The PACE/SENSE electrodes are used for sensing in conjunction with the SENSE2 electrode.
- The COMMON electrode is an electrode coil that serves as the cathode for cardioversion, defibrillation, and pacing.
- The PULSE2 electrode is an electrode coil that serves as the anode for cardioversion and defibrillation.
- The PULSE1 electrode is an optional electrode coil that serves as an additional anode for sequential and simultaneous cardioversion and defibrillation.

Cardioversion and defibrillation current pathways are between the PULSE2 and COMMON electrode coils and, if the additional lead is implanted, between the PULSE1 and COMMON electrode coils.

Other Capabilities

The physician may use the ETCD or the PCD devices to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the appropriate software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia.

The PCD device will provide the physician with information, via the Programmer, about its present programmed status and data on its operation accumulated between office visits. This information may be printed and retained in the patient's file.

The PCD Device and ETCD can also transmit an electrogram to the programmer. The electrogram is the electrical signal sensed on the leads.

A programmer-generated set of symbols, termed Marker Channel™, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

In addition, the ETCD provides a display of measurements and other information related to delivered cardioversion and defibrillation pulses. With this information and other features, the ETCD can be used to assess the suitability of the lead system and its placement for individual patients.

PCD Battery Longevity Expectations

The longevity of the Model 7217B PCD Device depends upon several factors, including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the pacing load, and on the frequency of high voltage capacitor charging. The longevity projections found in Table IV-A-1 apply under the following conditions:

- 65 ppm pacing rate,
- 5.4 V pacing pulse amplitude,
- 0.49 ms pacing pulse width, and
- 500 ohm pacing lead.

Projected Longevity[1]
Table IV-A-1

Pacing/Sensing	34 Joule Charging Frequency	Average Longevity Model 7217B
100% Sensing	Quarterly	5.0 years
15% Pacing	Monthly	4.2 years
100% Pacing	Monthly	3.4 years

The longevity of the device decreases with the following:

- An increase in pacing rate,
- An increase in pacing amplitude,
- A decrease in pacing impedance,
- An increase in pacing pulse width,
- An increase in the percentage of bradycardia paced to sensed events, or
- An increase in the charging frequency.

Each 34 Joule charging cycle will typically decrease the longevity of the device by approximately four to six days.

---

1 These preliminary longevity projections are based upon accelerated battery data and device modeling. With the stated condition, 100% pacing and monthly 34 Joule charging cycles, the minimum longevity of the device will be 2.5 years (7217B). Average refers to the projected mean longevity of the modeled run of PCD devices at the stated conditions. Minimum longevity means that virtually all (i.e., 99.9%) of all modeled production run of PCD devices will attain the value given.

C. Alternative Practices and Procedures

The use of implantable defibrillators in patients with drug refractory ventricular tachycardia/ fibrillation (VT/VF) and in survivors of sudden cardiac death has reduced the arrhythmic mortality in these patients. Other treatments available to treat ventricular tachyarrhythmias include antiarrhythmic drug therapy, ventricular tachycardia surgery, transthoracic defibrillation and other market released implantable defibrillators with epicardial defibrillation lead systems.

D. Marketing History

All of the Medtronic Tachyarrhythmia Control System device components which have been implanted in the U.S. to date have been part of the IDE clinical study and have followed the FDA approved investigational protocol. In November 1991, the Medtronic PCD Transvene System, and respective components described in this submission, were market released in Europe. In March 1991, the Medtronic PCD Epicardial System, and respective components, were market released in Europe. And in February 1992, the FDA Advisory Panel recommended the approval of the Medtronic PCD Epicardial System.

E. Adverse Effects

Potential adverse effects which may be associated with the use of the PCD Device include but are not limited to: failure to detect ventricular tachycardia or ventricular fibrillation; failure to terminate ventricular tachycardia or ventricular fibrillation; delivery of pacing or shock therapy when no ventricular tachyarrhythmia is present, which would precipitate an episode of ventricular tachycardia or ventricular fibrillation; acceleration of a ventricular arrhythmia; failure to capture after a shock delivery; discomfort or pain during or following the delivery of electrical shock; or infection.

The following additional, potential adverse effects associated with all pacemaker systems include loss of normal pacemaker function due to battery failure or other component failure, inability to program a pacemaker pulse generator because of programmer failure, infection, erosion, undesired muscle or nerve stimulation, and inadequate sensing or pacing. Any demand pulse generator can be affected by magnetic, electrical and electromagnetic signals of sufficient strength or with characteristics which mimic cardiac function. Possible effects of electrical interference on pulse generator operation include reversion to asynchronous pacing, inhibition of output pulses and rapid synchronous pacing. Certain environmental sources can couple sufficient energy into a cardiac pacing system to damage the pulse generator or cardiac tissue adjacent to the electrodes.

Failure of the pulse generator system to function properly may result in the patient experiencing the symptoms for which the pulse generator was originally indicated.

The potential complications related to the use of the PCD Transvene Lead System include, but are not limited to, the following patient-related conditions: fibrillation, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax and hemothorax. Other potential complications related to the lead system include, but are not limited to, the following: lead dislodgement, lead conductor fracture, and insulation failure.

The above referenced information is provided in the labelling of the PCD Transvene System.

F. Summary of Studies

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6966, Model 6963 and Model 6999 Transvene Leads, Model 7217B PCD, Model 5355 ETCD, and Model 9788 Memory Module.

The animal studies were performed to evaluate acute and chronic performance PCD Transvene System and to validate that the PCD and ETCD System are safe for human use.

Finally, human clinical trials were performed to evaluate the safety and effectiveness of the PCD Transvene System in treating patients with life-threatening ventricular arrhythmias.

All of the studies have demonstrated that the PCD Transvene System functions safely and is appropriate for human use.

The following summaries are provided in this section.

1. Model 6966, Model 6963 and Model 6999 Nonclinical Testing
2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod Model 7217B PCD Nonclinical Testing
3. Animal Testing
4. Clinical Study of the PCD Transvene System

1. Model 6966, Model 6963 and Model 6999 Defibrillation Leads: Summary of Nonclinical Testing

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6963 CS/SVC lead, Model 6966 RV lead, Model 6999 SQ patch lead, and related system components.

a. Electrical Testing

Electrical D.C. resistance testing was performed to ensure proper functioning of the Model 6963, 6966 and 6999 leads.

Seventeen Model 6963, thirty-five Model 6966 and eighteen Model 6999 leads were submitted for testing. Electrical resistance was measured utilizing a milliammeter under ambient room conditions. All samples measured were within the individual design specifications.

b. Environmental Analysis Testing

The purpose of the testing was to subject the lead to temperature extremes to determine the lead's resistance to the thermal stresses when transported from extremes of climate.

Thermal Shock

Fifteen Model 6963 and thirty-five Model 6966 leads were subjected to five cycles from -45°C to 70°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute. Thirty-five Model 6999 leads were subjected to five cycles from -40°C to 66°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute.

After the thermal shock testing was completed visual inspection and electrical resistance measurements were performed. There were no visual defects and the electrical D.C. resistance of all the samples met the design specification.

c. Mechanical Testing

The purpose of the mechanical testing was to determine the mechanical integrity of the leads to ensure that the devices are safe, reliable, and suitable for their intended use and conform to design specifications. The leads and/or assemblies were subjected to the following:

- flex testing
- composite pull strength testing
- crimp/weld pull strength testing
- insertion/withdrawal force testing
- A.C. impedance/leakage testing

Flex Testing

The flex testing consisted of mounting the insulated conductor coils and uninsulated electrode coils of the Models 6963, 6966 and 6999 in a lead flex test fixture. The insulated conductor coils and uninsulated electrode coils were flexed under ambient room conditions at a specified radius. Eleven samples were used in each test. Samples exceeded specifications and therefore are considered to be satisfactory for their intended use.

Lead Joint Tensile Strengths

Pull testing of the various lead joints is conducted to ensure that the integrity of the joint meets the design specification and is, therefore, adequate for its intended application. The testing conducted consists of a composite pull test which evaluates the overall pull strength of the lead and crimp pull testing that evaluates the crimped connections of the leads to assure specification conformance.

Composite Pull Strength

Leads were boiled in Ringer's solution or soaked in normal saline and pull tested, while wet (the lead is usually cut in half to facilitate fixturing limitations) utilizing a tensile testing machine. The samples were pulled until failure at a rate of five inches per minute. The initial failures were then analyzed statistically for the confidence level in meeting the specification for the composite lead which is 1.0 lb. minimum.

Model 6963 data demonstrates that with a 95% confidence at least 97% (distal) and 99.9% (proximal) of the leads will meet or exceed the specification.

Model 6966 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Model 6999 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Therefore, Models 6963, 6966 and 6999 leads, with respect to composite pull strength, are adequate for their intended use.

Crimp/Weld Pull Strengths

Crimp and weld pull strength tests were conducted to evaluate the strength of the connections to ensure that they meet the design specification and are, therefore, adequate for their intended application. The connections tested are:

- Distal crimp sleeve to conductor coil crimp (6963)
- Double crimp core to conductor coil crimp (6963)
- Electrode coil to double crimp core weld (6963)
- Electrode coil to distal crimp sleeve weld (6963)
- Tip crimp sleeve to conductor coil crimp (6963)
- Connector pin to conductor coil crimp (6963 and 6999)
- Helix electrode to inner conductor coil crimp (6966)
- Electrode ring to middle conductor coil crimp (6966)
- Transition sleeve to electrode coil weld (6966)
- Transition sleeve to outer conductor coil crimp (6966)
- Fixed connector pin to outer conductor coil crimp (6966)
- Connector ring to middle conductor coil crimp (6966)
- Rotating connector pin to inner conductor coil crimp (6966)
- Manifold crimp sleeve to conductor coil crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4) (b)(4) crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4) (b)(4) crimp (6999)

Subassemblies were submitted for testing and pull tested by using a tensile testing machine. The samples were pulled until failure at a rate of four inches per minute.

Pull strength testing consisted of a minimum of 15 subassemblies of each crimp connection and a minimum of 7 subassemblies of each weld connection All samples tested exceeded the individual specification. The test results indicated that with a 95% confidence, at least 95% of the leads will have crimp and weld strengths that exceed the specification.

Therefore, the Model 6963, 6966 and 6999 leads, with respect to crimp and weld connection pull strengths, are adequate for their intended use.

Insertion/Withdrawal Forces

Insertion/withdrawal forces are measured to ensure compatibility with the implantable device without causing damage to the lead. Twenty five each of the lead Models 6963, 6966 and 6999 were tested with the Model 7217B PCD Device connector modules. There were no physical changes and all measurements met the design specification.

A.C Impedance/Leakage Testing

Fluid leakage tests are conducted on the lead assemblies/implantable device connector to determine leakage. Ten of each lead model Models 6963, 6966 and 6999 were tested with the Model 7217B connector modules. A.C. impedance was measured from the PCD device case to the lead connections while immersed in fluid. All samples met the design specification.

d. Biocompatibility Testing

The materials used in the Models 6963, 6966 and 6999 that are directly exposed to body tissue are:

- Polyurethane
- Silicone rubber (methylvinylpolysiloxane)
- Silicone rubber/titanium dioxide
- Platinum/Iridium

These materials have been shown to be biocompatible through many years of use in Medtronic permanent implantable endocardial/myocardial permanent pacing leads. In addition to extensive implant experience with these materials, standard biocompatibility tests have been performed to verify the biocompatibility of the above-listed materials. Testing has demonstrated that all materials are nonhemolytic, nonpyrogenic, nontoxic, nonmutagenic and biocompatible. Therefore, the materials passed the tests and are considered suitable for human implant. The materials used in the Models 6963, 6966 and 6999 are identical to those used in other commercially available Medtronic pacing leads.

e. Lead Life Testing

In-vitro bench testing is performed to determine the chronic performance (integrity) of the non-thoracotomy leads. The leads were subjected to accelerated life testing. Testing included subjecting the

leads to visual, mechanical, and electrical evaluations before and after soaking, flexing, and high voltage pulsing under simulated use conditions.

D.C. resistance values and intermittence data measured before and after being subjected to multiple flexing and high voltage pulsing demonstrated the non-thoracotomy leads satisfy requirements and are acceptable for their intended use.

2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod

Non-clinical testing of these components was provided Volume 4 of the original PMA application (P900061) dated September 27, 1990, Volume 3 of the amendment dated March 8, 1991, and Volume 2 of the amendment dated August 30, 1991. A summary of the test results for each of the components is provided.

Model 7217B PCD: Summary of Nonclinical Testing

Testing of the Model 7217B pulse generators and the peripheral devices that comprise the system, i.e., the Pacing System Analyzers, the Model 9710 Programmer utilizing the Model 9788 MemoryMod and the Model 9751 Printer have been tested and found to be acceptable. All aspects of system interaction and operation are in accordance with the Model 7217B PCD Device and Model 9788 technical manuals and system specifications. Therefore, the Medtronic Tachyarrhythmia Control System, in its entirety, is acceptable for its intended use.

Model 9788 Memory Module: Summary of Nonclinical Testing

The Medtronic Model 9788 MemoryMod Cartridge was designed for insertion into the commercially available Model 9710 Programmer. When inserted, it becomes an integral part of the non-invasive programming system for the implantable PCD devices to establish pacing, ventricular tachycardia (VT) detection and therapy, ventricular fibrillation (VF) detection and therapy, and electrophysiological study (EPS) capabilities of an implanted pacemaker/ cardioverter/defibrillator (PCD). Both the Model 7217B PCD device and the Model 5355 ETCD are programmed with the Model 9788 MemoryMod cartridge when used with the Model 9710 Programmer.

Testing of the Model 9788 MemoryMod cartridge has demonstrated conformance to specification requirements. Therefore, the Model 9788 MemoryMod is acceptable for its intended use with the Model 7217B PCD Devices and the Model 5355 ETCD Device.

Model 5355 ETCD: Summary of Nonclinical Testing

Testing of the Model 5355 ETCD and respective accessories has shown conformance to specification requirements. Therefore, the Model 5355 ETCD Device/accessories are acceptable for their intended use.

3. Animal Testing

The information presented in this section is an accumulation of several studies, some of which FDA has previously reviewed in IDE submissions (G870102). These studies demonstrate the safety of the Transvene lead Models 6963, 6966 and 6999.

A variety of non-thoracotomy leads were evaluated in a series of four canine studies. Descriptions of the leads, as well as the study number(s) (1, 2, 3 or 4) in which they were evaluated, are presented below.

Description: Non-thoracotomy Leads

CORONARY SINUS/SUPERIOR VENA CAVA LEADS

(b)(4)

Model 6963, evaluated in Study No. 4, is a silicone, unipolar, coronary sinus or superior vena cava lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies.

Model 6881, evaluated in Study Nos. 2, 3 and 4 is functionally equivalent to the Model 6963 except the 6881 has a 3.2 mm connector.

(b)(4), (b)(5)

Model 10285, evaluated in Study No. 1, is the temporary version of the Model 6963/6881.

RIGHT VENTRICULAR LEADS

Model 6966, evaluated in Study No. 4, is a polyurethane, tripolar, extendable/retractable, screw-in lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies. Additionally, the 6966 has a 3.2 mm connector for pacing and sensing.

Model 6884, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6966 except the 6884 has a 3.2 mm connector in place of the 6.5 mm connector for the cardioversion-defibrillation electrode.

Model 10284, evaluated in Study No. 1, is the temporary version of the Model 6966/6884.

SUBCUTANEOUS PATCH LEADS

Model 6999, evaluated in Study No. 4, is a silicone, unipolar, oval, subcutaneous patch with a 6.5 mm connector and platinum alloy electrode coils that are partially embedded in the silicone patch for delivery of cardioversion and defibrillation therapies. Additionally, the patch is embedded with [(b)(4) (b)(4)]

Model 6895, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6999 except the 6895 has a 3.2 mm connector and is covered with [(b)(4) (b)(4)]

Model 10317, evaluated in Study No. 3, is functionally equivalent to the 6895 except it is embedded on the outer edge with [(b)(4) (b)(4)]

Although model numbers differ, all leads in each of the three groups are functionally equivalent. The various model numbers reflect an evolution of temporary to transvenous lead development, as well as minor changes, such as the connector pin modification from 3.2 mm to 6.5 mm.

Additional devices were used to evaluate the non-thoracotomy lead studies in canines. These are described below.

External Devices for Implant Support

Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD provides the same detection capabilities as the implantable Model 7217B PCD Device. Therapies are identical except that the maximum output energy is 40 joules (J) and automatic defibrillation and cardioversion are not available in the Model 5355. The Model 5355 ETCD provides measurement and display of output waveform parameters and ETCD status, an isolated electrogram signal, and passthrough connections of pacing and sensing electrodes to external instrumentation.

Model 2394 External Cardioverter/Defibrillator (ECVD)

The Model 2394 ECVD instrument can deliver: (1) a single stimulation pulse on one output channel, or (2) a pair of pulses, delivered individually on the two different output channels. Monophasic and biphasic pulses are provided, output capacitance can be varied between 10 and 150 microFarads (mf) depending on which external capacitor modules are used, and pulse width can be specified as a fixed duration (0.1-19.9 ms) or "tilt" (10-90%). Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Model 2376 External Cardioverter/Defibrillator (ECVD)

The output stimulation parameters of the Model 2376 are very similar to those of the Model 2394 except for the following modifications:

- All pulses are monophasic, truncated, exponential waveforms.
- Output capacitance is fixed at 50 microFarads and pulse width is determined by a fixed pulse duration only.
- Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Study Methods

All canine studies were conducted according to the 1966 and 1970 Animal Welfare Acts, 1985 NIH Laboratory Animal Use and Care Guidelines and GLP regulations. Adult mongrel canines were used for all studies. The dogs weighed 20 kg or more.

Specific details of each study are presented in the following "Animal Studies/Results" section.

Each study is briefly described below. Both acute and chronic studies were performed to assess the toxicity of the non-thoracotomy lead system as well as its stability over time.

Study #1: Acute Toxicity Testing of Non-thoracotomy Leads

The objective of this study was to quantify the amount and nature of shock-induced damage to the myocardial tissue resulting from multiple, high energy defibrillation shocks delivered through transvenous defibrillation leads and a subcutaneous patch. This information has previously been submitted to the agency in the Non-Thoracotomy IDE, reference Document Control Number G870102/S23; FDA Approved October 4, 1990. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results of these studies revealed only minimal shock-induced necrosis (<0.1-0.5 percent by weight), which did not result in functional impairment of the cardiac tissue. Therefore, the use of the Model 6963, 6966 and 6999 leads did not result in significant myocardial damage in canines and could be safely implanted in humans.

Study #2: Model 6881, 6884 and 6895 Chronic Lead Evaluation

The objective of this study was to evaluate the suitability of the lead system for human clinical use. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Study results demonstrate that the performance of the non-thoracotomy lead system when used with the PCD and ETCD devices is in conformance with system design and expected operation.

Study #3: Model 6881, 6884 and 6895 Chronic Lead Defibrillation Study

This study is an evaluation of the chronic stability of the non-thoracotomy lead system via the monitoring of defibrillation and pacing thresholds. In addition, histopathological examinations have been performed to assess the amount and nature of shock-induced damage to the myocardial tissue resulting from defibrillation shocks. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results demonstrate stable pacing, sensing and defibrillation thresholds over time. Additionally, histopathology analysis shows no cardiac tissue damage due to delivery of defibrillation shocks.

Study #4: Model 6963, 6966 and 6999 Chronic Lead Defibrillation Study

This study is an ongoing evaluation of the non-thoracotomy lead system to assess chronic defibrillation threshold stability, pacing thresholds, intracardiac sensing capabilities and tissue damage. Results indicate the lead system performs as intended; DFTs and pacing thresholds have remained stable throughout the study (40 weeks) and intracardiac sensing is appropriate. Additionally there is minimal localized trauma to the cardiac tissue (<0.05 percent by weight).

Conclusion

All of these canine studies have demonstrated that the non-thoracotomy lead system, which includes the Model 6963 CS/SVC lead, 6966 RV lead and 6999 SQ patch lead, functions safely and is therefore appropriate for human use.

4. Summary of Clinical Experience

A. Introduction

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) have been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT. However, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing. Additionally, it is necessary to perform a significantly more invasive procedure, a thoracotomy, in order to implant the epicardial leads. Thus, the need to incorporate programmability, multiple detection and therapeutic options, and a less invasive lead system has lead to the development of a tiered therapy device, the PCD™ Transvene™ System.

This report is on Medtronic's clinical experience with the Medtronic PCD™ Multiprogrammable Tachyarrhythmia Control System with Transvene™ Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of November 27, 1991. Analysis includes a total of 319 implants of the PCD™ System with a mean implant duration of 4.5 months. The data is a clinical experience update on 317 patients.

The PCD Transvene System components, except for the defibrillation lead systems, is identical to the PCD Epicardial System which received a recommendation for approval by the FDA Advisory panel on February 3, 1992. The objectives and the clinical protocol were identical for the two systems.

The data analysis is organized in functional rather than chronological categories in order to present a complete picture of each of the PCD™ Device's various functions. The sections included in this summary are:

- Indicated Patient Population/Therapeutic Options
- PCD Therapy Applications
- Study Objectives and Protocol Summary
- Overview of Clinical Experience
  - Implant Data
  - Spontaneous VT/VF Episode Experience
  - Overall Success Rate
- Complications and Observations
- Inactive Patients
- Patient Deaths
- Clinical Experience by Primary Indication
- Patients not Meeting Implant Criteria
- Comparison to AICD Clinical Experience
- Comparison to PCD™ Epicardial Clinical Experience
- PCD™ System Performance

This summary provides an overview of the clinical experience which verifies that the PCD™ System is safe and effective in the indicated patient population.

B. Indicated Patient Population and Therapeutic Options

B.1 Patient Population

The PCD™ Transvene™ System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD™ Device.

Results provided in this summary support Medtronic's request for Market Release of the PCD™ Transvene™ System for use in the following patient population:

Patients who have survived at least one episode of cardiac arrest, presumably due to a ventricular tachyarrhythmia, as evidenced by resuscitation using a transthoracic defibrillator. The ventricular arrhythmia should not be caused by an acute myocardial infarction; OR

In the absence of a prior cardiac arrest, patients with recurrent, sustained ventricular tachycardia that occur spontaneously or can be induced, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically.

Malignant ventricular tachyarrhythmias remain a major unsolved problem in the management and prevention of coronary artery disease. It is estimated that 450,000 people experience sudden cardiac death annually, and 80%-90% of these events are caused by ventricular fibrillation. (Gillum RF. Sudden coronary death in the United States. Circulation 1989; 79:756-765.)

Survivors of out-of-hospital cardiac arrest not associated with acute myocardial infarction are at risk for recurrent cardiac arrest as reported by Wilber, et al.(Wilber, et al. Out-of-Hospital Cardiac Arrest - Use of Electrophysiologic Testing in the Prediction of Long-Term Outcome. NEJM 1988; Vol.318:19-24.). In this study group of 166 survivors of out-of-hospital cardiac arrest, ventricular arrhythmias were inducible in 131 patients (79%) and were suppressed by antiarrhythmic drug therapy or surgery (or both) in 91 patients (72%). During a median follow-up of 21 months, cardiac arrest recurred in 29 patients: 11 in whom inducible arrhythmias had been suppressed, 12 in whom inducible arrhythmias persisted and 6 in whom arrhythmias could not be induced at initial electrophysiologic study.

B.2 Therapeutic Options

Therapeutic options for these patients include antiarrhythmic drug therapy, catheter ablation, surgical ablation, and electrical device therapy. The therapy indicated for a particular patient will be dependent on the patient's clinical ventricular tachyarrhythmia, the results of electrophysiologic evaluation, and the presence and severity of underlying cardiovascular disease.

There are currently multiple antiarrhythmic drugs available for the treatment of recurrent ventricular tachyarrhythmias. The sudden cardiac death survival at one year for patients treated with drug therapy alone ranges from 34 to 73% (Graboys, et al. Long Term Survival of Patients with Malignant Ventricular Arrhythmias Treated with Antiarrhythmic Drugs. American Journal of Cardiology. 1982; Vol 50:437-443 and Swerdlow, et al. Determinants of Survival in Patients with Ventricular Tachyarrhythmias. NEJM. 1983; Vol.308:1436-1442).

The success rate of catheter ablation for recurrent ventricular tachyarrhythmias averages 25% with no further need for drug therapy and 25% for suppression with drugs where drugs were previously ineffective. (Zipes, et al. Nonpharmacologic Therapy: Can it Replace Antiarrhythmic Drug Therapy? Journal of Cardiovascular Electrophysiology. Vol.2, No.3:255-272.)

A 10 year analysis of data from a multi-center registry on patients who underwent surgical ablation for recurrent ventricular tachyarrhythmias reveals survival of 78% at one year and 60% at 5 years. (Zipes, et al).

The reported one year sudden cardiac death survival for patients receiving an ICD for treatment of recurrent ventricular tachyarrhythmias is 98.0%. (Thomas,et al. Implantable Defibrillation: Eight Years Clinical Experience. PACE. 1988; 11(II):2053-8).

C. PCD™ Transvene System Therapy Applications

The PCD™ System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias and/or recurrent ventricular tachycardia.

For this patient population, the primary benefits from the use of the PCD™ System center on the detection and termination of life-threatening ventricular arrhythmias. The use of the PCD™ Transvene™ system allows for the application of identical therapies as an epicardial system without requiring an open chest procedure for implantation of the lead system. This less invasive surgical approach allows the system to be applied in patients who may not be able to undergo an open chest procedure. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD™ pulse generator.

The PCD™ System allows the titration of therapies for patients with ventricular tachycardia while providing critical defibrillation backup. Multiple detection algorithms are designed to allow the device to distinguish ventricular tachycardia from sinus tachycardia and atrial fibrillation. In addition, independent detection algorithms for VT and VF allow the delivery of different types of therapy for each of these two arrhythmias. The incorporation of antitachycardia pacing algorithms allows the use of pacing for the termination of well tolerated ventricular tachycardia. These algorithms, which are rate adaptive, can adapt to changes in the ventricular tachycardia and successfully terminate the episode. Defibrillation therapy is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The incorporation of multiple cardioversion and defibrillation pathways (SINGLE, SEQUENTIAL and SIMULTANEOUS) allows the physician to provide an adequate cardioversion/defibrillation efficacy safety margin for all patients. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia.

Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters, and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

D. Study Objectives

The clinical study was designed to evaluate the operation, safety, and effectiveness of the PCD™ System in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD™ system, including the implantable pulse generator and associated Transvene™ lead system (Models 6895/6999, 6884/6966/SP2100, 6881/6963 and its use in this patient population. The analysis includes the clinical experience with the PCD™ system, pace/sense, detection, and therapy functions in both the acute and chronic settings. Data is provided on the PCD™ System efficacy in terminating spontaneous VT/VF episodes, clinical observations, clinical complications, and deaths in this patient population.

This summary presents safety and efficacy evaluation performed on 317 patients, 116 of which have implant durations equal to or greater than six months.

All patients underwent extensive pre-implant testing which included electrophysiologic evaluation of the patient's clinical ventricular tachyarrhythmias. Operative testing was performed to verify that the final implanted lead configuration properly detected and treated episodes of ventricular fibrillation, and when appropriate, ventricular tachycardia.

All patients were evaluated prior to hospital discharge, one (1) month post implant, three months post-implant, and then at intervals of every three months. In some cases, additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD™ System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

International centers were subject to the appropriate requirements (e.g. the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD™ System with Transvene™ Leads is included in this report.

E. Overview of Clinical Experience

This report covers a total of 319 implants in 317 patients of the PCD™ Device with the Transvene™ Defibrillation Lead System. A total of 52 investigative centers participated in the clinical trial with 20 centers in the U.S. and 32 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table E-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD™ Transvene™ System Implant Distribution			
	Total	**U.S.**	**Int'l**
7216A	18 (5.6%)	3 (2.2%)	15 (8.2%)
7217B	301 (94.4%)	134 (97.8%)	167 (91.8%)

Table E-1: PCD™ Transvene™ System - Implant Distributions - 11/27/91

The mean documented implant duration for this patient population is 4.5 months and ranged from implant to 22.0 months. The cumulative implant duration is 1426 months. There are 116 patients with implant durations equal to or greater than six months. Table E-2 shows the follow-up time by type of data form. The number presented for the PHD includes 12 patients that had 2 PHD visits. Thirty seven patients did not have a PHD.

PCD™ Transvene™ System Follow-Up Quantity by Data Form Type									
	PHD	**1 M**	**3 M**	**6 M**	**9 M**	**12 M**	**15 M**	**18 M**	**21 M**
All Models	294	224	154	116	78	34	15	10	4

Table E-2: PCD™ Transvene™ System - Follow-Up Quantity - 11/27/91

The patient population enrolled in the clinical trial was predominately male (82.0%) with a mean age of 58.5 years. In the majority of patients (45.7%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Coronary artery disease was the primary heart disease in 72.2% of the patient population with a mean reported ejection fraction of 36.7% Table E-3 provides a data summary on these patients. Also included is the data summary of the patients with 6 months of follow-up and the data summary from the PCD™ Epicardial experience that formed the basis for the PCD™ Epicardial PMA submission.

PCD™ Transvene™ System Data Summary			
	All Patients (3 Electrode Systems)	Patients with 6 months of Follow-up	Patients with PCD™ Epicardial System
Number of Patients	317	116	434
Device Months Follow-up	1426.5	1159.2	4778.0
Mean Follow-up Time	4.5 mo	10.0 mo	11.0 mo
Maximum Follow-up Time	22.0 mo	22.0 mo	27.8 mo
Number, % Male **Number, % Female**	260 82.0% 57 18.0%	94 81.0% 22 19.0%	374 86.2% 60 13.8%
Mean Age	58.5 yrs	57.1 yrs	58.3 yrs
Primary Indication: **SCD** **VT** **SCD/VT**	 120 37.9% 145 45.7% 52 16.4%	 41 35.3% 54 46.6% 21 18.1%	 118 27.2% 233 53.7% 83 19.1%
Coronary Artery Disease	229 72.2%	83 71.6%	325 74.7%
Mean Ejection Fraction	290 36.7%	105 40.0%	415 34.6%
Defibrillation Pathway: **Sequential** **Simultaneous** **Single**	 247 77.4% 67 21.0% 5 1.6%	 85 73.3% 28 24.1% 3 2.6%	 184 42.4% 7 1.6% 243 56.0%
Mean LED	15.1J (N=288)	15.7J (N=106)	10.6J (N=395)
Mean DFT	13.7J (N=147)	14.2J (N=60)	9.2 (N=264)
Spontaneous VT: **Number of Patients** **Number of Episodes** **% Success**	 79 1648 99.2%	 52 1099 99.1%	 277 8672 97.7%
Spontaneous VF: **Number of Patients** **Number of Episodes** **% Success**	 61 376 99.2%	 31 212 98.6%	 177 1034 98.1%
One Year SCD Survival	100.0%	100.0%	98.8%

Table E-3: PCD™ System Data Summary - All Transvene™ Patients vs Transvene™ Patients with 6 mo Follow-up vs Epicardial Patients - 11/27/91

E.1 Implant Data

Implants of the PCD™ Device may use two or three Transvene™ leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

Table E-4 illustrates the lowest mean energy of defibrillation (LED) and mean defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD™ Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. All patients may not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD™ Transvene™ System LED and DFT Values				
Lead System	**Implant Frequency**	**LED**	**Implant Frequency**	**DFT**
All Systems	289	15.1J	147	13.7J
RV-SVC-SQ	186	15.9J	84	14.6J
RV-CS-SQ	77	13.6J	48	11.6J
RV-CS-SVC	26	14.4J	15	15.5J

Table E-4: PCD™ Transvene™ System - LED and DFT Values - 11/27/91

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 15.1J and mean implant Defibrillation threshold (DFT) for all lead systems was 13.7J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD™ Device.

E.2 Spontaneous VT and VF Episode Experience

A total of 103 patients (32.5%) have experienced a spontaneous ventricular tachyarrhythmia episode that has been detected and treated by the PCD™ Device. Forty two patients (13.2%) experienced VT only, 24 patients (7.6%) experienced VF only and 37 patients (11.7%) experienced an episode of both VT and VF.

There have been a total of 2024 episodes of spontaneous VT or VF as detected by the PCD™. The overall PCD™ Device success rate in terminating spontaneous VT/VF episodes is presented in Table E-5.

PCD™ Transvene™ System Success Rate in Terminating Spontaneous VT/VF Episodes			
	Number of Episodes Successful	Total Number of Episodes	Efficacy Rate
VT	1634	1648	99.2%
VF	373	376	99.2%
Total	2007	2024	99.2%

Table E-5: PCD™ Transvene™ System - Success Rate for Spontaneous VT/VF Episodes - 11/27/91

E.2.1 Spontaneous VT

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection must be fulfilled to be detected as a VT episode. Successful termination of the episode was defined as satisfying the VT detection of episode termination criteria.

To date, 1648 spontaneous episodes of VT have been detected by the PCD™ Device in 79 patients. The mean number of episodes per patient was 9 and ranged from 1 - 254 episodes.

The majority of spontaneous VT episodes (93.4%) were successfully treated with VT Therapy #1 and 99.2% were successfully treated with one of the four programmable VT therapies.

Of the 1634 successfully terminated spontaneous VT episodes, 94.6% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD™ Transvene™ System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is often not perceptible by the patient.

Nine patients experienced 14 episodes (14/1648 - 0.8%) in which the PCD™ Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirteen episodes were due to sinus tachycardia or atrial fibrillation with a rapid ventricular response that had been detected as VT. A modification of programmed parameters or of antiarrhythmic drug therapy was completed to reduce the incidence of detecting sinus tachycardia or atrial fibrillation in these patients. It should be noted that the PCD™ Transvene™ System responded appropriately in all cases based on the programmed detection parameters.

The remaining episode was in one patient in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. This patient's antiarrhythmic drug regimen was modified to improve therapy efficacy. **No patient deaths occurred as a result of ineffective VT therapy.**

E.2.2 Spontaneous VT Episode Experience By Primary Indication

The primary indications for implant of the PCD Transvene System were sudden cardiac death (**SCD**), recurrent sustained ventricular tachycardia (**VT**) and sudden cardiac death associated with recurrent sustained ventricular tachycardia (**SCD/VT**). Spontaneous VT episode efficacy by primary indication is provided in Table E-6. The overall efficacy for spontaneous VT episodes is greater than 98% for each of the patient groups. There is no difference in therapy efficacy among the patient's indications. Table E-6 contains the spontaneous VT episode therapeutic efficacy.

PCD™ Transvene™ System Spontaneous VT Episode Therapeutic Efficacy By Primary Indication			
Indication	**# Episodes Successful**	**# Total Episodes**	**% Success**
SCD	379	380	99.7%
VT	826	835	98.9%
SCD/VT	429	433	99.1%
TOTAL	1634	1648	99.2%

Table E-6: PCD™ Transvene™ System - Spontaneous VT Episode Efficacy by Primary Indication - 11/27/91

E.2.3 Spontaneous VT Episode Experience By Therapy Type

The PCD™ Device incorporates three programmable VT therapy types, RAMP, BURST and CARDIOVERSION, for the treatment of recurrent ventricular tachycardia. Spontaneous VT episode efficacy by programmed therapy type is provided in Table E-7.

PCD™ Transvene™ System Spontaneous VT Episode Efficacy By Programmed Therapy Type			
VT Therapy Type	**# Success**	**# Attempts**	**% Efficacy**
Ramp	1158	1245	93.0%
Burst	388	426	90.9%
Cardioversion	88	102	86.3%

Table E-7: Spontaneous VT Episode Efficacy by Therapy Type - 11/27/91

E.2.4 Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VT detection must be fulfilled to be detected as a VT episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 376 spontaneous episodes of VF have been detected by the PCD™ Device in 61 patients. The mean number of episodes per patient was 4 and ranged from 1 - 75 episodes. A review of the chart for this patient that experienced the 75 episodes of VF revealed that this was most likely due to atrial fibrillation.

The majority (81.1%) of spontaneous VF episodes were successfully treated with VF Therapy #1 and 99.2% were successfully treated with one of the four programmable VF therapies.

Two patients experienced 3 episodes of spontaneous VF (3/376 - 0.8%) in which the PCD™ Device was ineffective in terminating the episode despite delivery of all four programmed VF therapies. One patient (b)(6) had two reported ineffective VF spontaneous episodes that were due to atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved the problem. The other patient (b)(6) required external defibrillation to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Both of these patients have subsequently done well with no more reported ineffective VF therapies.

E.2.5 Spontaneous VF Episode Experience By Primary Indication

The primary indications for implant of the PCD™ Transvene™ System were sudden cardiac death (**SCD**), recurrent sustained ventricular tachycardia (**VT**) and sudden cardiac death associated with recurrent sustained ventricular tachycardia (**SCD/VT**). Spontaneous VF episode efficacy by primary indication is provided in Table E-8. There is no difference in therapy efficacy among the patient's indications. The overall efficacy for spontaneous VF episodes is greater than 98% for each of the patient groups.

PCD™ Transvene™ System
Spontaneous VF Episode Therapeutic Efficacy
By Primary Indication

Indication	# Episodes Successful	# Total Episodes	% Success
SCD	122	124	98.4%
VT	120	120	100.0%
SCD/VT	131	132	99.2%
TOTAL	373	376	99.2%

Table E-8: PCD™ Transvene™ System - Spontaneous VF Episode Efficacy by Primary Indication - 11/27/91

E.2.6 Spontaneous VF Episode Experience By Therapy Type

The PCD™ Device incorporates three programmable defibrillation pathways, SEQUENTIAL, SINGLE and SIMULTANEOUS, for the treatment of ventricular fibrillation. Spontaneous VF episode efficacy by programmed defibrillation pathway is provided in Table E-9.

PCD™ Transvene™ System Spontaneous VF Episode Efficacy By Programmed Therapy Type			
VF Therapy Type	**# Success**	**# Attempts**	**% Efficacy**
Sequential	317	320	99.1%
Simultaneous	56	56	100.0%

Table E-9: PCD™ Transvene™ System - Spontaneous VF Episode Efficacy by Therapy Type - 11/27/91

E.3 Overall Success Rate

Of the 317 patients who received a PCD™ Transvene™ System, 267 patients (84.2% - 267/317) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. The performance of the PCD™ Transvene™ System therapies have been thoroughly evaluated and been shown to be effective in detecting and terminating episodes of ventricular tachyarrhythmia.

There have been no reports of a patient death due to the PCD™ Transvene™ System not detecting a spontaneous episode of VT or VF.

The overall success rate of the PCD™ Transvene™ System in terminating spontaneous episodes of either VT or VF is 99.2% with a VT success rate of 99.2% and VF success rate of 99.2%.

The incidence of unsuccessful termination of an apparent "true" episode of ventricular tachycardia despite delivery of all four therapies was 0.06% (1/1648). The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite delivery of all four therapies was 0.3% (1/376).

The evaluation of spontaneous episode experience indicates that the PCD™ Transvene™ System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

F. Complications and Observations

The introduction of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve the majority of relevant medical events by noninvasively changing programmed parameters rather than requiring invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of November 27, 1991, there have been a total of 48 complications identified in 45 patients and 57 observations identified in 56 patients in the PCD™ Transvene™ System patient population. Thus, 14.2% (45/317) of the patients have experienced a clinical event which was defined as a complication and 17.7% (56/317) of the patients have experienced a clinical event which was defined as an observation. Table F-1 summarizes how these events were reported with U.S versus International.

PCD™ Transvene™ System
Reported Complications/Observations
U.S versus International

	Complications		Observations	
	# of Patients	# of Events	# of Patients	# of Events
U.S.	18	20	10	10
International	27	28	46	47
Total	45	48	56	57

Table F-1: PCD™ Transvene™ System Complications/Observations U.S. versus International - 11/27/91

Table F-2 summarizes the reported PCD™ Transvene™ System complications and observations by category. The category "Ineffective Therapies" included patients in whom increased defibrillation requirements were documented; "Inappropriate Therapies" includes patients in whom VT/VF therapies were delivered for nonpathological rhythms; "Pacing or Pace/Sense Related"

includes patients in whom undersensing, oversensing or loss of capture was documented; "Infection Related" includes reports of pocket infection, seroma, and hematoma was documented; "Lead Related" includes lead dislodgement, lead fracture, subcutaneous patch crinkling, and perforation; and "Device Related" includes patients in whom the device was explanted for reasons other than patient death, infection, or transplant.

The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD™ device and Transvene™ manual.

PCD™ Transvene™ System Reported Complications/Observations By Category		
Category	**Complications**	**Observations**
Ineffective Therapies	0.9%	0.9%
Inappropriate Therapies	-	8.2%
Pacing or Pace/Sense Related	0.3%	2.2%
Infection Related	3.2%	5.4%
Lead Related	9.7%	0.6%
Device Related	0.6%	-

Table F-2: PCD™ Transvene™System - Complications/Observations - 11/27/91

The "**Lead Related**" complications/observations include perforation, lead fracture, subcutaneous patch crinkling, and lead dislodgement. Table F-3 contains a summary of the reported "**Lead Related**" complications and observations.

PCD™ Transvene™ System Lead Related Complications/Observations		
Category	**Complication**	**Observation**
Right Ventricular Perforation	2 (0.6%)	-
Subclavian Vein Thrombosis	-	-
Lead Fracture	2 (0.6%)	-
Subcutaneous Patch Crinkling	2 (0.6%)	2 (0.6%)
Seroma at SQ Patch	-	5 (1.6%)
Lead Dislodgement	25 (7.8%)	-

Table F-3: PCD™ Transvene™ System Lead Related Complications/Observations - 11/27/91

There have been a total of twenty five lead dislodgements reported in twenty patients over a mean implant duration of 4.5 months. Thus, the incidence of lead dislodgements in this patient population is 7.8% (25 dislodgements/319 implants). The incidence of right ventricular lead dislodgement was 2.0% (6 dislodgements/304 implants), the incidence of coronary sinus lead dislodgement was 6.3% (7 dislodgements/112 implants) and the superior vena cava lead dislodgement was 4.7% (11 dislodgements/234 implants).

None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all twenty five cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD™ Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent pervenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

G. Inactive Patients

There are a total of 17 patients who had received a PCD™ System and are no longer active in the study as of 11/27/91. Table G-1 shows the distribution of inactive patients by reason for no longer being active in the PCD™ Transvene™ System clinical study.

PCD™ Transvene™ System Inactive Patients	
Inactive Patients	**All Patients**
Patient Deaths	5
Infection (Explant)	8
Heart Transplant	4
Total	17

Table G-1: Inactive Patients - 11/27/91

H. Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD™ System component, or as a result of a device induced arrhythmia, or an interaction between a PCD™ System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD™ System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD™ Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD™ System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 5 patient deaths reported in the PCD™ Transvene™ System patient population. Table H-1 summarizes how these patient deaths have been classified. There have been no sudden cardiac deaths in this patient population.

PCD™ Transvene™ System Summary of Death Classifications	
Classifications	**All Patients (N=317)**
Sudden Cardiac	-
Non-Sudden Cardiac	4
Noncardiac	1
TOTAL	5

Table H-1: PCD™ Transvene™ System - Summary of Death Classifications - 11/27/91

None of the patient deaths were attributed to a malfunction of the PCD™ Transvene™ System.

Actuarial survival analysis on the PCD™ Transvene™ System was done on all patients in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat**. Those patients in whom the PCD™ Device was OFF at the time of death or in whom no device was implanted are included in the survival analysis. Those patients that were screened for a PCD™ Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table H-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.3% (1/317).

PCD™ Transvene™ System One Year Actuarial Survival	
Sudden Cardiac Death	100.0%
Non-Sudden Cardiac	97.9%
All Cardiac	97.9%
Noncardiac	99.3%
Perioperative	0.3%
Overall	96.8%

Table H-2: PCD™ Transvene™ System - One Year Actuarial Survival - 11/27/91

Overall, the PCD™ Transvene™ Device has been safe and effective in reducing the sudden cardiac arrhythmic death rate in the indicated patient population. The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

I. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD™ Transvene™ System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.9% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 45.7% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 16.4% of the patients.

The performance of the PCD™ Transvene™ System in these three groups are summarized in Table I.1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 99.4%, in the VT patient group 99.1%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD™ Transvene™ System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was 100%.

This analysis indicates that the PCD™ Transvene™ System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

PCD™ Transvene™ System Data Summary by Primary Indication

Table I-1: PCD™ Transvene™ System Data Summary by Primary Indication - 11/27/92

J. Patients Not Meeting Implant Criteria

The PCD™ Transvene™ System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD™ Transvene™ System decreases the potential perioperative mortality and long term morbidity and mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. For these patients, the PCD™ Transvene™ System is the only therapy available. Because of the surgical risks and postsurgical complications associated with epicardial lead system, implantation in the following patient groups may not be possible - patients that pose high surgical risk because of their state of health, patients who are potential heart transplant candidates and patients who may eventually require open heart surgery for treatment of their coronary artery disease. The PCD™ Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, options for future therapy remain available; e.g. CABG is associated with decreased morbidity and mortality if there has been no prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In a epicardial lead system, greater electrode surface area would theoretically decrease defibrillation requirements.

The smaller electrode surface areas of the PCD™ Transvene™ System might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that 70% of patients tested may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD™ Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not necessary.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

A total of 368 patients were evaluated for implantation of the PCD™ Transvene™ System. The PCD™ Transvene™ System was implanted in 86.1% (317/368) of the patients who were screened for the system. A total of 257 patients, or 70%, met the recommended defibrillation implant criteria which compares favorably with the predicted success rates published in the literature (Wilber et al).

However, 18.9% (60/317) of the patients did not meet the recommended PCD™ Transvene™ System defibrillation efficacy implant criteria and still received the PCD™ Transvene™ System. The major reasons for not meeting implant criteria included 3/4 successes at 24 Joules or less (35%), two successes at 18 Joules (31.7%), failure to induce at least three episodes of VF at implant (20%), and deteoriating patient condition (11.7%). However, in 80% of the patients (48/60), at least one episode of induced VF was successfully reverted with 24 Joules or less.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did demonstrate an adequate defibrillation safety margin when programming VF Therapy #1.

This is particularly true in those patients (N=40) in whom 3/4 successes at 24 Joules or two successes at 18 Joules was documented. In these patients, a safety margin of 10 Joules was provided between the successful defibrillation energy (24 J or less) and the maximum output of the PCD™ Device (34 J). The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup P., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321. Finally and perhaps most importantly, the investigators also felt that these patients medical condition precluded a PCD™ Epicardial System implant with a thoracotomy approach and its associated morbidity and mortality.

In the patients screened for the PCD™ Epicardial System, 11.0% did not meet the recommended implant criteria but ultimately received the system. The spontaneous VT/VF episode efficacy, one year sudden cardiac death survival and overall one year survival rate is similar in the two patients populations.

Thus, the patients who received the PCD™ Transvene™ System despite not meeting the recommended implant criteria were not a higher risk for sudden cardiac death.

There were 51 patients (13.9%) in whom the PCD™ Transvene™ System implant criteria could not be met despite multiple inductions and the evaluation of multiple PCD™ Transvene™ System lead configurations. In these patients, there was not a 10J safety margin between the lowest energy that successfully defibrillate the patient and the maximum output of the PCD™ Device (34J). These patients all received PCD™ Epicardial System implants and in all cases met the required defibrillation implant criteria.

Patients Receiving PCD™ Transvene™ System & Did Not Meet Implant Criteria

In order to determine if the patient's not meeting implant criteria had a higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table J-1.

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population that did not meet the implant criteria there were no patients who experienced episodes of VT/VF where all four programmed therapies failed to terminate a "true" episode. Those episodes which were not terminated were delivery of inappropriate therapy for atrial fibrillation with rapid ventricular response or sinus tachycardia.

There was no difference in the one year sudden cardiac survival of the overall survival in the two groups. This indicates, that despite not meeting the implant criteria, these patients were not at higher risk of sudden cardiac death.

PCD™ Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	257	60
Spontaneous VT Episode Efficacy	99.2%	99.1%
Spontaneous VF Episode Efficacy	99.7%	97.4%
Number of Patient Deaths	4	1
Perioperative Mortality	0.4%	-
One Year Survival		
Sudden Cardiac	100%	100%
Non-Sudden Cardiac	98.1%	96.9%
All Cardiac	98.1%	96.9%
Noncardiac	99.1%	100%
Overall	96.8%	96.9%

Table J-1: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 11/27/91

The survival of patients receiving a PCD™ Transvene™ System without meeting implant criteria (N=60) was compared to patients receiving a PCD™ Epicardial System without meeting implant criteria (N=44). This comparison is provided in Table J-2. Though the PCD™ Transvene™ System had a higher incidence of patients not meeting implant criteria but receiving the system (18.9%), the overall survival of these patients was statistically significantly better as compared to the PCD™ Epicardial System patients not meeting implant criteria.

determined this to be an appropriate demonstration of device effectiveness and that the PCD Transvene System could be implanted.

The clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 100% and the overall one year actuarial survival was also 100%.

PCD™ Transvene™ System Patients Not Meeting Implant Criteria 3/4 Success at ≤ 24 Joules	
Number of Patients	21
Lowest Energy of Defibrillation **20 Joules** **22 Joules** **24 Joules**	 9 5 7
Number of Patients with 1 Success at 18J	15
Overall Spontaneous VF Episode Efficacy	100%
One Year Survival **Sudden Cardiac** **Overall**	 100% 100%

Table J-3: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at ≤ 24 Joules Clinical Experience - 11/27/91

Two Successes at 18 Joules

There were 19 patients in whom the PCD™ Transvene™ System was implanted with 2 successes at 18 Joules. A third success at 18 Joules was not obtained either because VF could not be induced or the physician felt that adequate testing had been completed to evaluate the PCD™ Transvene™ System.

The clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 100% and the overall one year actuarial survival was also 100%.

Based on this analysis, of the sixty patients who received the PCD™ Transvene™ System despite not meeting the recommended implanted criteria, 40 (66.7%) had successful termination of VF at 24 Joules or less. There were no patient deaths in this group and the overall spontaneous VF episode efficacy was 100%. **Thus, there were no patients in whom the PCD™ Transvene™ System was implanted**

without a safety margin of at least 10 Joules provided between the successful defibrillation energy (24 J or less) and the maximum output of the PCD Device (34 J).

Failure to Induce Three Episodes of VF

There were 12 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. The indication for implant was sudden cardiac death (SCD) in four patients, recurrent ventricular tachycardia (VT) in four patients and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in four patients.

There were four patients (33.3%) who had at least one episode of VF induced which was successfully reverted with 18 Joules. In the remaining eight patients, there were no episodes of VF induced. Five of these patients were on Amiodarone therapy which may have contributed to the inability to induce VF. In the eight patients in whom no VF was induced at implant, either VT, polymorphic VT or ventricular flutter was induced and successfully reverted with 18 Joules or less. Since the indication for implant in these eight patients was either VT or SCD/VT, the investigator felt the effective termination of VT was adequate to allow implantation of the PCD™ Transvene™ System.

Of the 12 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant, seven (58.3%) have either experienced a spontaneous VF episode or have had VF induced during a electrophysiology study. In all cases, VF was successfully reverted by VF Therapy #1 (34J).

There has been one reported patient death, (Patient ID (b)(6), which was classified as non-sudden cardiac secondary to end stage heart failure. Thus the one year sudden cardiac death survival in this patient population is 100% while the one year overall survival is 88.9%.

Patient Condition

In seven patients the PCD™ Transvene™ System implant procedure was terminated prior to meeting the recommended implant criteria due to the patient's deteriorating condition. The mean ejection fraction of this group was 24.5% which may have placed the patients at increased risk for perioperative mortality and morbidity. This group had a mean of nine VF inductions and 2.5 lead configurations evaluated in an attempt to meet the recommended implant criteria.

without a safety margin of at least 10 Joules provided between the successful defibrillation energy (24 J or less) and the maximum output of the PCD Device (34 J).

Failure to Induce Three Episodes of VF

There were 12 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. The indication for implant was sudden cardiac death (SCD) in four patients, recurrent ventricular tachycardia (VT) in four patients and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in four patients.

There were four patients (33.3%) who had at least one episode of VF induced which was successfully reverted with 18 Joules. In the remaining eight patients, there were no episodes of VF induced. Five of these patients were on Amiodarone therapy which may have contributed to the inability to induce VF. In the eight patients in whom no VF was induced at implant, either VT, polymorphic VT or ventricular flutter was induced and successfully reverted with 18 Joules or less. Since the indication for implant in these eight patients was either VT or SCD/VT, the investigator felt the effective termination of VT was adequate to allow implantation of the PCD™ Transvene™ System.

Of the 12 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant, seven (58.3%) have either experienced a spontaneous VF episode or have had VF induced during a electrophysiology study. In all cases, VF was successfully reverted by VF Therapy #1 (34J).

There has been one reported patient death, (Patient ID (b)(6), which was classified as non-sudden cardiac secondary to end stage heart failure. Thus the one year sudden cardiac death survival in this patient population is 100% while the one year overall survival is 88.9%.

Patient Condition

In seven patients the PCD™ Transvene™ System implant procedure was terminated prior to meeting the recommended implant criteria due to the patient's deteriorating condition. The mean ejection fraction of this group was 24.5% which may have placed the patients at increased risk for perioperative mortality and morbidity. This group had a mean of nine VF inductions and 2.5 lead configurations evaluated in an attempt to meet the recommended implant criteria.

Four of the patients (57.1%), had at least one successful termination of VF at 18 Joules prior to the termination of the implant procedure. The lowest energy of defibrillation in this group ranged from 18-22 Joules. Thus at least a 10 Joule defibrillation margin was provided between the successful defibrillation energy and the maximum output (34J) of the PCD™ Device.

In two patients, VT, polymorphic VT or ventricular flutter was repeatedly induced and terminated however VF could not be induced. The physicians elected to terminate the procedure due to the patients poor hemodynamic status rather than attempt further inductions to obtain ventricular fibrillation.

One final patient (Patient ID (b)(6) VF could only be successfully terminated by 34 Joules despite evaluation of multiple configurations. The physician elected to implant the system and reevaluate the PCD™ Transvene™ System at the prior to hospital discharge electrophysiology study. At this evaluation, VF was still only successfully reverted by 34 Joules. The PCD™ Transvene™ System was explanted and the patient received a PCD™ Epicardial System with the lowest energy of defibrillation being 24 Joules.

The clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 100% and the overall one year actuarial survival was also 100%.

Equipment

Finally, in one patient (Patient ID (b)(6) the implant procedure was terminated prior to meeting implant criteria due to inappropriate lead system impedance values measured on the Model 5335 ETCD. The patient has had induced episodes of ventricular fibrillation successfully reverted by VF Therapy #1 (34J). Analysis of the Model 5355 ETCD indicated appropriate performance of the device.

In conclusion, 60 patients received the PCD™ Transvene™ System despite not meeting the recommended implant criteria. The major reasons for not meeting implant criteria included 3/4 successes at 24 Joules or less (35%), two successes at 18 Joules (31.7%), failure to induce at least three episodes of VF at implant (20%), and deteoriating patient condition (11.7%). However, 80% of the patients (48/60) had at least one successful reversion of an induced episode of VF with 24 Joules or less.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate defibrillation safety margin when programming VF Therapy #1.

No patient received the PCD™ Transvene™ System without a safety margin of at least 10 Joules provided between the successful defibrillation energy (24 J or less) and the maximum output of the PCD Device (34 J).

The clinical outcome of the patients was not adversely affected by not meeting the recommended implant criteria as is seen by an overall spontaneous VF episode efficacy of 97.4%, one year sudden cardiac death survival rate of 100% and a one year overall survival rate of 96.9%. Thus, despite not meeting the recommended implant criteria, the PCD™ Transvene™ System performed safely and effectively in this patient population.

Patients Not Meeting Implant Criteria - Conclusion

The PCD™ Transvene™ System offers a simpler and safer implantation technique for implantable cardioverter defibrillator systems. However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds than those obtained with traditional epicardial lead systems. Despite this, physicians elected to utilize the PCD™ Transvene™ System in patients who did not meet the recommended implant defibrillation criteria because of their cardiovascular condition and increased risk for morbidity and mortality associated with a thoracotomy. **It should be noted that the PCD™ Transvene™ System was not implanted in any patient without at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD Device (34J).**

A total of 368 patients were evaluated for the implantation of the PCD™ Transvene™ System. Of these, 86% (317/368) ultimately received the PCD™ Transvene™ System. A total of 257 patients, or 70%, met the recommended defibrillation criteria which compares favorably with the predicted success rates published in the literature (Wilber, et al).

There were 60 patients (18.9%) who received the PCD™ Transvene™ System and did not meet the recommended implant criteria. The reasons for not meeting implant criteria were 3/4 successes at 24 Joules or less (35%), 2 successes at 18 Joules (31.7%), failure to induce at least 3 episodes of VF at implant (20%), and deteoriating patient condition (11.7%). However, 80% of the patients (48/60) had at least one episode of VF successfully reverted with 24 Joules.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate defibrillation safety margin when programming VF Therapy #1.

The incidence of not meeting implant criteria in the PCD™ Transvene™ System (18.9%) is similar to that reported with the PCD™ Epicardial System (11.0%). More importantly, there is no difference in spontaneous VT/VF episode efficacy, one sudden cardiac death survival and overall one year survival in the two groups. Thus, despite not meeting the PCD™ Transvene™ System implant criteria, these patients were not a increased for sudden cardiac death. Though these results are important, Medtronic is **not recommending** a modification of the PCD™ Transvene™ System implant criteria.

There were 51 patients (13.9%) who did not meet the recommended implant criteria and received a PCD™ Epicardial System. Analysis indicated a increased perioperative mortality in patients undergoing both a PCD™ Transvene™ and Epicardial System evaluation. This was related to both a depressed left ventricular function and increased VF inductions and VF duration experienced during the implant procedure. Based on this clinical experience, Medtronic is modifying the labeling to 1) recommend that the physician limit the number of inductions and duration of VF during PCD™ Transvene™ System implants and 2) recommend that the physician consider the number of VF inductions performed and duration of VF episodes prior to preceding to an PCD Epicardial System implant.

The current recommended implant defibrillation criteria for the PCD™ Transvene™ System is 3/4 successes at 18 Joules or less. The clinical experience presented both in this section and the entire reports indicates that this criteria is safe and effective in predicting effective termination of a spontaneous VF episode. Medtronic does not intend to modify the implant criteria at this time.

There are patients, due to their underlying cardiovascular condition, who are not candidates for an epicardial system and who may not meet the recommended PCD™ Transvene™ System implant criteria. Clinical experience indicates that if a safety margin of 10 Joules is provided between the successful defibrillation energy and the maximum output of the PCD™ Device (34J) these patients are not at increased risk for sudden cardiac death.

K. Comparison to AICD Epicardial System Clinical Experience

The Automatic Implantable Cardioverter/Defibrillator produced by Cardiac Pacemakers, Inc. is the only device to have obtained approval from the U.S. FDA for Market release. This system represents the only market released device available to compare with the PCD™ Transvene™ System. There are important differences in the capabilities and operation of these two systems, particularly in the area of antibradycardia and anticardia pacing. In addition, the current market-approved AICD System is implanted only with defibrillation lead systems requiring a thoracotomy. Nevertheless, a comparison of those aspects that are similar is provided in Table K-1. Note that the percentage reported for the PCD™ Transvene™ System includes both complications and observations.

PCD™ Transvene™ System Comparison of Reported Complications/Observations PCD™ versus AICD		
Category	**PCD™%**	**AICD%**
Fail to Cardiovert/Defibrillate	1.9%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	8.2%	20%
Pocket Infection	3.5%	2.2%
Erosion	0.3%	0.7%

Table K-1: PCD™ Transvene™ System versus AICD System: Comparison of Complication/Observation Rates - 11/27/91

The AICD complications are based on a recent published article (Winkle, et al. Long-Term Outcome With the Automatic Implantable Cardioverter-Defibrillator; JACC. May, 1989; 13(6); 135-161).

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD™ Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD™ Transvene™ System patient population were associated with increased defibrillation requirements, none of which resulted on patient death and all of which occurred during electrophysiologic testing. In three cases, the implanted lead system was modified to provide adequate defibrillation efficacy, in two cases, the patient's drug therapy was modified and, in the final case, reprogramming provided for defibrillation efficacy.

The instances of failure to cardiovert of defibrillate in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture, and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD™ Transvene™ System patient population. This is to be anticipated since this device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate therapy included sinus tachycardia being detected as VT/VF and atrial fibrillation with rapid ventricular response being detected as VT/VF.

The circumstances reported in the Winkle, et al article were non-sustained VT, recurrent stable VT, sinus tachycardia, atrial fibrillation with rapid ventricular response and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

The incidence of pocket infection is higher in the PCD™ Transvene™ System patient population. This is not unexpected since the PCD™ Transvene™ System implant procedure may require the evaluation of multiple lead orientations to obtain adequate defibrillation efficacy and may result i an increased procedure time. In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD™ Transvene™ System experience, the incidence of device explant secondary to pocket infection was 2.5%, which would then make the incidence of pocket infection comparable in the two patient groups.

Thus, the incidence of complications and observations was similar to that of the AICD in the categories of ineffective VT/VF therapy, infection, and erosion. Clinically significant, however, is that the incidence of inappropriate therapy delivery in the PCD™ Transvene™ System is lower than that of the AICD System.

This analysis indicates that the PCD™ Transvene™ System offers potential clinical advantages since the need for a thoracotomy is eliminated. The associated mortality and morbidity is reduced.

Table K-2 contains a comparison of the actuarial survival rate of the PCD™ Transvene™ System versus Ventak-P Epicardial System [The patient population used for comparison is the one described in the Summary of Safety and Effectiveness Data, PMA P890061, dated May 2, 1991 available through the Freedom of Information Act]. For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD™ Transvene™ and Ventak-P group exclude perioperative patient deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P System had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, one patient death was **censored** in the PCD™ Transvene™ System patient population because the device was deactivated at the time of the patients death.

PCD™ Transvene™ System Comparison of Actuarial Survival Rate PCD™ versus Ventak-P		
One Year Survival	**PCD™**	**Ventak-P**
Number of Patients	317	292
Sudden Death	100%	98.6%
Overall	97.3%	90.8%

Table K-2: Comparison of the Actuarial Survival PCD™ Transvene™ System versus Ventak-P Epicardial System - 11/27/91

This comparison indicates that the projected survival from sudden cardiac death of patients receiving a PCD™ Transvene™ System is improved to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, this comparison indicates that the projected survival from all causes of death (**Overall**) in patients receiving a PCD™ Transvene™ System is markedly improved as compared to the Overall one year survival reported for the Ventak-P Epicardial System. This improvement is directly related to the decrease in the perioperative mortality in patients receiving a PCD™ Transvene™ System due to the elimination of the requirement for a thoracotomy.

L. Comparison to PCD™ Epicardial System Clinical Experience

The PCD™ Epicardial System, which is a tiered therapy device, combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

However, the PCD™ Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to increased surgical risk an potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD™ Transvene™ System, would decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD™ Epicardial System and PCD™ Transvene™ System are identical except for the implanted defibrillation lead system. Thus the performance of the PCD™ device is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the lead system implanted may impact clinical outcome.

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has improved the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

In comparing the clinical experience with the PCD™ Transvene™ System to the PCD™ Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The patient characteristics of the patients receiving the PCD™ Transvene™ System were compared to the patients discussed in the PCD™ Epicardial System PreMarket Approval Application (P900061) dated December 16, 1991.

PCD™ Transvene™ System Comparison of Patient Characteristics		
	PCD™ Transvene™ System	**PCD™ Epicardial System**
Number of Patients	317	434
Mean Follow-Up Time	4.5 months	11.0 months
% Males **% Females**	260 82.0% 57 18.0%	374 86.2% 60 13.8%
Mean Age	58.5 years	58.3 years
Primary Indication*: **SCD** **VT** **SCD/VT**	 120 37.9% 145 45.7% 52 16.4%	 118 27.2% 233 53.7% 83 19.1%
Cardiovascular History **Coronary Artery Disease** **Cardiomyopathy**	 229 72.2% 45 14.2%	 325 74.7% 66 15.2%
Mean Ejection Fraction	36.7%	34.6%
Number of Drugs Failed	2.9	3.2
Spontaneous VT Efficacy	99.2%	97.7%
Spontaneous VF Efficacy	99.2%	98.1%
Incidence of Complications	14.2%	13.6%
Incidence of Observations*	17.7%	26.3%
Number of Deaths	5	64
Perioperative Mortality*	0.3%	5.5%
One Year Survival **Sudden Cardiac** **Overall***	 100% 96.8%	 98.8% 85.6%

* **Statistically Significant**

Table L-1: Comparison of Patient Characteristics, PCD™ Transvene System versus PCD Epicardial System - 11/27/91

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 36.7% for the PCD™ Transvene™ System patient group and 34.6% for the PCD™ Epicardial patient group.

Analysis indicated that the PCD™ Transvene™ System patient population had a statistically significant higher percentage of patients whose indication for implant was sudden cardiac death ($p=0.008$). It

is not expected that this difference will result in a different clinical outcome in the PCD™ Transvene™ System patient population as compared to the PCD™ Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD™ Transvene™ System.

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to perioperative complications, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival.

There was a significant increase in overall survival in the patients receiving a PCD™ Transvene™ System. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD™ Transvene™ System was 96.4%. This is significantly improved as compared to the overall one year actuarial survival for the PCD™ Epicardial System (85.6%) [p=0.001]. This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD™ Transvene™ System having a 0.3% perioperative mortality versus the a perioperative mortality of 5.5% in the PCD™ Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for surgical thoracotomy and its associated morbidity and mortality.

A comparison of PCD™ Transvene™ System clinical experience and PCD™ Epicardial System clinical experience indicates that the devices are being used in patients with similar cardiovascular disease history.

The reported incidence of complications is comparable between the two systems. The reported incidence of observations was statistically lower in the PCD™ Transvene™ System.

Finally, the reported Sudden Cardiac Death survival rates in the two patient groups is very similar (PCD™ Transvene™ = 100%; PCD™ Epicardial = 98.8%). However, there is statistical improvement in the overall survival in the PCD™ Transvene™ System patient population. This is directly related to the decreased perioperative morbidity and mortality associated with the PCD™ Transvene™ System.

The PCD™ Transvene™ System eliminates the need for a thoracotomy for the implantation of defibrillation lead systems. This directly impacts the overall patient survival by decreasing the perioperative patient morbidity and mortality when compared to the PCD™ Epicardial System. This is added benefit however is not gained at the expense the PCD™ Transvene™ System efficacy in treating spontaneous VT/VF episodes when compared to the PCD™ Epicardial System.

M. PCD™ System Performance

M.1 PCD™ Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection and therapy performance and analysis of explanted devices were evaluated to assess the performance of the PCD™ Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD™ Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD™ Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD™ Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 19 devices explanted. Reasons for explant were patient death (5), infection (8), cardiac transplant (4), low battery voltage (1) and high voltage arcing (1). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other device indicated that arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the

low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

This clinical data indicates the PCD™ Device has performed safely and reliably in the indicated patient population.

M.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 319 Right Ventricular leads (15 with the SP2100 and 304 with the Model 6884/6966), 336 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 292 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 1426.5 months. The reported incidence of right ventricular conductor coil fracture is 0.6% (2/319).

Based on the clinical data collected, the Transvene™ leads have performed safely and reliably.

N. Summary

The overall clinical experience with the PCD™ Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following conclusions can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 100.0%, 97.9%, 97.9%, and 99.3%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 100.0% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD™ Device malfunction.

Complications/Observations

- Complications were reported in 14.2% of the patient population and observations were reported in 17.7% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.9% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 45.7 % of the patients and SCD/VT was the primary indication in 16.4% of the patients.

- The number of patients (32.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD™ Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 100.% and the SCD/VT patient group 100.0%.

VT/VF Detection and Therapy Performance

- The PCD™ Transvene™ System properly detects and treats VT as is demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 99.2%.

- The PCD™ Transvene™ System properly detects and treats VF as is demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 99.2%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD™ Transvene™ System.

PCD™ Transvene™ System Performance

- The PCD™ Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

O. Clinical Experience Summary Conclusions

The PCD™ Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The incorporation of a nonthoracotomy lead system has allowed for a safer and as effective implantation procedure. The elimination of the need for a thoracotomy has improved both perioperative and long term patient morbidity and mortality.

Medtronic asserts and the PCD™ Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population. In addition, the continued excellent performance of the PCD Transvene System warrants the expansion of the clinical study to additional investigative centers as well as the submission of this PreMarket Approval Application.

G. Summary of Safety and Effectiveness Conclusion

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT, however this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing. The need to incorporate programmability and multiple detection and therapeutic options has lead to the development of a tiered therapy device, the Medtronic PCD System.

However, the current market released system requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to increased surgical risk an potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD™ Transvene™ System, would decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

For the indicated patient population, the primary benefits from the PCD Transvene System center on the detection and termination of life threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD Device pulse generator. In addition, the PCD Transvene System offers the potential for decreased patient morbidity and mortality due to the elimination of the need for a thoracotomy.

Extensive laboratory and animal testing and human clinical trials of the PCD System were performed to demonstrate the safety and efficacy of the PCD Transvene System and its components in the indicated patient population.

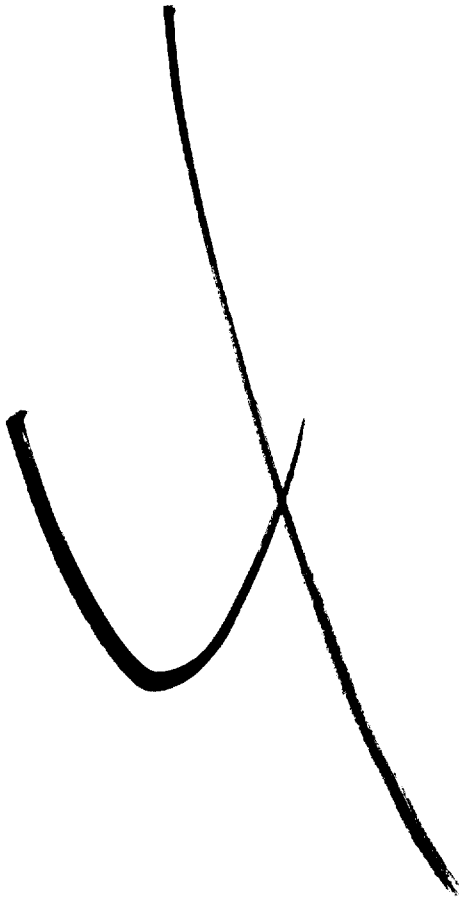
Nonclinical laboratory studies included testing at the component, hybrid and system level. All requirements were satisfied and the components and device-level testing performed according to specification. Results of animal testing demonstrated safe and reliable performance of the PCD Transvene System.

The indications for use of the PCD System include:

- Patients who have survived at least one episode of cardiac arrest due to ventricular arrhythmia not caused by an acute myocardial infarction; or
- Patients with recurrent sustained, ventricular tachycardia that remains inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most effacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

The safety and efficacy of the PCD Transvene System in patients with VT and VF was evaluated in 317 patients with a mean implant duration of 4.5 months. The overall success rate in terminating spontaneous VT/VF episodes was 99.2%. The one year sudden cardiac death survival rate was 100% which was comparable to the reported sudden cardiac death rate of the PCD Epicardial System (98.8%) and Ventak-P Epicardial System (98.6%) patient populations. More importantly, the PCD Transvene System provided a significant improvement in overall one year survival (96.8%) when compared to the PCD Epicardial System (85.6%) and the Ventak-P Epicardial System (90.8%) patient populations. This improvement in overall survival was primarily due to the decreased perioperative mortality associated with the PCD Transvene System.

These data, in total, demonstrate the safe and effective performance of the PCD Transvene System in the indicated patient population. Therefore, the PCD Transvene System as reported in this PMA application is safe and effective for its intended use.



IV. Device Description and Manufacturing Section

A Device Description of all components of the Transvene/PCD System is provided in this section. This includes:

1. Description of the Model 6963, 6966 and 6999 Leads.

2. Description of the Model 7217B PCD Device.

3. Description of the Model 5355 ETCD Device.

First, however, a description of the Transvene Lead/Tachyarrhythmia Control System is presented.

Summary of System

A non-thoracotomy lead system is defined as one in which no electrode is placed in or on the pericardial sac. This system is designed to provide a minimally invasive alternative to an epicardial patch lead system for those patients who are candidates for an implantable tachyarrhythmia control device.

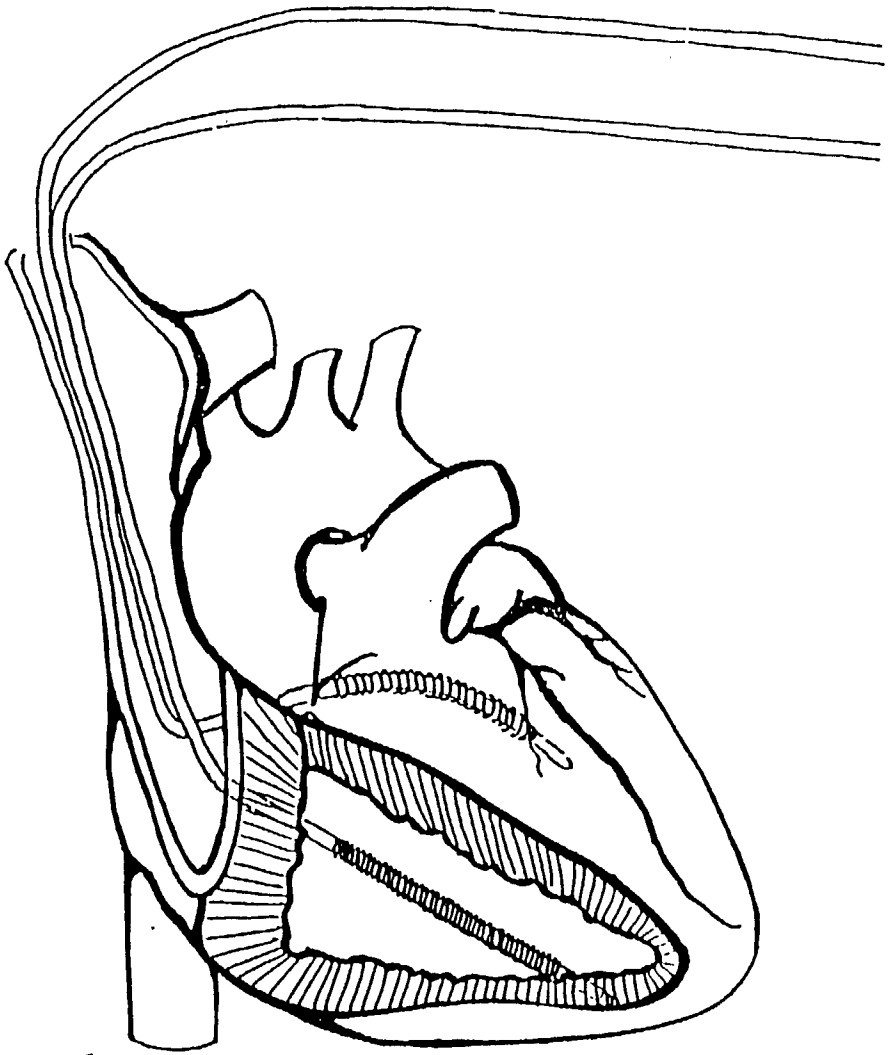
The non-thoracotomy lead system for the Model 7217B PCD device, called the Transvene lead system, consists of the following:

- Model 6963 Coronary Sinus/Superior Vena Cava Defibrillation Lead
- Model 6966 Right Ventricular Pacing, Sensing, and Defibrillation Lead
- Model 6999 Subcutaneous Patch Lead

Descriptions of these leads are contained in Section IV of this submission.

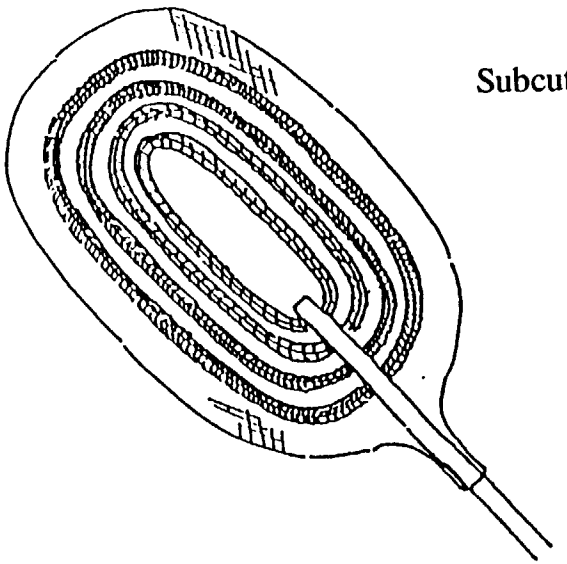
The figure on the following page is an illustration of the PCD Transvene lead system.

Non-Thoracotomy Lead System for PCD



Model 6963 Coronary Sinus or Superior Vena Cava

Model 6966 Right Ventricle



Subcutaneous Patch

Model 6999

MEDTRONIC CONFIDENTIAL

IV. Device Description

This section contains a general description of the Transvene lead system, which, in addition to the leads, includes the PCD and ETCD devices. This is then followed by more detailed device descriptions of the non-thoracotomy leads.

A. Description of the Transvene Lead/PCD System

The Medtronic Tachyarrhythmia Control System consists of two fundamental configurations: (1) the implantable configuration and (2) the external configuration. Both configurations use the Transvene lead system. See Figure IV-A-1.

The implantable configuration is composed of a Pacer-Cardioverter-Defibrillator (PCD) device, implantable leads, and a programmer. The PCD device is an implantable, multiprogrammable, automatic tachyarrhythmia control device.

The external configuration is composed of an External Tachyarrhythmia Control Device (ETCD), a patient cable, implantable leads, and a programmer. The ETCD is an externally-operated, multiprogrammable, tachyarrhythmia control device.

Intended Uses - Transvene Leads

Model 6963 Lead

The Medtronic Transvene Model 6963 Unipolar, Coronary Sinus or Superior Vena Cava, Tranvenous Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use in the coronary sinus or superior vena cava and is designed to be used with an implantable tachyarrhythmia control device along with at least one other lead, such as the Model 6966 Tripolar, Right Ventricular, Transvenous Lead.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6966 Lead

The Medtronic Transvene Model 6966 Tripolar, Endocardial, Screw-In Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. The lead has application where implantable tachyarrhythmia control systems are indicated.

The Model 6966 lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool.

Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be potential a problem.

The three electrodes of this lead are the coil, ring, and helix:

> The defibrillating **coil electrode** is most proximal to the pulse generator and connects electrically to the connector pin of the unipolar leg of the bifurcation. This unipolar leg will not accept a stylet.
>
> The **ring electrode** is proximal to the helix and connects electrically to the connector ring of the bipolar leg of the bifurcation.
>
> The **helix tip electrode** is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector pin with a special fixation tool. The helix electrode connects electrically to the connector pin of the bipolar leg of the bifurcation. This bipolar leg is the only one that will accept a stylet.

The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; the coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6999 Lead

The Medtronic Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use and is designed to be used with an implantable tachyarrhytmia control device along with at least one complementary defibrillating electrode and a pacing/sensing lead; a third defibrillating electrode may also be used.

The lead has application for patients in whom implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Intended Uses - PCD Device

The Model 7217B PCD device is intended for use in patients who are at high risk of sudden death due to ventricular tachyarrhythmia.

Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or

- in the absence of a prior cardiac arrest, have recurrent, sustained ventricular tachycardias that occur spontaneously or can be induced, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically.

Extensive electrophysiologic evaluation and testing of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Model 7217B PCD device. Before permanently programming the PCD device to the automatic detection and delivery of the VT and/or VF therapies, the patient should have demonstrated a satisfactory response to the proposed therapy.

Intended Uses - ETCD

The Model 5355 External Tachyarrhythmia Control Device is intended for use in conjunction with an antitachycardia/defibrillation lead system during diagnostic studies for implanting the Model 7217B PCD device.

Indications for use of the ETCD include

- Patients experiencing recurrent episodes of ventricular tachyarrhythmia,
- Patients who survived a cardiac arrest due to a ventricular tachyarrhythmia and are at risk for repeated episodes,
- Patients who are undergoing electrophysiologic studies and serial antitachycardia drug testing,
- Patients who have ventricular tachycardia and are being evaluated to assess the efficacy of pacing-level therapies on their arrhythmia, and
- Patients who are undergoing an assessment of the efficacy of antitachycardia pacing, cardioversion, or defibrillation therapies in anticipation of an implantable cardioverter-defibrillator.

Components of the System

A list of components used in the system is given below. It is separated into a listing of those components for which market approval is sought and those components that are now commercially available.

Components Used in the Implantable Configuration

The implantable configuration is composed of a PCD Device, lead system, and a 9710 Programmer with applicable software cartridge. The implantable device is a Model 7217B PCD Device. The PCD device requires an appropriate lead system consisting of up to three cardioversion/defibrillation electrodes. See Figure IV-A-2. The Transvene leads used with the Model 7217B PCD Device are the Models 6963, 6966, and 6999.

The Model 9710 Programmer is commercially available. Two printers are also commercially available. When higher printing speeds are desired, it is recommended that the programmer be used with the faster printer, the Model 9751. If slower printing speeds are acceptable, as may be the case in some follow-up situations, the Model 9710 Programmer can be used with the battery-powered Model 9712 Printer.

Components used in the External Configuration

The external tachyarrhythmia control system is composed of the Model 5355 ETCD, a Model 5418 Patient Cable, a Model 5419 cable, lead system, and a Model 9710 Programmer with applicable software cartridge, see Figures IV-A-3, 4. The ETCD uses replaceable batteries as its power source. The Model 5418 Patient Cable and Model 5419 Cable are designed to connect the Transvene leads to the ETCD. Like the impantable system, the ETCD uses the same Transvene leads (Models 6963, 6966, and 6999).

Purpose of the System

PCD System Configuration

The PCD Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or a progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation. The PCD Device also has bradycardia pacing capability. The Transvene leads allow the PCD device to deliver these therapies to the heart.

ETCD System Configuration

The ETCD is an external tachyarrhythmia control device designed to deliver overdrive pacing, cardioversion, defibrillation, and bradycardia therapies in the same fashion as the PCD device. The ETCD can be programmed to automatically deliver overdrive pacing therapy upon detection of VT. When used as a component of a system that includes the appropriate Medtronic programmer and applicable software cartridge, the ETCD can deliver manually-initiated VT pacing, cardioversion, and defibrillation therapies. The ETCD allows the assessment of the Transvene lead system characteristics and aids in the assessment of lead system pacing and sensing characteristics.

Overview of System Features

General

The PCD device is designed to automatically detect episodes of VT or VF and, upon detection, deliver the appropriate programmed pacing, cardioversion, or defibrillation therapies. The device has two independently programmable detection and therapy procedures, one for VT and a second for VF.

When used as a component of a system that includes the appropriate Medtronic programmer and dedicated software, the ETCD is designed to deliver manually initiated cardioversion and defibrillation therapies. The ETCD is also designed to detect episodes of VT and VF. It can automatically deliver VT overdrive therapies (burst and ramp) upon detection of a VT.

VT Detection and Therapy

Both the PCD device and ETCD use a VT detection algorithm which can use up to three separately programmable criteria as it monitors the cardiac cycle length to identify the presence of a tachycardia. Upon detection, the devices deliver their first programmed VT therapy. If the VT episode persists and is again detected, up to three additional independently programmable VT therapies may be delivered to restore the patient's normal cardiac rhythm. This progression of four VT therapies can be tailored to each patient's need. For the PCD device the therapies may be selected from two methods of overdrive pacing (burst and ramp) and synchronized cardioversion.

For the ETCD the same overdrive pacing therapies can be automatically delivered, with cardioversion therapy being available as a manual therapy.

VF Detection and Therapy

The VF Detection algorithm monitors the cardiac cycle length to identify a VF episode. Upon detection, the PCD device provides a programmable high energy defibrillation pulse for VF therapy. Up to a maximum of four VF therapies may be delivered for ongoing detected VF episodes. Each defibrillation therapy consists of one (single pulse) or two (simultaneous or sequential) high voltage pulses designed to restore the normal cardiac rhythm.

For the ETCD, each cardioversion or defibrillation therapy, which must be initiated manually via the programmer, also consists of one high-voltage pulse or two (simultaneous or sequential) high-voltage pulses in the same fashion as the PCD devices.

Bradycardia Therapy

For both the ETCD and PCD devices, bradycardia pacing is delivered in the VVI mode. Asynchronous, (VOO), pacing is not available, and is avoided even with magnet application since this type of pacing has increased potential to initiate ventricular arrhythmias in patients receiving this system.

Lead Systems

The PCD Device and the ETCD perform pacing, sensing, cardioversion, and defibrillation through multiple electrodes in the lead system. Listed below are the electrodes and their function:

- The PACE/SENSE electrodes are incorporated in the right ventricular defibrillation lead. These electrodes function as the sensing circuit and deliver pacing pulses. The PACE/SENSE electrodes are used for sensing in conjunction with the SENSE2 electrode.

- The COMMON electrode is an electrode coil that serves as the cathode for cardioversion, defibrillation, and pacing.

- The PULSE2 electrode is an electrode coil that serves as the anode for cardioversion and defibrillation.

- The PULSE1 electrode is an optional electrode coil that serves as an additional anode for sequential and simultaneous cardioversion and defibrillation.

Cardioversion and defibrillation current pathways are between the PULSE2 and COMMON electrode coils and, if the additional lead is implanted, between the PULSE1 and COMMON electrode coils.

Other Capabilities

The physician may use the ETCD or the PCD devices to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the appropriate software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia.

The PCD device will provide the physician with information, via the Programmer, about its present programmed status and data on its operation accumulated between office visits. This information may be printed and retained in the patient's file.

The PCD Device and ETCD can also transmit an electrogram to the programmer. The electrogram is the electrical signal sensed on the leads.

A programmer-generated set of symbols, termed Marker Channel™, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

In addition, the ETCD provides a display of measurements and other information related to delivered cardioversion and defibrillation pulses. With this information and other features, the ETCD can be used to assess the suitability of the lead system and its placement for individual patients.

PCD Battery Longevity Expectations

The longevity of the Model 7217B PCD Device depends upon several factors, including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the pacing load, and on the frequency of high voltage capacitor charging. The longevity projections found in Table IV-A-1 apply under the following conditions:

- 65 ppm pacing rate,
- 5.4 V pacing pulse amplitude,
- 0.49 ms pacing pulse width, and
- 500 ohm pacing lead.

Projected Longevity[1]
Table IV-A-1

Pacing/Sensing	34 Joule Charging Frequency	Average Longevity Model 7217B
100% Sensing	Quarterly	5.0 years
15% Pacing	Monthly	4.2 years
100% Pacing	Monthly	3.4 years

The longevity of the device decreases with the following:

- An increase in pacing rate,
- An increase in pacing amplitude,
- A decrease in pacing impedance,
- An increase in pacing pulse width,
- An increase in the percentage of bradycardia paced to sensed events, or
- An increase in the charging frequency.

Each 34 Joule charging cycle will typically decrease the longevity of the device by approximately four to six days.

---

1 These preliminary longevity projections are based upon accelerated battery data and device modeling. With the stated condition, 100% pacing and monthly 34 Joule charging cycles, the minimum longevity of the device will be 2.5 years (7217B). Average refers to the projected mean longevity of the modeled run of PCD devices at the stated conditions. Minimum longevity means that virtually all (i.e., 99.9%) of all modeled production run of PCD devices will attain the value given.

DESCR.

1. Description: Model 6963 Coronary Sinus/Superior Vena Cava, Model 6966 Right Ventricular and Model 6999 Subcutaneous Patch Leads

Illustrations of these leads are provided on the pages following this discussion.

The Medtronic Tachyarrhythmia Control System uses a tripolar, screw-in, right ventricular lead for (RV) pacing, sensing, cardioversion and defibrillation; a unipolar, coronary sinus/superior vena cava lead (CS/SVC); and a unipolar, subcutaneous oval patch electrode (SQ). The available models of the system are as follows:

- Model 6963 CS/SVC Lead
- Model 6966 RV Lead
- Model 6999 SQ Lead

The Model 6963, 6966 and 6999 leads are intended to be used with the Model 7217B PCD Device. The leads have a 6.5 mm connector intended for direct insertion into a 6.5 mm port of the 7217B PCD Device.

The Model 6963 lead is intended for use in the coronary sinus or superior vena cava. The lead features a platinum alloy electrode coil which provides the necessary surface area for cardioversion and defibrillation. Silicone insulation surrounds a low-resistance metal-alloy conductor coil.

The Model 6966 lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the right ventricle. The lead features three metal-alloy conductors in (b)(4) surrounded by polyurethane insulation. The lead has a platinum alloy electrode coil which provides the necessary surface area for cardioversion and defibrillation. This electrode is most proximal (closest) to the pulse generator and connects to the unipolar (6.5 mm) leg of the bifurcated connector. This leg does not accept a stylet. The lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a small tool. The helix tip electrode is most distal to the pulse generator and connects to the pin of the bipolar (3.2 mm) leg of the bifurcated connector. The ring electrode is made of a platinum alloy. It is proximal to the helix and connects to the ring of the bipolar (3.2 mm) leg of the bifurcated connector. Bipolar sensing occurs between the helix tip and the ring electrodes. Bipolar pacing occurs between the helix tip and the defibrillation coil electrode.

The Model 6999 lead is intended for use subcutaneously, submuscularly, or directly on the periosteum of the ribs. The lead features platinum alloy electrode coils and a low-resistance metal-alloy conductor surrounded by silicone insulation. Four helical coils are partially embedded into the silicone patch and provide the necessary surface area for cardioversion and defibrillation. A (b)(4) is molded into the patch and provides support for sutures. There are three nodes in the center and two nodes at the junction of the lead body and patch electrode of one side of the patch electrode. These nodes are intended to designate the insulated side of the patch electrode.

The following section describes the functional components, device properties, and principles of operation for the Model 6963, 6966 and 6999 leads.

Illustrations of the Model 6963, 6966 and 6999 leads are provided on the following pages.

PATCH LEAD

a. Functional Components

1) Platinum Alloy Electrode Coil

The Model 6963 coronary sinus/superior vena cava lead and the Model 6966 right ventricular lead each feature a platinum alloy coil electrode that delivers cardioversion and defibrillation pulses to the heart. The Model 6963 lead uses silicone adhesive and the Model 6966 lead employs polyurethane tubing to help prevent tissue in-growth and aid in chronic lead removal.

The conductive surface of the Model 6999 subcutaneous patch electrode consists of four platinum helical coils partially embedded in molded silicone rubber. These coils serve as the electrodes that deliver cardioversion and defibrillation pulses to the heart. Inside the helical coils is silicone rubber to help prevent tissue in-growth and aid in chronic lead removal.

2) Low Resistance Metal Alloy Conductor Coil

This conductor coil consists of (b)(4) alloy that provides a low resistance pathway for delivery of cardioversion and defibrillation pulses from the tachyarrhythmia control device to the platinum alloy electrode coils. The (b)(4) was selected for use due to its proven long term reliability when used in implanted bradycardia lead systems. The use of (b)(4) coil provides the low resistance needed for the delivery of high voltage pulses. The coil used on the Model 6966 is (b)(4) The coils used on the Model 6963 and 6999 are not sputter coated.

3) Metal Alloy Conductor Coil (applicable only to the Model 6966 Lead)

The Model 6966 inner and middle conductor coils consist of several fine wires. The wires are (b)(4) in diameter for the inner coil and (b)(4) in diameter for the middle coil. The wires are made of (b)(4) alloy and (b)(4)

4) Helical Electrode (Model 6966 only)

The Model 6966 (b)(4) distal, helical electrode is extended into and retracted from the myocardium through a self-sealing electrode head by turning the connector terminal pin with a

140

pinch-on torquing tool. The stimulating surface area of the helical electrode is (b)(4) (nominal).

5) Ring Electrode (Model 6966 only)

The (b)(4) ring electrode for bipolar pacing and sensing is positioned just proximal to the distal, helical tip of the lead. The (nominal) surface area of the ring electrode is (b)(4)

6) Insulation

- Model 6963 and 6999 Leads

  These leads are comprised of (b)(4) insulation. This material has a long history (since 1962) of use on Medtronic pacing leads. Insulation wall thickness for both the 6963 and 6999 is (b)(4)

- Model 6966 Lead

  This lead is comprised of (b)(4) (b)(4)
  Insulation wall thicknesses are:

  inner (b)(4)
  middle (b)(4)
  outer

7) Anchoring Sleeve

There is an anchoring sleeve positioned on the lead body of the Model 6963 and 6966 leads. It is intended to be used for fixation of the lead body to soft tissues near the site of insertion of the lead into the vein at the time of the implant. It is designed to protect the lead from undue strains and stresses at the point of fixation.

8) (b)(4) Embedded into Silicone Rubber

(b)(4) is embedded into each subcutaneous patch and provides support when suturing the lead to the subcutaneous muscle.

9) Stylets

Stylets are (b)(4) which stiffen the lead and/or temporarily alter its shape during implant. This is accomplished through a controlled stiffness of the distal tip, allowing it to bend with the application of excessive force. Stylets are also designed to help minimize damage to the coil during insertion and removal. The Models 6963 and 6966 use stylets, the Model 6999 does not.

10) Connector Assembly

The Model 6963 and 6999 leads feature a (b)(4) terminal assembly consisting of a (b)(4) connector pin and (b)(4) rubber sleeve. The distal part of the sleeve provides a strain relief area.

The Model 6966 lead features a (b)(4) terminal assembly identical to that used on the 6963 and 6999 as described above. In addition, the lead connector is bifurcated and has an additional (b)(4) in-line, bipolar terminal assembly consisting of a (b)(4) connector pin, a cylindrical (b)(4) (ring) terminal just distal to the pin, and a (b)(4) rubber sleeve. This distal part of the sleeve provides a strain relief area.

b. Device Properties

The Model 6963, 6966 and 6999 non-thoracotomy leads are designed for sensing, pacing, cardioversion and defibrillation. These leads have application where implantable tachyarrhythmia control devices are indicated. Reference the technical manuals for the Model 6963, 6966 and 6999 leads for specific device features.

c. Principles of Operation

The PCD Transvene System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three different leads may be used to deliver cardioversion and defibrillation pulses. These configurations are comprised of a tripolar, right ventricular (RV) lead (Model 6966), and either a coronary sinus (CS) lead (Model 6963) or a subcutaneous (SQ) lead (Model 6999), or all three of these leads. The Model 6963 lead can be placed in either the coronary sinus/great cardiac vein or the superior vena cava (SVC).

In these systems, the helical tip and ring of the RV lead is used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE 2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

A system using two leads delivers cardioversion and defibrillation pulses between two coils (one on each lead). A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE 1 and PULSE 2) to the COMMON defibrillation electrode.

To detect VT/VF, the PCD device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD confirms episode termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

1) At implant by the evaluation of the pacing and sensing thresholds and defibrillation efficacy when treating VT/VF

2) Chronically by evaluation of stability of chronic defibrillation efficacy in induced episodes of VT/VF and successful termination of spontaneous episodes of VT/VF.

Re: Premarket Approval Application (PMA) for the Medtronic® Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, i.e., the PCD™ Transvene System, Lead Models 6963, 6966 and 6999.

This submission is a PMA application for the Medtronic Transvene Lead System used in conjunction with the Model 7217B pacer-cardioverter-defibrillator (PCD), Model 5355 external tachyarrhythmia control device (ETCD) and Model 9788 MemoryMod Software Module.

The PCD and ETCD devices as used with an epicardial lead system were recommended for approval by the FDA Advisory Panel on February 3, 1992 (P900061). The purpose of this PMA application is to obtain approval for the use of the non-thoracotomy lead system for use with the Medtronic PCD and ETCD. The terms non-thoracotomy leads (NTL), transvenous leads and Transvene Lead System are synonymous and may be used interchangeably throughout this application.

The Transvene System, in conjunction with the PCD device, is intended to treat patients at risk of sudden cardiac death due to ventricular arrhythmias. Like the epicardial electrodes/PCD System, the primary benefits from the use of the Transvene/PCD System center on the detection and termination of these life-threatening ventricular arrhythmias. The incorporation of a non-thoracotomy lead system allows for a safer and effective implantation procedure, and improving both perioperative and long-term patient morbidity and mortality.

The Transvene/PCD System clinical study (IDE G870102) includes 319 Transvene lead implants with a mean implant duration of 4.5 months and a total of 1426 device months experience. There are 116 patients with lead system implant duration equal to or greater than six months. The data included in this submission is all data that was received by Medtronic and entered onto the clinical database as of November 27, 1991. The results from the clinical study are provided in Volume 5 of this application.

Market approval is not being sought for use of the Transvene/PCD System with other manufacturers' implantable-cardioverter-defibrillators, nor is it sought for use of the PCD device with other manufacturers' transvenous defibrillation lead systems.

Two manufacturing facilities are to be used in the assembly, sterilization and packaging of the Transvene leads. These are:

1. Medtronic, Inc.
   Rice Creek Facility
   7000 Central Avenue N.E.
   Minneapolis, MN 55432
   Tel: 612-574-4000
   Establishment Registration Number: 2182208
   Is presently prepared for inspection.
   Most recent FDA inspection: January 21-February 8, 1992.

2. Medtronic, B.V.
   Wenckebachstraat 10
   6466 NC Kerkrade West
   The Netherlands
   Tel: 31-45-43-85-85
   Is presently prepared for inspection.
   Most recent FDA inspection: January 6-9, 1992.

The existence of this PMA application and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

4

In accordance with 21 CFR 814.42(a), the FDA has 45 days from the date of receipt to notify Medtronic if this application is sufficiently complete for a substantive review and acceptable for filing.

Six copies of this application are enclosed. Should additional information be required by the Agency, please contact the undersigned.

Sincerely,

III. Device Description: Model 6966 Right Ventricular Lead

Illustrations of this lead are provided on the pages following this discussion.

The Medtronic Tachyarrhythmia Control System uses a tripolar, screw-in, right ventricular lead for (RV) pacing, sensing, cardioversion and defibrillation; a unipolar, coronary sinus/superior vena cava lead (CS/SVC); and a unipolar, subcutaneous oval patch electrode (SQ). The available models of the system are as follows:

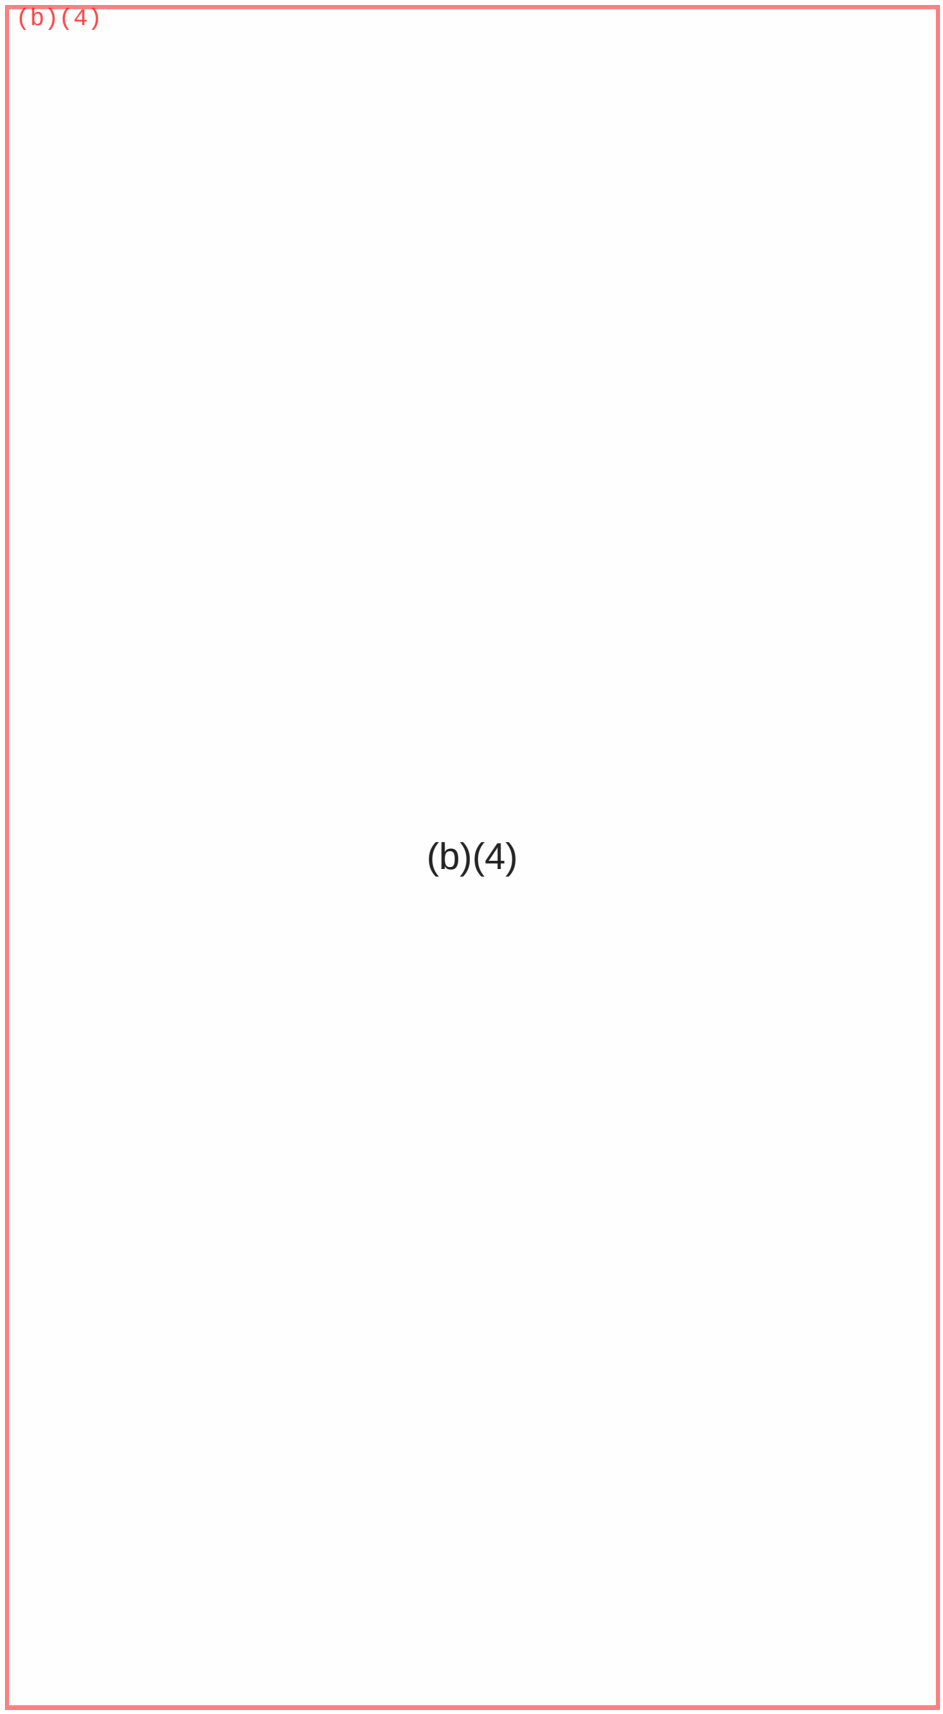
- Model 6963 CS/SVC Lead
- Model 6966 RV Lead
- Model 6999 SQ Lead

The Model 6966 lead is intended to be used with the Model 7217B PCD Device.

The Model 6966 lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the right ventricle. The lead features three metal-alloy conductors in (b)(4) (b)(4) surrounded by polyurethane insulation. The lead has a platinum alloy electrode coil which provides the necessary surface area for cardioversion and defibrillation. This electrode is most proximal (closest) to the pulse generator and connects to the unipolar (6.5 mm) leg of the bifurcated connector. This leg does not accept a stylet. The lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a small tool. The helix tip electrode is most distal to the pulse generator and connects to the pin of the bipolar (3.2 mm) leg of the bifurcated connector. The ring electrode is made of a platinum alloy. It is proximal to the helix and connects to the ring of the bipolar (3.2 mm) leg of the bifurcated connector. Bipolar sensing occurs between the helix tip and the ring electrodes. Bipolar pacing occurs between the helix tip and the defibrillation coil electrode.

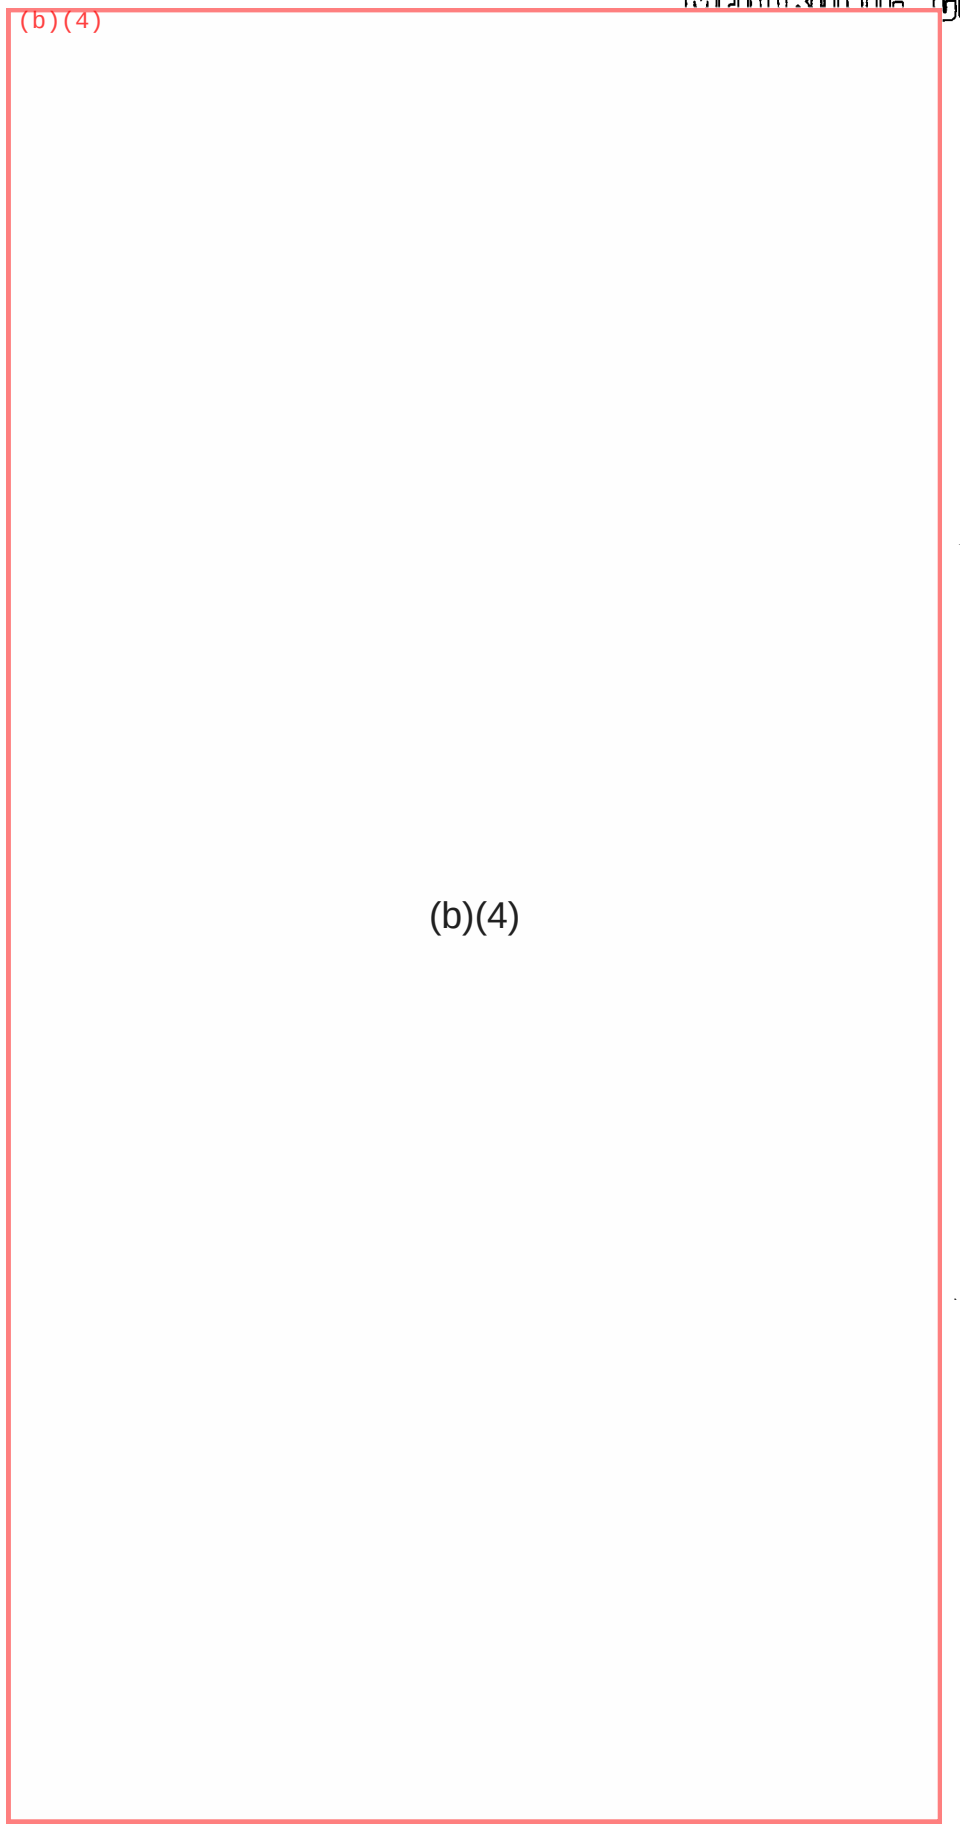
The following section describes the functional components, device properties, and principles of operation for the Model 6966 lead.

(b)(4)



MODEL 6966 RIGHT VENTRICULAR LEAD
DISTAL END

(b)(4)



MODEL 6966 RIGHT VENTRICULAR LEAD
PROXIMAL END

a. Functional Components

1) Platinum Alloy Electrode Coil

The Model 6966 right ventricular lead features a platinum alloy coil electrode that delivers cardioversion and defibrillation pulses to the heart. The Model 6966 lead employs polyurethane tubing to help prevent tissue in-growth and aid in chronic lead removal.

2) Low Resistance Metal Alloy Conductor Coil

This conductor coil consists of (b)(4) alloy that provides a low resistance pathway for delivery of cardioversion and defibrillation pulses from the tachyarrhythmia control device to the platinum alloy electrode coils. The (b)(4) was selected for use due to its proven long term reliability when used in implanted bradycardia lead systems. The use of (b)(4) coil provides the low resistance needed for the delivery of high voltage pulses. The coil used on the Model 6966 is (b)(4)

3) Metal Alloy Conductor Coil

The Model 6966 inner and middle conductor coils consist of several fine wires. The wires are (b)(4) in diameter for the inner coil and (b)(4) in diameter for the middle coil. The wires are made of (b)(4) alloy and (b)(4)

4) Helical Electrode

The Model 6966 (b)(4) distal, helical electrode is extended into and retracted from the myocardium through a self-sealing electrode head by turning the connector terminal pin with a pinch-on torquing tool. The stimulating surface area of the helical electrode is (b)(4) (nominal).

5) Ring Electrode

The (b)(4) ring electrode for bipolar pacing and sensing is positioned just proximal to the distal, helical tip of the lead. The (nominal) surface area of the ring electrode is (b)(4)

6) Insulation

The Model 6966 lead is comprised of (b)(4) and (b)(4). Insulation wall thicknesses are:

inner (b)(4)
middle
outer

7) Anchoring Sleeve

There is an anchoring sleeve positioned on the lead body of the Model 6966 lead. It is intended to be used for fixation of the lead body to soft tissues near the site of insertion of the lead into the vein at the time of the implant. It is designed to protect the lead from undue strains and stresses at the point of fixation.

8) Stylets

Stylets are (b)(4) which stiffen the lead and/or temporarily alter its shape during implant. This is accomplished through a controlled stiffness of the distal tip, allowing it to bend with the application of excessive force. Stylets are also designed to help minimize damage to the coil during insertion and removal.

9) Connector Assembly

The Model 6966 lead features a (b)(4) terminal assembly consisting of a (b)(4) connector pin and (b)(4) rubber sleeve. In addition, the lead connector is bifurcated and has an additional (b)(4), bipolar terminal assembly consisting of a (b)(4) connector pin, a cylindrical, (b)(4) (ring) terminal just distal to the pin, and a (b)(4) rubber sleeve. This distal part of the sleeve provides a strain relief area.

b. Device Properties

The Model 6966 non-thoracotomy lead is designed for sensing, pacing, cardioversion and defibrillation. This lead has application where implantable tachyarrhythmia control devices are indicated. Reference the technical manual for the Model 6966 lead for specific device features.

c. Principles of Operation

The PCD Transvene System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three different leads may be used to deliver cardioversion and defibrillation pulses. These configurations are comprised of a tripolar, right ventricular (RV) lead (Model 6966), and either a coronary sinus (CS) lead (Model 6963) or a subcutaneous (SQ) lead (Model 6999), or all three of these leads. The Model 6963 lead can be placed in either the coronary sinus/great cardiac vein or the superior vena cava (SVC).

In these systems, the helical tip and ring of the RV lead is used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE 2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

A system using two leads delivers cardioversion and defibrillation pulses between two coils (one on each lead). A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE 1 and PULSE 2) to the COMMON defibrillation electrode.

To detect VT/VF, the PCD device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD confirms episode termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

1) At implant by the evaluation of the pacing and sensing thresholds and defibrillation efficacy when treating VT/VF

2) Chronically by evaluation of stability of chronic defibrillation efficacy in induced episodes of VT/VF and successful termination of spontaneous episodes of VT/VF.

Manufacturing Description: Model 6966 RV Lead, Rice Creek

The following Manufacturing Description has been prepared in conformance with the "Guidance for Preparation of PMA Manufacturing Information" made available by FDA August 21, 1991. Copies of the device description and labeling from other parts of the PMA have been included in the first part of this volume, as indicated in the cover letter.

This section contains a complete description of the methods used in, and the facilities and controls used for, the manufacture, processing, packaging, storage and distribution of the Model 6966 RV Lead. Process qualification testing and results are included in Section F.3. As requested, a summary describing how applicable GMP requirements are met has been provided for each area identified. In some cases copies of actual procedures are also provided.

The Model 6966 RV Lead meets the definition of a critical device; implantable leads are currently on the Critical Device List. We have thus addressed specifically additional controls that are in place to meet the critical device requirements.

DESCRIPTION AND INTENDED USE

The Medtronic® Model 6966 Tripolar, Endocardial, Screw-In Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. It is intended for long-term use and is designed to be used only a Medtronic implantable tachyarrhythmia control device, such as the Medtronic Model 7217B PCD Device along with at least one other complementary lead, such as TRANSVENE™ - RV Model 6963 Coronary Sinus or Superior Vena Cava lead, or the TRANSVENE™ - SQ Model 6999 Unipolar, Subcutaneous, Oval Patch Lead.

The TRANSVENE™-SVC lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool. Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be a potential problem.

The three electrodes of this lead are: coil, ring, and helix (Figure 1).

The defibrillating coil electrode is most proximal to the pulse generator and connects electrically to the connector PIN of the UNIPOLAR leg of the bifurcation. This UNIPOLAR leg will not accept a stylet.

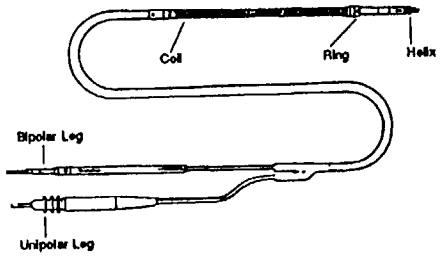

Figure 1. The three electrodes and two connector legs.

The ring electrode is proximal to the helix and connects electrically to the connector RING of the BIPOLAR leg of the bifurcation.

The helix tip electrode is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector PIN with a special fixation tool. The helix electrode connects electrically to the connector PIN of the BIPOLAR leg of the bifurcation. This BIPOLAR leg is the only one that will accept a stylet.

The coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses. The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; however, when used with standard bipolar PCD™ pulse generators, pacing occurs between the helix tip electrode and the coil electrode.

The lead's conductors are in a multifilar configuration and are insulated with polyurethane.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE™-RV lead with anchoring sleeve, stylet, and stylet guide
- 2 fixation tools
- 1 vein lifter
- Extra stylets
- Product literature

CONTRAINDICATIONS

When tricuspid valvular disease or a mechanical heart valve is present, use of a ventricular endocardial lead is contraindicated.

WARNINGS

The safety, efficacy, and procedures for using the Model 6966 Tripolar, Endocardial, Screw-in Ventricular Lead are being evaluated under an investigational protocol. Patients must be advised that this lead is investigational. **Do not attempt to use this lead with a non-Medtronic Implantable Cardioverter/Defibrillator device.** Do not use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

PRECAUTIONS

Necessary Hospital Equipment

External defibrillating equipment should be kept nearby for immediate use during the acute lead system testing, implanta-

tion procedure, and whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the package before opening. If the container, the package, or the lead appear to have been damaged, do not use the lead. Return the damaged lead to your Medtronic representative.

Before Inserting the Lead

Use an anchoring sleeve with all leads. Ensure that the anchoring sleeve is positioned close to the lead's bifurcation sleeve. This will prevent inadvertent passage of the anchoring sleeve into the vein.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, to minimize contamination, protect the lead from materials shedding these substances. Handle the lead with sterile surgical gloves that have been rinsed in sterile water or equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

The maximum number of revolutions of the electrode fixation tool needed to extend or retract the helix is 20. **Exceeding the maximum revolutions may damage the lead.**

Chronic Repositioning

Chronic repositioning or removal of screw-in leads may not be possible because of blood or fibrotic tissue development into the helix mechanism. Removal of the lead could result in avulsion of the endocardium, valve, or vein. In addition, the lead junctions may separate, leaving the lead tip and bare wire in the heart or vein. In most clinical situations, it is preferable to abandon unused leads in place.

However, if a lead must be removed or repositioned, proceed with extreme caution. If a helix does not disengage from the endocardium by rotating the connector pin, rotating the lead body counterclockwise may withdraw the helix and decrease the possibility of damage to the cardiovascular structures during removal. If a lead is removed, inspect it carefully for insulator or conductor coil damage. (Medtronic requests that all removed or unused leads or portions thereof be returned for analysis.)

If a lead is abandoned, it should be capped to avoid transmitting electrical signals from the pin to the heart. A lead that

has been cut off should have the remaining lead end sealed and it should be sutured to adjacent tissue to avoid migration into the heart.

See additional cautions in the section "Suggested Implantation Procedure."

POTENTIAL COMPLICATIONS

The potential complications related to the use of endocardial leads include, but are not limited to, the following patient-related conditions: fibrillation, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax, and hemothorax.

Other potential complications related to the lead system and the programmed parameters of a pulse generator include, but are not limited to the following:

Complication	Possible Effects
Displacement, lead insulation or conductor fracture, poor connection to the tachyarrhythmia control device	Intermittent or continuous loss of sensing; oversensing; intermittent or continuous loss of defibrillation, cardioversion, or pacing therapy; and possible muscle or nerve stimulation in the pocket area*
Electrode fracture	Intermittent or continuous loss of defibrillation, cardioversion therapy, sensing, or pacing therapies*
Threshold elevation or exit block sion,	Loss of defibrillation, cardiover- or pacing therapy efficacy*

*Loss of detection, defibrillation, cardioversion, or pacing therapies may occur due to lead dislodgement, fracture, or threshold elevation. Therefore, the patient's ECG should be monitored during the hospital stay. If such a loss occurs, check sensing thresholds or X rays for lead dislodgement or conductor fracture.

ENSURING PRODUCT INTEGRITY

Carefully inspect the package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the package has been compromised prior to the product expiration date, place the contents in a gas-permeable package and resterilize it with ethylene oxide as described below.

CAUTION: Use ethylene oxide only.

The process should not exceed temperatures of 55° C (125° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

The implantation procedure generally includes checking the mechanical functioning of the lead electrode before it is inserted; using a stylet guide, stylets, and vein lifter; selecting an insertion site; positioning the lead; securing the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; and connecting the lead to the pulse generator.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition. As described below, the techniques for selecting an insertion site, using a stylet guide or a stylet, positioning a lead, and anchoring a lead suggest one or two possible versions, while more may exist.

Verifying the Mechanical Functioning of the Helix Electrode

Before implantation, verify the mechanical functioning of the electrode, as described below.

1. Within the sterile field, remove the lead and the accompanying stylets from the sterile packaging. The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin that accepts the stylet controls the helix mechanism.

2. To attach the fixation tool, first remove the stylet guide. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).

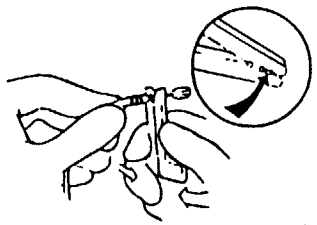

Figure 2. Attachment of the fixation tool to the connector pin.

3. Rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

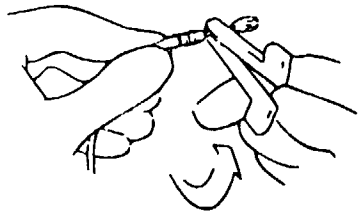

Figure 3. Rotating the fixation tool.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions may damage the lead.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the lead and its conductor coil to unwind.

5. After allowing the lead and its conductor coil to unwind, reattach the fixation tool and turn it counterclockwise until the helix tip is retracted in the sheath.

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin with the stylet in it controls the helix mechanism. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 4).

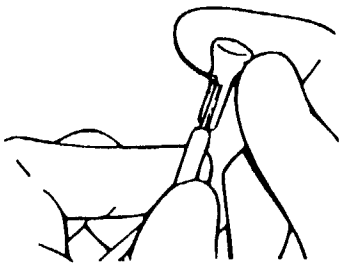

Figure 4. Stylet guide attachment.

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness to accommodate a physician's preference for lead and stylet flexibility.

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increase the chance that blood may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

After the stylet is inserted, gently remove the stylet guide so that it rests alongside the stylet knob.

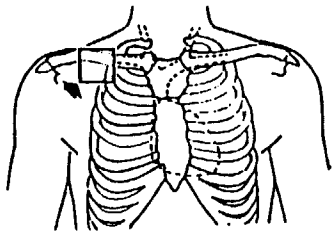
Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein.

CAUTION: If insertion is done via a subclavian approach, the lead should be positioned far laterally to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead may eventually cause the conductor to fractur, may cause damage to the insulation, or may cause other damage to the lead. This may result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, may also precipitate pinching and subsequent fracture of the lead. If significant resis-

tance is encountered during a subclavian stick implant procedure, do not force the lead by adjucting patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. In such cases it is recommended that an alternate venous entry site be used.

Use fluoroscopy to facilitate accurate lead placement.



Using the Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 5).

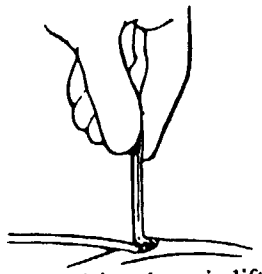


Figure 5. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Ventricular Lead

Advance the lead into the right atrium. For added control in maneuvering the lead tip through the tricuspid valve, the distal end of the lead may be slightly curved by inserting a gently curved stylet (Figure 6). After the lead tip is passed into the ventricle, the curved stylet may be replaced with a straight stylet. Then the lead tip may be advanced to the right ventricular apex while taking care to avoid perforation of the ventricular wall.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 6).

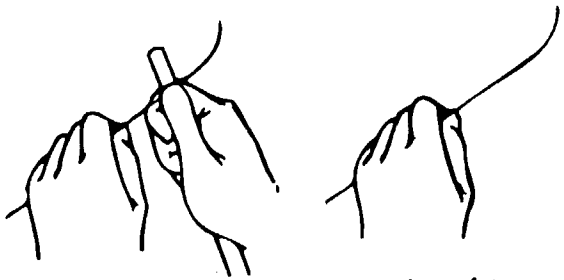

Figure 6. Imparting a curve to the stylet.

Accurate positioning of the electrode is essential for stable endocardial pacing. A satisfactory position is usually achieved when the lead tip points straight toward the apex, or when the distal end dips or bends slightly.

Use fluoroscopy (lateral position) to ensure that the tip is not in a retrograde position or is not lodged in the coronary sinus.

The patient should have x-rays taken every six months to verify the integrity of the PCD™ system.

After placing the lead in a satisfactory position, secure the lead by extending the helix into the endocardium.

Securing the Electrode Into the Endocardium

The following procedure is recommended for electrode fixation:

1. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).
2. Gently press the lead tip against the endocardium by pushing the stylet and the lead at the vein entry site. Then, rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions to extend or retract the helix may damage the lead.

3. Use fluoroscopy to verify helix electrode exposure. Closing of the space between the conductor (A) and the indicator ring (B) implies complete exposure of the helix electrode (Figure 7).

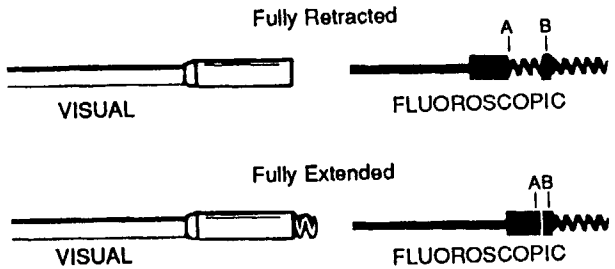

Figure 7. Possible views of the electrode.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the residual torque in the lead to be relieved.
5. After allowing the residual torque in the lead to be relieved, rotate the whole lead body clockwise approximately one revolution to ensure that the helical electrode is secured to the endocardium.
6. Carefully withdraw the stylet part way.
7. Obtain electrical measurements to verify satisfactory placement and electrode fixation. Refer to the following section, Taking Electrical and Defibrillation Efficacy Measurements, for recommended procedures and values.
8. Verify that the helix is affixed by gently pulling back on the lead and checking for resistance. A properly affixed helix will remain in position. If the helix is not properly affixed, the lead tip may become loose in the right ventricle.
9. If repositioning is required, reattach and rotate the fixation tool counterclockwise until the electrode is withdrawn. Use fluoroscopy to verify withdrawal. Repeat the procedure above.

CAUTION: When retracting the helix, do not rotate the fixation tool more than 20 revolutions. When the electrode is fully retracted, 2 coils of the helix will be visible between the indicator ring and the conductor.

10. Remove the stylet guide and stylet completely. When removing the stylet guide, grip the lead firmly just below the connector pin; this will help prevent possible lead dislodgement.
11. Obtain final electrical measurements. The lead may be repositioned, if necessary, to meet the implant defibrillation efficacy criteria outlined in the following section.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

In order to demonstrate reliable defibrillation efficacy, it is recommended that ventricular fibrillation be initiated and successfully terminated three out of four times at a stored output energy of 18 joules or less.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold	≤ 1.5 V - epicardial	≤ 3.0 V
(at 0.5 ms pulse width)	≤ 1.0 V - endocardial	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

200

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Anchoring the Lead

Use the anchoring sleeve to secure the lead from moving and to protect the lead insulation and conductor coil from damage caused by tight ligatures.

Anchor the lead with nonabsorbable sutures.

TRANSVENE™-RV uses a triple groove anchoring sleeve illustrated in Figure 8.

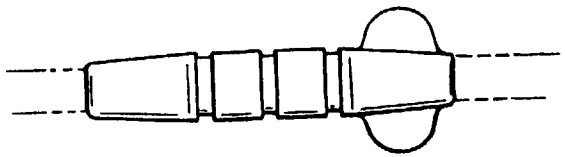

Figure 8. The triple groove anchoring sleeve.

With a triple groove anchoring sleeve, generally two or three of the grooves may be used with the following procedure (Figure 9 or 10):

The triple groove anchoring sleeve is situated at the connector end of the lead. Partially insert the anchoring sleeve into the vein.

Use the most distal suture groove to secure the anchoring sleeve to the vein.

Use the middle groove to secure the anchoring sleeve to the fascia and lead. First, create a base by looping a suture through the fascia underneath the middle groove and tying a knot. Continue by firmly wrapping the suture around the middle groove and tying a second knot.

Use the third and most proximal groove to secure the anchoring sleeve to the lead body.

Alternatively, only two of the three grooves may be used on the anchoring sleeve to tie down the lead. In that case, follow the anchoring procedure for the distal and middle groove (Figure 10).

CAUTION: Do not use the anchoring sleeve tabs for suturing.

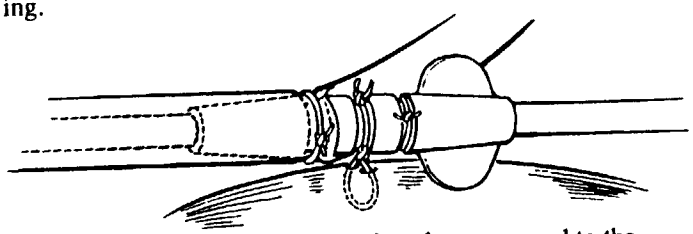

Figure 9. Triple groove anchoring sleeve secured to the lead and fascia using three grooves.

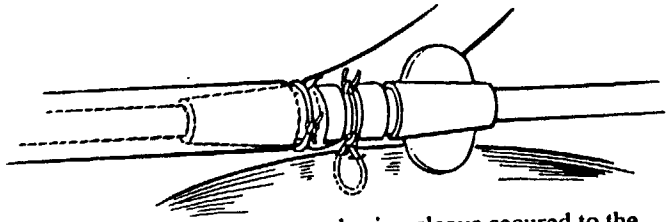

Figure 10. Triple groove anchoring sleeve secured to the lead and fascia using two grooves.

Tie the sutures securely but gently to prevent damage to the anchoring sleeve.

CAUTION: Do not secure the ligatures so tightly that they damage the vein or lead. **Do not tie a ligature directly to the lead body** (Figure 11). During anchoring, take care to avoid dislodging the lead tip.

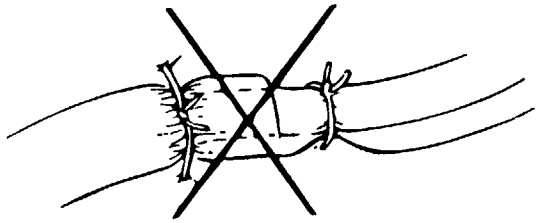

Figure 11. Do NOT secure the sutures too tightly and do NOT tie a suture to the lead body.

Connecting the Lead to a Tachyarrhythmia Device

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Tunnel the lead subcutaneously to the pulse generator pocket. A tunneling tool may be used to pull all the leads through to the pocket area. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead.

Refer to Figures 12a and 12b for instructions and illustrations showing lead connections to the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

Insert the lead connector into the connector block. Refer to the tachyarrhythmia control device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing and defibrillation efficacy.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillating Electrodes	Endocardial Two-Electrode System Connection Diagram
Medtronic® Model 7217B PCD™ Device	2	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE™-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE™-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the connector plug packaged with the pulse generator into the PULSE1 port. **PULSE2** Insert the lead connector of either the TRANSVENE™-RV, -SVC, or -SQ lead into the PULSE2 port.

Figure 12a. Connections for endocardial and subcutaneous leads (single pulse) into the Medtronic® PCD™ Tachyarrhythmia Control Device 7217B.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillating Electrodes	Endocardial Three-Electrode System Connection Diagram
Medtronic® Model 7217B PCD™ Device	3	
Figure 12b. Connections for endocardial and subcutaneous leads (simultaneous or sequential pulse) into the Medtronic® PCD™ Tachyarrhythmia Control Device 7217B.

CAUTION: Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

CAUTION: To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 13). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

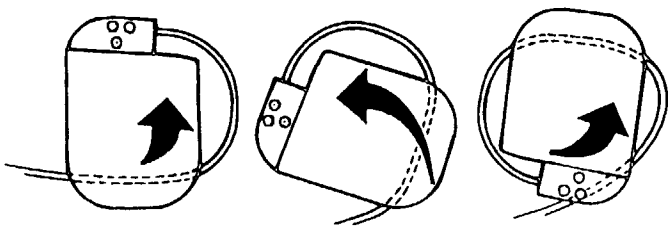

Figure 13. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

CAUTION: When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 14).
- Do NOT grip the lead or pulse generator with surgical instruments.

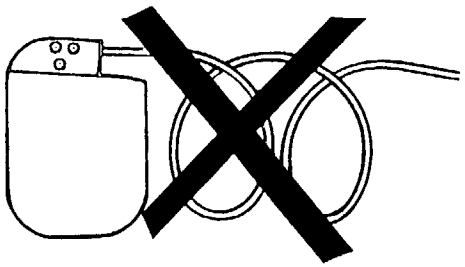

Figure 14. Do not coil the lead body.

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

TECHNICAL SPECIFICATIONS (Nominal)

PARAMETER		MODEL 6966
Type		Tripolar
Chamber		Ventricle
Fixation		Screw-In
Length		110 cm

Maximum Revolutions that can be used to extend or retract the helix when using a straight stylet		20

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications (including perforation of the heart) will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

MEDTRONIC® DEFIBRILLATION LEAD DISCLAIMER OF WARRANTIES

THIS MEDTRONIC® TRANSVENE™-RV MODEL 6966 PERMANENT IMPLANTABLE DEFIBRILLATION LEAD (THE "LEAD") HAS BEEN MANUFACTURED UNDER CAREFULLY CONTROLLED CONDITIONS TO ASSURE ITS QUALITY AND RELIABILITY. HOWEVER, BECAUSE MEDTRONIC HAS NO CONTROL OVER CONDITIONS UNDER WHICH THE LEAD IS USED, MEDTRONIC PROVIDES THE FOLLOWING DISCLAIMER:

THE LEAD IS SOLD IN AN "AS IS" CONDITION. MEDTRONIC DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THE LEAD, INCLUDING BUT NOT LIMITED TO, ANY IMPLIED WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. MEDTRONIC SHALL NOT BE LIABLE TO ANY PERSON OR ENTITY FOR ANY MEDICAL EXPENSES OR ANY DIRECT OR CONSEQUENTIAL DAMAGES CAUSED BY ANY DEFECT, FAILURE, OR MALFUNCTION OF THE LEAD, WHETHER A CLAIM FOR SUCH DAMAGES IS BASED UPON WARRANTY, CONTRACT, TORT, OR OTHERWISE. NO PERSON HAS ANY AUTHORITY TO BIND MEDTRONIC TO ANY REPRESENTATION OR WARRANTY WITH RESPECT TO THE LEAD.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

Re: Premarket Approval Application (PMA) for the Medtronic® Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, i.e., the PCD™ Transvene System, Lead Models 6963, 6966 and 6999.

This submission is a PMA application for the Medtronic Transvene Lead System used in conjunction with the Model 7217B pacer-cardioverter-defibrillator (PCD), Model 5355 external tachyarrhythmia control device (ETCD) and Model 9788 MemoryMod Software Module.

The PCD and ETCD devices as used with an epicardial lead system were recommended for approval by the FDA Advisory Panel on February 3, 1992 (P900061). The purpose of this PMA application is to obtain approval for the use of the non-thoracotomy lead system for use with the Medtronic PCD and ETCD. The terms non-thoracotomy leads (NTL), transvenous leads and Transvene Lead System are synonymous and may be used interchangeably throughout this application.

The Transvene System, in conjunction with the PCD device, is intended to treat patients at risk of sudden cardiac death due to ventricular arrhythmias. Like the epicardial electrodes/PCD System, the primary benefits from the use of the Transvene/PCD System center on the detection and termination of these life-threatening ventricular arrhythmias. The incorporation of a non-thoracotomy lead system allows for a safer and effective implantation procedure, and improving both perioperative and long-term patient morbidity and mortality.

The Transvene/PCD System clinical study (IDE G870102) includes (b)(4) Transvene lead implants with a mean implant duration of 4.5 months and a total of 1426 device months experience. There are (b)(4) with lead system implant duration equal to or greater than six months. The data included in this submission is all data that was received by Medtronic and entered onto the clinical database as of November 27, 1991. The results from the clinical study are provided in Volume 5 of this application.

Market approval is not being sought for use of the Transvene/PCD System with other manufacturers' implantable-cardioverter-defibrillators, nor is it sought for use of the PCD device with other manufacturers' transvenous defibrillation lead systems.

Two manufacturing facilities are to be used in the assembly, sterilization and packaging of the Transvene leads. These are:

1. Medtronic, Inc.
   Rice Creek Facility
   7000 Central Avenue N.E.
   Minneapolis, MN 55432
   Tel: 612-574-4000
   Establishment Registration Number: 2182208
   Is presently prepared for inspection.
   Most recent FDA inspection: January 21-February 8, 1992.

2. Medtronic, B.V.
   Wenckebachstraat 10
   6466 NC Kerkrade West
   The Netherlands
   Tel: 31-45-43-85-85
   Is presently prepared for inspection.
   Most recent FDA inspection: January 6-9, 1992.

The existence of this PMA application and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

In accordance with 21 CFR 814.42(a), the FDA has 45 days from the date of receipt to notify Medtronic if this application is sufficiently complete for a substantive review and acceptable for filing.

Six copies of this application are enclosed. Should additional information be required by the Agency, please contact the undersigned.

Sincerely,

MEDTRONIC, INC.

III. Device Description: Model 6963 Coronary Sinus/Superior Vena Cava and Model 6999 Subcutaneous Patch Leads

Illustrations of these leads are provided on the pages following this discussion.

The Medtronic Tachyarrhythmia Control System uses a tripolar, screw-in, right ventricular lead for (RV) pacing, sensing, cardioversion and defibrillation; a unipolar, coronary sinus/superior vena cava lead (CS/SVC); and a unipolar, subcutaneous oval patch electrode (SQ). The available models of the system are as follows:

- Model 6963 CS/SVC Lead
- Model 6966 RV Lead
- Model 6999 SQ Lead

The Model 6963 and 6999 leads are intended to be used with the Model 7217B PCD Device. The leads have a 6.5 mm connector intended for direct insertion into a 6.5 mm port of the 7217B PCD Device.

The Model 6963 lead is intended for use in the coronary sinus or superior vena cava. The lead features a platinum alloy electrode coil which provides the necessary surface area for cardioversion and defibrillation. Silicone insulation surrounds a low-resistance metal-alloy conductor coil.

The Model 6999 lead is intended for use subcutaneously, submuscularly, or directly on the periosteum of the ribs. The lead features platinum alloy electrode coils and a low-resistance metal-alloy conductor surrounded by silicone insulation. Four helical coils are partially embedded into the silicone patch and provide the necessary surface area for cardioversion and defibrillation. A (b)(4) (b)(4) is molded into the patch and provides support for sutures. There are three nodes in the center and two nodes at the junction of the lead body and patch electrode of one side of the patch electrode. These nodes are intended to designate the insulated side of the patch electrode.

The following section describes the functional components, device properties, and principles of operation for the Model 6963 and 6999 leads.

(b)(4)

(b)(4)

MODEL 6963 CS/SVC LEAD

(b)(4)

(b)(4)

MODEL 6999 SUBCUTANEOUS
PATCH LEAD

a. Functional Components

1) Platinum Alloy Electrode Coil

The Model 6963 coronary sinus/superior vena cava lead features a platinum alloy coil electrode that delivers cardioversion and defibrillation pulses to the heart. The Model 6963 lead uses silicone adhesive to help prevent tissue in-growth and aid in chronic lead removal.

The conductive surface of the Model 6999 subcutaneous patch electrode consists of four platinum helical coils partially embedded in molded silicone rubber. These coils serve as the electrodes that deliver cardioversion and defibrillation pulses to the heart. Inside the helical coils is silicone rubber to help prevent tissue in-growth and aid in chronic lead removal.

2) Low Resistance Metal Alloy Conductor Coil

This conductor coil consists of (b)(4) alloy that provides a low resistance pathway for delivery of cardioversion and defibrillation pulses from the tachyarrhythmia control device to the platinum alloy electrode coils. The (b)(4) was selected for use due to its proven long term reliability when used in implanted bradycardia lead systems. The use of (b)(4) coil provides the low resistance needed for the delivery of high voltage pulses. The coils used on the Model 6963 and 6999 are not (b)(4)

3) Insulation

The Model 6963 and 6999 leads are comprised of silicone rubber insulation. This material has a long history (since 1962) of use on Medtronic pacing leads. Insulation wall thickness for both the 6963 and 6999 is (b)(4)

4) Anchoring Sleeve

There is an anchoring sleeve positioned on the lead body of the Model 6963. It is intended to be used for fixation of the lead body to soft tissues near the site of insertion of the lead into the vein at the time of the implant. It is designed to protect the lead from undue strains and stresses at the point of fixation.

5) (b)(4) Embedded into (b)(4) Rubber

(b)(4) is embedded into the Model 6999 subcutaneous patch and provides support when suturing the lead to the subcutaneous muscle.

6) Stylets

Stylets are (b)(4) which stiffen the lead and/or temporarily alter its shape during implant. This is accomplished through a controlled stiffness of the distal tip, allowing it to bend with the application of excessive force. Stylets are also designed to help minimize damage to the coil during insertion and removal. The Model 6963 uses a stylet, the Model 6999 does not.

7) Connector Assembly

The Model 6963 and 6999 leads feature a 6.5 mm terminal assembly consisting of a (b)(4) connector pin and silicone rubber sleeve. The distal part of the sleeve provides a strain relief area.

b. Device Properties

The Model 6963 and 6999 non-thoracotomy leads are designed for sensing, pacing, cardioversion and defibrillation. These leads have application where implantable tachyarrhythmia control devices are indicated. Reference the technical manuals for the Model 6963 and 6999 leads for specific device features.

c. Principles of Operation

The PCD Transvene System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three different leads may be used to deliver cardioversion and defibrillation pulses. These configurations are comprised of a tripolar, right ventricular (RV) lead (Model 6966), and either a coronary sinus (CS) lead (Model 6963) or a subcutaneous (SQ) lead (Model 6999), or all three of these leads. The Model 6963 lead can be placed in either the coronary sinus/great cardiac vein or the superior vena cava (SVC).

In these systems, the helical tip and ring of the RV lead is used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE 2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

A system using two leads delivers cardioversion and defibrillation pulses between two coils (one on each lead). A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE 1 and PULSE 2) to the COMMON defibrillation electrode.

To detect VT/VF, the PCD device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD confirms episode termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

1) At implant by the evaluation of the pacing and sensing thresholds and defibrillation efficacy when treating VT/VF

2) Chronically by evaluation of stability of chronic defibrillation efficacy in induced episodes of VT/VF and successful termination of spontaneous episodes of VT/VF.

Manufacturing Description:

Model 6999 Subcutaneous Lead
Model 6963 Coronary Sinus Lead

Medtronic European Service and Technology Center (ESTC), Kerkrade, The Netherlands

The following Manufacturing Description has been prepared in conformance with the "Guidance for Preparation of PMA Manufacturing Information" made available by FDA August 21, 1991. Copies of the device description and labeling from other parts of the PMA have been included in the first part of this volume, as indicated in the cover letter.

This section contains a complete description of the methods used in, and the facilities and controls used for, the manufacture, processing, packaging, storage and distribution of the Models 6999 and 6963 Nonthoracotomy (NTL) Leads. Process qualification testing and results are included in Section F.3. As requested, a summary describing how applicable GMP requirements are met has been provided for each area identified. Copies of actual procedures are provided when specifically requested by the Guidance.

The Models 6999 and 6963 Leads meet the definition of a critical device; implantable leads are currently on the Critical Device List. We have thus addressed specifically additional controls that are in place to meet the critical device requirements.
