The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate demonstration of device effectiveness and justified the implant of the PCD Transvene System. Finally, there have been no patients deaths secondary to unsuccessful termination of a spontaneous VT or VF episode in this patient population.

J.3 Description of Patients Not Meeting Implant Criteria

As noted previously, the patients not meeting implant criteria (N = 214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules [79.4% of the patients]; (2) Difficult to induce VF [11.2% of the patients]; and (3) Implant procedure terminated due to poor patient condition [9.4% of the patients]. These patient groups are reviewed in the following discussion.

Lowest Energy of Defibrillation < 24 Joules

There were 170 patients in whom the PCD® Transvene™ System was implanted with a defibrillation safety margin of at least 10 Joules. Table J-5 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD® Transvene™ System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD® Transvene™ System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System (141 patients or 82.9% had only VF induced). In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4%% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, however, is limited to an average of 9.7 months.

PCD® Transvene™ System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation:	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7
Overall Spontaneous VF Episode Efficacy	99.4%
One Year Survival:	
Sudden Cardiac	99.4%
Overall	93.8%

Table J-5: PCD® Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at $\leq$ 24 Joules Clinical Experience - 2/1/93

Difficult to Induce VF

There were 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of the these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least

three episodes of VF were not induced at the time of implant, 13 patients (54.2%) have experienced a spontaneous VF episode and 21 patients (87.5%) have had VT or VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD® Transvene™ System.

There has been one reported patient death (b)(4), (b)(6) in the patient group with a resultant one year sudden cardiac death and overall actuarial survival of 100%.

Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

27

Of these 20 patients, VT or VF has been induced at a chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD® Transvene™ System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, further reviewed indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus, there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

K. Comparison to AICD System Experience

K.1 Overview

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD® Transvene™ System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD® Transvene™ System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD® Transvene™ System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

K.2 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD® Transvene™ System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table K-1.

29

There were no differences between the two patient groups.

PCD® Transvene™ System Comparison of Patient Characteristics PCD® versus AICD		
	PCD®	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males % Females	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: SCD VT SCD/VT	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table K-1: Comparison of Patient Characteristics, PCD® versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD® Transvene™ System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD® Transvene™ population than in the AICD population ($p = 0.001$).

39

K.3 Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD® Transvene™ System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD® device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead

system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD® Transvene™ System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD® Transvene™ System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD® device provides information on the total number of VT and VF episodes detected by the PCD® device and the total number of VT and VF episodes successfully treated by the PCD® device as well as the number of VT/VF episodes where the PCD® device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD® device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD® Transvene™ System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD® Transvene™ System detection criteria.

A total of 10,027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD® device

32

episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

Table K-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD® Transvene™ System includes **both complications and observations.** In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD® Transvene™ System
Comparison of Complication/Observation Rates
PCD® versus AICD

Category	PCD®%	AICD%
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table K-2: Comparison of Complication/Observation Rates: PCD® Transvene™ System vs AICD Epicardial System - 2/1/93

33

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD® Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD® Transvene™ System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD® Transvene™ System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD® device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 3.2% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

54

This analysis indicates that the PCD® Transvene™ System offers clinical advantages in reducing the need for a thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing.

K.4 Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD® Transvene™ System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 51 deaths (6.7%) were reported in the PCD® Transvene™ System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD® Transvene™ System population had a lower perioperative mortality, 0.7% vs 2.7% ($p = 0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD® Transvene™ System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be

nonfunctional and awaiting replacement. For purposes of this comparison, 7 patient deaths were **censored** in the PCD® Transvene™ System patient population because the devices were deactivated at the time of patient death.

This PCD® Transvene™ System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD® Transvene™ System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD® Transvene™ System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD® System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD® Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

L. Comparison to PCD® Epicardial System Clinical Results

The PCD® Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

40

The PCD® Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD® Transvene™ System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD® Epicardial System and PCD® Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD® device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD® Transvene™ System clinical experience to the reported PCD® Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

L.1 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the PCD® Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table L-1 contains the characteristics of the 757 patients receiving the PCD® Transvene™ System versus the

37

characteristics of the 742 patients who received the PCD® Epicardial System as of 1/5/93.

PCD® Transvene™ System
Comparison of Patient Characteristics

	PCD® Transvene™ System	PCD® Epicardial System
Number of Patients	757	742
Mean Follow-Up Time	11.7 months	16.3 months
% Males*	610 80.6%	637 85.8%
% Females	147 19.4%	105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication*:		
SCD	281 37.1%	214 28.8%
VT	377 49.8%	405 54.6%
SCD/VT	99 13.2%	123 16.6%
Cardiovascular History:		
Coronary Artery Disease	561 74.1%	569 76.7%
Cardiomyopathy	238 13.1%	222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* (b)(4) (b)(4)

Table L-1: Comparison of Patient Characteristics, PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34.0% for the PCD® Epicardial patient group.

Analysis indicated that the PCD® Transvene™ System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death (p = (b)(4) (b)(4) and higher percentage of females (b)(4) (b)(4) It is not expected that these differences will result in a different clinical outcome in the PCD® Transvene™ System patient population as compared to the PCD® Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD® Transvene™ System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups (b)(4) The PCD® Transvene™ System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD® Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD® Transvene™ System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but were non-inducible during electrophysiologic testing so that drug testing was not feasible.

L.2 Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD® Transvene™ System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table L-2 provides a comparison of the efficacy of the PCD® Transvene™ and PCD® Epicardial System in treating spontaneous episodes of VT and VF.

PCD® Transvene™ System Performance Comparison of Spontaneous VT/VF Efficacy PCD® Transvene™ vs Epicardial		
Spontaneous VT Episodes		
	PCD® Transvene™ System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	10,027	20,061
% Overall Efficacy	98.4%	98.3%
% Unsuccessful Termination	0.7%	1.0%
Spontaneous VF Episodes		
	PCD® Transvene System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	1092	2636
% Overall Efficacy	98.4%	98.7%
% Unsuccessful Termination	0.3%	0.5%

Table L-2: PCD® Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of VT or VF is 98.5%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD® Epicardial System which was 98.4%. Therefore, the PCD® Transvene™ System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

L.3 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD® Transvene™ System and the PCD® Epicardial System. The PCD® Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with

340

(b)(4) a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD® System. In the PCD® Transvene™ System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD® Epicardial System, 12.8% of the patients experienced a clinical complication and 25.7% of the patients experienced a clinical observation.

Table L-3 provides a comparison of the reported complications and the incidence in the two patient populations.

PCD® Transvene System
PCD® Transvene System versus PCD® Epicardial System
Reported Complications

Reported Complications	PCD® Transvene™ System	PCD® Epicardial System
	(b)(4)	
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	2.8%
Device Related	0.5%	0.9%

Table L-3: Reported Complications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

41

L.4 Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD® Transvene™ and Epicardial System was performed.

Table L-4 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD® Transvene™ System patient population was 11.7 months while for the PCD® Epicardial System it was 16.3 months.

PCD® Transvene™ System
Death Classifications
PCD® Transvene™ System versus PCD® Epicardial System

Death Classification	PCD® Transvene™ System (b)(4)	PCD® Epicardial System (b)(4)
Sudden Cardiac	5	24
Non-Sudden Cardiac	30	54
All Cardiac	35	78
Noncardiac	16	34
Total	51	112

Table L-4: Death Classifications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Table L-5 provides a comparison of actuarial survival rates between the PCD® Transvene™ and PCD® Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths

47

which occur in the first thirty days post implant of the PCD® System.

PCD® Transvene™ System
Comparison of Actuarial Survival
PCD® Transvene™ System versus PCD® Epicardial System

One Year Survival	PCD® Transvene™ System	PCD® Epicardial® System	(b)(4)
Number of Patients	757	742	
Sudden Cardiac	99.5%	98.9%	
Non-Sudden Cardiac	96.2%	96.7%	(b)(4)
All Cardiac	95.8%	95.7%	
Noncardiac	98.1%	98.0%	
Overall*	93.3%	88.6%	

* (b)(4) (b)(4)

Table L-5: Comparison of Actuarial Survival: PCD® Transvene™ System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD® Transvene System®. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD® Transvene™ System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD® Epicardial System (88.6%) (b)(4) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD® Transvene™ System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD® Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

43

M. PCD® System Performance

M.1 PCD® Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection, therapy performance, and analysis of explanted devices were evaluated to assess the performance of the PCD® Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD® Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD® Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD® Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 58 devices explanted. Reasons for explant were patient death (23), infection (22), cardiac transplant (9), low battery voltage (1) and PCD Device performance issues (3). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits and this affected the battery indicator circuit only and did not affect the critical functions of the device. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other three devices indicated that two were due to random component failure and one due to shorting on Pulse 2 output. Thus, arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily

49

applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

Based on the clinical data collected, the PCD® Device has performed safely and reliably in the indicated patient population.

M.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of conductor coil fracture is 0.5% (4/757).

Based on the clinical data collected, the Transvene™ leads have performed safely and reliably.

N. Summary

The overall clinical experience with the PCD® Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD® Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD® Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD® Transvene™ System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD® Transvene™ System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD® Transvene™ System.

PCD® Transvene™ System Performance

- The PCD® Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

5

O. Clinical Experience Summary Conclusions

The PCD® Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The PCD® Transvene™ System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the perioperative and overall patient mortality as compared to the PCD® Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of 7.6 days as opposed to a mean of 10.6 days (b)(4) for the PCD® Epicardial System.

Medtronic asserts and the PCD® Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

4

Summary of Clinical Experience

A. Introduction

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device (Medtronic Model 7217B with Epicardial Cardioversion/Defibrillation Leads) incorporates multiprogrammability, multiple detection and therapeutic options for the treatment of ventricular tachycardia and fibrillation. The current system, while providing lifesaving treatment of ventricular arrhythmias, requires a significant surgical procedure (thoracotomy, median sternotomy, etc.) for the placement of the epicardial lead system. The need to reduce the surgical mortality and morbidity associated with epicardial cardioversion/defibrillation lead systems has lead to the development of the PCD® Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene™ Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of **February 1, 1993.**

The PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, with the addition of Transvene™ leads.

The data analysis is organized in functional rather than chronological categories in order to present a complete picture of each of the PCD® Device's various functions. The sections included in this summary are:

- Name, Intended Use of System
- Tachyarrhythmia Control System Features
- Indicated Patient Population
- Study Objectives and Protocol Summary
- Overview of Clinical Experience
  - Implant Data
  - Spontaneous VT/VF Episode Experience

- Comparison to PCD® Epicardial Clinical Experience
- PCD® Transvene™ System Performance

This summary provides an overview of the clinical experience which verifies that the PCD® Transvene™ System is safe and effective in the indicated patient population.

B. Name and Intended Use of the System

The Pacer-Cardioverter-Defibrillator (PCD®) device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD® Device is used in conjunction with appropriate lead systems for the treatment of patients with ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The PCD® Device also provides backup pacing in the VVI mode and noninvasive electrophysiologic (EP) study capabilities.

The PCD® Device is programmed with the market released Medtronic programmer and a unique MemoryMod™ Cartridge. The PCD® Device incorporates a two-way telemetry system which receives operational instructions from the programmer and transmits status, electrogram and event information back to the programmer for display and/or printout.

The External Tachyarrhythmia Control Device (ETCD) is an external, multiprogrammable, tachyarrhythmia control device. Its operation is similar to the PCD® Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it displays measurements of cardioversion and defibrillation therapy parameters. The ETCD is used for making defibrillation threshold measurements during the PCD® Device implantation procedure.

Components

The Medtronic PCD® Transvene™ System, which is represented in Figures 1A and 1B, for which market release approval is being requested, consists of the following components:

S1

Implanted Device and Related Programming System
Pacer-Cardioverter-Defibrillator (PCD®) Device
Model 7217B

Programmer
Model 9710 programmer and related accessories (currently market released), plus
Model 9788 MemoryMod™ Software Cartridge
Lead System
Electrode Leads:
Model 6966
Model 6963
Model 6999

Implant Measurements System
Model 5355 ETCD™ External Tachyarrhythmia Control Device
Model 5418 Patient Cable
Model 5414 Test Load
Model 5417 EGM Cable
Model 5419 Jumper Cable

The physical characteristics of the Model 7217B are summarized in Table IB-1:

PCD® Model 7217B Physical Characteristics	
Feature	**Model 7217B**
Volume	113 cc
Weight	198 grams
Connector Module	Four connector ports
Power Source	Wilson Greatbatch Model 8830 Lithium Silver Vanadium Oxide
Sensing Configuration	Standard Bipolar
Pacing Configuration	Integrated Bipolar

Table IB-1: Features: Model 7217B - 2/1/93

The Model 7217B PCD® Device uses the pace/sense leads for sensing, thus providing **standard bipolar** sensing. Pacing is delivered in the integrated bipolar configuration.

C. Tachyarrhythmia Control System Features

C.1 PCD® Device

The PCD® Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation.

The main features of the PCD® Device include the detection and treatment of recurrent ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The device has two independently programmable detection and therapy algorithms, one for VT and a second for VF. A series of up to four tiered therapies can be delivered after detection of VT and a separately programmed series of up to four therapies after the detection of VF. If a therapy does not convert the arrhythmia, the next programmed therapy is delivered.

Other features of the device include VVI back-up pacing, flexible programming, noninvasive electrophysiology study capabilities, and information reports.

VT Detection and Therapy

The VT detection algorithm includes up to three separately programmable criteria to identify the presence of a tachycardia.

The PCD® Device employs a feature that automatically adjusts signal detection sensitivity to assure proper detection while minimizing sensing of T-waves following intrinsic cardiac events. This function, **Auto-Adjusting Sensitivity**, is active during any sensing period, including VT and VF detection. It allows use of sensitive settings required for VF detection without oversensing during normal sinus rhythm.

The device utilizes interval length as the primary VT detection criterion; it also provides two additional detection

criteria to add specificity in detecting pathological VT. The two programmable parameters of the Interval Criterion are:

- **Tachycardia Detection Interval (TDI):** Intervals shorter than this value (and longer than FDI are classified as VT intervals.

- **Number of Intervals to Detect (VT NID):** This parameter determines how many consecutive VT intervals must be sensed for therapy to be delivered.

The two additional criteria are:

- **Onset Criterion:** Used to determine when the rate of change in cycle length is sufficiently abrupt to qualify as the onset of paroxysmal VT and not sinus tachycardia.

- **Stability Criterion:** Used to determine when the intervals vary sufficiently on a beat to beat basis to differentiate VT from a rapid ventricular response due to atrial fibrillation.

After a VT episode has fulfilled the programmed detection criteria, the system treats the arrhythmia by delivering one of the three types of VT therapies: Burst, Ramp, or Cardioversion Therapy. Therapy delivery is highly programmable and is "tiered" to allow progression through different therapies selected by the physician to match a patient's particular clinical needs. Up to four separate therapies may be programmed in any combination of the three types to treat each arrhythmia episode. The three therapies are detailed below:

Burst Therapy treats the VT episode by pacing the heart with a "burst" of pulses at a rate greater than that of the VT episode but adapted to the VT rate. The rate adaptive pulse intervals are a programmed percentage of actual tachycardia cycle length. If a pacing sequence is ineffective and the episode is redetected, the pulse interval of the next sequence can be decremented further resulting in a higher pacing rate.

Ramp Therapy decrements each pulse interval within a single sequence of multiple pulses with the first pulse to pulse interval adapted to the VT cycle length. Each subsequent pulse interval in the Ramp sequence is shortened from the preceding interval by a programmed value. If the pacing sequence is ineffective and the VT is redected, Ramp Therapy adds an additional stimulus in each subsequent sequence.

Cardioversion Therapy: delivers synchronized, high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

VF Detection and Therapy

In order to ensure appropriate sensing and detection of VF, the device uses a probabilistic detection algorithm that allows for missed detections due to variations in ventricular depolarization amplitudes and intervals during VF.

Similar to the VT detection algorithm, the PCD® Device detects VF by monitoring the cardiac cycle length and comparing it to the programmed VF detection criteria, which is called the VF Interval Criterion.

The two programmable parameters of this criterion are:

- **Fibrillation Detection Interval (FDI)**: Intervals equal to or shorter than this value are classified as VF intervals.
- **Number of Intervals to Detect (VF NID)**: This parameter determines how many VF intervals must be sensed for therapy to be delivered.

After a VF episode has fulfilled the programmed detection

criteria, the system treats the arrhythmia by delivering up to four defibrillation therapies.

Defibrillation Therapy delivers high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

Bradycardia Therapy

The PCD® Device delivers bradycardia pacing in the VVI mode.

Other Capabilities

The PCD® Device can be used to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the Model 9788 MemoryMod™ software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia episode.

The PCD® Device will provide the physician with information, via the Programmer about its present programmed status and data on its operation. This information may be printed and retained in the patient's file.

A programmer-generated set of symbols, termed Marker Channel, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

Figure 2 provides an ECG example of an induced episode of VT detected and terminated by antitachycardia pacing and Figure 3 shows an induced episode of VF detected and terminated by a defibrillation therapy delivered by the PCD® Device.

C.2 Transvene™ Lead Systems

The PCD® Transvene™ System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three leads may be used to deliver cardioversion and defibrillation pulses. These configurations are based on a tri-polar, Right Ventricular (RV) lead (Model 6966), and either a Coronary Sinus (CS)/Superior Vena Cava (SVC) lead (Model 6963) or a Subcutaneous (SQ) lead (Model 6999) or all three of these leads (e.g. RV/CS/SQ, RV/SVC/SQ or RV/SQ, RV/SVC). The Model 6963 lead can be placed in either the Coronary Sinus/Great Cardiac vein or the Superior Vena Cava (SVC).

A system using two leads delivers cardioversion and defibrillation pulses between two electrodes. A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE1 and PULSE2) to the COMMON defibrillation electrode.

In these systems, the retractable, helical tip and ring of the RV lead are used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

To detect VT/VF, the PCD® device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD® device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD® confirms termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

1) At implant by evaluating the pacing and sensing thresholds and the defibrillation efficacy in treating

60

induced VF;

2) Chronically by evaluating (1) the defibrillation efficacy in terminating induced episodes of VT or VF; (2) the efficacy of VT and VF therapies in treating spontaneous episodes; (3) the evaluation of pace/sense characteristics of the implanted lead system and (4) the incidence of lead complications or observations such as dislodgement or fracture.

C.3 Model 9788 MemoryMod™ Software Cartridge and 9710 Programmer

Programming and interrogation of the PCD® Device is performed using the Model 9788 MemoryMod™ software cartridge in conjunction with the Model 9710 programmer. The use of the programmer allows the modification of VT and VF detection, therapy, and bradycardia support therapy parameters. It allows the physician the ability to review and record programmed device settings, perform noninvasive EP procedures and deliver emergency therapy and review other non-programmable information including charge time, battery voltage and event recording. In addition, it allows the user to evaluate the battery status of the PCD® Device as well as determine if the device has delivered therapy for spontaneous episodes of VT and VF.

C.4 Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD is intended for use in conjunction with an antitachycardia/defibrillation lead system to evaluate VT and VF sensing and therapy efficacy for terminating ventricular tachycardia and ventricular fibrillation prior to the implantation of the PCD® system.

Testing the lead system for permanent implantation, including VF sensing and defibrillation efficacy, is done using the Model 5355 ETCD™ or Model 2394 ECVD. The 5355 is an external, multiprogrammable, tachyarrhythmia control device, which can automatically deliver bradycardia and tachycardia pacing therapies and can deliver manually initiated cardioversion or defibrillation therapies. Its operation is similar to the PCD® Device except that

62

cardioversion and defibrillation therapies are delivered manually. In addition, it measures and displays parameters, e.g., pathway impedance of cardioversion and defibrillation therapies. The Model 2394 ECVD is also an external cardioverter defibrillator. However, its functions are limited to only manual cardioversion and defibrillation. The output pulses are equivalent to the Model 5355 and Model 7217B PCD®. Additionally, the Model 2394 ECVD does not have the capability to deliver either bradycardia or tachycardia pacing therapies.

The Model 5355 ETCD™ is controlled via the Model 9710 programmer and the MemoryMod™ software cartridge, Model 9788. The Model 2394 ECVD is controlled manually.

D. Indicated Patient Population

The PCD® System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD® Device.

Results provided in this application will support Medtronic's request for market release of the PCD® System for use in the following patient population:

> Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
>
> Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

For this patient population the primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD® pulse generator.

The PCD® System allows the titration of therapies for patients

with ventricular tachycardia while providing the critical defibrillation backup. Defibrillation backup is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia. Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

E. Study Objectives and Protocol Summary

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD® System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD® system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD® system, pace/sense, detection and therapy functions in both the acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population. The analysis will also provide data demonstrating the safety and effectiveness of the Model 5355 ETCD.

The objectives of the clinical study were:

* to evaluate the sensitivity and specificity of the PCD® Device with Transvene™ lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms;

* to monitor the efficacy of the PCD® Device with Transvene™ lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (Successful Termination/Number of Detected Episodes with Therapy Delivered). Investigators were free to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely;

* to evaluate the performance of the Model 6966, 6963 and 6999 Transvene™ leads;

* to monitor the patient selection criteria and patient management methods required by the PCD® Device and Transvene™ leads.

* to evaluate the safety and effectiveness of the Model 5355 ETCD™ when used during the implant procedure. Specifically, tachyarrhythmia episode induction, detection, termination and ease of use were analyzed.

* to evaluate the safety and performance of the Model 9710 Programmer and the 9788 MemoryMod™ Software Cartridges in programming sensing and therapy parameters and the appropriate delivery of noninvasive electrophysiologic stimulation.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD® System:

Pre-implant Patient Assessment
Lead System Testing at Implant
Implantable Pulse Generator Testing at Implant
Pre-hospital Discharge Testing
Follow-up Evaluation 1 and 3 months post implant then at 3 month intervals

Specific data was collected at each of these points to meet the objectives of the clinical study. This included:

Pre-implant Patient Assessment - extensive pre-implant testing was performed to ensure that the general patient selection criteria were met. This testing included at least an electrophysiologic evaluation, measurement of ejection fraction, and assessment of the patient's New York Heart Association (NYHA) classification of their cardiovascular status. Depending on the patient history, cardiac catheterization and exercise testing were also conducted.

Lead System Testing - implant evaluation was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate, ventricular tachycardia. The Model 5355 ETCD™ or the 2394 External Cardioverter Defibrillator (ECVD) was used for testing.

This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The PCD® Device implant criteria were:

1) successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2) a 2:1 VF sensing safety margin.

Implanted Pulse Generator Testing - this implant evaluation was performed to demonstrate proper detection and termination of ventricular fibrillation by the implanted PCD® System with VF Therapy #1 programmed to 34 Joules in addition to pacing and sensing thresholds.

Pre-hospital Discharge Testing - testing performed at the pre-hospital discharge included proper detection and termination of induced ventricular tachycardia. Final sensing and therapy parameters are programmed at the PHD.

Follow-up Evaluation - regular testing was performed to evaluate the chronic stability of detection and therapy parameters of the PCD® System. This testing included an assessment of the relative stability of the energy required to defibrillate a patient and efficacy and acceleration rate assessment of the VT therapies. The number of spontaneous VT/VF episodes treated by the PCD® Device were evaluated. Complication rates and patient mortality data were also evaluated.

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD® System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

Clinical data presented in this summary includes experience with the Model 7216A and 7217B PCD® Devices with the Model 6966, 6963 and 6999 Transvene™ Leads. This report presents the clinical evaluation of the safety and efficacy of the PCD® Device with Transvene™ Leads implanted in 757 patients of which 657 have implant durations equal to or greater than six months.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD® System with Transvene™ Leads is included in this report.

F. Overview of Clinical Experience

This report covers a total of 762 implants in (b)(4) of the PCD® Device with the Transvene™ Defibrillation Lead System. A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table IF-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD® Transvene™ System
Implant Distribution

	Total	U.S.	Int'l
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table IF-1: PCD® Transvene™ System - Implant Distributions - 2/1/93

The mean documented implant duration for this patient population is 11.7 months and ranged from implant to 37.4 months. The cumulative implant duration is 8894.8 months. There are 657 patients with implant durations equal to or greater than 6 months and 393 patients with implant durations equal to or greater than 1 year.

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table IF-2 provides a data summary on these patients. Also included is the data summary of the patients with 6 months and 12 months of follow-up.

PCD® Transvene™ System Data Summary	All Patients (3 Electrode Systems)	Patients with **6** months of Follow-up	Patients with **12** months of Follow-up

Table IF-2: PCD® System Data Summary - All Transvene™ Patients versus Transvene™ Patients with 6 mo Follow-up - 2/1/93

18

F.1 Implant Data

Implants of the PCD® Device may use two or three Transvene™ leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

Two terms were developed to accurately report defibrillation efficacy, Lowest Energy of Defibrillation (LED) and Defibrillation Threshold (DFT). They are defined as follows:

> Lowest Energy of Defibrillation (LED): The lowest programmed energy that successfully defibrillated the patient with the implanted lead system.
>
> Defibrillation Threshold (DFT): The lowest programmed energy which successfully defibrillated the heart provided there is a failure at an energy below the lowest success or a success at less than or equal to 5J.

Table IF-3 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD® Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD® Transvene™ System Mean LED and DFT Values				
Lead System	Implant Frequency	Mean LED	Implant Frequency	Mean DFT
All Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table IF-3: PCD® Transvene™ System - LED and DFT Values - 2/1/93

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD® Device.

F.2 Spontaneous VT and VF Episode Experience

A total of 458 patients (60.5%) have experienced a spontaneous ventricular tachyarrhythmia episode that has been detected and treated by the PCD® Device. A total of 141 (18.6%) experienced VT only, 142 patients (18.8%) experienced VF only and 175 patients (23.1%) experienced both an episode of VT and VF.

There have been a total of 12,009 episodes of spontaneous VT or VF as detected by the PCD®. The overall PCD® Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD® is presented in Table IF-4.

PCD® Transvene™ System Success Rate in Terminating Spontaneous VT/VF Episodes			
	Number of Episodes Successful	Total Number of Episodes	Efficacy Rate
VT	9864	10,027	98.4%
VF	1951	1982	98.4%
Total	11,815	12,009	98.4%

Table IF-4: PCD® Transvene™ System - Success Rate for Spontaneous VT/VF Episodes - 2/1/93

F.2.1 Spontaneous VT

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 10,027 spontaneous episodes of VT have been detected by the PCD® Device in 316 patients. The mean number of episodes per patient with VT was 31.7 and ranged from 1 - 531 episodes.

Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Of the 9864 successfully terminated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® Transvene™ System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Sixty patients experienced 163 (1.6%) episodes in which

the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirty-nine patients experienced 95 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 68 episodes occurred in 21 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

F.2.2 Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 1982 spontaneous episodes of VF have been detected by the PCD® Device in 317 patients. The mean number of episodes per patient was 4.3 and ranged from 1 - 77 episodes. A review of the chart per investigator for this patient that experienced the 77 episodes of VF revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (89.1%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 98.4% were successfully treated with one of the four programmable VF therapies.

Sixteen patients experienced 31 episodes (1.3%) in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Nine patients had 22 reported ineffective VF spontaneous episodes that were due to sinus

tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Four patients experienced 5 ineffective episodes that were detected as VF by the PCD® System. One of these patients (b)(6) required external defibrillation to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Another patient (b)(6) had an episode recorded as ineffective on the event counters but presented in sinus rhythm. Subsequent evaluation demonstrated appropriate PCD® function. Another of these patients (b)(6) had two spontaneous episodes of VT that were detected as VF by the PCD® while in the hospital for progressive CHF. These episodes required external cardioversion. The patient requested the PCD® be turned OFF. Patients was alive at the last known follow-up. The last of these four patients (b)(6) experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on a monitor the patient developed VF. The PCD® delivered the programmed therapy which terminated the episode but the patients developed EMD, arrived at the ER comatose and died.

Four patients (one patient (b)(6) experienced 2 episodes due to AF but is described below again) experienced 4 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. One patient (b)(6) experienced an episode where all four therapies failed secondary to RV lead fracture. The patient had Twiddlers Syndrome. Reoperation was required. It appears that the inappropriate therapy was not due to VT/VF but due to noise. Another patient (b)(6) had a surgical procedure (CABG) where the CS lead dislodged post surgery. The episode that was detected was due to the lead dislodgement. The third patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The fourth patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

B

F.3 Overall Success Rate

Of the 757 patients who received a PCD® Transvene™ System, 597 patients (78.9% - 597/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. The performance of the PCD® Transvene™ System therapies have been thoroughly evaluated and been shown to be effective in detecting and terminating episodes of ventricular tachyarrhythmia.

There have been no reports of a patient death due to the PCD® Transvene™ System not detecting a spontaneous episode of VT or VF.

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of either VT or VF was 98.4% with a VT success rate of 98.4% and VF success rate of 98.4%. The incidence of unsuccessful termination of an apparent "true" episode of ventricular tachycardia despite delivery of all four therapies was 0.7% (68/10027). The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite delivery of all four therapies was 0.3% (5/1982).

The evaluation of spontaneous episode experience indicates that the PCD® Transvene™ System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

74

G. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, there have been a total of 176 complications reported in 147 patients and 214 observations reported in 180 patients in the PCD® Transvene™ System patient population. Thus, 19.4% (147/757) of the patients had reported a clinical event which was categorized as a complication and 23.8% (180/757) of the patients had reported a clinical event which was categorized as an observation. Table IG-1 summarizes how these events were reported with U.S versus International.

PCD® Transvene™ System
Reported Complications/Observations
U.S versus International

	# of Complications	# of Observations
U.S.	104	93
International	72	121
Total	176	214

Table IG-1: PCD® Transvene™ System Complications/Observations U.S. versus International - 2/1/93

Table IG-2 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System
Reported Complications/Observations
By Category

Category	Complications	Observations
Increased Defibrillation Requirements	9 (1.2%)	8 (1.1%)

Table IG-2: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table IG-3 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD® Transvene System
Reported Complications/Observations
Lead Dislodgements <30 days and >30 days

Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=741	14 (1.9%)	10 (1.3%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 261	12 (4.6%)	10 (3.8%)	2 (0.8%)	2 (0.8%)
SVC Lead Dislodgement n=535	16 (3.0%)	29 (5.4%)	1 (0.2%)	6 (1.1%)
Total Dislodgement n=757	42 (5.6%)	49 (6.5%)	3 (0.4%)	9 (1.2%)

Table IG-3: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 49 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 49 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

H. Inactive Patients

There are a total of 82 patients who had received a PCD® System and are no longer active in the study as of 2/1/93. Table IH-1 shows the distribution of inactive patients by reason for no longer being active in the PCD® Transvene™ System clinical study.

PCD® Transvene™ System Inactive Patients	
Reason for Inactivity	**# of Patients**
Patient Deaths	51
Infection (Explant)	22
Heart Transplant	9
Total	82

Table IH-1: Inactive Patients - 2/1/93

I. Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD® Transvene™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac: Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.

Cardiac: Deaths that occurred where the primary cause of death was determined to be cardiac in nature.

Non-Sudden: Deaths that occur greater than one hour after the onset of symptoms.

Sudden: Deaths that occur within one hour of the onset of symptoms or where the death is

unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**

Perioperative: Deaths that occur within thirty days of implant.

System Related: A death which results from a malfunction (operation not according to design specification) of a PCD® System component, or as a result of a device induced arrhythmia, or an interaction between a PCD® System component and the patient.

Procedure Related: A death which occurs as a result of a procedure required to implant, follow or test a PCD® System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD® Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD® System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 51 patient deaths reported in the PCD® Transvene™ System patient population. Table II-1 summarizes how these patient deaths have been classified.

PCD® Transvene™ System
Summary of Death Classifications
(n = 757)

Classifications	Number of Deaths
Sudden Cardiac	5
Non-Sudden Cardiac	30
Noncardiac	16
Total	51

Table II-1: PCD® Transvene™ System - Summary of Death Classifications - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD® Transvene™ System.

Actuarial survival analysis on the PCD® Transvene™ System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD® Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD® Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table II-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD® System with Epicardial leads (5.3% - 39/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD® Transvene™ System (n = 757) and all patients that were screened for a PCD® Transvene™ System (n = 854) regardless of implant outcome.

PCD® Transvene™ System One Year Actuarial Survival		
	Received PCD® Transvene™ System	**Screened for a PCD® Transvene™ System**
Sudden Cardiac Death	99.5%	99.4%
Non-Sudden Cardiac	96.2%	96.6%
All Cardiac	95.8%	96.1%
Noncardiac	98.1%	98.3%
Perioperative	0.7%	1.6%
Overall	93.3%	92.9%

Table II-2: PCD® Transvene™ System - One Year Actuarial Survival - 2/1/93

380

The positive impact of the PCD® Transvene™ System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.5% for those in the patient group that received a Transvene™ System and 99.4% for those who were screened for a Transvene™ System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

J. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD® Transvene™ System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD® Transvene™ System in these three groups are summarized in Table IJ-1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 98.4%, in the VT patient group 98.3%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD® Transvene™ System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 98.6%

This analysis indicates that the PCD® Transvene™ System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

PCD® Transvene™ System

Table IJ-1: PCD® Transvene™ System Data Summary by Primary Indication - 2/1/93

K. Patients Not Meeting Implant Criteria

K.1 Overview

The PCD® Transvene™ System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD® Transvene™ System decreases the potential perioperative and long term mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who can not tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality following a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, a transvenous ICD System is the only therapy available. The PCD® Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, more options for future therapy remain available; e.g. CABG is associated with increased morbidity and mortality if there has been prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In an epicardial lead system, the lead system has a larger

electrode surface area theoretically decreasing defibrillation requirements.

The smaller electrode surface areas of the PCD® Transvene™ System defibrillation leads might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that 70% of patients evaluated may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not required.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

A total of 854 patients had an evaluation of a PCD® Transvene™ System and are divided into the following groups - (1) Patients who received a PCD® Transvene™ System; and (2) Patients screened for a PCD® Transvene™ System and received a PCD® Epicardial System. Figure 1 provides an overview of the outcome of these patients.

(b)(4)

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD® Transvene™ System ultimately received the system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD® Transvene™ System. It should be noted that 97.4% of the patients (737/757) received the PCD® Transvene™ System with at least a 10 Joule defibrillation safety margin between the lowest energy of success (24J) and the maximum output (34J) of the PCD® Device.

The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup P., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321. Finally, and perhaps most importantly, the investigators also felt that for these patients the risk associated with not meeting the recommended implant criteria was outweighed by the risk of not implanting an ICD or implanting an epicardial system.

There were twenty patients (2.6%), who received a PCD® Transvene™ System, whose cardiovascular condition precluded further completion of the PCD® Transvene™ System and adequate definition of a defibrillation safety margin. In all cases, the physician felt that the benefit of the PCD® Transvene™ System outweighed the risk of further inductions or the risk of a thoracotomy and elected not to evaluate or implant a PCD® Epicardial System.

K.2 Patients Receiving PCD® Transvene™ System & Did Not Meet Implant Criteria

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration at an output energy of 18 Joules or less. Of the 757 patients who **received** a PCD® Transvene™ System, 214 patients (28.3%) did not meet the recommended defibrillation implant criteria and yet still received the PCD® Transvene™ System. The physicians justification for implanting the PCD® Transvene™ System despite not meeting the recommended defibrillation implant criteria are presented in Table IK-1.

PCD® Transvene™ System
Reasons for Not Meeting Implant Criteria
Physician Justification

Reason	Number of Patients
Success at $\leq$ 24 Joules	170
Difficult/Unable to Induce VF	24
Patient Condition	20
Total	214

Table IK-1: PCD® Transvene™ System: Physician Justification for Not Meeting Implant Criteria - 2/1/93

Further analysis of the patient who did not meet the recommended implant criteria indicates however, that 91% (194/214) had a 10 Joule safety margin between the lowest energy of successful defibrillation and the maximum output of the PCD Device (34J). Therefore, of the 757 patients who received a PCD® Transvene™ System, 97.4% (737/757) had at least a 10 Joule defibrillation safety with the implanted lead configuration.

There were 20 patients (2.6%) in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as

follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules and or equal to 34 Joules (**N = 11**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3**).

Table IK-2 provides a comparison of patient characteristics between patients who met the PCD® Transvene™ System implant criteria and those patients who did not meet the implant criteria but still received the PCD® Transvene™ System.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Patient Characteristics		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Follow-Up	12.3 months	10.1 months
Male*	422 (77.7%)	188 (87.9%)

* Statistically Significant ($p \leq 0.05$)

Table IK-2: PCD® Transvene™ System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 2/1/93

Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with coronary disease with concomitant life threatening

ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD® Transvene™ System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD® Transvene™ System.

Implant data obtained in these two patient groups is presented in Table IK-3. As would be expected the patients not meeting the implant criteria had higher mean DFT and LED values when compared to the patients who did meet the implant criteria. However, the mean DFT (18.8J) and LED (19.5J) values obtained in patients not meeting implant criteria provided at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD® Device (34J) in nearly all (97.4%) of the patients.

91

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table IK-4.

PCD® Transvene™ System
Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria

Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Spontaneous VT Episode Efficacy	98.7%	97.6%
Spontaneous VF Episode Efficacy	98.2%	99.0%

One Year Survival		
Sudden Cardiac	99.5%	99.5%
Non-Sudden Cardiac	95.8%	97.2%
All Cardiac	95.4%	96.7%
Noncardiac	98.5%	97.1%
Overall	93.2%	93.5%

Table IK-4: PCD® Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 2/1/93

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD® Device therapies failed to terminate the episode.

Five patients experienced 7 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Three patients had 5 reported ineffective VF

spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Two patients experienced 2 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. The first patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The second patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

Eighteen patients experienced 68 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Nine patients experienced 44 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 24 episodes occurred in 8 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (10.1 vs 12.3 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Finally, the survival of patients receiving a PCD® Transvene™ System without meeting implant criteria

(N = 214) was compared to patients receiving a PCD® Epicardial System without meeting implant criteria (N = 92). This comparison is provided in Table IK-5.

PCD® Transvene™ System Patients Not Meeting Implant Criteria Survival Analysis versus PCD Epicardial System Patients Not Meeting Implant Criteria Survival Analysis		
	PCD Transvene System Not Meeting Implant Criteria	PCD Epicardial System Not Meeting Implant Criteria
Number of Patients	214/757 (28.5%)	92/742 (12.4%)
Number of Deaths	14	17
Sudden Cardiac	99.5%	98.6%
Non-Sudden Cardiac	97.2%	98.8%
Noncardiac	97.1%	97.3%
Overall*	93.5%	87.6%

* Statistically Significant ($p \leq 0.05$)

Table IK-5: PCD® Transvene™ System: Patients Not Meeting Implant Criteria - PCD Transvene System vs PCD® Epicardial System - 2/1/93

Though the PCD® Transvene™ System had a higher incidence of patients not meeting implant criteria (28.5%) compared to the PCD® Epicardial System (12.4%), there was no statistical difference in the sudden cardiac death patient survival. However, the overall survival of patients not meeting implant criteria with the Transvene™ System was significantly better ($p = 0.037$) when compared to the PCD® Epicardial System patients not meeting implant criteria, 93.5% and 87.6%, respectively.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate demonstration of device effectiveness and justified the implant of the PCD Transvene System. Finally, there have been no patients deaths secondary to unsuccessful termination of a spontaneous VT or VF episode in this patient population.

94

K.3 Description of Patients Not Meeting Implant Criteria

As noted previously, the patients not meeting implant criteria (N=214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules [79.4% of the patients]; (2) Difficult to induce VF [11.2% of the patients]; and (3) Implant procedure terminated due to poor patient condition [9.4% of the patients]. These patient groups are reviewed in the following discussion.

Lowest Energy of Defibrillation < 24 Joules

There were 170 patients in whom the PCD® Transvene™ System was implanted with a defibrillation safety margin of at least 10 Joules. Table IK-6 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD® Transvene™ System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD® Transvene™ System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System. In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, however, is limited to an average of 9.7 months.

PCD® Transvene™ System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation **1 Success with 10J Safety Margin** **2 Success with 10J Safety Margin** **3 Success with 10J Safety Margin** **> 3 Success with 10J Safety Margin**	 87 58 18 7
Overall Spontaneous VF Episode Efficacy	99.4%
One Year Survival: **Sudden Cardiac** **Overall**	 99.4% 93.8%

Table IK-6: PCD® Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at ≤ 24 Joules Clinical Experience - 2/1/93

Difficult to Induce VF

There were 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of the these patients (33.0%) were on (b)(4) (b)(4) therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of

implant, 13 patients (54.2%) have experienced a spontaneous VF episode and 21 patients (87.5%) have had VT or VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD® Transvene™ System.

There has been one reported patient death (b)(6) in this patient group. Since this patient died after one year, the one year sudden cardiac death and overall actuarial survival remains 100%.

Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these 20 patients, VT or VF has been induced at a

chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD® Transvene™ System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, examination of events indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

Conclusion

In conclusion, 214 patients received the PCD® Transvene™ System despite not meeting the recommended implant criteria. These 214 patients are divided into the following groups:

- successful defibrillation of VF at 24 Joules or less (170/214),
- difficult to induce at least three episodes of VF at implant (24/214), and
- worsening patient condition which prevented further inductions (20/214).

98

It should be noted that 91 % (194/214) of the patients not meeting the recommended implant criteria had at least one successful termination of induced ventricular tachyarrhythmia (VT, VFlutter or VF) at 24 Joules or less.

L. Comparison to AICD System Experience

L.1 Overview

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD® Transvene™ System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD® Transvene™ System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD® Transvene™ System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

L.2 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD® Transvene™ System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table IL-1. There were no differences between the two patient groups.

PCD® Transvene™ System
Comparison of Patient Characteristics
PCD® versus AICD

	PCD®	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table IL-1: Comparison of Patient Characteristics, PCD® versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD® Transvene™ System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD® Transvene™ population than in the AICD population ($p = 0.001$).

400

L.3 Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD® Transvene™ System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD® device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead

system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD® Transvene™ System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD® Transvene™ System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD® device provides information on the total number of VT and VF episodes detected by the PCD® device and the total number of VT and VF episodes successfully treated by the PCD® device as well as the number of VT/VF episodes where the PCD® device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD® device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD® Transvene™ System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD® Transvene™ System detection criteria.

A total of 10027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD® device

02

episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

Table IL-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD® Transvene™ System includes **both complications and observations.** In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD® Transvene™ System
Comparison of Complication/Observation Rates
PCD® versus AICD

Category	PCD®%	AICD%
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection (explant)	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table IL-2: Comparison of Complication/Observation Rates: PCD® Transvene™ System vs AICD Epicardial System - 2/1/93

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD® Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in

the PCD® Transvene™ System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD® Transvene™ System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD® device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 3.2% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD® Transvene™ System offers clinical advantages in reducing the need for a

04

thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing.

L.4 Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD® Transvene™ System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 51 deaths (6.7%) were reported in the PCD® Transvene™ System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD® Transvene™ System population had a lower perioperative mortality, 0.7% vs 2.7% ($p = 0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD® Transvene™ System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, seven patient deaths were **censored** in the

PCD® Transvene™ System patient population because the devices were deactivated at the time of patient death.

This PCD® Transvene™ System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD® Transvene™ System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD® Transvene™ System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD® System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD® Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

M. Comparison to PCD® Epicardial System Clinical Results

The PCD® Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD® Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the

type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD® Transvene™ System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD® Epicardial System and PCD® Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD® device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD® Transvene™ System clinical experience to the reported PCD® Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

M.1 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the PCD® Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table IM-1 contains the characteristics of the 757 patients receiving the PCD® Transvene™ System versus the characteristics of the 742 patients who received the PCD® Epicardial System as of 1/5/93.

PCD® Transvene™ System Comparison of Patient Characteristics		
	PCD® Transvene System	**PCD® Epicardial System**
Number of Patients	757	742
Mean Follow-Up Time	11.7 months	16.3 months
% Males*	610 80.6%	637 85.8%
% Females	147 19.4%	105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication*		
SCD	281 37.1%	214 28.8%
VT	377 49.8%	405 54.6%
SCD/VT	99 13.2%	123 16.6%
Cardiovascular History		
Coronary Artery Disease	561 74.1%	569 76.7%
Cardiomyopathy	238 13.1%	222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* **Statistically Significant**

Table IM-1: Comparison of Patient Characteristics, PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34.0% for the PCD® Epicardial patient group.

Analysis indicated that the PCD® Transvene™ System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that these differences will result in a different clinical outcome in the PCD® Transvene™ System patient population as compared to the PCD® Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD® Transvene™ System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested

68

between the two patient groups (p = 0.001). The PCD® Transvene™ System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD® Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD® Transvene™ System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but were non-inducible during electrophysiologic testing so that drug testing was not feasible.

M.2 Implant Data Comparison

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and were:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. At least a 2:1 VF sensing safety margin

Pace/Sense Performance

In both the PCD® Transvene™ and PCD® Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:	$\leq$ 1.5V @ 0.5 ms
R-Wave Amplitude:	$\geq$ 5 mV
Slew Rate:	$\geq$ 0.75 volt/sec
Resistance:	200 - 880 ohms

Table IM-2 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD® Transvene™ and Epicardial Systems. It should be noted

that the pace/sense values presented for the PCD® Epicardial System are for the Model 7217B PCD® Device.

PCD® Transvene™ System Performance Comparison Implant Pace/Sense Parameters		
Parameter	**PCD® Transvene System**	**PCD® Epicardial System**
Pacing Threshold*	0.87 V (0.1-3.6V)	0.98 V (0.2-5.3 V)
R Wave Amplitude*	14.2 mV (1.3-32 mV)	13.5 mV (2.2-37.2 mV)
Slew Rate*	1.66 v/S (0.25-9.8 v/S)	1.38 v/S (0.15-7.2 v/S)
Resistance*	575 ohms (264-1381 ohms)	438 ohms (157-1206)

* **Statistically Significant**

Table IM-2: PCD® Transvene™ System: Comparison of Implant Pace/Sense Parameters - 2/1/93

The implant pace/sense parameters obtained for the PCD® Transvene™ System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). This is anticipated because endocardial pace/sense parameters are better than epicardial values for bradycardia pacing electrode systems. This difference has no clinical impact on the pacing and sensing performance of the PCD® Transvene™ System.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is presented in Table IM-3. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

4D

PCD® Transvene™ System Performance Comparison Chronic Pace/Sense Parameters		
Parameter	**PCD® Transvene System**	**PCD® Epicardial System**
Electrogram Amplitude	10.0 mV (0.5 - 25 mV)	9.5 mV (0.5 - 40 mV)
Pulse Width Threshold	0.24 ms (0.03-1.59 ms)	0.24 ms (0.03-1.59 ms)

Table IM-3: PCD® Transvene™ System: Comparison of Chronic Pace/Sense Parameters - 2/1/93

The incidence of loss of capture requiring lead system modification in the PCD® Transvene™ System was 0.8% while the incidence in the PCD® Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD® Transvene™ System while the incidence in the PCD® Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense data performance indicates that the performance of the PCD® Transvene™ System is similar to that reported with the PCD® Epicardial System. The PCD® Transvene™ System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table IM-4 provides a comparison of defibrillation thresholds determined at implant for the PCD® Transvene™ and PCD® Epicardial Systems.

PCD® Transvene™ System Performance Comparison Implant Defibrillation Thresholds	
System	**Mean DFT**
PCD® Transvene™ System*	14.8J
PCD® Epicardial System	9.8J

* **Statistically Significant ($p \leq 0.05$)**

Table IM-4: PCD® Transvene™ System: Comparison of Implant DFT - 2/1/93

The PCD® Transvene™ System did have a significantly higher mean implant defibrillation threshold ($p = 0.0001$). It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

The programmed defibrillation pathways for the two patient populations is presented in Table IM-5. The implanted PCD® Transvene™ Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD® Transvene™ System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD® Transvene™ System implant criteria. Most of the PCD® Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

12

PCD® Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD® Transvene System**	**PCD® Epicardial System**
Sequential	574 (75.3%)	251 (33.0%)
Simultaneous	178 (23.4%)	14 (1.8%)
Single	10 (1.3%)	496 (65.2%)

Table IM-5: PCD® Transvene™ System: Comparison of Programmed Defibrillation Pathway - 2/1/93

The differences in the programmed status of the PCD® device in the PCD® Transvene™ System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD® device performed safely and effectively in both patient populations.

M.3 Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD® Transvene™ System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table IM-6 provides a comparison of the efficacy of the PCD® Transvene™ and PCD® Epicardial System in treating spontaneous episodes of VT and VF.

13

PCD® Transvene™ System Performance Comparison		
Spontaneous VT Episodes		
	PCD® Transvene™ System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	10,027	20,061
% Overall Efficacy	98.4%	98.3%
% Unsuccessful Termination	0.7%	1.0%
Spontaneous VF Episodes		
	PCD® Transvene System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	1982	2636
% Overall Efficacy	98.4%	98.7%
% Unsuccessful Termination	0.3%	0.5%

Table IM-6: PCD® Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of VT or VF is 98.5%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD® Epicardial System which was 98.4%. Therefore, the PCD® Transvene™ System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

14

M.4 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD® Transvene™ System and the PCD® Epicardial System. The PCD® Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with 742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD® System. In the PCD® Transvene™ System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD® Epicardial System, 14.2% of the patients experienced a clinical complication and 32.9% of the patients experienced a clinical observation.

Table IM-7 and IM-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD® Transvene System
PCD® Transvene System versus PCD® Epicardial System Reported Complications

Reported Complications	PCD® Transvene™ System (N = 757)	PCD® Epicardial System (N = 742)
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	2.8%
Device Related	0.5%	0.9%

Table IM-7: Reported Complications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

PCD® Transvene™ System PCD® Transvene System versus PCD® Epicardial System Reported Observations		
Reported Observations	**PCD® Transvene™ System (N=757)**	**PCD® Epicardial System (N=742)**
Ineffective Therapy	1.1%	1.1%
Inappropriate Therapy	9.6%	13.6%
Pace/Sense Related	9.0%	14.0%
Infection Related	5.3%	2.5%
Lead Related	2.3%	1.2%
Device Related	-	-

Table IM-8: Reported Observations: PCD® Transvene System versus PCD® Epicardial System - 2/1/93

M.5 Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD® Transvene™ and Epicardial System was performed.

Table IM-9 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD® Transvene™ System patient population was 11.7 months while for the PCD® Epicardial System it was 16.3 months.

PCD® Transvene™ System Death Classifications PCD® Transvene™ System versus PCD® Epicardial System		
Death Classification	**PCD® Transvene™ System (N=757)**	**PCD® Epicardial System (N=742)**
Sudden Cardiac	5	24
Non-Sudden Cardiac	30	54
All Cardiac	35	78
Noncardiac	16	34
TOTAL	51	112

Table IM-9: Death Classifications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Table IM-10 provides a comparison of actuarial survival rates between the PCD® Transvene™ and PCD® Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD® System.

PCD® Transvene™ System Comparison of Actuarial Survival PCD® Transvene™ System versus PCD® Epicardial System			(b)(4)
One Year Survival	**PCD® Transvene™ System**	**PCD® Epicardial System**	
Number of Patients	757	742	(b)(4)
Sudden Cardiac	99.5%	98.9%	
Non-Sudden Cardiac	96.2%	96.7%	
All Cardiac	95.8%	95.7%	
Noncardiac	98.1%	98.0%	
Overall*	93.3%	88.6%	

* (b)(4) (b)(4)

Table IM-10: Comparison of Actuarial Survival: PCD® Transvene™ System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD® Transvene System™. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD® Transvene™ System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD® Epicardial System (88.6%) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD® Transvene™ System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD® Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

N. PCD® System Performance

N.1 PCD® Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection, therapy performance, and analysis of explanted devices were evaluated to assess the performance of the PCD® Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD® Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD® Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD® Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 58 devices explanted. Reasons

18

for explant were patient death (23), infection (22), cardiac transplant (9), low battery voltage (1) and PCD Device performance issues (3). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits and this affected the battery indicator circuit only and did not affect the critical functions of the device. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other three devices indicated that two were due to random component failure and one due to shorting on Pulse 2 output. Thus, arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

Based on the clinical data collected, the PCD® Device has performed safely and reliably in the indicated patient population.

N.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of conductor coil fracture is 0.5% (4/757).

Based on the clinical data collected, the Transvene™ leads

have performed safely and reliably.

O. Summary

The overall clinical experience with the PCD® Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD® Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD® Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD® Transvene™ System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD® Transvene™ System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD® Transvene™ System.

PCD® Transvene™ System Performance

- The PCD® Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

21

P. Clinical Experience Summary Conclusions

The PCD® Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The PCD® Transvene™ System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the perioperative and overall patient mortality as compared to the PCD® Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of 7.6 days as opposed to a mean of 10.6 days ($p = 0.001$) for the PCD® Epicardial System.

Medtronic asserts and the PCD® Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015/Amendment
Subject: Transvene Lead System
Date: June 3, 1993
Office: DCRND/ODE

The manufacturer submitted the referenced amendment to inform us of a case of "cosmetic" metal ion oxidation (MIO). The MIO was found on the Model 6884 (comparable to Model 6966) Transvene RV lead explanted from a patient who underwent a heart transplant.

According to the manufacturer, the presence of MIO on the middle insulation is not entirely unexpected. It was stated that if the middle insulation completely degrades (shorting the sensing ring), then an integrated bipolar sensing system would result (sensing would occur between the unipolar pacing tip and the common defibrillation electrode instead of true bipolar (sensing between the pace/sense tip and the ring electrodes). However, if the innermost insulation degrades and the pacing tip electrode is shorted, intermittent sensing could result. This type of behavior such as intermittent sensing, oversensing, undersensing, etc. could be detected at the follow-up intervals.

Consultation and the review of the issue in the referenced amendment, as well as previous IDE supplements, have taken place with (b)(6) Due to the failure of the Medtronic, Inc. brady leads which employ the platinum sputtering process as the Model 6966 and 6884 leads, she is very concerned. In past reviews, we have requested that the manufacturer institute long term testing to asses the MIO problem.

The monthly report of all observations and complications, as referenced in our letter regarding the IDE expansion, was requested. In addition, the following concerns were conveyed to the manufacturer:

1. The differences between the Model 6884 and the Model 6966 Transvene leads. (The Model 6884 (b)(4) connector size and the Model 6966 -(b)(4) connector size). The number of leads explanted to date and the MIO and environmental stress cracking (ESC) noted. (As of 150 explants, there was no evidence of MIO).

2. To date, how many patients have received the Transvene lead System? How many patients have been implanted for 2 years and greater? (at least 50) What is the compliance to follow-up of these patients. (Compliance to follow-up 98 to 99 percent). Update on clinical experience: lead related complications, first shock VT/VF efficacy, survival rates,

etc. Are there patients with a dilated RV counted in the group followed for 2 years or more? At what intervals were the complications noted?

3. A description of the expected failure mechanism of the leads. In the referenced case, evidence of MIO was noted at 2 years (MIO visible on the innermost insulation and the middle insulation). What is considered the life expectancy of the leads void of signs of MIO? What is the projected rate of progression. Are their studies to confirm these speculations?

4. Based upon the review of the requested data, the protocol and testing at follow-up might need to be modified to include the following: x-rays or fluoroscopy when there are recurring and/or suspect lead complications or observations and periodically at preset intervals.

5. Regarding the patient whose lead was explanted:

   a. When were the 6 spontaneous VT/VF shocks delivered? Was the system interrogated after explant? [This was the implant history].

   b. Was there more damage noted on the innermost or middle insulation?

   c. What were the lead impedance and threshold measurements?

   d. Explain how the patient's dilated RV contributed to the MIO noted.

The occurrence of MIO noted upon explant of the Model 6966 leads and its significance will be brought to the attention of the Panel.

The manufacturer agreed to provide answers to the above questions and additional supporting data in the Panel volumes.

Re: Transvene® Lead System, PMA Amendment
(Document Control Number P920015) Ac 2/1

The purpose of this submission is to provide a follow-up report detailing the analysis of an explanted Model 6884 right ventricular, transvenous lead, as described in the March 26, 1993 PMA amendment. The follow-up analysis is provided in Attachment 1. For reference, a copy of the relevant information provided on March 26 is also enclosed in this submission as Appendix A.

The existence of the PMA Amendment and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

Three copies of this PMA amendment are provided. Should additional information be required by the Agency, please contact the undersigned.

Sincerely yours,

MEDTRONIC, INC.

Attachment

4

ATTACHMENT 1

A Model 6884, screw-in, right ventricular, pace/sense, cardioversion/ defibrillation lead was returned to Medtronic 27 months post implant. The lead was returned to Medtronic following explant from a patient that was undergoing a heart/lung transplant. Note that the lead had been fully functional while implanted and was found to be fully functional upon explant.

Upon undergoing further analysis at Medtronic, some MIO (metal ion oxidation) was observed on the lumen of the middle insulation approximately 20 cm proximal of the pacing tip electrode, and on the outside of the inner insulation. The MIO was further characterized to be "cosmetic" in that it had not functionally affected the lead in any way. Cosmetic MIO is defined as any crack that has not breached the insulation.

Initial analysis indicated that the presence of the MIO was in the clavicular region of the body; i.e., the location, 20 cm proximal of the tip, would be in the first rib clavicle region of a small adult. There was no evidence, however, of conductor coil fracture and the lead was fully functional. Given the Model 6884 lead is generally implanted via subclavian vein insertion, this type of observation may occasionally be expected. However, subsequent analysis of the patient X-rays showed that the area of MIO was actually in the right ventricle. The patient's right ventricle was extremely dilated, secondary to pulmonary hypertension. Therefore, 20 cm from the proximal tip electrode located the area of MIO at the point of maximum curvature of the lead, in the right ventricle, rather than in the clavicular region.

Detailed Analysis Results

Visual/Microscopic

Shallow (cosmetic) environmental stress cracking (ESC) was visible. No coil deformation was visible in the first rib/clavicle region. Possible MIO was visible 20 cm proximal of the electrode tip extending approximately 0.5 cm on the middle insulation. Possible MIO was also visible on the innermost insulation starting at 19.3 cm proximal of the electrode tip and extending 5.4 cm proximally.

Scanning Electron Microscopy

MIO was observed on the lumen of the middle insulation and on the outside of the innermost insulation. The MIO penetration was less than five percent of the insulation wall thickness. In addition to the insulation, both the middle and inner coils were evaluated up to 2500 times magnification. There were no

anomalies apparent on the inside or outside of the middle coil in the region of the MIO. The innermost coil showed no signs of crush or fatigue in the region of the MIO.

FTIR-ATR

FTIR spectra were obtained for a control area (no MIO) of the inner tubing and the cracked area of the tubing. Relative ratios of key bonds were calculated using the absorption intensities. These ratios indicated that the ether segments were oxidized in the polyurethane, which is characteristic of MIO. In addition, peaks appeared, indicative of carboxylic acids or esters (oxidation byproducts).

Discussion

Contrary to the initial dimensional analysis of this lead that indicated the area of MIO was located to the clavicular region of implant, review of the patient's X-rays revealed that the heart was significantly enlarged due to the advanced disease state. Subsequently, a significant portion of the insulated lead body was located in the heart, including the portion with cosmetic MIO. Typically, 20 cm proximal of the tip electrode approximates the clavicular region.

Consistent with our previous analysis of MIO relative to the 6884/6966 lead, the observed MIO did not, in any way, affect the clinical performance of this lead. Patient data analysis shows that the implanted lead system, inclusive of the 6884 lead, performed appropriately. Of six spontaneous VT/VF episodes reported (4VT/2VF), all were appropriately detected and treated via the implanted PCD Transvene system.

In addition, the presence of MIO on the middle insulation is not entirely unexpected (reference February 18, 1993, Medtronic/FDA meeting). If the middle insulation had been degraded to the point of electrically shorting the sensing ring (middle conductor coil) to the common defibrillation electrode (middle coil), an integrated bipolar sensing system would, in essence, be created. In this type of system, sensing occurs between the unipolar pacing tip and the common defibrillation electrode, versus standard, or true, bipolar sensing between the pace/sense tip and the ring electrodes. This type of sensing system is identical to the (b)(4) (b)(4) as well as Medtronic's earlier design of a Transvene RV lead, i.e., the Model SP2100. These types of integrated systems have been shown to be clinically acceptable. Note that canine testing of a shorted, RV cardioversion/defibrillation lead, indicated that this type of failure does not result in the lack of therapy delivery.

If the innermost insulation had degraded such that the pacing tip electrode shorted, this could manifest as intermittent sensing of the brady pace/sense function of the lead. This type of anomalous system performance is expected to be observed at follow-up sessions, given the frequent monitoring of patients

(every three months) or as necessary when the patient experiences VT/VF episodes or anything unusual. Similar to brady pacing patients, problems related to pace/sense performance are typically observed at the time of follow-up (pace/sense threshold measurements are standard follow-up procedure for both brady and tachy lead systems) and/or when the patient reports to his/her physician for any unusual events, e.g., intermittent pacing/sensing.

The extensive dilatation of the right ventricle in which this lead was implanted resulted in a large portion of insulated lead body being in the right ventricle, as opposed to primarily just the cardioversion/defibrillation electrode coil. Subsequently, this lead may have been subject to more flexing in the heart than what is typical for the RV lead. Note: this was demonstrated in the videotape that was presented to FDA at the February 18, 1993, Medtronic/FDA meeting.

Clinical data from brady pacing leads indicates that the portion of the lead subject to the flexing motion in the heart may be related to the occurrence of MIO in brady lead bodies. Brady pacing leads, proximal to the tip/ring electrodes are subject to more flexing motion, relative to a cardioversion/defibrillation RV lead, while contained in the heart. On the other hand, cardioversion/defibrillation leads, like the 6884/6966, are comprised of a comparatively stiff portion proximal to the tip/ring electrode. This length of defibrillation electrode, 5 cm, appears to flex less than a typical brady pacing lead while in the heart, as a result of greater stiffness. However, in the extremely hypertrophic heart, as was the case with this particular RV lead, the lead may be subject to more flexing, similar to that of a brady pacing lead.

Conclusions

As noted, Medtronic cannot assure that MIO, or other lead failure mechanisms will not occur in the 6884/6966 lead. However, one should consider the actual benefits of the lead versus the **potential** for MIO occurrence. Specifically, clinical data to date for the Transvene system show that one year actuarial survival from SCD is 99.5 percent and the average hospital stay for Transvene implant is only seven days (versus ten for an epicardial system)*. Regarding the potential for MIO occurrence, analysis shows this would result in a bipolar integrated sensing system, or in an intermittent pace/sense system. Integrated sensing has been shown to be clinically acceptable, and intermittent pacing/sensing is assessed as part of standard follow-up procedures. Additionally, with postmarket surveillance mechanisms in place, such as returned product analysis and chronic lead monitoring, Medtronic is well positioned to appropriately evaluate and manage potential failure mechanisms of implantable cardiac leads. We are committed to these surveillance mechanisms in the interest of delivering optimal implantable technology products to the health care market.

*Values are lower than those reported February 1993 due to increased follow-up data.

APPENDIX A

(from March 26, 1993 PMA Amendment,
Response to deficiency #36)

36. **In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.**

RESPONSE:

Background on Brady Pacing Lead Experiences

Medtronic utilizes two systems to monitor performance of its brady pacing leads. The analysis of returned product is used to identify lead failure mechanisms. However, it cannot be used to estimate clinical performance since all leads/lead segments are not explanted or returned. Clinical performance is monitored through our Chronic Lead Study (CLS), a multi-center study currently involving eleven representative U.S. Clinical centers and over 20,000 leads. Lead performance in the CLS is presented as actuarial survival from clinical complications resulting in lead explants or abandonment. Specific complication criteria have been established (reference Medtronic Product Performance Report, February 1993, in Appendix C). Since all leads are not explanted it is not always possible to relate a clinical complication to a specific failure mechanism and not all complications are associated with lead failure.

The primary failure mechanisms for brady pacing leads are conductor fracture and insulation failure. Conductor fractures are primarily associated with the widely accepted "Subclavian Stick" implant procedure using percutaneous lead introducers. Leads implanted by this procedure can be clamped and crushed between the first rib and clavicle, leading to fracture of the conductor, and sometimes, insulation failures as well. Bipolar leads are more susceptible to this failure mechanism than unipolar leads because of their larger lead body diameter. Crush fractures tend to occur primarily during the first two years post implant.

For leads with polyurethane insulation, the primary insulation failure mechanisms are Environmental Stress Cracking (ESC) and Metal Ion

Oxidation (MIO); both tend to occur starting about 2 years post implant. Bipolar leads tend to be more susceptible to insulation failure than unipolar leads.

ESC is associated with stress on the lead either induced during manufacture or via implant procedure. Newer generation Medtronic leads have greater ESC resistance due to improvements in design, manufacturing processes and materials.

MIO is an oxidative degradation of polyurethane insulation. The reaction is catalyzed by metal ions released by the corrosion of the conductor coils. To reduce the potential for MIO, newer Medtronic lead designs have applied a sputtered coating of platinum to the conductor coils. Also, (b)(4) polyurethane tends to be more resistant to MIO than (b)(4) Medtronic has used an accelerated oxidation environment, (b)(4) to evaluate MIO and potential factors that can minimize its occurrence.

A table depicting the frequency of these failure mechanisms (conductor fractures, MIO and ESC) for brady leads, Models 4004/M and 4058/M, follows this response. As shown, conductor fracture due to crush is the predominate failure mode. See table, Failure Mechanisms, following this response.

The Model 4004/M is a bipolar lead incorporating (b)(4) polyurethane and platinum coating. As of February 28, 1993, survival probability of the Models 4004/4004M is 97.0 ± 1.7% at 36 months (reference the February 1993 Product Performance Report in Appendix C). Crush fracture is the primary source of lead failures to date, with rates comparable to that of earlier bipolar lead designs.

Over the past several months Medtronic and FDA have had numerous discussions about the occurrences of failure associated with MIO in the Model 4004/M lead. As of February 28, 1993, Returned Product Analyses has identified 22 MIO failures out of approximately 74,000 leads implanted (.030%). MIO failures in previous lead designs tend to predominate in 3 areas: proximally in the pacemaker pocket, medially in the clavicular region, and distally near the ring electrode. With Models 4004/M, platinum sputter coating appears to reduce the occurrence of MIO proximally and medially. The majority of the MIO failures (20 of 22) occurred distally. Distal failure occurs between the ring electrode and the AV valve and appear to be related to flexing of the lead associated with ventricular contractions.

Initial (b)(4) testing was conducted under static conditions and gave no indication of this failure mechanism. Currently testing is underway to develop a dynamic (b)(4) test to study factors affecting this

18

failure mechanism and potential corrective actions. To date, we have been able to induce failures and are conducting experiments to understand contributing factors.

In order to illustrate the similarities and differences between the brady and tachy leads, a side-by-side comparison of the Model 6966 to the 4,000 series brady leads is presented in a table following this response. Note that only bipolar, polyurethane, brady leads from the 4,000 series are presented (includes Models 4016A, 4058/M, 4024, 4004/M and 4012/4082). This is due to their similarity of design characteristics to the 6966, and also because these brady leads are being, or were, widely used in the field, and therefore present with comprehensive data from the Chronic Lead Study and Medtronic's returned product analysis. Tests performed to qualify the brady leads were the same as those used for the tachy leads (except for high voltage system and crush testing). All tests are consistent with Medtronic standards and requirements for implantable cardiac leads (reference response to #34). Drawings of these brady leads are also presented following the comparative tables.

Some common features to all the leads in the table are the (b)(4) conductor coil, coaxial coil design, polyurethane insulation (b)(4) and/or (b)(4) and platinum alloy electrode material. Like the 6966 lead, the Models 4016A, 4058/M and 4024 also have platinum coating on the conductor coil and (b)(4) as the inner insulation. Individual lead differences include the electrode fixation mechanisms, i.e., screw-in helix versus tines and the (b)(4) versus (b)(4) insulation usage. Using (b)(4) insulation provides more stiffness, and greater resistance to insulation failure, whereas (b)(4) provides for greater ease of handling.

As presented in the lead comparison table, the brady lead most similar to the 6966 lead is the 4016A. Both have (b)(4) polyurethane as the inner(most) insulation, (b)(4) for the middle/outer insulations, distal screw-in fixation mechanisms, similar French (introduction) sizes and virtually identical insulation dimensions. Only the coil dimensions vary slightly. Note that the 4058/M lead is also very similar to the 4016A; the only substantive change is the introduction size, (b)(4) Model 4016A and 4058/M leads have shown excellent clinical performance; for the 4016A actuarial survival is 98.2% at three years (3,800 implants) and for the 4058/M actuarial survival is 99.7% at three years (37,000 implants), reference the CLS and returned product analysis as presented in the Medtronic Product Performance Report, Appendix C.

As previously presented, the 6966 lead has a larger body diameter than the brady leads. This is to be expected given the tripolar coaxial design of the lead. Given the larger French size of the 6966, it is more susceptible to crush between the clavicle and rib than the smaller French

leads. Lead fracture due to crush in this area is, however, a recognized failure mechanism for all transvenous leads implanted via subclavian insertion, (brady or tachy leads). This is vigorously addressed in product labeling (lead technical manuals) and includes appropriate cautions about the use of the procedure.

Also, the larger diameter of the 6966 lead body and presence of a defibrillation coil electrode proximal to the distal pace/sense ring of the 6966 lead imparts more stiffness to it than the brady leads. Hence, there is less lead body movement below the valve when the 6966 is implanted in the right ventricle as compared to a brady lead. This was clearly evident in the videotape comparing the in-vivo flexing of both a brady and tachy lead (presented in FDA/Medtronic meeting of February 18, 1993). Decreased flexing of the 6966 lead below the valve is our basis for expecting flex-related MIO will not be a significant failure mechanism of the 6966 lead.

Analysis of Transvene Model 6966 Lead and Clinical Presentation

The Model 6966 tripolar tachy lead is comparatively less flexible than brady leads. Therefore, distal MIO as evident in a very small percent (.030%) of brady 4004/4004M leads is not necessarily indicative of a similar occurrence in the 6966 lead. A videotape illustrating the clinical flex performance differences between brady and tachy leads was presented during the FDA/Medtronic meeting on February 18.

Analysis of the Model 6966 lead, as it relates to the potential for MIO, indicates that it would be more likely to occur on the middle versus the outer or innermost insulations. Lead failure due to MIO typically is found on the inner insulation on returned bipolar brady leads. Therefore, this failure mechanism is not expected to significantly affect the (b)(4) outer insulation of the 6966 lead. Should MIO occur on the outer insulation of the 6966 lead, the net effect would be an increased defibrillation electrode surface area. This would not be expected to significantly affect system performance. Additionally, the more resistant properties of (b)(4) (to MIO), of the 6966 innermost insulation, are expected to further reduce the potential for MIO (99.7% survival Model 4058/M at three years, see Product Performance Report, Appendix C).

For the Model 6966 lead, should the middle, (b)(4) insulation fail, it would likely present initially as an intermittent short (as is more typical with brady leads) and can progress over time if not identified and treated, to a hard (direct) short. These could manifest initially as oversensing, and ultimately as integrated bipolar sensing, respectively (intermittent versus hard short). In the case of a hard short of the middle insulation, specifically, shorting the pacing tip to the common

defibrillation electrode, an integrated bipolar sensing system is created. In this type of system, sensing occurs between the unipolar pacing tip and the common defibrillation electrode (versus standard bipolar sensing between the pace/sense tip and the ring electrodes). This type of sensing system is identical to the (b)(4) (b)(4) currently in clinical trials, and also to Medtronic's historic Transvene RV lead, the Model SP2100 lead. These type of integrated systems have been shown to be clinically acceptable. Note that fifteen Model SP2100 leads were implanted at the start of the Transvene clinical study. There have been no observations or reported problems related to the SP2100 lead performance. (Data from the SP2100 lead have been incorporated in the clinical experience analysis reported in this PMA application.)

Intermittent sensing could result in oversensing, if the detection criteria are also met, and this could result in delivery of inappropriate, i.e., not needed, therapies. This can be considered a "safe failure" given the system would "err" by oversensing (versus undersensing) and the patient could receive an unnecessary therapy. Also, patients are instructed to report therapies to their physicians; this facilitates identification of any inappropriate therapy.

Recently, a Model 6884[1] lead was explanted after 27 months when the patient received a heart transplant. The lead was fully functional at explant, however, returned product analysis has indicated the presence of some MIO in the clavicular region. Transvene leads, like brady leads, are implanted by subclavian insertion and are susceptible to being crushed between the clavicle and first rib. As indicated above, with brady leads this can result in conductor fractures, insulation failures or both. Analysis of the specific Model 6884 lead is ongoing and a more detailed report will be provided in approximately 30 days.

It should be noted that MIO is only one potential failure mechanism of implantable leads. As discussed, others include fracture due to crush in the area of subclavian insertion, environmental stress cracking due to stresses the in-vivo environment may impart to the lead and lead dislodgement.

---

[1] The Model 6884 lead is the earlier version of the Model 6966 lead and differs only in the connector pin configuration; the 6884 has a (b)(4) high voltage connector pin and the 6966 has a (b)(4) high voltage connector pin. Otherwise the leads are the same.

Transvene Clinical Assessment Experience

Given over 2000 worldwide Transvene patients implanted to date, ranging from zero to forty months implant duration, there have been no reports of undersensing, insulation failures, or oversensing that could not be managed via reprogramming. Furthermore, the benefits of Transvene implantation are dramatically apparent from the perspective of perioperative mortality, 0.7 percent for Transvene versus 5.3 percent for epicardial implants. Transvene survival from SCD is 99.5 percent and overall survival is 93.3 percent at one year. Additionally, Transvene implants, on average, require 8 days in hospital versus 11 days for an epicardial system; a significant cost savings. In summary, the benefits of the Transvene system performance clearly surpass the potential for MIO, or other potential failure mechanisms, in the 6966 lead.

Conclusions

Although Medtronic cannot assure that MIO or other lead failure mechanisms will not occur in the Model 6966 lead, the actual benefits of the Transvene system, as previously discussed, would appear to exceed the potential risk due to MIO. Analysis shows that the potential for MIO to occur in the 6966 lead would result in a "safe failure." Note that preclinical and animal testing cannot completely simulate the long-term implant environment, thereby eliminating all potential for lead failures in-vivo. This was recognized by Congress in implementing the Postmarket surveillance provision in the Safe Medical Device Act of 1990. It is clear that postmarket surveillance mechanisms, e.g., returned product analysis and chronic lead monitoring, are more appropriate mechanisms for evaluating and managing potential failure mechanisms of implantable cardiac leads.

Memorandum

Date October 29, 1993

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistics Branch, Division of Biometric Sciences, OSB

Subject Statistical Review of PMA P920015 Panel Package, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To

Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices, ODE
Through: Director, Division of Biometric Sciences, OSB
Through: Chief, Statistics Branch, DBS, OSB

In my July 9, 1993 memo to you, I asked for the numerators and denominators used for the percent success (Table I-1, page 233, Table 1F-2, page 287 and Table 1F-4, page 290, PMA Amendment, March 26, 1993) for the treatment of spontaneous episodes. After thorough investigation, I have the following results:

Spontaneous VT % success 98.4% of Table I-1, p. 233 can be obtained from Table 8-1, p. 110, June 11, 1993. (9864/10027 = 98.4%)

Spontaneous VF % success 98.4% of Table I-1, p. 233 can be obtained from Table ID2-6, p.98, June 11, 1993. (1951/1982 = 98.4%)

Spontaneous VT % success 99.0% after 12 months of follow-up of Table 1F-2, p. 287 can be obtained from Table ID3-1, p.78, Vol. 2, June 11, 1993. (6273/6338 = 99.0%)

Spontaneous VF % success 98.6% after 12 months of follow-up of Table IF-2, p. 287 can be obtained from ID3-1, p. 78, Vol. 2, June 11, 1993. (1090/1105 = 98.6%)

I couldn't locate the section or table to address 6 months of follow-up for spontaneous VT and VF % success.

Table IF-4, p. 290, March 26, 1993 agrees with the table in the June 11, 1993 panel package.

If you have any questions concerning this memorandum, please contact me at 594-0627.

MEMORANDUM TO THE RECORD

From: R. Subramanian, M.D., DCRND

Subj: Addendum to review of death summaries, Medtronic Transvene Lead - P920015

Date: October 1, 1993

::

The death summaries were rereviewed to determine if the infections noted:
a) were related to the device, and to
b) obtain further details regarding time and sites of infection.
This rereview does not include "pocket infections" which have been listed separately in the submission and have been addressed previously (see memo from Dr. J. Jones).

1. A total of 68 deaths were reported in the PCD Transvene System population of 1330.

2. Eleven (11) of these patients had clinical evidence of (or were clinically suspected to have had) infections as follows:

#	Patient #	Infection	Autopsy
1.	(b)(6)		
2.			
3.			
4.			
5.			
6.			
7.			
8.			
9.			
10.			
11.			

(b)(6)

NA = Not available

Conclusion: Although the information provided in the death summaries is limited, there does not appear to be any evidence of device related infection causing death in this group of patients.

CC Ms. Doris Terry, reviewer, DCRND

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Medtronic® Transvene® Lead System
Date: August 16, 1993
Office: DCRND/ODE

On August 2, 1993, the Circulatory System Devices Panel reviewed the PMA application for the Medtronic® Transvene® Lead System. Specific questions and labeling concerns generated from FDA's review of the PMA application are included in my memoranda of July 9, 1993 (FDA review and panel presentation).

The panel addressed all FDA's questions, and concurred with the labeling recommendations.

The panel recommended approval of the Medtronic® Transvene® PMA with modifications to the labeling. A list of FDA's and the panel's recommendations are listed below.

FDA's and the Panel's Recommendations

The labeling should be modified to include the following:

- diagrams which show proper insertion of the endocardial leads and how the patch lead should be applied to the subcutaneous tissue;
- a caution statement that the patch lead is not for use on the pericardium or epicardium;
- efficacy data of the different lead configurations via the different pathways;
- pictures or diagrams of the various electrode configurations which serve as a guide for selection;
- information and/or recommendations about implanting the leads and testing the different configurations. For example, when to use a two-lead versus a three-lead configuration and when to implant in the superior vena cava (SVC) versus the coronary sinus CS);
- information or recommendations regarding implanting in patients who do not have the 10 Joule safety margin;
- information about how the incidence of infection can be reduced;
- a reference about using 5-minute intervals between ventricular fibrillation (VF) inductions during testing;

- stronger language regarding the use of dual anchoring sleeves on the right ventricle (RV), SVC and CS leads;

- information which states that a thoracotomy after extensive testing with a nonthoracotomy lead system should be delayed at least 2 days (the clinical data showed that when a thoracotomy was performed immediately after testing, the perioperative mortality rate was increased from 0.7 to 9.3 percent);

- guidance regarding separating pacemaker leads from the Transvene leads;

- a statement which emphasizes the need for x-rays and pace/sense threshold testing at follow-up to check for lead dislodgement;

- information regarding placing the leads via the cephalic vein when possible; and

- an explanation regarding the necessity for explant and return of the leads upon the patient's death.

In addition the manufacturer should note the following:

- The indications and contraindications for use of the Medtronic® Transvene® Lead System should be the same (with certain modifications) as those for the PCD™ Epicardial System.

- The technical manuals for the Transvene® Leads should state that the leads are for use together as a system. The labeling (where appropriate) should be consistent in all of the Transvene® Lead manuals. The information regarding the Transvene® Leads in the PCD™ Manual should also be included in the Transvene® Lead manuals.

- There should be an identifying mark on the package label which distinguishes nonthoracotomy leads from thoracotomy leads.

- The Warnings and Precautions in the labeling should be identified and reported separately according to FDA's Blue Book Memorandum of March 8, 1991 (a copy of this memorandum was previously sent to you).

- Postmarket surveillance will track the explanted leads for evidence of metal ion oxidation (MIO).

The manufacturer should provide a copy of the Patient's Manual which includes a reference to use of the nonthoracotomy leads with the PCD™ models.

Recommendation

The above information will be included in an approvable letter to the manufacturer.

MEMORANDUM

From: Doris Terry (HFZ-450)
To: File # P920015
Subject: Review - Transvene PMA
Date: July 9, 1993
Office: DCRND/ODE

Description of the System

The PCD Transvene System consists of the Model 7217B PCD pulse generator, programmer, external accessories and leads (Model 6966 RV lead, Model 6966 CS/SVC lead and the Model 6999 patch lead, see description of leads and summary of testing in attached memo and in Volume 3, Section A, Bench Testing). The leads may be implanted in 3 configurations: RV/CS/SQ, RV/SVC/SQ and RV/CS/SVC via a single, simultaneous or sequential pathway.

Study Design and Objectives

The PCD Transvene System was designed to evaluate the safety and effectiveness of the Model 7217B PCD and Transvene leads. The objectives of the study include the following: (1) evaluating and monitoring the system in the detection and treatment of VT and VF; and (2) estimating the survival from sudden cardiac death and overall survival.

The manufacturer used two controls: the Model 7217B PCD Epicardial Lead System as a concurrent control and the Ventak P AICD Epicardial Lead System as a historical control.

The manufacturer believed that a study which employed randomization of a nonthoracotomy lead system and a thoracotomy lead system was not clinically or ethically appropriate.

Patient Population

The total patient population (patients screened and implanted with the Transvene Lead System) includes 897 patients (see patient tree, Vol 2, page 36). The PMA population includes 757 patients (447 U.S. and 315 foreign) implanted at 78 centers (35 U.S. and 43 foreign). The U.S. and foreign data were pooled to evaluate the safety and effectiveness of the Transvene Lead System. Statistically significant variations were found between the U.S. and foreign populations. These variations included a higher mean age, a greater percentage of patients with CAD and cardiomyopathy and a lower mean ejection fraction within the U.S. population versus the foreign population. Also, there were more U.S. patients with VT as a primary indication. Even though the

(b)(5)

(b)(5)

differences between the two populations were statistically significant, the manufacturer does not consider the factors to be clinically significant to require stratification of the data.

The PMA patient population is predominantly male (80.6 percent) with a mean age of 59.4 years. There are 377 (49.8 percent) patients with recurrent sustained VT without an episode of sudden cardiac death (SCD); 281 (37.1 percent) SCD patients; and 99 (13.1 percent) patients with a combination of recurrent sustained VT and SCD.

Of the 757 Transvene patients, 744 (97.6 percent) patients were implanted with the PCD Model 7217B and 18 (2.4 percent) patients were implanted with the PCD Model 7216A. Sixteen patients have brady pulse generators in conjunction with the PCD. Five hundred and seventy-four patients were implanted using the sequential defibrillation pathway, 178 patients were implanted using the simultaneous pathway and 10 patients have the single pathway. Data were collected on each patient during: preimplant assessment; lead system testing at implant; prehospital discharge; and follow-up evaluations at 1 month, 3 months (chronic testing period) and at 3 month intervals thereafter. There are 657 patients followed for 6 months and 393 patients followed for 12 months. The mean follow-up of the patient population is 11.7 months with 8894.8 total device months of experience. Patient compliance to follow-up is within a range of 95.3 to 97.6 percent from 12 to 24 months.

The PMA population was stratified by primary indication, patients who met implant criteria, patients who did not meet the implant criteria, patients followed for one year and greater, patients with non-standard lead configurations and additional patients who were not counted in the PMA cohort.

Clinical Experience

As of February 1, 1993 (the data cutoff), the clinical experience includes data from 762 implants in 757 patients. The data (stratified as described above) were provided in support of the Transvene Lead System. The data included the following: (1) the results of testing at implant and the follow-up intervals; (2) the efficacy of the treatment of VT and VF (spontaneous and induced episodes); (3) complications and observations; (4) patient deaths; and (5) survival. A comparison of the data obtained from the patient population and the different subgroups is also included.

Defibrillation Threshold (DFT) Testing

Three hundred and sixteen patients had DFT testing at implant. The mean DFT was 14.8 Joules (J). The remaining patients had testing which involved the lowest energy to

8

defibrillate (LED) and/or DFT testing. The mean LED was 16 J (N= 702).

Twenty patients were implanted with the Transvene System without a 10 J safety margin (see Volume 2, page 42).

Spontaneous and Induced Episode Experience and Treatment Efficacy of VT and VF - Total Patient Population

- 597 (78.9 percent) patients had a spontaneous VT or VF episode or had VT or VF induced post implant.
- 458 (60.5 percent) patients had a spontaneous episode of either VT and/or VF treated by the PCD Transvene System.
- 141 (60.5 percent) patients had VT only.
- 142 (18.8 percent) patients had VF only.
- 175 patients (23.1 percent) had an episode of VT and VF.
- 90.7 percent of VT episodes were successfully treated with VT therapy # 1.
- 89.1 percent of the VF episodes were successfully treated with VF therapy # 1.
- 60 patients experienced 163 (1.6 percent) spontaneous VT episodes which the PCD Transvene System was ineffective in terminating the arrhythmia (see Volume 2, page 19).
- 16 patients experienced 31 (1.3 percent) spontaneous VF episodes which the PCD Transvene System was ineffective in terminating the arrhythmia (see Volume 2, pages 20 - 21).
- 450 (59.5 percent) patients had induced or spontaneous episodes by the 3 month follow-up.
- 532 (70.3 percent) patients had either a spontaneous or induced episode by the 6 month follow-up.
- 597 (78.9 percent) patients had a spontaneous or induced episode by the 12 month follow-up.

Device Experience - Patients Followed for 6 months or More

- Of 657 patients followed for 6 months or more, 544 (82.8 percent) patients had an induced or spontaneous episode at predischarge or later.

- 113 patients did not have a chronic episode, however pace/sense parameters were measured at the chronic follow-up intervals on all patients except one (see Appendix I).

Summary of Complications and Observations

- 176 complications (required invasive intervention) occurred in 147 patients, included pocket infection (24), lead fracture (9), patch crinkling (7), explants (4) and total lead dislodgement (91). (The 91 cases of lead dislodgement occurred in 86 patients, see Appendix I).

- 212 observations (corrected by reprogramming or antiarrhythmic drug therapy) in 178 patients included inappropriate VT delivery (57), oversensing (52), seroma (17), hematoma (17), patch crinkling (5) and total lead dislodgement (12).

The manufacturer provided tables which report the complications and observations over time (see Table IB3-2 and Table IB3-3, Volume 2, pages 24-25).

The manufacturer stratified the complications and observations by U.S. and foreign patients (see Table IB3-6 Vol. 2, page 28). The complication and observation rates were comparable for the two patient groups. However, more total lead dislodgements (complications) were reported for the U.S. patients and more cases (observations) of inappropriate delivery of VT therapy occurred in the foreign population. There was also a higher incidence of oversensing (observations) in the U.S. population. It should be noted that there should be 7 observations related to loss of capture for the foreign patients instead of 9 (Volume 2, Table IB3-6, page 28).

Because of our concerns about the complications involving lead dislodgement and infection the manufacturer responded as follows: In resolving the concern regarding lead dislodgement, the manufacturer received IDE approval (September 1992) to use dual anchoring sleeves on the Models 6963 and 6966 leads. However, it is unclear if all patients, after IDE approval, are implanted with dual sleeves. The manufacturer confirmed that all patients are receiving dual sleeves. In support of the dual anchoring

10

sleeves in reducing the rate of lead dislodgement, a report of the clinical experience of additional patients was provided. Data from 439 patients (not a part of the PMA cohort) implanted with dual anchoring sleeves were submitted. Of the 439 patients, 292 were followed for 1 month, 195 were followed for 3 months and 17 were followed for 6 months. Thirteen dislodgements in 10 patients were reported (incidence of dislodgement of 2.3 percent (10/439). Regarding the cases of infection, the manufacturer stated that the incidence of infection in the Transvene study is not significantly different from that reported for the Ventak P Epi study. Therefore, the applicant feels that there is no substantial increase, and that labeling to address this concern is not warranted. (b)(5) (b)(5)

Patient Deaths

There have been 51 deaths (sudden cardiac (5), nonsudden cardiac (31), noncardiac (15). Five perioperative deaths (sudden cardiac (2), nonsudden (2) and noncardiac (1)) are counted within the 51 deaths. None of the deaths were attributed to the PCD Transvene System.

Explants

Sixty-three PCD Transvene Systems were explanted (N=762), patient death (22), infection (22), heart transplant (9), low battery voltage (1), PCD performance issues (4), integrated circuit problem (1) and lead problems (4). The results of analyses on 42 units returned indicated that the devices were performing within specifications.

Of the 42 PCD Transvene Systems returned, (b)(4) lead systems or portions of systems were returned and analyzed. Of these the helix of one Model 6966 lead was damaged. The remaining leads were found to be within specification. The analyses (b)(4) lead systems are still outstanding. (It should be noted that one of the Model 6884 leads (implanted for 27 months) which was explanted due to heart transplant, exhibited metal ion oxidation (MIO) upon analysis. Metal ion oxidation can cause the polyurethane of the leads to degrade (see Volume 2, Section on Explants, page 296 or Appendix I).

Survival Analysis

The survival analyses encompassed all patients (screened and implanted). The projected one year actuarial survival rates for the PMA cohort (N=757) are as follows: sudden cardiac death (99.5 percent); nonsudden cardiac (96.2 percent); all cardiac (95.8 percent); noncardiac (98.1 percent); and overall (93.3 percent). The perioperative mortality is 0.7 percent.

The survival rates for 854 patients are included in Volume 2, Table IB4-2, page 31. The survival data were updated to include the 897 patients screened for the Transvene System. The one year actuarial survival rates for these patients are as follows: sudden cardiac death (99.5 percent); nonsudden cardiac (96.6 percent); all cardiac (96.1 percent); noncardiac (98.4 percent); and overall (92.9 percent). The perioperative mortality rate is 1.6 percent (see Appendix I).

Comparison Between the Patients Who Met the Implant Criteria and Patients Who Did Not Meet the Implant Criteria

A comparison of the clinical outcome between the patients who met the implant criteria and those patients who did not meet the implant criteria was included. The comparison was made to determine if there was a greater risk of morbidity and mortality among the patients who did not meet the implant criteria and received the Transvene System. The data showed the following: The efficacy of the patient groups in the treatment of spontaneous episodes of VT and VF was similar. There was no significant difference in the one year sudden cardiac death survival and the overall survival reported for the two groups. Ninety-one per cent of the patients who did not met the implant criteria had at least one successful termination of an induced ventricular comparison at 24 joules or less. In addition, there were 170 patients who had successful defibrillation of VF at less than or equal to 24 Joules. As a result the manufacturer requested and received IDE approval for a change in the implant criteria. Instead of 3 of 4 successes at 18 Joules or less, the manufacturer can implant with successful defibrillation at 24 Joules (referenced in Volume 2, page 53).

Labeling

The manufacturer has included information about the Transvene leads in the PCD Manual as well as in the technical manual for each Transvene lead model.

The technical manuals of the Transvene Models 6966, 6963 and 6999 leads should be modified to included additional information. The following modifications are included for the Panel's consideration:

- The indications and contraindications for use of the Transvene lead system should be identical to those of the PCD (with certain modifications).

- The technical manuals for the Models 6966, 6963 and 6999 leads should state that the leads are intended for use together as a system. The labeling (where appropriate) should be consistent throughout the manuals. The

information in the PCD Manual regarding the Transvene leads should also be included in the technical manuals for the leads.

- There should be more explicit diagrams in the technical manuals which show the proper insertion of the endocardial leads and the various positions for placement of the patch lead.

- Efficacy data of the different lead configurations via the different pathways should be included.

- The labeling should recommend and/or provide some direction about implanting the leads and testing the different configurations. For example, when to use a two lead versus a three lead configuration and when to implant in the SVC versus the coronary sinus.

- Information or recommendations regarding implanting in patients who do not have the 10 J safety margin should be addressed.

- There should be stronger language regarding the use of 2 anchoring sleeves.

- The labeling should address how the incidence of infection can be reduced.

MEMORANDUM

From: (b)(6) (b)(6)
To: File # P920015
To: (b)(6) (b)(6)
Subject: Transvene Lead System - Consulting Review
Date: July 6, 1993
Office: DCRND/ODE

Please review the death summaries included in the referenced file (Volume 2, Section III, Death Summaries). The review should evaluate the accuracy in classifying the deaths. In addition, please look at the causes of death to determine if any of the deaths could be possibly linked to device performance.

Please note the following: A definition of the different death classifications can be found in Volume 2, page 293. Medtronic, Inc. has reported 51 deaths (sudden cardiac (5), nonsudden cardiac (31), noncardiac (15) in the PCD Transvene population (N=757). The perioperative deaths (5) are counted within the following classifications: sudden cardiac (2) nonsudden (2) and noncardiac (1).

Please let me know if you can review the data. If so, when do you think you will be done? Hopefully, by the first of next week? Your assistance is greatly appreciated.

77

MEMORANDUM

To: Doris Terry, DCRND

From: R. Subramanian, DCRND

Subj: Review of death summaries, Medtronic Transvene lead - P920015

Date: August 4, 1993

==========

I have reviewed the death summaries provide with the amendment to the above application. As we have discussed previously:

1. The classification of deaths appears to be reasonable.

2. It is not possible, with the information provided in the death summaries, to state categorically, whether or not any of the deaths could be possibly linked to device performance.

3. As indicated by the sponsor, there appears to be only one death (Patient (b)(6) vol 2, page 134) that is clearly device related.

Recommendation: In future studies, instances where the cause of death is considered unknown, and no autopsy is performed, such death should classified as device related.

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Memorandum

Date .July 9, 1993

From Mathematical Statistician (T. C. Lu) HFZ-162
Statistics Branch, Division of Biometric Sciences, OSB

Subject Statistical Review of PMA P920015 Panel Package, Medtronic Multiprogrammable Tachyarrhythmia Control System with Non-thoracotomy Cardioversion and Defibrillation Electrodes, Medtronic, Inc.

To Doris Terry - HFZ-450
Division of Cardiovascular, Respiratory, and Neurological Devices, ODE
Through: Director, Division of Biometric Sciences, OSB
Through: Chief, Statistical Branch, DBS, OSB

1. Background

The original PMA was submitted in April 1992. Amendment two was submitted for review in March 1993. The purpose of this memo is to review the response from the sponsor to the deficiencies stated in the FDA letter and in the telephone conference call held on July 7, 1993. Information provided in this panel package includes clinical experience of 757 patients through February 1, 1993.

2. Reviewer's Comments

2.1. Cox Regression

This reviewer wants the sponsor to provide a description of the computer program, including data input and output, and the decision criteria used to support the sponsor's claim that primary indication and gender do not impact survival. Sponsor stated that "Appropriate data will be submitted in the panel volumes to address this issue" in response to statistician's review. In the telephone conversation, the sponsor stated that (b)(4) was used for survival curve comparison, but the (b)(4) test was used for testing the equality of survival curves. (Table 1D2-10, page 76).

2.2. Actuarial Survival

In my March 10, 1993 memo to you, I asked for the number of deaths, number at risk for transvene and epicardial by month intervals (0-3, 3-6, 6-9 and 9-12). Sponsor claims that Table 1B1-5, page 17 "Patient Compliance" will serve this purpose. The compliance rate is very high, according to this table. However, to use this patient compliance table for survival analysis would be misleading, because it does not give survival probability. Sponsor said they will fax a copy of their survival curve graphical comparison.

2.3. Percentage Success

This reviewer needs to review the numerators and the denominators used for the percent success (Table I-1, page 233, Table 1F-2, page 287 and Table IF-4, page 290) for the treatment of spontaneous episodes. Sponsor pointed out that those numbers are located in other sections of the panel package.

2.4. P-values

The sponsor was asked to address the calculation of the p-values reported in Table 2.165, page 24. I calculated the p-values and obtained different values than those reported by the sponsor. Sponsor claimed that (b)(4) was used for the calculation. Subsequently, a computer output was faxed to me by the sponsor for review.

3. Conclusion

In my previous memos to you, I raised questions about the safety and effectiveness of the device. My telephone conversation with the sponsor certainly helped to answer some of these questions. The safety and effectiveness of the device should be evaluated from a clinical perspective.

Re: Transvene® Lead System, PMA Amendment
(Document Control Number P920015)
Panel Package

AC2V1

The purpose of this submission is to provide information for FDA Panel review of the Transvene System Premarket Approval Application.

Information in this submission is consistent with that provided to the FDA in the March 26, 1993 PMA amendment. However, the information has been rearranged and/or represented to facilitate review, and in some cases, updated to incorporate the most recent data, e.g., complications, patient deaths, device explants.

Clinical experience information is provided on 757 patients implanted with a Transvene System between October 16, 1990 to February 1, 1993. Mean implant duration for these patients is 11.7 months. Information is provided on 573 additional patients implanted in the U.S. from June 25, 1992 to February 1, 1993.

Clinical data presented in this Amendment demonstrates the PCD Transvene System performs as specified and is, therefore, safe and effective for its intended use. Results indicate 99.3 percent survival from sudden cardiac death at one year (N = 1330).

Following this cover letter is a telephone conversation record that documents several discussions between FDA and Medtronic regarding the Transvene file. FDA's questions and/or requests for clarification of clinical information are presented as discussed in these conversations, along with the applicable sections of the Clinical Experience Report and Appendices where the topics are addressed.

Volume 1 contains an abbreviated Summary of Safety and Effectiveness for the Transvene System. A detailed Table of Contents is provided in the front of Volume 2, detailing the contents of Volumes 2, 3 and 4.

The existence of this PMA Amendment and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

Twenty-five copies of this PMA Amendment are provided. Should additional information be required by the Agency, please contact the undersigned.

Sincerely yours,

MEDTRONIC, INC.

Jennifer M. Marrone
Manager, Regulatory Affairs
Cardiac Pacing Business

Attachment

Telephone Conversation Records -- Transvene PMA Application, P920015; April 29, May 3, 12, 13, 17, 27, June 2; 1993

The following is a summary of telephone conversations that occurred with Medtronic and FDA regarding Medtronic's Transvene PMA application. Medtronic participants included: Jennifer Marrone, Sue Norenberg, Diana Roberts and Dan Schaber.

A primary objective of these discussions was to emphasize that the deficiency responses provided in the March 1993 amendment (and in some cases, September 1992 amendment) be incorporated into the text of the clinical report for the Panel package, in the appropriate sections. Further format detail addressed organization of sections, specifically, tabbing key sections in the Clinical Report such that Panel members will be able to identify them with relative ease.

Several topics were discussed as they related to the information provided in the March 26 PMA amendment (response to FDA deficiency letter). In some cases, data are represented or rearranged, and/or clarified. These topics are presented below, along with the applicable section(s) of the Clinical Experience Report and Appendices, where they can be found in this submission.

Lead-related complications/observations, e.g., pace/sense complications and dislodgements (use of dual anchoring sleeves), and their recurrence. Relative to dislodgements, occurrence pre and post 30 days are presented, as well as more chronically, e.g., at three and six months post implant. Section I.B.3.

Patients not meeting implant criteria and those that later received epicardial systems, non-standard lead configurations, e.g., combination epicardial/ Transvene system, implanted at the time of Transvene implant screening or sometime later, post implant. Note that some non-standard (those patients implanted with a three-lead system) were included in the 757 PMA population and some were not. This is delineated. Section I.C.2.d.

Study design, objectives and use of concurrent epicardial system as control, and identification of the pros and cons of an epicardial vs. a Transvene system. Section I.A.2.

Specific patient groups are stratified relative to survival, e.g., by indication. Specific patient populations are discussed, e.g., non-standard system (I.D.4.), not meeting implant criteria (I.C.2.), implants greater than one year (I.D.3.).

Episode experience, both spontaneous and induced, via follow-up. Appendix D.

Some data presented only in text form is represented in tables and/or graphs, e.g., survival of non-standard implant patients.

Further clarification (via presentation of data in table format) of the subgroups from the population that did not meet implant criteria (n = 214) is provided, i.e., patients with LEDs less than 24 joules are stratified as those in which it was difficult to induce VF and received a 10 joule safety margin (and later were induced) vs. those patients in which their condition precluded VF induction. Section I.C.2.b.

A cross reference of explants vs. device (lead) analyses is provided to clarify those explanted devices and their subsequent analysis, if indeed the device(s) was returned. Section I.E.1. Include returned product analysis procedure (Appendix F).

As provided in the March amendment, complications/observations are updated relative to pace/sense and dislodgements. The resulting population was N = 1330, (757 + 573 = 1330). The additional 573 are represented separately. Section IV.

The tree diagram (flow chart) on page 236 of the March amendment was modified to include the number of patients (in addition to the percentages), and also to include the total number of non-standard systems implanted (currently only some of the non-standard are presented on this page, although all non-standard are clearly discussed in the text). Sections I.B.1., I.C.

The protocol compliance table, as presented in the September 1992 amendment, is included. Section I.B.1.

Foreign data demographic information (justification for pooling) is delineated. Section I.A.3.

Survival curves are provided along with the tables of survival statistics that are provided. Section I.B.4.

Comparison table of PCD epicardial to PCD Transvene. Include number of patients along with percentage. Section I.D.2. Also, Ventak-P comparison data is provided in table form. Section I.D.1.

Death information includes devices programmed off, both the N and percent, incorporated by type of death (e.g., SCD, non SCD, etc.). Section I.D.2.

Literature update, e.g., anything relevant to lead dislodgement and subcutaneous patch locations. Appendix C.

Foreign versus U.S. complications/observations are discussed with any differences noted in reporting methods between international and U.S. Section I.B.3.

All statistical tests are identified, e.g., Chi-square, t-test, Hochberg, Wilcoxin, etc. Appendix E.

The recurrence of ineffective therapies is addressed in complications/ observation section. Of 60 ineffective, there were 39 ineffective VT therapies due to AF and 21 inappropriate therapies. None of these 21 were related to patient deaths. Section I.B.2.

Any reprogramming due to observations is noted and put in table format in observation section. Section II.

Incidence of infection rate, Transvene versus epicardial. Section I.D.2.

Clarify the null hypothesis of a three-lead configuration based on patient demographics. Section I.A.3.

Choice of lead configuration made by the physician. Section I.B.1.

Measurements made for those patients followed for a year or greater. Assessment of pace/sense parameters, dislodgements, etc. Section I.D.3.

Patients followed for one year or longer. Take the 393 patients followed for one year or longer and look at their spontaneous and induced VT and VF episodes. Provide evidence of system performance, spontaneous and induced. Section I.D.3.

Analysis showed the epicardial and Transvene patient groups were comparable; provide the statistics that support this. Appendix E.

Describe the computer program used to show comparable groups. Include the data inputs and outputs, and description of the decision used to support the claim of comparable groups. Provide the data set used for survival calculations, e.g., the denominator and numerator. (Because of the immense amount of raw data, we are providing a description of how we did this.) Appendix E.

Provide the confidence intervals for one year and overall survival. Section I.D.1.

Provide justification for denoting 30 days as the acute cutoff point with respect to dislodgements. Section II.D.7.

Address patients lost to follow up or withdrawn from the study and how they were addressed in calculations. Appendix E.

Use page 93, table 4.6 of "Statistical Methods Used For Survival Data Analysis," by Elisa Lee, for our survival analysis. Appendix E.

Provide numerator and denominator for spontaneous VT and VF episodes. Section I.B.2.

What lead configurations are recommended in the labeling? Was a two-lead configuration used? If so, how many and what are they? Does the labeling also address these? Data for the two-lead non-standard configurations are reported consistent with the rest of the lead configurations. Section I.D.4. and Appendix G.

How many patients of the 757 were implanted via a subclavian stick procedure? Were the cases of lead fracture related to the use of subclavian insertion? How many fractures were there? Were the physicians following instructions? At what point in time did the fractures occur? Compare the N = 757 to the N = 573 population relative to fractures (N = 1330 total). Section II.D.

Where/how is the subcutaneous patch implanted? Section I.B.1.

Regarding complications, specifically, increased defibrillation requirements, were there any recurrences of the N = 14 of these reported? Section II.

Transvene Summary of Safety and Effectiveness (June 11, 1993)

A. Indications For Use

The Medtronic PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System with Nonthoracotomy Cardioversion and Defibrillation Electrodes (hereafter referred to as the PCD Transvene System) is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias. Indications for use include:

- Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
- Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.
- Patients undergoing replacement of a previously implanted implantable cardioverter defibrillator.

The patients who meet the above patient selection criteria should have also undergone a complete cardiological evaluation that includes electrophysiological testing. Electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the PCD Transvene System.

The PCD Transvene System components, except for the defibrillation lead system, are identical to the PCD Epicardial System which was unanimously recommended for approval by the FDA Advisory Panel on February 3, 1992 and granted FDA premarket approval on February 11, 1993.

Market approval is not being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems. In addition, market approval is not being sought for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

One Place Your Text Could Go (see Documentation Section 6)

B. Description of the Transvene Lead/PCD System

The Medtronic Tachyarrhythmia Control System consists of two fundamental configurations: (1) the implantable configuration and (2) the external configuration. Both configurations use the Transvene lead system. See Figure III B-1

The implantable configuration is composed of a Pacer-Cardioverter-Defibrillator (PCD) device, implantable leads, and a programmer. The PCD device is an implantable, multiprogrammable, automatic tachyarrhythmia control device.

The external configuration is composed of an External Tachyarrhythmia Control Device (ETCD), a patient cable, implantable leads, and a programmer. The ETCD is an externally-operated, multiprogrammable, tachyarrhythmia control device.

Intended Uses - Transvene Leads

Model 6963 Lead

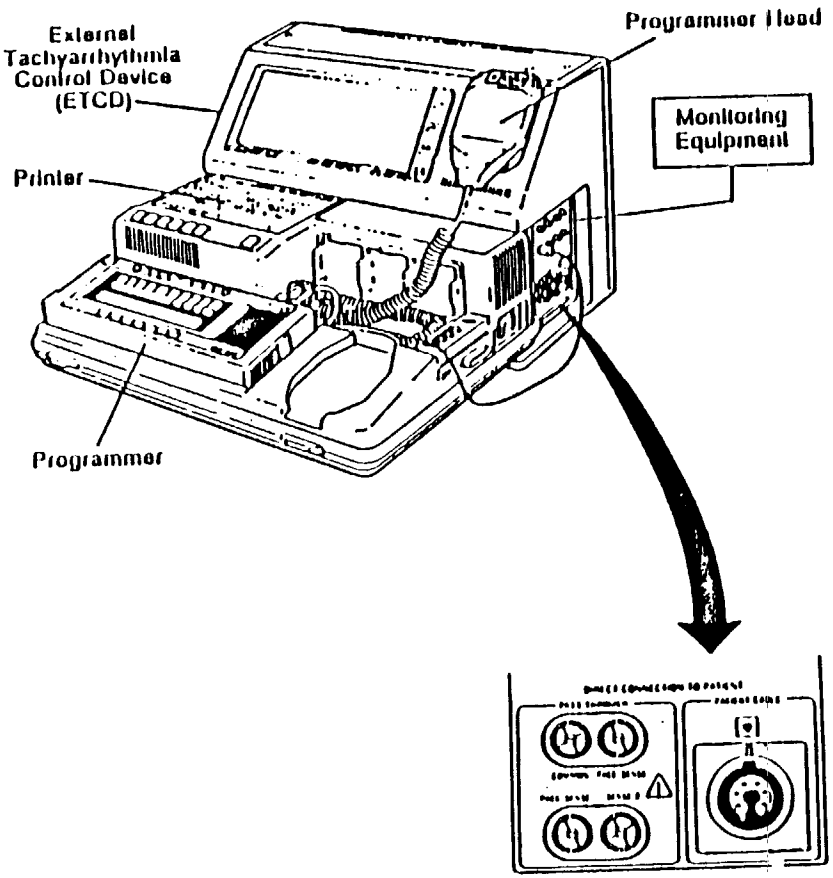
The Medtronic Transvene Model 6963 Unipolar, Coronary Sinus or Superior Vena Cava, Transvenous Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use in the coronary sinus or superior vena cava and is designed to be used with an implantable tachyarrhythmia control device along with at least one other lead, such as the Model 6966 Tripolar, Right Ventricular, Transvenous Lead.

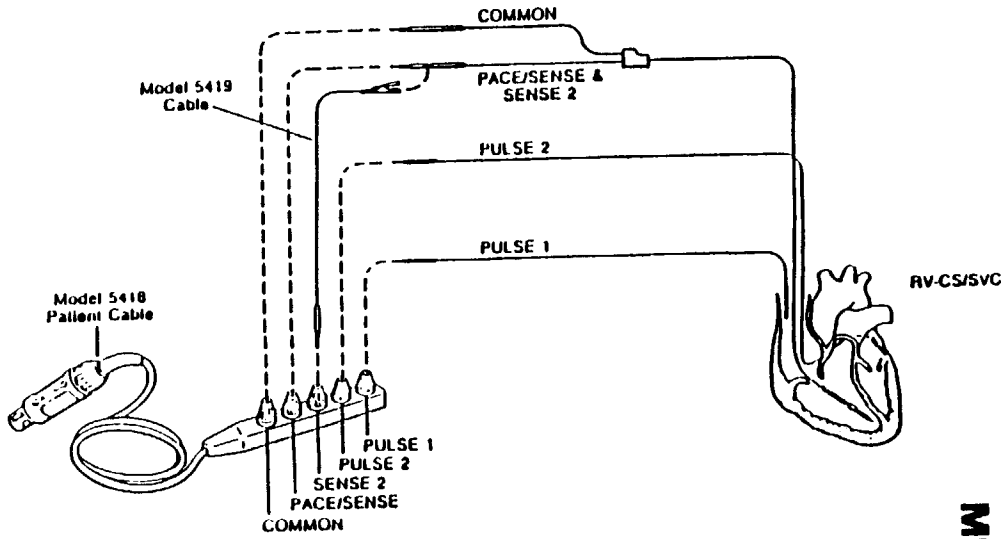
The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6966 Lead

The Medtronic Transvene Model 6966 Tripolar, Endocardial, Screw-In Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. The lead has application where implantable tachyarrhythmia control systems are indicated.

The Model 6966 lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool.





Connections to Model 5418 Patient Cable for
Typical Simultaneous or Sequential Pathway (RV-CS/SVC).

FIGURE III B-1

MEDTRONIC CONFIDENTIAL

Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be potential a problem.

The three electrodes of this lead are the coil, ring, and helix:

The defibrillating coil electrode is most proximal to the pulse generator and connects electrically to the connector pin of the unipolar leg of the bifurcation. This unipolar leg will not accept a stylet.

The ring electrode is proximal to the helix and connects electrically to the connector ring of the bipolar leg of the bifurcation.

The helix tip electrode is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector pin with a special fixation tool. The helix electrode connects electrically to the connector PIN of the bipolar leg of the bifurcation. This bipolar leg is the only one that will accept a stylet.

The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; the coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6999 Lead

The Medtronic Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use and is designed to be used with an implantable tachyarrhythmia control device along with at least one complementary defibrillating electrode and a pacing/sensing lead; a third defibrillating electrode may also be used.

The lead has application for patients in whom implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

37

Intended Uses - PCD Device

The Model 7217B PCD device is intended for use in patients who are at high risk of sudden death due to ventricular tachyarrhythmia.

Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or

- in the absence of a prior cardiac arrest, have recurrent, sustained ventricular tachycardia that occur spontaneously or can be induced, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically.

Extensive electrophysiologic evaluation and testing of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Model 7217B PCD device. Before permanently programming the PCD device to the automatic detection and delivery of the VT and/or VF therapies, the patient should have demonstrated a satisfactory response to the proposed therapy.

Intended Uses - ETCD

The Model 5355 External Tachyarrhythmia Control Device is intended for use in conjunction with an antitachycardia/defibrillation lead system during diagnostic studies for implanting the Model 7217B PCD device.

Indications for use of the ETCD include:

- Patients experiencing recurrent episodes of ventricular tachyarrhythmia,

- Patients who survived a cardiac arrest due to a ventricular tachyarrhythmia and are at risk for repeated episodes,

- Patients who are undergoing an assessment of the efficacy of antitachycardia pacing, cardioversion, or defibrillation therapies in anticipation of an implantable cardioverter-defibrillator.

Components of the System

A list of components used in the system is given below. It is separated into a listing of those components for which market approval is sought and those components that are now commercially available. Market approval is not being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems or for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

Seeking Approval:

Transvene Leads
- Model 6963
- Model 6966
- Model 6999

Pacer-Cardioverter-Defibrillator (PCD) Device
- Model 7217B

External Tachyarrhythmia Control Device (ETCD)
- Model 5355 ETCD
- Model 5418 Patient Cable
- Model 5419 Patient Cable
- Model 5414 Test Load
- Model 5417 EGM Cable

Programmer Software Cartridge
- Model 9788 - Memory Module for 7217B PCD Device and 5355 ETCD Devices

Lead Accessories
- Model 6701 Lead End Cap

Commercially Available:

Programmers Model 9710 and accessories

Printers Model 9751/9712

Components Used in the Implantable Configuration

The implantable configuration is composed of a PCD Device, lead system, and a 9710 Programmer with applicable software cartridge. The implantable device is a Model 7217B PCD Device. The PCD device requires an appropriate lead system consisting of up to three cardioversion/defibrillation electrodes. See Figure III B-2. The Transvene leads used with the Model 7217B PCD Device are the Models 6963, 6966, and 6999.

The Model 9710 Programmer is commercially available. Two printers are also commercially available. When higher printing speeds are desired, it is recommended that the programmer be used with the faster printer, the Model 9751. If slower printing speeds are acceptable, as may be the case in some follow-up situations, the Model 9710 Programmer can be used with the battery-powered Model 9712 Printer.

Components used in the External Configuration

The external tachyarrhythmia control system is composed of the Model 5355 ETCD, a Model 5418 Patient Cable, a Model 5419 cable, lead system, and a Model 9710 Programmer with applicable software cartridge, see Figures IV-A-3, 4. The ETCD uses replaceable batteries as its power source. The Model 5418 Patient Cable and Model 5419 Cable are designed to connect the Transvene leads to the ETCD. Like the implantable system, the ETCD uses the same Transvene leads (Models 6963, 6966, and 6999).

Purpose of the System

PCD System Configuration

The PCD Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or a progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation. The PCD Device also has bradycardia pacing capability. The Transvene leads allow the PCD device to deliver these therapies to the heart.

ETCD System Configuration

The ETCD is an external tachyarrhythmia control device designed to deliver overdrive pacing, cardioversion, defibrillation, and bradycardia therapies in the same fashion as the PCD device. The ETCD can be programmed to automatically deliver overdrive pacing therapy upon detection of VT. When used as a component of a system that includes the appropriate Medtronic programmer and applicable software cartridge, the ETCD can deliver manually-initiated VT pacing, cardioversion, and defibrillation therapies. The ETCD allows the assessment of the Transvene lead system characteristics and aids in the assessment of lead system pacing and sensing characteristics.

Overview of System Features

General

The PCD device is designed to automatically detect episodes of VT or VF and, upon detection, deliver the appropriate programmed pacing, cardioversion, or defibrillation therapies. The device has two independently programmable detection and therapy procedures, one for VT and a second for VF.

When used as a component of a system that includes the appropriate Medtronic programmer and dedicated software, the ETCD is designed to deliver manually initiated cardioversion and defibrillation therapies. The ETCD is also designed to detect episodes of VT and VF. It can automatically deliver VT overdrive therapies (burst and ramp) upon detection of a VT.

VT Detection and Therapy

Both the PCD device and ETCD use a VT detection algorithm which can use up to three separately programmable criteria as it monitors the cardiac cycle length to identify the presence of a tachycardia. Upon detection, the devices deliver their first programmed VT therapy. If the VT episode persists and is again detected, up to three additional independently programmable VT therapies may be delivered to restore the patient's normal cardiac rhythm. This progression of four VT therapies can be tailored to each patient's need. For the PCD device the therapies may be selected from two methods of overdrive pacing (burst and ramp) and synchronized cardioversion.

For the ETCD the same overdrive pacing therapies can be automatically delivered, with cardioversion therapy being available as a manual therapy.

VF Detection and Therapy

The VF Detection algorithm monitors the cardiac cycle length to identify a VF episode. Upon detection, the PCD device provides a programmable high energy defibrillation pulse for VF therapy. Up to a maximum of four VF therapies may be delivered for ongoing detected VF episodes. Each defibrillation therapy consists of one (single pulse) or two (simultaneous or sequential) high voltage pulses designed to restore the normal cardiac rhythm.

For the ETCD, each cardioversion or defibrillation therapy, which must be initiated manually via the programmer, also consists of one high-voltage pulse or two (simultaneous or sequential) high-voltage pulses in the same fashion as the PCD devices.

Bradycardia Therapy

For both the ETCD and PCD devices, bradycardia pacing is delivered in the VVI mode. Asynchronous, (VOO), pacing is not available, and is avoided even with magnet application since this type of pacing has increased potential to initiate ventricular arrhythmias in patients receiving this system.

Lead Systems

The PCD Device and the ETCD perform pacing, sensing, cardioversion, and defibrillation through multiple electrodes in the lead system. Listed below are the electrodes and their function:

- The PACE/SENSE electrodes are incorporated in the right ventricular defibrillation lead. These electrodes function as the sensing circuit and deliver pacing pulses. The PACE/SENSE electrodes are used for sensing in conjunction with the SENSE2 electrode.
- The COMMON electrode is an electrode coil that serves as the cathode for cardioversion, defibrillation, and pacing.
- The PULSE2 electrode is an electrode coil that serves as the anode for cardioversion and defibrillation.
- The PULSE1 electrode is an optional electrode coil that serves as an additional anode for sequential and simultaneous cardioversion and defibrillation.

Cardioversion and defibrillation current pathways are between the PULSE2 and COMMON electrode coils and, if the additional lead is implanted, between the PULSE1 and COMMON electrode coils.

Other Capabilities

The physician may use the ETCD or the PCD devices to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the appropriate software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia.

The PCD device will provide the physician with information, via the Programmer, about its present programmed status and data on its operation accumulated between office visits. This information may be printed and retained in the patient's file.

The PCD Device and ETCD can also transmit an electrogram to the programmer. The electrogram is the electrical signal sensed on the leads.

A programmer-generated set of symbols, termed Marker Channel™, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

In addition, the ETCD provides a display of measurements and other information related to delivered cardioversion and defibrillation pulses.

46

With this information and other features, the ETCD can be used to assess the suitability of the lead system and its placement for individual patients.

PCD Battery Longevity Expectations

The longevity of the Model 7217B PCD Device depends upon several factors, including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the pacing load, and on the frequency of high voltage capacitor charging. The longevity projections found in Table IV-A-1 apply under the following conditions:

- 65 ppm pacing rate,
- 5.4 V pacing pulse amplitude,
- 0.49 ms pacing pulse width, and
- 500 ohm pacing lead.

Projected Longevity[1]
Table IV-A-1

Pacing/Sensing	34 Joule Charging Frequency	Average Longevity Model 7217B
100% Sensing	Quarterly	5.0 years
15% Pacing	Monthly	4.2 years
100% Pacing	Monthly	3.4 years

The longevity of the device decreases with the following:

- An increase in pacing rate,
- An increase in pacing amplitude,
- A decrease in pacing impedance,
- An increase in pacing pulse width,
- An increase in the percentage of bradycardia paced to sensed events, or
- An increase in the charging frequency.

Each 34 Joule charging cycle will typically decrease the longevity of the device by approximately six days.

---

[1] These preliminary longevity projections are based upon accelerated battery data and device modeling. They include an estimate of five months between time of manufacture of a PCD device and its implant. If a device was stored for the full twelve-month shelf life, the average longevity would be reduced an estimated 4.3 to 5.9 months, depending on device use. With the stated condition, 100% pacing and monthly 34 Joule charging cycles, the minimum longevity of the device will be 2.5 years (7217B). Average refers to the projected mean longevity of the modeled run of PCD devices at the stated conditions. Minimum longevity means that virtually all (i.e., 99.9%) of all modeled production run of PCD devices will attain the value given.

C. Alternative Practices and Procedures

The use of implantable defibrillators in patients with drug refractory ventricular tachycardia/ fibrillation (VT/VF) and in survivors of sudden cardiac death has reduced the arrhythmic mortality in these patients. Other treatments available to treat ventricular tachyarrhythmias include antiarrhythmic drug therapy, ventricular tachycardia surgery, transthoracic defibrillation and other market released implantable defibrillators with epicardial defibrillation lead systems.

D. Marketing History

All of the Medtronic Transvene Tachyarrhythmia Control System device components which have been implanted in the U.S. to date have been part of the IDE clinical study and have followed the FDA approved investigational protocol. In November 1991, the Medtronic PCD Transvene System, and respective components described in this submission, were market released in Europe. In March 1991, the Medtronic PCD Epicardial System, and respective components, were market released in Europe. And in February 1993, the FDA approved the Medtronic PCD Epicardial System.

E. Adverse Effects

Potential adverse effects which may be associated with the use of the PCD Device include but are not limited to: failure to detect ventricular tachycardia or ventricular fibrillation; failure to terminate ventricular tachycardia or ventricular fibrillation; delivery of pacing or shock therapy when no ventricular tachyarrhythmia is present, which would precipitate an episode of ventricular tachycardia or ventricular fibrillation; acceleration of a ventricular arrhythmia; failure to capture after a shock delivery; discomfort or pain during or following the delivery of electrical shock; or infection.

The following additional, potential adverse effects associated with all pacemaker systems include loss of normal pacemaker function due to battery failure or other component failure, inability to program a pacemaker pulse generator because of programmer failure, infection, erosion, undesired muscle or nerve stimulation, and inadequate sensing or pacing. Any demand pulse generator can be affected by magnetic, electrical and electromagnetic signals of sufficient strength or with characteristics which mimic cardiac function. Possible effects of electrical interference on pulse generator operation include reversion to asynchronous pacing, inhibition of output pulses and rapid synchronous pacing. Certain environmental sources can couple sufficient energy into a cardiac pacing system to damage the pulse generator or cardiac tissue adjacent to the electrodes.

Failure of the pulse generator system to function properly may result in the patient experiencing the symptoms for which the pulse generator was originally indicated.

The potential complications related to the use of the PCD Transvene Lead System include, but are not limited to, the following patient-related conditions: fibrillation, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax and hemothorax. Other potential complications related to the lead system include, but are not limited to, the following: lead dislodgement, lead conductor fracture, and insulation failure.

The above referenced information is provided in the labelling of the PCD Transvene System.

F. Summary of Studies

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6966, Model 6963 and Model 6999 Transvene Leads, Model 7217B PCD, Model 5355 ETCD, and Model 9788 Memory Module.

The animal studies were performed to evaluate acute and chronic performance PCD Transvene System and to validate that the PCD and ETCD System are safe for human use.

Finally, human clinical trials were performed to evaluate the safety and effectiveness of the PCD Transvene System in treating patients with life-threatening ventricular arrhythmias.

All of the studies have demonstrated that the PCD Transvene System functions safely and is appropriate for human use.

The following summaries are provided in this section.

1. Model 6966, Model 6963 and Model 6999 Nonclinical Testing

2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod Model 7217B PCD Nonclinical Testing

3. Animal Testing

4. Clinical Study of the PCD Transvene System

1. Model 6966, Model 6963 and Model 6999 Defibrillation Leads: Summary of Nonclinical Testing

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6963 CS/SVC lead, Model 6966 RV lead, Model 6999 SQ patch lead, and related system components.

a. Electrical Testing

Electrical D.C. resistance testing was performed to ensure proper functioning of the Model 6963, 6966 and 6999 leads.

Seventeen Model 6963, thirty-five Model 6966 and eighteen Model 6999 leads were submitted for testing. Electrical resistance was measured utilizing a milliammeter under ambient room conditions. All samples measured were within the individual design specifications.

b. Environmental Analysis Testing

The purpose of the testing was to subject the lead to temperature extremes to determine the lead's resistance to the thermal stresses when transported from extremes of climate.

Thermal Shock

Fifteen Model 6963 and thirty-five Model 6966 leads were subjected to five cycles from -45°C to 70°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute. Thirty-five Model 6999 leads were subjected to five cycles from -40°C to 66°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute.

After the thermal shock testing was completed visual inspection and electrical resistance measurements were performed. There were no visual defects and the electrical D.C. resistance of all the samples met the design specification.

57

c. Mechanical Testing

The purpose of the mechanical testing was to determine the mechanical integrity of the leads to ensure that the devices are safe, reliable, and suitable for their intended use and conform to design specifications. The leads and/or assemblies were subjected to the following:

- flex testing
- composite pull strength testing
- crimp/weld pull strength testing
- insertion/withdrawal force testing
- A.C. impedance/leakage testing

Flex Testing

The flex testing consisted of mounting the insulated conductor coils and uninsulated electrode coils of the Models 6963, 6966 and 6999 in a lead flex test fixture. The insulated conductor coils and uninsulated electrode coils were flexed under ambient room conditions at a specified radius. Eleven samples were used in each test. Samples exceeded specifications and therefore are considered to be satisfactory for their intended use.

Lead Joint Tensile Strengths

Pull testing of the various lead joints is conducted to ensure that the integrity of the joint meets the design specification and is, therefore, adequate for its intended application. The testing conducted consists of a composite pull test which evaluates the overall pull strength of the lead and crimp pull testing that evaluates the crimped connections of the leads to assure specification conformance.

Composite Pull Strength

Leads were boiled in Ringer's solution or soaked in normal saline and pull tested, while wet (the lead is usually cut in half to facilitate fixturing limitations) utilizing a tensile testing machine. The samples were pulled until failure at a rate of five inches per minute. The initial failures were then

23

analyzed statistically for the confidence level in meeting the specification for the composite lead which is 1.0 lb. minimum.

Model 6963 data demonstrates that with a 95% confidence at least 97% (distal) and 99.9% (proximal) of the leads will meet or exceed the specification.

Model 6966 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Model 6999 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Therefore, Models 6963, 6966 and 6999 leads, with respect to composite pull strength, are adequate for their intended use.

Crimp/Weld Pull Strengths

Crimp and weld pull strength tests were conducted to evaluate the strength of the connections to ensure that they meet the design specification and are, therefore, adequate for their intended application. The connections tested are:

- Distal crimp sleeve to conductor coil crimp (6963)
- Double crimp core to conductor coil crimp (6963)
- Electrode coil to double crimp core weld (6963)
- Electrode coil to distal crimp sleeve weld (6963)
- Tip crimp sleeve to conductor coil crimp (6963)
- Connector pin to conductor coil crimp (6963 and 6999)
- Helix electrode to inner conductor coil crimp (6966)
- Electrode ring to middle conductor coil crimp (6966)
- Transition sleeve to electrode coil weld (6966)
- Transition sleeve to outer conductor coil crimp (6966)
- Fixed connector pin to outer conductor coil crimp (6966)
- Connector ring to middle conductor coil crimp (6966)
- Rotating connector pin to inner conductor coil crimp (6966)
- Manifold crimp sleeve to conductor coil crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4)(b)(4) crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4)(b)(4) crimp (6999)

54

Subassemblies were submitted for testing and pull tested by using a tensile testing machine. The samples were pulled until failure at a rate of four inches per minute.

Pull strength testing consisted of a minimum of 15 subassemblies of each crimp connection and a minimum of 7 subassemblies of each weld connection All samples tested exceeded the individual specification. The test results indicated that with a 95% confidence, at least 95% of the leads will have crimp and weld strengths that exceed the specification.

Therefore, the Model 6963, 6966 and 6999 leads, with respect to crimp and weld connection pull strengths, are adequate for their intended use.

Insertion/Withdrawal Forces

Insertion/withdrawal forces are measured to ensure compatibility with the implantable device without causing damage to the lead. Twenty five each of the lead Models 6963, 6966 and 6999 were tested with the Model 7217B PCD Device connector modules. There were no physical changes and all measurements met the design specification.

A.C Impedance/Leakage Testing

Fluid leakage tests are conducted on the lead assemblies/implantable device connector to determine leakage. Ten of each lead model Models 6963, 6966 and 6999 were tested with the Model 7217B connector modules. A.C. impedance was measured from the PCD device case to the lead connections while immersed in fluid. All samples met the design specification.

d. Biocompatibility Testing

The materials used in the Models 6963, 6966 and 6999 that are directly exposed to body tissue are:

- Polyurethane
- Silicone rubber (methylvinylpolysiloxane)
- Silicone rubber/titanium dioxide
- Platinum/Iridium

These materials have been shown to be biocompatible through many years of use in Medtronic permanent implantable endocardial/myocardial permanent pacing leads. In addition to extensive implant experience with these materials, standard biocompatibility tests have been performed to verify the biocompatibility of the above-listed materials. Testing has demonstrated that all materials are nonhemolytic, nonpyrogenic, nontoxic, nonmutagenic and biocompatible. Therefore, the materials passed the tests and are considered suitable for human implant. The materials used in the Models 6963, 6966 and 6999 are identical to those used in other commercially available Medtronic pacing leads.

e. Lead System (Life) Testing

In addition to the aforementioned tests, the Transvene leads were subjected to system, or life, testing. Further testing also evaluated the leads with respect to crush resistance. Testing included subjecting the leads to soaking, flexing and high-voltage pulsing. A separate test evaluated crush performance. The purpose of these tests was to subject the leads to severe conditions and assess the overall integrity of the system.

D.C. resistance values and intermittance data measured before and after being subjected to soaking, multiple flexing and high voltage pulsing, as well as crushing, demonstrated the non-thoracotomy leads satisfied requirements and are therefore acceptable for their intended use.

2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod

Non-clinical testing of these components was provided Volume 4 of the original PMA application (P900061) dated September 27, 1990, Volume 3 of the amendment dated March 8, 1991, and Volume 2 of the amendment dated August 30, 1991. A summary of the test results for each of the components is provided.

Model 7217B PCD: Summary of Nonclinical Testing

Testing of the Model 7217B pulse generators and the peripheral devices that comprise the system, i.e., the Pacing System Analyzers, the Model 9710 Programmer utilizing the Model 9788 MemoryMod and the Model 9751 Printer have been tested and found to be acceptable. All aspects of system interaction and operation are in accordance with the Model 7217B PCD Device and Model 9788 technical manuals and system specifications. Therefore, the Medtronic Tachyarrhythmia Control System, in its entirety, is acceptable for its intended use.

Model 9788 Memory Module: Summary of Nonclinical Testing

The Medtronic Model 9788 MemoryMod Cartridge was designed for insertion into the commercially available Model 9710 Programmer. When inserted, it becomes an integral part of the non-invasive programming system for the implantable PCD devices to establish pacing, ventricular tachycardia (VT) detection and therapy, ventricular fibrillation (VF) detection and therapy, and electrophysiological study (EPS) capabilities of an implanted pacemaker/ cardioverter/defibrillator (PCD). Both the Model 7217B PCD device and the Model 5355 ETCD are programmed with the Model 9788 MemoryMod cartridge when used with the Model 9710 Programmer.

Testing of the Model 9788 MemoryMod cartridge has demonstrated conformance to specification requirements. Therefore, the Model 9788 MemoryMod is acceptable for its intended use with the Model 7217B PCD Devices and the Model 5355 ETCD Device.

Model 5355 ETCD: Summary of Nonclinical Testing

Testing of the Model 5355 ETCD and respective accessories has shown conformance to specification requirements. Therefore, the Model 5355 ETCD Device/accessories are acceptable for their intended use.

3. Animal Testing

The information presented in this section is an accumulation of several studies, some of which FDA has previously reviewed in IDE submissions (G870102). These studies demonstrate the safety of the Transvene lead Models 6963, 6966 and 6999.

A variety of non-thoracotomy leads were evaluated in a series of four canine studies. Descriptions of the leads, as well as the study number(s) (1, 2, 3 or 4) in which they were evaluated, are presented below.

Description: Non-thoracotomy Leads

CORONARY SINUS/SUPERIOR VENA CAVA LEADS

Model 6963, evaluated in Study No. 4, is a silicone, unipolar, coronary sinus or superior vena cava lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies.

Model 6881, evaluated in Study Nos. 2, 3 and 4 is functionally equivalent to the Model 6963 except the 6881 has a 3.2 mm connector.

Model 10285, evaluated in Study No. 1, is the temporary version of the Model 6963/6881.

RIGHT VENTRICULAR LEADS

Model 6966, evaluated in Study No. 4, is a polyurethane, tripolar, extendable/retractable, screw-in lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies. Additionally, the 6966 has a 3.2 mm connector for pacing and sensing.

Model 6884, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6966 except the 6884 has a 3.2 mm connector in place of the 6.5 mm connector for the cardioversion-defibrillation electrode.

Model 10284, evaluated in Study No. 1, is the temporary version of the Model 6966/6884.

59

SUBCUTANEOUS PATCH LEADS

Model 6999, evaluated in Study No. 4, is a silicone, unipolar, oval, subcutaneous patch with a 6.5 mm connector and platinum alloy electrode coils that are partially embedded in the silicone patch for delivery of cardioversion and defibrillation therapies. Additionally, the patch is embedded with (b)(4) (b)(4)

Model 6895, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6999 except the 6895 has a 3.2 mm connector and is covered with (b)(4) (b)(4)

Model 10317, evaluated in Study No. 3, is functionally equivalent to the 6895 except it is embedded on the outer edge with (b)(4) (b)(4)

Although model numbers differ, all leads in each of the three groups are functionally equivalent. The various model numbers reflect an evolution of temporary to transvenous lead development, as well as minor changes, such as the connector pin modification from 3.2 mm to 6.5 mm.

Additional devices were used to evaluate the non-thoracotomy lead studies in canines. These are described below.

External Devices for Implant Support

Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD provides the same detection capabilities as the implantable Model 7217B PCD Device. Therapies are identical except that the maximum output energy is 40 joules (J) and automatic defibrillation and cardioversion are not available in the Model 5355. The Model 5355 ETCD provides measurement and display of output waveform parameters and ETCD status, an isolated electrogram signal, and passthrough connections of pacing and sensing electrodes to external instrumentation.

Model 2394 External Cardioverter/Defibrillator (ECVD)

The Model 2394 ECVD instrument can deliver: (1) a single stimulation pulse on one output channel, or (2) a pair of pulses, delivered individually on the two different output channels. Monophasic and biphasic pulses are provided, output capacitance

can be varied between 10 and 150 microFarads (mf) depending on which external capacitor modules are used, and pulse width can be specified as a fixed duration (0.1-19.9 ms) or "tilt" (10-90%). Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Model 2376 External Cardioverter/Defibrillator (ECVD)

The output stimulation parameters of the Model 2376 are very similar to those of the Model 2394 except for the following modifications:

- All pulses are monophasic, truncated, exponential waveforms.
- Output capacitance is fixed at 50 microFarads and pulse width is determined by a fixed pulse duration only.
- Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Study Methods

All canine studies were conducted according to the 1966 and 1970 Animal Welfare Acts, 1985 NIH Laboratory Animal Use and Care Guidelines and GLP regulations. Adult mongrel canines were used for all studies. The dogs weighed 20 kg or more.

Specific details of each study are presented in the following "Animal Studies/Results" section.

Each study is briefly described below. Both acute and chronic studies were performed to assess the toxicity of the non-thoracotomy lead system as well as its stability over time.

Study #1: Acute Toxicity Testing of Non-thoracotomy Leads

The objective of this study was to quantify the amount and nature of shock-induced damage to the myocardial tissue resulting from multiple, high energy defibrillation shocks delivered through transvenous defibrillation leads and a subcutaneous patch. This information has previously been submitted to the agency in the Non-Thoracotomy IDE, reference Document Control Number G870102/S23; FDA Approved October 4, 1990. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results of these studies revealed only

minimal shock-induced necros (b)(4) (b)(4)
which did not result in functional impairment of the cardiac tissue. Therefore, the use of the Model 6963, 6966 and 6999 leads did not result in significant myocardial damage in canines and could be safely implanted in humans.

Study #2: Model 6881, 6884 and 6895 Chronic Lead Evaluation

The objective of this study was to evaluate the suitability of the lead system for human clinical use. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Study results demonstrate that the performance of the non-thoracotomy lead system when used with the PCD and ETCD devices is in conformance with system design and expected operation.

One canine in this study has presented with two mastocytomas; a common type of skin tumor in middle-aged canines. This observation is not related to the PCD system, nor is it relevant to the clinical application of the PCD system. The tumors were excised and the animal remains in good health.

Study #3: Model 6881, 6884 and 6895 Chronic Lead Defibrillation Study

This study is an evaluation of the chronic stability of the non-thoracotomy lead system via the monitoring of defibrillation and pacing thresholds. In addition, histopathological examinations have been performed to assess the amount and nature of shock-induced damage to the myocardial tissue resulting from defibrillation shocks. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results demonstrate stable pacing, sensing and defibrillation thresholds over time. Additionally, histopathology analysis shows no cardiac tissue damage due to delivery of defibrillation shocks.

Study #4: Model 6963, 6966 and 6999 Chronic Lead Defibrillation Study

This study is an ongoing evaluation of the non-thoracotomy lead system to assess chronic defibrillation threshold stability, pacing thresholds, intracardiac sensing capabilities and tissue damage. Results indicate the lead system performs as intended; DFTs and

pacing thresholds have remained stable throughout the study (60 weeks) and intracardiac sensing is appropriate. Additionally, pathology data, to date, indicates minimal localized trauma to the cardiac tissue (<0.05 percent by weight).

Conclusion

All of these canine studies have demonstrated that the non-thoracotomy lead system, which includes the Model 6963 CS/SVC lead, 6966 RV lead and 6999 SQ patch lead, functions safely and is therefore appropriate for human use.

4. Clinical Experience Report

A. System and Study Description

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT, however, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing. It is necessary to perform a significantly more invasive procedure, a thoracotomy, in order to implant the epicardial leads. Thus, the need to incorporate programmability, multiple detection and therapeutic options, and a less invasive lead system has lead to the development of a tiered therapy device, the PCD™ Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of **February 1, 1993.**

The PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, and approved by the FDA February 11, 1993, with the addition of Transvene leads.

This summary provides an overview of the clinical experience which verifies that the PCD Transvene System is safe and effective in the indicated patient population.

1. Implanted Devices, Leads, and Pulse Generator

The Pacer-Cardioverter-Defibrillator (PCD) device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD Device is used in conjunction with appropriate lead systems for the treatment of patients with ventricular tachycardia (VT) and/or ventricular fibrillation

64

(VF). The PCD Device also provides backup pacing in the VVI mode and noninvasive electrophysiologic (EP) study capabilities.

The PCD Device is programmed with the market released Medtronic programmer and a Model 9788 or equivalent MemoryMod™ Cartridge. The PCD Device incorporates a two-way telemetry system which receives operational instructions from the programmer and transmits status, electrogram and event information back to the programmer for display and/or printout.

The External Tachyarrhythmia Control Device (ETCD) is an external, multiprogrammable, tachyarrhythmia control device. Its operation is similar to the PCD Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it displays measurements of cardioversion and defibrillation therapy parameters. The ETCD is used for making defibrillation threshold measurements during the PCD Device implantation procedure.

Components

The Medtronic PCD Transvene System, which is represented in Figures 1A and 1B, for which market release approval is being requested, consists of the following components:

Implanted Device and Related Programming System
Pacer-Cardioverter-Defibrillator (PCD) Device
Model 7217B

Programmer
Model 9710 programmer and related accessories (currently market released), plus
Model 9788 MemoryMod™ Software Cartridge

Lead System
Electrode Leads:
Model 6966
Model 6963
Model 6999
Market Released Medtronic Epicardial Leads

Implant Measurements System
Model 5355 ETCD™ External Tachyarrhythmia Control Device
Model 5418 Patient Cable
Model 5414 Test Load
Model 5417 EGM Cable
Model 5419 Jumper Cable

The physical characteristics of the Model 7217B are summarized in Table IA1-1:

PCD Model 7217B Physical Characteristics	
Feature	**Model 7217B**
Volume	113 cc
Weight	198 grams
Connector Module	Four connector ports
Power Source	Wilson Greatbatch Model 8830 Lithium Silver Vanadium Oxide
Sensing Configuration	Standard Bipolar
Pacing Configuration	Integrated Bipolar

Table IA1-1: Features: Model 7217B - 2/1/93

The Model 7217B PCD Device uses the pace/sense leads for sensing, thus providing **standard bipolar** sensing. Pacing is delivered in the integrated bipolar configuration.

2. Study Design and Objectives

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD system, pace/sense, detection and therapy functions in both the

acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population.

The objectives of the clinical study were:

* to evaluate the sensitivity and specificity of the PCD Device with Transvene lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms;

* to monitor the efficacy of the PCD Device with Transvene lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (Successful Termination/Number of Detected Episodes with Therapy Delivered). Investigators were free to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely;

* to evaluate the performance of the Model 6966, 6963 and 6999 Transvene leads;

* to monitor the patient selection criteria and patient management methods required by the PCD Device and Transvene leads.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD System:

Pre-implant Patient Assessment
Lead System Testing at Implant
Implantable Pulse Generator Testing at Implant
Pre-hospital Discharge Testing
Follow-up Evaluation 1 and 3 months post implant then at 3 month intervals

Specific data was collected at each of these points to meet the objectives of the clinical study. This included:

Pre-implant Patient Assessment - extensive pre-implant testing was performed to ensure that the general patient selection criteria were met. This testing included at least an electrophysiologic evaluation, measurement of ejection fraction, and assessment of the patient's New York Heart Association

(NYHA) classification of their cardiovascular status. Depending on the patient history, cardiac catheterization and exercise testing were also conducted.

Lead System Testing - implant evaluation was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate, ventricular tachycardia. The Market Released Model 5355 ETCD™ or the 2394 External Cardioverter Defibrillator (ECVD) was used for testing.

This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The PCD Device implant criteria were:

1) successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2) a 2:1 VF sensing safety margin.

Implanted Pulse Generator Testing - this implant evaluation was performed to demonstrate proper detection and termination of ventricular fibrillation by the implanted PCD System with VF Therapy #1 programmed to 34 Joules in addition to pacing and sensing thresholds.

Pre-hospital Discharge Testing - testing performed at the pre-hospital discharge included proper detection and termination of induced ventricular tachycardia. Final sensing and therapy parameters are programmed at the PHD.

Follow-up Evaluation - regular testing was performed to evaluate the chronic stability of detection and therapy parameters of the PCD System. This testing included an assessment of the relative stability of the energy required to defibrillate a patient and efficacy and acceleration rate assessment of the VT therapies. The number of spontaneous VT/VF episodes treated by the PCD Device were evaluated. Complication rates and patient mortality data were also evaluated.

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

Clinical data presented in this summary includes experience with the Model 7216A and 7217B PCD Devices with the Model 6966, 6884, 6963, 6881, 6999, and 6895 Transvene Leads (the only difference between the Models 6884/6881/6895 and Models 6966/6963/6999 are the size of the connector pins). This report presents the clinical evaluation of the safety and efficacy of the PCD Device with Transvene Leads implanted in 757 patients of which 657 have implant durations equal to or greater than six months.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD System with Transvene Leads is included in this report.

Patient data from U.S. and International patients, Model 7216A and 7217B, and the three implanted lead configurations (RV/CS/SQ, RV/SVC/SQ, and RV/CS/SVC) analyzed in this report were compared with the appropriate statistical tests to justify data pooling. Data analyzed included: age, sex, ejection fraction, primary indication, NYHA classification, and underlying heart disease. No clinically significant differences were found among the patient groups.

Indicated Patient Population

The PCD System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD Device.

Results provided in this application will support Medtronic's request for market release of the PCD Transvene System for use in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

These are the same indications that were approved for the PCD Epicardial System.

For this patient population the primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD pulse generator.

The PCD System allows the titration of therapies for patients with ventricular tachycardia while providing the critical defibrillation backup. Defibrillation backup is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia. Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

Study Controls

The clinical experience obtained in the PCD Epicardial System clinical study provides a concurrent control for comparing the clinical performance of the PCD Transvene

System. Using the PCD Epicardial System clinical data as a control is appropriate because the patients were being enrolled in the two studies concurrently by the same investigators, and the patient indications, implant criteria, and clinical data requirements were identical for the two patient groups.

The Ventak-P Epicardial System is used as a historical control, since it was the most similar implantable defibrillation system that was market released and had published performance data.

The PCD investigators believe that there is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. For these patients, the PCD Transvene System is the only therapy available. Therefore, randomization between the Epicardial and the Transvene lead systems would not be feasible or clinically or ethically appropriate in these patient groups. There was no market released transvenous system available which would make a randomized study design possible.

3. Justification for Data Pooling

This section will describe the results of the analysis to demonstrate that the data from the U.S. and International investigative centers and the two device model numbers may be pooled. This section will also compare the three lead systems which will be presented throughout the report.

a. Comparison of U.S. and International Patients

Statistical comparisons were made between the two populations age, sex, ejection fraction, primary indication, NYHA, and previous cardiovascular history. Table E1 in Appendix E summarizes the results of statistical analysis.

All study investigators used the same:

a. patient selection criteria,
b. investigational protocol procedures, and
c. indications for implant of PCD™ Transvene™ System.

Of the variables analyzed patient age, ejection fraction, primary indication, NYHA classification, coronary artery disease and cardiomyopathy showed a statistically significant difference between the U.S. and the International patient populations at a 0.05 significance level. The difference in NYHA classification becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix E for multiple inference adjustments. Coronary artery disease, ejection fraction, cardiomyopathy, primary indication and age remain statistically significant after adjusting for multiple inference. The U.S. patient population has a higher percentage of patients with coronary artery disease and cardiomyopathy, lower mean ejection fraction, more patients with VT as their primary indication and a higher mean age. The difference in age may explain the differences in underlying disease and cardiac ejection fraction. These factors that are statistically significant but are not considered to be clinically significant enough to require stratification of the U.S. and International patient populations. The differences may have to do with regional attitudes toward access to health care for the aged.

b. Comparison of Model 7216A and Model 7217B

Table E2 in Appendix E summarizes the results of statistical analysis comparing the Model 7216A to Model 7217B. No parameters were found to be statistically significant between the two PCD models at a 0.05 significance level.

c. **Lead Configurations**

Table E3 in Appendix E shows comparisons of patient variables for the three lead systems. This was done to document that there were no significant differences in patient characteristics between the implanted lead configurations.

Of the variables analyzed in Table E3 sex and cardiomyopathy showed a statistically significant difference between the three lead configurations at a 0.05 significance level. The difference in sex and percentage of patients with cardiomyopathy becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix E for multiple inference adjustments.

d. **Statistical Analysis Conclusions**

The statistical comparisons between the U.S. and International populations indicated no clinically significant differences therefore the data may be pooled. Analysis of the patients receiving the two PCD models indicates no statistically significant differences therefore the data from the two devices may be pooled.

The results from the comparison of lead systems indicated no statistically significant differences in patient demographics, primary indication, or heart disease.Data Pooling/U.S. Demographics

B. **Overview of Clinical Experience**

This report covers a total of 762 implants of the PCD Device with the Transvene Defibrillation Lead System in 757 patients who received a 3 lead system. There was a total of 97 patients that were screened for Transvene system that did not meet the implant criteria and received a Medtronic Epicardial system and a total of 43 patients that received a non-standard lead system. These

n3

patients are described in Section C2, Patients not Meeting Implant Criteria and Section D4, Non-standard Lead Configurations, respectively.

A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table IB-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD Transvene System Implant Distribution			
	Total	U.S.	Int'l
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table IB-1: PCD Transvene System - Implant Distributions - 2/1/93

The mean documented implant duration for this patient population is 11.7 months and ranged from implant to 37.4 months. The cumulative implant duration is 8894.8 months. There are 657 patients with implant durations equal to or greater than 6 months and 393 patients with implant durations equal to or greater than 1 year.

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table IB-2 provides a data summary on these patients. Also included is the data summary of the patients with 6 months and 12 months of follow-up.

PCD Transvene System Data Summary			
	All Patients (3 Electrode Systems)	Patients with 6 months of Follow-up	Patients with 12 months of Follow-up
Number of Patients	757	657	393
Device Months Follow-up	8894.8	8602.6	6454.6

One Year SCD Survival	99.5%	99.7%	100.0%

Table IB-2: PCD System Data Summary - All Transvene Patients versus Transvene Patients with 6 mo Follow-up - 2/1/93

1. Implant Information

Implants of the PCD Device may use two or three Transvene leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

The venous entry site used for placement of the Transvene leads is determined by the implanting physician. Table IB1-1 shows that the Left Subclavian vein is the most popular venous entry site regardless of type of lead or intended lead location. The total number of RV lead entry sites is greater than the total number of patients included in this report because of patients with multiple lead evaluation sessions (e.g. patients that received a second PCD Transvene system if the initial system was removed due to infection).

PCD Transvene System Venous Entry Site			
	RV Lead Models 6884/6966/SP2100	CS/SVC Lead Models 6881/6963	All Transvene Leads
Left Subclavian	483	583	1066
Right Subclavian	40	47	87
Left Cephalic	213	180	393
Right Cephalic	8	7	15
Left Internal Jugular	7	9	16
Right Internal Jugular	11	9	20
Other	5	4	9
Total	767	839	2097

Table IB1-1: Venous Entry Site - 2/1/93

The location of the subcutaneous patch is presented in Table IB1-2. Location is defined by both anatomical line and intercostal space. The study protocol does not restrict investigators in subcutaneous patch placement. Investigators are free to place it in the most appropriate location for each individual patient.

The most common subcutaneous patch location laterally is the mid axillary line (55.7%). the next most common location is the anterior axillary line (34.3%). The majority of subcutaneous patches are placed between the third and sixth intercostal (53.4%).

The majority of the investigators (92.8%) placed the patch electrode subcutaneously. Fifty-two (52) or 7.2% if investigators placed the patch electrode in a submuscular location.

PCD Transvene System
Location of the Subcutaneous Patch Electrode

Intercostal Space	Mid Clavicular Line	Anterior Axillary Line	Mid Axillary Line	Posterior Axillary Line	Subscapular	Total
1-2	11	1	3	0	0	15 2.1%
3-6	21	127	237	1	0	386 53.4%
7-11	1	17	18	0	0	36 5.0%
Not Specified	17	103	145	6	15	286 39.5%
Total	50 6.9%	248 34.3%	403 55.7%	7 1.0%	15 2.1%	723 100.0%

Table IB1-2: Location of the Subcutaneous Patch Electrode - 2/1/93

Table IB1-3 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD Transvene System Mean LED and DFT Values				
Lead System	Implant Frequency	Mean LED	Implant Frequency	Mean DFT
Total Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table IB1-3: PCD Transvene System - LED and DFT Values - 2/1/93

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD Device.

There was a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. Since there were no differences in the patient populations implanted with any of the 3 lead configurations, this may be a configuration that results in lower DFTs than the other configurations. In theory, this may be due to better defibrillation current distribution throughout the myocardium. There is no intent to show that a lower DFT results in a better patient outcome. The premise of the PCD Epicardial and Transvene studies was to demonstrate that if a patient was evaluated at implant and shown to meet the implant criteria, that they would be reliably defibrillated over time, and therefore, have a high probability of survival from SCD regardless of which lead system or defibrillation pathway was chosen or the absolute value of the DFT.

Follow-up Data - Quantity

The combined experience from the Model 7216A and the Model 7217B with Transvene lead systems discussed in this analysis is 762 implants in 757 patients followed for a mean of 11.7 months. Maximum follow-up is 37.4 months

38

with 8894.8 total device months of experience. Six-hundred-fifty-seven (657) patients have been followed for at least 6 months and 393 patients have a minimum of one year of follow-up.

2. Spontaneous VT and VF Episode Experience

Of the 757 patients who received a PCD Transvene System, 597 patients (78.9% - 597/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. A total of 458 patients (60.5%) have experienced a spontaneous episode of either VT and/or VF that has been detected and treated by the PCD Device. A total of 141 (18.6%) experienced VT only, 142 patients (18.8%) experienced VF only and 175 patients (23.1%) experienced both an episode of VT and VF.

There have been a total of 12,009 episodes of spontaneous VT or VF as detected by the PCD. The overall PCD Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD is presented in Table IB2-1.

For those episodes where all four programmed VT/VF therapies failed to terminate the episode, the clinical follow-up data form was reviewed for investigator's comments on the episode. The investigator reviewed the patient's symptoms at the time of the episode as well as the stored episode information provided by the PCD Device and indicates on the clinical dataform whether the ineffective therapy was due to a nonventricular tachyarrhythmia such as sinus tachycardia or atrial fibrillation. If there is no such indication on the clinical dataform, it is assumed that the ineffective therapy was for a spontaneous VT or VF episode. It should be noted that for all current ICD Systems, the delivery of inappropriate therapy for atrial fibrillation or sinus tachycardia is a known risk of the therapy.

PCD Transvene System Success Rate for Spontaneous VT/VF Episodes		
	Spontaneous VT Episodes	**Spontaneous VF Episodes**
Mean Follow-Up	11.7 months	11.7 months
Number of Episodes	10,027	1982
Number of Patients with Episodes	316	317
% Overall Efficacy	9,864/10,027 98.4%	1951/1982 98.4%
% Unsuccessful Termination (VT or VF)	68/10,027 0.7%	5/1982 0.3%
% Unsuccessful Termination (AF,ST, other)	95/10,027 0.9%	26/1982 1.3%

Table IB2-1: PCD Transvene System: Success Rate for Termination of Spontaneous VT/VF Episodes (n = 757) - 2/1/93

90

a. **Spontaneous VT**

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 10,027 spontaneous episodes of VT have been detected by the PCD Device in 316 patients. The mean number of episodes per patient with VT was 31.7 (316/10,027) and ranged from 1 - 531 episodes.

Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Of the 9864 successfully terminated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD Transvene System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Sixty patients experienced 163 (1.6%) episodes in which the PCD Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirty-nine patients experienced 95 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD Device responded appropriately based on the programmed detection parameters.

81

The remaining 68 episodes occurred in 21 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy**. Reprogramming and pharmacologic intervention resolved these events.

b. Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 1982 spontaneous episodes of VF have been detected by the PCD Device in 317 patients. The mean number of episodes per patient was 6.3 and ranged from 1 - 77 episodes. A review of the chart by the investigator for this patient that experienced the 77 episodes of VF revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (89.1%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 98.4% were successfully treated with one of the four programmable VF therapies.

Sixteen patients experienced 31 episodes (1.3%) in which the PCD Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Nine patients had 22 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Four patients experienced 5 ineffective episodes that were detected as VF by the PCD® System. One of these patients (b)(6) required external defibrillation

to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Another patient (b)(6) had an episode recorded as ineffective on the event counters but presented in sinus rhythm. Subsequent evaluation demonstrated appropriate PCD function. Another of these patients (b)(6) had two spontaneous episodes of VT that were detected as VF by the PCD while in the hospital for progressive CHF. These episodes required external cardioversion. The patient requested the PCD be turned OFF. The patient was alive at the last known follow-up. The last of these four patients (b)(6) experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on a monitor the patient developed VF. The PCD delivered the programmed therapy which terminated the episode but the patient developed EMD, arrived at the ER comatose and died.

Four patients (one patient (b)(6) experienced 2 episodes due to AF but is described below again) experienced 4 episodes in which the PCD detected the episodes as VF but were actually episodes due to extraordinary circumstances. One patient (b)(6) experienced an episode where all four therapies failed secondary to RV lead fracture. The patient had Twiddlers Syndrome. Reoperation was required. It appears that the inappropriate therapy was not due to VT/VF but due to noise. Another patient (b)(6) had a surgical procedure (CABG) where the CS lead dislodged post surgery. The episode that was detected was due to the lead dislodgement. The third patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The fourth patient (b)(6) was in the hospital and there was an episode of VF detected by the PCD and therapy was delivered. However, the device was interrogated before termination of the episode was detected by the PCD. There was external intervention (transthoracic defibrillation) associated with the terminal event. However, the patient ultimately expired. The device was not interrogated again.

The evaluation of spontaneous episode experience indicates that the PCD Transvene System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

3. Summary of Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, there have been a total of 176 complications identified in 147 patients and 212 observations identified in 178 patients in the PCD Transvene System patient population. Thus, 19.4% (147/757) of the patients have experienced a clinical event which was defined as a complication and 23.5% (178/757) of the patients have experienced a clinical event which was defined as an observation.

Table IB3-1 summarizes the reported PCD Transvene System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

PCD Transvene System Reported Complications/Observations By Category		
Category	**Complications**	**Observations**
	Num (% of Pts)	Num (% of Pts)
Increased Defibrillation Requirements	9 (1.2%)	8 (1.1%)
Inappropriate VF Therapy Delivery	-	14 (1.9%)

Table IB3-1: PCD Transvene System: Reported Complications and Observations - 2/1/93

* This number indicates the number of patients with 2 events

Table IB3-4 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days. The $\leq$30 day period is defined as the acute period. This definition is consistent when compared to endocardial bradycardia lead terminology.

PCD Transvene System
Reported Complications/Observations
Lead Dislodgements <30 days and >30 days

Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=741	14 (1.9%)	10 (1.3%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 261	12 (4.6%)	10 (3.8%)	2 (0.8%)	2 (0.8%)
SVC Lead Dislodgement n=535	16 (3.0%)	29 (5.4%)	1 (0.2%)	6 (1.1%)
Total Lead Dislodgement n=757	42 (5.6%)	49 (6.5%)	3 (0.4%)	9 (1.2%)

Table IB3-4: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 58 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In 49 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system and in 9 cases repositioning of the lead was not required..

Lead dislodgements are not specific to the PCD Transvene System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring

leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

In an attempt to reduce the rate of lead dislodgement, modifications were made to the lead anchoring sleeve and a second sleeve was added to the lead. The sleeve was modified to increase the grip pressure on the lead body and two sleeves were provided on each lead at the time of manufacture. Analysis has been completed on 439 patients implanted with the Transvene system using leads that are packaged with two anchoring sleeves. **(NOTE: These 439 patients were enrolled in the Clinical Trial after 6-24-92 and are not included in the 757 patient population).** Table IB3-5 contains a data summary for the 439 patients. This group of patients has similar characteristics to the 757 patient population in most areas with a slightly higher percentage of patients with VT reported as the primary indication for implant than the 757 group of patients (61.1% vs 49.8%).

PCD Transvene System **Data Summary of Patients with Two Anchoring Sleeves**	
Number of Patients	439
Number, % Male **Number, % Female**	354 80.6% 85 19.4%
Mean Age	61.2 yrs
Primary Indication: **SCD** **VT** **SCD/VT**	 137 31.2% 268 61.1% 34 7.7%
Coronary Artery Disease	324 73.8%
Mean Ejection Fraction	32.5% (N=390)

Table IB3-5: PCD System Data Summary for Patients with Two Anchoring Sleeves -2/1/93

Of these 439 patients, 292 have completed their 1 month follow-up and 195 have completed their 3 month follow-up and 17 have completed a 6 month follow-up. Since the introduction of the dual anchoring sleeve the incidence of

lead dislodgement has been dramatically reduced. There has been 13 dislodgements in 10 patients for a per patient incidence of dislodgement of 2.3% (10/439).

U.S. versus International

Table IB3-6 contains a summary of the complications and observations for the U.S. patients versus the Internal patients.

Table IB3-6: PCD Transvene System: Reported Complications and Observations - 2/1/93

4. Summary of Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death and overall survival in the PCD Transvene System patient population was performed based on the categorization by the investigators and subsequently reviewed by the Clinical Event Review Committee (CERC).

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed**.
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD System component, or as a result of a device induced arrhythmia, or an interaction between a PCD System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD Transvene System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 51 patient deaths reported in the PCD Transvene System patient population. Table IB4-1 summarizes how these patient deaths have been classified.

PCD Transvene System
Summary of Death Classifications
(n = 757)

Classifications	Number of Deaths
Sudden Cardiac	5
Non-Sudden Cardiac	31
Noncardiac	15
TOTAL	51

Table IB4-1: PCD Transvene System - Summary of Death Classifications - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD Transvene System.

Actuarial survival analysis on the PCD Transvene System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat**. Those patients in whom the PCD Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD Transvene System but failed to receive a Transvene system and received a Medtronic Epicardial system are also included in this analysis.

90

Projected one year survival calculations for the various death classifications are provided in Table IB4-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD System with Epicardial leads (5.3% - 39/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD Transvene System (n = 757) and all patients that were screened for a PCD Transvene System (n = 854) regardless of implant outcome. The outcome of the 854 patients screened for a PCD Transvene System are described more fully in section IC2.

PCD Transvene System One Year Actuarial Survival		
	Received a Transvene System (N = 757)	**Screened for a Transvene System (n = 854)**
Sudden Cardiac Death	99.5%	99.4%
Non-Sudden Cardiac	96.2%	96.6%
All Cardiac	95.8%	96.1%
Noncardiac	98.1%	98.3%
Perioperative	0.7%	1.6%
Overall	93.3%	92.9%

Table IB4-2: PCD Transvene System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD Transvene System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.5% for those in the patient group that received a Transvene System and 99.4% for those who were screened for a Transvene System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

C. Specific Patient Populations

1. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD Transvene System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Note: These patient indications are identical to those approved for the Medtronic PCD Epicardial System.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD Transvene System in these three groups are summarized in Table IC1-1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 98.4%, in the VT patient group 98.3%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD Transvene System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 98.6%

This analysis indicates that the PCD Transvene System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

PCD Transvene System
Data Summary by Primary Indication

Table IC1-1: PCD Transvene System Data Summary by Primary Indication - 2/1/93

2. Patients Not Meeting Implant Criteria

a. Overview

For purposes of the PCD Transvene System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less.

A total of 897 patients had an evaluation of a PCD Transvene System and are divided into the following groups: (1) patients who received a PCD Transvene System, (2) patients screened for a PCD Transvene System and received a PCD Epicardial System, and (3) patients who received a non-standard lead system. Figure 1 provides an overview of the outcome of these patients.

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD Transvene System ultimately received a 3 lead system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria, which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD Transvene System.

Ninety-seven (97) patients (10.8%) were screened for a Transvene lead system but received an epicardial system. Forty-three (43) patients (4.8%) were screened for a Transvene lead system but received an non-standard system.

PCD TRANSVENE SYSTEM IMPLANT EVALUATION

MEDTRONIC CONFIDENTIAL

a. **Overview**

The physician's justification for implanting the PCD Transvene System despite not meeting the recommended defibrillation implant criteria are presented in Table IC2-1. As noted previously, the patients not meeting implant criteria (N = 214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules (79.4% of the patients); (2) Difficult to induce VF (11.2% of the patients); and (3) Implant procedure terminated due to poor patient condition (9.4% of the patients).

PCD Transvene System
Reasons for Not Meeting Implant Criteria
Physician Justification

Reason	Number of Patients (% of Total)
Success at $\leq$ 24 Joules	170 (79.4%)
Difficult/Unable to Induce VF	24 (11.2%)
Patient Condition	20 (9.4%)
Total	214

Table IC2-1: PCD Transvene System: Physician Justification for Not Meeting Implant Criteria - 2/1/93

Table IC2-3: PCD Transvene System: Patients Not Meeting Implant by Justification - Clinical Outcome - 2/1/93

In summary, the physician made an appropriate judgement to implant the PCD Transvene system based on the clinical outcome of the patient especially those patients with a 10 Joule safety margin. Their outcome is clinically equivalent to that of the entire 757 patient population.

98

1) **Lowest Energy of Defibrillation < 24 Joules**

There were 170 patients in whom the PCD Transvene System was implanted with a defibrillation safety margin of at least 10 Joules. Table IC2-4 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD Transvene System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD Transvene System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System. In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, an average of 9.7 months, is similar to that of the entire patient group (11.7 months).

99

PCD Transvene System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7

Table IC2-4: PCD Transvene System: Patients Not Meeting Implant Criteria with 3/4 Successes at ≤ 24 Joules Clinical Experience - 2/1/93

2) Difficult or Unable to Induce VF

There were 24 patients who did not meet the recommended PCD Transvene System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD Transvene System implant criteria because at least three episodes of VF were not induced at the time of implant, 13 patients (54.2%) have experienced a spontaneous VF episode

100

and 21 patients (87.5%) have had VT or VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD Transvene System.

There has been one reported patient death (b)(6) in this patient group (at xx months) with a resultant one year sudden cardiac death and overall actuarial survival of 100%.

3) Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD Transvene System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients are summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (N = 11 patients);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (N = 6 patients); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (N = 3 patients).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

01

Of these 20 patients, VT or VF has been induced at a chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD Transvene System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, examination of events indicated that one patient experienced multiple episodes of atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may be due to the lower mean ejection fraction of this patient group.

The VF Therapy efficacy and SCD survival in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

c. **Complications and Observations: Patients Not Meeting Implant Criteria**

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following previously described definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Of the 170 patients with successful defibrillation at 24 Joules, as of February 1, 1993, there have been a total of 41 complications reported in 33 patients and 34 observations reported in 31 patients in the PCD Transvene System patient population. Thus, 19.4% (33/170) of the patients had a clinical event reported which was categorized as a complication and 18.2% (31/170) of the patients had a clinical event reported which was categorized as an observation. The percent of patients with complications reported in the overall population of 757 patients was 19.4% (147/757), the same percentage as in this subgroup of 170. There were 23.8% (180/757) of the patients in the overall population with reported observations, a slightly higher percentage than in this subgroup of 170 patients.

Of the 24 patients that did not meet the implant criteria due to difficulty or inability to induce sustained VF, as of February 1, 1993, there have been a total of 4 complications reported in 4 patients and 10 observations reported in 8 patients in the PCD Transvene System patient population. Thus, 16.7% (4/24) of the patients had a clinical event reported which was categorized as a complication and 30.0% (8/24) of the patients had a clinical event reported which was categorized as an observation.

Of the 20 patients that did not meet the implant criteria due to patient condition, as of February 1, 1993, there have been a total of 6 complications reported in 4 patients and 7 observations reported in 5 patients in the PCD Transvene System patient population. Thus, 20.0% (4/20) of the patients had a clinical event reported which was categorized as a complication and 25.0% (5/20) of the patients had a clinical event reported which was categorized as an observation.

Table IC2-5 and IC2-6 summarizes the reported PCD Transvene System complications and observations by category in these 3 patient groups, respectively. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

Table IC2-7: PCD Transvene System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 2/1/93

Statistical analysis was completed on the 543 patients that net implant criteria versus the 214 patients that did not meet criteria. Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with coronary disease with concomitant life threatening ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD Transvene System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD Transvene System.

Implant data obtained in these two patient groups is presented in Table IC2-8. As would be expected the patients not meeting the implant criteria had higher mean DFT and LED values when compared to the patients who did meet the implant criteria. However, the mean DFT (18.8J) and LED (19.5J) values obtained in patients not meeting implant criteria provided at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD Device (34J) in nearly all (97.4%) of the patients.

PCD Transvene System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Number of Inductions	7.0	8.2

Mean LED	14.8J	19.5J
Implanted Lead System		
RV-SVC-SQ	351 (64.6%)	145 (67.8%)
RV-CS-SQ	159 (29.3%)	63 (29.4%)
RV-CS-SVC	33 (6.1%)	6 (2.8%)
Defibrillation Pathway		
Sequential	414 (75.7%)	160 (74.4%)
Simultaneous	127 (23.2%)	51 (23.7%)
Single	6 (1.1%)	4 (1.9%)

Table IC2-8: PCD Transvene System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Implant Data - 2/1/93

When the mean number of inductions and the mean number of configurations tested of 8.2 and 2.7, respectively, for those patients that did not meet the implant criteria is compared to those that did meet the implant criteria, 7.0 and 2.0, it is apparent the implanting physicians did induce more VF and were more likely to try more than 1 lead configuration in an attempt to meet the implant criteria.

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table IC2-9.

PCD Transvene System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Spontaneous VT Episode Efficacy	98.7%	97.6%
Spontaneous VF Episode Efficacy	98.2%	99.0%
Number of Patient Deaths	37	14
Perioperative Mortality	0.7%	0.5%
One Year Survival		
Sudden Cardiac	99.5%	99.5%
Non-Sudden Cardiac	95.8%	97.2%
All Cardiac	95.4%	96.7%
Noncardiac	98.5%	97.1%
Overall	93.2%	93.5%

Table IC2-9: PCD Transvene System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 2/1/93

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD Device therapies failed to terminate the episode.

Five patients experienced 7 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Three patients had 5 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Two patients experienced 2 episodes in which the PCD detected the episodes as VF but were actually episodes due to extraordinary circumstances. The first patient (b)(6)

110

had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The second patient (b)(6) was in the hospital and there was an episode of VF detected by the PCD and therapy was delivered. However, the device was interrogated before termination of the episode was detected by the PCD. There was external intervention (transthoracic defibrillation) associated with the terminal event. However, the patient ultimately expired. The device was not interrogated again.

Eighteen patients experienced 68 episodes in which the PCD Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Nine patients experienced 44 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD Device responded appropriately based on the programmed detection parameters.

The remaining 24 episodes occurred in 8 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (10.1 vs 12.3 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Conclusion

In conclusion, 214 patients received the PCD Transvene System despite not meeting the recommended implant criteria. These 214 patients are divided into the following groups:

- successful defibrillation of VF at 24 Joules or less (170/214),
- difficult to induce at least three episodes of VF at implant (24/214), and
- worsening patient condition which prevented further inductions (20/214).

It should be noted that 91% (194/214) of the patients not meeting the recommended implant criteria had at least one successful termination of induced ventricular tachyarrhythmia (VT, VFlutter or VF) at 24 Joules or less. Additionally, their clinical outcome, especially in the 170 patients with successful defibrillation of VF at $\leq$24 Joules is similar and is part of the support to request changing the implant criteria to the following:

* Two consecutive successful defibrillations with the final lead configuration with a stored output of 24 Joules or less; or
* Three successful defibrillations in four attempts with the final lead configuration at a stored output energy of 24 J or less.

D. System Comparison

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The Ventak-P Epicardial System provides cardioversion and defibrillation therapy for VT and hemodynamically unstable VT. However, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing due to the pain associated with cardioversion shock therapy. The need to incorporate programmability, multiple detection and therapeutic options has lead to the development of the PCD Device.

17

However, the Ventak-P Epicardial System and PCD Epicardial System are implanted only with a defibrillation lead system requiring a thoracotomy. The PCD Transvene System allows the implantation of an ICD System without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy.

In the PCD Transvene System PMA Application a comparison of the PCD Transvene System clinical experience was made to both the Ventak-P Epicardial System and the PCD Epicardial System. (Reference: Clinical Experience Report Section X, Comparison to AICD Clinical Results and Section XI, Comparison to PCD Epicardial System Clinical Results). A comparison to the Ventak-P Epicardial System was done because this was the most similar FDA approved ICD System available at the time of the original submission. A comparison to the PCD Epicardial System was done since this system incorporated the same tiered therapy ICD Device as well as being a concurrent clinical study using the same protocol and clinical investigators.

The comparison between the Ventak-P Epicardial System and the PCD Transvene System was limited in scope due to the limited availability of clinical data from the Ventak-P Epicardial System Summary of Safety and Effectiveness, but included patient characteristics, implant defibrillation thresholds, incidence of spontaneous VT/VF episodes, incidence of complications and one year actuarial survival.

The comparison between the PCD Transvene System and the PCD Epicardial System included patient characteristics, implant data, implant defibrillation thresholds, programmed parameter status, spontaneous VT/VF episode efficacy, incidence of complications and observations and one year actuarial survival.

1. **Comparison to AICD (Ventak-P) Epicardial System**

   The current AICD (Ventak-P) Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD Transvene System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy.

13

This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD Transvene System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD Transvene System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

a. Patient Characteristics

In comparing the clinical experience with the PCD Transvene System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD Transvene System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table ID1-1.

14

PCD Transvene System Comparison of Patient Characteristics PCD versus AICD		
	PCD	**Ventak-P**
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table ID1-1: Comparison of Patient Characteristics, PCD versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD Transvene System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD Transvene population than in the AICD population ($p = 0.001$).

b. Clinical Characteristics

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of

spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

1) Implant Defibrillation Thresholds

For the purposes of the PCD Transvene System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD Transvene System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

2) Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD Transvene System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD device provides information on the total number of VT and VF episodes detected by the PCD device and the total number of VT and VF episodes successfully treated by the PCD device as well as the number of VT/VF episodes where the PCD device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous

ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD Transvene System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD Transvene System detection criteria.

A total of 10,027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD device episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

3) Incidence of Complications

Table ID1-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD Transvene System includes **both complications and observations**. In the following table, the complications are reported for the categories of Failure to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD Transvene System Comparison of Complication/Observation Rates PCD versus AICD		
Category	**PCD%**	**AICD%**
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection (explant)	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table ID1-2: Comparison of Complication/Observation Rates: PCD Transvene System vs AICD Epicardial System - 2/1/93

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD Transvene System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD Transvene System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD Transvene System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus

tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 2.9% which was comparable to Winkle's article.

Thus, the incidence of complications and observations in the categories of ineffective VT/VF therapies, infection requiring explant and erosion was similar to that of the AICD Epicardial System. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD Transvene System offers clinical advantages in reducing the need for a thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing and inappropriate therapy incidence.

c. Survival Analysis

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD Transvene System, the Ventak-P Epicardial system is the most comparable Market Released system. Table ID1-3 summarizes how the

P20

patient deaths have been classified for the PCD Transvene System and the Ventak-P epicardial System.

PCD Transvene System Comparison of Death Classification PCD Transvene System versus Ventak-P Epicardial System		
	PCD Transvene System	Ventak-P Epicardial System
Sudden Cardiac	5	4
Non-Sudden Cardiac	31	8
All Cardiac	15	6
Unknown	0	1
Total	51	19
Perioperative	5 (0.7%)	8 (2.7%)

Table ID1-3: PCD Transvene System - Death Classification- PCD Transvene VS Ventak=P - 2/1/93

A total of 51 deaths (6.7%) were reported in the PCD Transvene System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD Transvene System population had a lower perioperative mortality, 0.7% vs 2.7% ($p=0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths.

All other calculations in both the PCD Transvene System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, seven patient deaths were **censored** in the PCD Transvene System patient population because the devices were deactivated at the time of patient death.

Table ID1-4 contains the survival comparison of the PCD Transvene System versus the Ventak-P Epicardial System.

PCD Transvene System Survival Comparison PCD versus Ventak-P		
	PCD Transvene System	**Ventak-P Epicardial System**
Sudden Cardiac	99.7%	98.6%
Overall	94.2%	90.8%

Table ID1-3: PCD Transvene System - Survival Comparison - PCD vs Ventak-P - 2/1/93

The PCD Transvene System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD Transvene System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD Transvene System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality. The survival

probability at one year for the Transvene population was 95.3%. From the analysis run, using commercially available statistical software package (SAS), the survival standard error was also calculated. The confidence interval was calculated by taking the survival probability +/- the 1.96 (survival standard error). The survival standard error was 1.1, therefore, the confidence interval for Transvene survival at 1 year is 95.3 (b)(4) (b)(4) (b)(4)

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD Transvene System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

2. Comparison to PCD Epicardial Study

The PCD Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The

incorporation of a nonthoracotomy lead system, such as the PCD Transvene System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD Epicardial System and PCD Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD Transvene System clinical experience to the reported PCD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

The PCD Epicardial System clinical data was chosen as a control because the patients were being enrolled in the two studies concurrently by the same investigators, and the patient indications, implant criteria, and clinical data requirements were identical for the two patient groups.

a. Patient Characteristics

In comparing the clinical experience with the PCD Transvene System to the PCD Epicardial System

clinical experience, it is important to determine that the patients who received the device are comparable.

Table ID2-1 contains the characteristics of the 757 patients receiving the PCD Transvene System versus the characteristics of the 742 patients who received the PCD Epicardial System as of 1/5/93.

PCD Transvene System
Comparison of Patient Characteristics

	PCD Transvene System	PCD Epicardial System
Number of Patients	757	742
Mean Follow-Up Time	11.7 months	16.3 months
% Males* % Females	610 80.6% 147 19.4%	637 85.8% 105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication* SCD VT SCD/VT	 281 37.1% 377 49.8% 99 13.2%	 214 28.8% 405 54.6% 123 16.6%
Cardiovascular History Coronary Artery Disease Cardiomyopathy	 561 74.1% 238 13.1%	 569 76.7% 222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* Statistically Significant

Table ID2-1: Comparison of Patient Characteristics, PCD Transvene System versus PCD Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34.0% for the PCD Epicardial patient group.

Analysis indicated that the PCD Transvene System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that these differences will result in a different clinical outcome in the PCD Transvene System patient population as compared to the PCD Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD Transvene System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups ($p = 0.001$). The PCD Transvene System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD Transvene System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients are not required to have drug therapy screening, therefore, fewer drugs were tested in this group.

b. Implant Data

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and was:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. At least a 2:1 VF sensing safety margin

Pace/Sense Performance

In both the PCD Transvene and PCD Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:	$\leq$ 1.5V @ 0.5 ms
R-Wave Amplitude:	$\geq$ 5 mV
Slew Rate:	$\geq$ 0.75 volt/sec
Resistance:	200 - 880 ohms

Table ID2-2 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD Transvene and Epicardial Systems. It should be noted that the pace/sense values presented for the PCD Epicardial System are for the Model 7217B PCD Device.

PCD Transvene System
Performance Comparison
Implant Pace/Sense Parameters

Parameter	PCD Transvene System	PCD Epicardial System
Pacing Threshold*	0.87 V (0.1-3.6V)	0.98 V (0.2-5.3 V)
R Wave Amplitude*	14.2 mV (1.3-32 mV)	13.5 mV (2.2-37.2 mV)
Slew Rate*	1.66 v/S (0.25-9.8 v/S)	1.38 v/S (0.15-7.2 v/S)
Resistance*	575 ohms (264-1381 ohms)	438 ohms (157-1206)

* Statistically Significant

Table ID2-2: PCD Transvene System: Comparison of Implant Pace/Sense Parameters - 2/1/93

The implant pace/sense parameters obtained for the PCD Transvene System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). This is anticipated because

endocardial pace/sense parameters are better than epicardial values for bradycardia pacing electrode systems.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is presented in Table ID2-3. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

PCD Transvene System
Performance Comparison
Chronic Pace/Sense Parameters

Parameter	PCD Transvene System	PCD Epicardial System
Electrogram Amplitude	10.0 mV (0.5 - 25 mV)	9.5 mV (0.5 - 40 mV)
Pulse Width Threshold	0.24 ms (0.03-1.59 ms)	0.24 ms (0.03-1.59 ms)

Table ID2-3: PCD Transvene System: Comparison of Chronic Pace/Sense Parameters - 2/1/93

The incidence of loss of capture requiring lead system modification in the PCD Transvene System was 0.8% while the incidence in the PCD Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD Transvene System while the incidence in the PCD Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense data performance indicates that the performance of the PCD Transvene System is similar to that reported with the PCD Epicardial System and potentially may be improved over the PCD Epicardial system. The

PCD Transvene System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table ID2-4 provides a comparison of defibrillation thresholds determined at implant for the PCD Transvene and PCD Epicardial Systems.

PCD Transvene System Performance Comparison Implant Defibrillation Thresholds	
System	**Mean DFT**
PCD Transvene System*	14.8J
PCD Epicardial System	9.8J

(b)(4) (b)(4)

Table ID2-4: PCD Transvene System: Comparison of Implant DFT - 2/1/93

The PCD Transvene System did have a significantly higher mean implant defibrillation threshold (b)(4) (b)(4) It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional epicardial system, the

increased electrode surface area would theoretically decrease defibrillation requirements.

The programmed defibrillation pathways for the two patient populations is presented in Table ID2-5. The implanted PCD Transvene Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD Transvene System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD Transvene System implant criteria. Most of the PCD Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

PCD Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD Transvene System**	**PCD Epicardial System**
Sequential	574 (75.3%)	251 (33.0%)
Simultaneous	178 (23.4%)	14 (1.8%)
Single	10 (1.3%)	496 (65.2%)

Table ID2-5: PCD Transvene System: Comparison of Programmed Defibrillation Pathway - 2/1/93

The differences in the programmed status of the PCD device in the PCD Transvene System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD device performed safely and effectively in both patient populations.

c. Spontaneous VT/VF Efficacy

The primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD Transvene System is the elimination of the need for a thoracotomy for

implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table ID2-6 provides a comparison of the efficacy of the PCD Transvene and PCD Epicardial System in treating spontaneous episodes of VT and VF.

PCD Transvene System Performance Comparison		
Spontaneous VT Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Patients with VT Episodes	316	386
Number of Episodes	10,027	20,061
% Overall Efficacy	9,864/10,027 98.4%	19,726/20,061 98.3%
% Unsuccessful Termination (VT)	68/10,027 0.7%	150/20,061 0.8%
% Unsuccessful Termination (AF,ST)	95/10,027 0.9%	185/20,061 0.9%
Spontaneous VF Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Patients with VF Episodes	317	342
Number of Episodes	1982	2,636
% Overall Efficacy	1951/1982 98.4%	2601/2636 98.7%
% Unsuccessful Termination (VF)	5/1982 0.3%	15/2636 0.5%
% Unsuccessful Termination (AF,ST, Other)	26/1982 1.3%	24/2636 0.8%

Table ID2-6: PCD Transvene System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD Transvene System in terminating spontaneous episodes of VT or VF is 98.5%. This success rate compares very favorably with the overall success rate of the PCD Epicardial System which was 98.4%. Therefore, the PCD Transvene System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

d. Complications and Observations

A comparison of the reported complications and observations was made between the PCD Transvene System and the PCD Epicardial System. The PCD Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with 742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD System. In the PCD Transvene System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD Epicardial System, 14.2% of the patients experienced a clinical complication and 32.9% of the patients experienced a clinical observation.

Table ID2-7 and ID2-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD Transvene System PCD Transvene System versus PCD Epicardial System Reported Complications		
Reported Complications	**PCD Transvene System (N = 757)**	**PCD Epicardial System (N = 742)**
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	3.0%
Device Related	0.5%	0.9%

Table ID2-7: Reported Complications: PCD Transvene System versus PCD Epicardial System - 2/1/93

PCD Transvene System PCD Transvene System versus PCD Epicardial System Reported Observations		
Reported Observations	**PCD Transvene System (N = 757)**	**PCD Epicardial System (N = 742)**
Ineffective Therapy	1.1%	1.1%
Inappropriate Therapy	9.6%	13.6%
Pace/Sense Related	9.0%	14.0%
Infection Related	5.3%	2.6%
Lead Related	2.3%	1.2%
Device Related	-	-

Table ID2-8: Reported Observations: PCD Transvene System versus PCD Epicardial System - 2/1/93

e. Survival Analysis

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide

23

positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD Transvene and Epicardial System was performed.

Table ID2-9 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD Transvene System patient population was 11.7 months while for the PCD Epicardial System it was 16.3 months. Patients with the device programmed OFF and perioperative deaths are not mutually exclusive.

PCD Transvene System Death Classifications PCD Transvene System versus PCD Epicardial System		
Death Classification	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**
Sudden Cardiac	5 0.7%	24 3.2%
# Off	1 0.1%	3 0.4%
# Perioperative	2 0.3%	9 1.2%
Non-Sudden Cardiac	31 4.1%	54 7.3%
# Off	4 0.5%	12 1.6%
# Perioperative	2 0.3%	18 2.4%
All Cardiac	36 4.8%	78 10.5%
# Off	5 0.7%	15 2.0%
# Perioperative	4 0.5%	27 3.6%
Noncardiac	15 2.0%	34 4.6%
# Off	2 0.3%	7 0.9%
# Perioperative	1 0.1%	12 1.6%
Total	51 6.7%	113 15.2%
# Off	7 0.9%	23 3.1%
# Perioperative	5 0.7%	39 5.3%

Table ID2-9: Death Classifications: PCD Transvene System versus PCD Epicardial System - 2/1/93

Table ID2-10 provides a comparison of actuarial survival rates between the PCD Transvene and PCD Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of

survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD System.

PCD Transvene System Comparison of Actuarial Survival PCD Transvene System versus PCD Epicardial System			
One Year Survival	**PCD Transvene System**	**PCD Epicardial System**	**P-Value**
Number of Patients	757	742	-
Sudden Cardiac	99.5%	98.9%	0.197
Non-Sudden Cardiac	96.2%	96.7%	0.542
All Cardiac	95.8%	95.7%	0.992
Noncardiac	98.1%	98.0%	0.820
Overall*	93.3%	88.6%	0.004

* **Statistically Significant** $p \leq 0.05$

Table ID2-10: Comparison of Actuarial Survival: PCD Transvene System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD Transvene System. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD Transvene System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD Epicardial System (88.6%) [p=0.004]. This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD Transvene System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

E. Transvene PCD System Performance

1. Explants; Leads and PCD Devices

Transvene Lead Performance

The Transvene Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of fracture for the RV lead is 0.9% (7/757) and 0.3% (2/757) for the SQ lead.

A Model 6884, screw-in, right ventricular, pace/sense, cardioversion/ defibrillation lead was returned to Medtronic 27 months post implant. The lead was returned to Medtronic following explant from a patient that was undergoing a heart/lung transplant. Note that the lead had been fully functional while implanted and was found to be fully functional upon explant.

Upon undergoing further analysis at Medtronic, some MIO (metal ion oxidation) was observed on the lumen of the middle insulation approximately 20 cm proximal of the pacing tip electrode, and on the outside of the inner insulation. The MIO was further characterized to be "cosmetic" in that it had not functionally affected the lead in any way. Cosmetic MIO is defined as any crack that has not breached the insulation.

Initial analysis indicated that the presence of the MIO was in the clavicular region of the body; i.e., the location, 20 cm proximal of the tip, would be in the first rib clavicle region of a small adult. There was no evidence, however, of conductor coil fracture and the lead was fully functional. Given the Model 6884 lead is generally implanted via subclavian vein insertion, this type of observation may occasionally be expected. However, subsequent analysis of the patient X-rays showed that the area of MIO was actually in the right ventricle. The patient's right ventricle

was extremely dilated, secondary to pulmonary hypertension. Therefore, 20 cm from the proximal tip electrode located the area of MIO at the point of maximum curvature of the lead, in the right ventricle, rather than in the clavicular region.

Detailed Analysis Results

Visual/Microscopic

Shallow (cosmetic) environmental stress cracking (ESC) was visible. No coil deformation was visible in the first rib/clavicle region. Possible MIO was visible 20 cm proximal of the electrode tip extending approximately 0.5 cm on the middle insulation. Possible MIO was also visible on the innermost insulation starting at 19.3 cm proximal of the electrode tip and extending 5.4 cm proximally.

Scanning Electron Microscopy

MIO was observed on the lumen of the middle insulation and on the outside of the innermost insulation. The MIO penetration was less than five percent of the insulation wall thickness. In addition to the insulation, both the middle and inner coils were evaluated up to 2500 times magnification. There were no anomalies apparent on the inside or outside of the middle coil in the region of the MIO. The innermost coil showed no signs of crush or fatigue in the region of the MIO.

FTIR-ATR

FTIR spectra were obtained for a control area (no MIO) of the inner tubing and the cracked area of the tubing. Relative ratios of key bonds were calculated using the absorption intensities. These ratios indicated that the ether segments were oxidized in the polyurethane, which is characteristic of MIO. In addition, peaks appeared, indicative of carboxylic acids or esters (oxidation byproducts).

Discussion

Contrary to the initial dimensional analysis of this lead that indicated the area of MIO was located to the clavicular region of implant, review of the patient's X-rays revealed that the heart was significantly enlarged due to the advanced disease state. Subsequently, a significant portion of the insulated lead body was located in the heart, including the portion with cosmetic MIO. Typically, 20 cm proximal of the tip electrode approximates the clavicular region.

Consistent with our previous analysis of MIO relative to the 6884/6966 lead, the observed MIO did not, in any way, affect the clinical performance of this lead. Patient data analysis shows that the implanted lead system, inclusive of the 6884 lead, performed appropriately. Of six spontaneous VT/VF episodes reported (4VT/2VF), all were appropriately detected and treated via the implanted PCD Transvene system.

In addition, the presence of MIO on the middle insulation is not entirely unexpected (reference February 18, 1993, Medtronic/FDA meeting). If the middle insulation had been degraded to the point of electrically shorting the sensing ring (middle conductor coil) to the common defibrillation electrode (middle coil), an integrated bipolar sensing system would, in essence, be created. In this type of system, sensing occurs between the unipolar pacing tip and the common defibrillation electrode, versus standard, or true, bipolar sensing between the pace/sense tip and the ring electrodes. This type of sensing system is identical to the CPI Endotak configuration, as well as Medtronic's earlier design of a Transvene RV lead, i.e., the Model SP2100. These types of integrated systems have been shown to be clinically acceptable. Note that canine testing of a shorted, RV cardioversion/defibrillation lead, indicated that this type of failure does not result in the lack of therapy delivery.

If the innermost insulation had degraded such that the pacing tip electrode shorted, this could manifest as intermittent sensing of the brady pace/sense function of the lead. This type of anomalous system performance is expected to be observed at follow-up sessions, given the

frequent monitoring of patients (every three months) or as necessary when the patient experiences VT/VF episodes or anything unusual. Similar to brady pacing patients, problems related to pace/sense performance are typically observed at the time of follow-up (pace/sense threshold measurements are standard follow-up procedure for both brady and tachy lead systems) and/or when the patient reports to his/her physician for any unusual events, e.g., intermittent pacing/sensing.

The extensive dilatation of the right ventricle in which this lead was implanted resulted in a large portion of insulated lead body being in the right ventricle, as opposed to primarily just the cardioversion/defibrillation electrode coil. Subsequently, this lead may have been subject to more flexing in the heart than what is typical for the RV lead. Note: this was demonstrated in the videotape that was presented to FDA at the February 18, 1993, Medtronic/FDA meeting.

Clinical data from brady pacing leads indicates that the portion of the lead subject to the flexing motion in the heart may be related to the occurrence of MIO in brady lead bodies. Brady pacing leads, proximal to the tip/ring electrodes are subject to more flexing motion, relative to a cardioversion/defibrillation RV lead, while contained in the heart. On the other hand, cardioversion/defibrillation leads, like the 6884/6966, are comprised of a comparatively stiff portion proximal to the tip/ring electrode. This length of defibrillation electrode, 5 cm, appears to flex less than a typical brady pacing lead while in the heart, as a result of greater stiffness. However, in the extremely hypertrophic heart, as was the case with this particular RV lead, the lead may be subject to more flexing, similar to that of a brady pacing lead.

Conclusions

As noted, Medtronic cannot assure that MIO, or other lead failure mechanisms will not occur in the 6884/6966 lead. However, one should consider the actual benefits of the lead versus the **potential** for MIO occurrence. Specifically, clinical data to date for the Transvene system show that one year actuarial survival from SCD is 99.5 percent and

the average hospital stay for Transvene implant is only seven days (versus ten for an epicardial system)*. Regarding the potential for MIO occurrence, analysis shows this would result in a bipolar integrated sensing system, or in an intermittent pace/sense system. Integrated sensing has been shown to be clinically acceptable, and intermittent pacing/sensing is assessed as part of standard follow-up procedures. Additionally, with postmarket surveillance mechanisms in place, such as returned product analysis and chronic lead monitoring, Medtronic is well positioned to appropriately evaluate and manage potential failure mechanisms of implantable cardiac leads. We are committed to these surveillance mechanisms in the interest of delivering optimal implantable technology products to the health care market.

Based on the clinical data collected, the Transvene leads have performed safely and reliably.

PCD Devices

In the 762 implants, a total of 63 units (8.3%) were explanted secondary to patient deaths, infection, heart transplant, low battery voltage measurement and PCD Device performance issues. Table IE1-1 provides an overview of the units explanted, and returned to Medtronic for analysis and reason for explant.

PCD Transvene System Reasons for PCD Device Explant n = 762		
Reason	**All Models**	
	Explanted	Received for analysis
Patient Death	22	17
Infection	22	10
Cardiac Transplant	9	5
Low Battery Voltage Measurement	1	1
PCD Device Performance Issues	4	4
L23	1	1
Lead Issues	4	4
Total	63	42

Table IE1-1 Reasons for PCD Device Explant - 2/1/93

The investigational plan requests that if the patient expires during the course of the clinical study that the PCD device be explanted and returned to Medtronic for analysis. There were 51 reported patient deaths and 22 devices were explanted. Seventeen have been received at Medtronic for analysis. In the 29 deaths where the device was not explanted, the patients expired and were buried before the devices could be explanted.

Results of analysis performed on the 42 explanted devices is presented in Table IE1-2.

PCD Transvene System Final Analysis on Explanted PCD Devices (N = 762)	
Within Normal Specifications	36
Hermetic Leakage at IC	1
Random Component Failure	2
Shorted on Pulse 2 Output	2
L23	1
Analysis Pending	0
Total	42

Table IE1-2: Final Analysis on Explanted PCD Devices - 2/1/93

Of the 42 devices explanted, final analysis on 36 units indicated that the devices were functioning within normal specifications.

Six PCD Devices were explanted for the following device performance issues:

- explanted due to a Power On Reset (POR) condition that was not related to the delivery of external defibrillation or cautery (N = 1);
- explanted for lower than expected battery voltage for time in service, includes L23 (N = 2);
- explanted secondary to failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode (N = 1); and
- explanted post inappropriate delivery of VF therapy during a manual capacitor charge time (N = 2).

These devices are discussed in detail in the discussion that follows.

In the case of the device explanted for PCD Device performance issue (b)(4) (b)(4) the device experienced a Power On Reset (POR) condition that was not related to

the delivery of external defibrillation or electrocautery. Under certain conditions, the use of direct defibrillation or electrosurgical cautery in the vicinity of a Model 7217B PCD System (i.e., device and electrodes) may cause the device to be set to its reset parameter values (VT/VF detection and therapies disabled and nominal VVI pacing parameters). In the case of this patient, the POR condition occurred during the pre-hospital discharge evaluation and the patient was under no increased risk.

Since external defibrillation or electrocautery had not been used near the device, it was recommended that the device be explanted. The patient received a second PCD Device without difficulties. The explanted PCD Device underwent initial evaluation and was found to be performing within specifications. Additional testing is currently ongoing.

Analysis of the device which had the documented short on the Pulse 2 output was found in a device which was explanted secondary to patient death. The death was classified as nonsudden and not related to the implanted PCD Transvene System. It appears that this diode failed post explant of the system probably due to electrocautery being used at the time of explant and was not related to the patient's death.

There was one device (b)(4) that was explanted due to lower than expected battery voltage for time in service. Analysis indicated that hermetic leakage at the input to one of the integrated circuits lead to a voltage drop across a resistor where the voltage measurement is taken. Thus the actual battery voltage was appropriate but the telemetry reading was incorrectly low.

There have been no reports of lower than expected battery voltage for time in service due to failure in an integrated circuit which increases current drain or leakage of tantalum capacitors on the printed circuit board as reported in the PCD Epicardial System experience.

None of these issues are related to the PCD device battery performance. The battery has performed according to specifications and there is no clinical data indicating otherwise.

In the case of the PCD Device (b)(4) which did not appropriately synchronize cardioversion therapy, during the pre-hospital discharge electrophysiology study, VT was induced and cardioversion therapy failed to appropriately synchronize and deliver therapy for the induced episode. The PCD Device was explanted and the patient received a second device without difficulties. Analysis of the explanted PCD Device indicated a random device failure. The manufacturing process was modified to incorporate a screening process to identify any further devices which may exhibit this behavior.

In the PCD Device (b)(4) in which VF therapy was delivered during a capacitor charge time, appropriate function of the Model 7217B PCD Device was documented at the time of implant. At the time of the one month follow-up, the device was interrogated and there were no spontaneous episodes between hospital discharge and the one month follow-up. During the monitor, the capacitors were being charged according to protocol and the patient indicated she felt a sensation in her abdomen. Subsequently, the PCD device did not respond to telemetry.

The patient was monitored again in an effort to assess telemetry. Another programmer was used and various radiofrequency sensitivities were used in attempts to gain telemetry. Still there was no response. The implanted system was assessed via x-ray and device (leads) dislodgement was not seen. Alternative implant, e.g., another commercially available defibrillator, was not considered an option as the Medtronic lead connections were not known to be compatible with other manufacturer's devices. The PCD Device was explanted and a second Model 7217B PCD device was implanted without difficulty. This patient has done well since the second implant procedure. No further device performance issues such as this one have been reported in this patient or other implanted devices.

Analysis of the explanted unit indicated that arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power

hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. The mechanism that initiated the arcing could not be identified.

Even though the arcing mechanism could not be identified, it is important to note that the hybrid manufacturing procedure has processing steps to ensure that arcing does not occur. Traceability data on this unit indicated there were no processing anomalies related to this hybrid.

Since this was the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this is considered a random component failure.

F. Clinical Conclusions

The overall clinical experience with the PCD Transvene System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study from the 757 patients with a mean follow-up of 11.7 months:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the 757 patients who received a 3 lead system in this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD Transvene System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD Transvene System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD Transvene System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD Transvene System.

PCD Transvene System Performance

- The PCD Transvene System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

Medtronic asserts and the PCD Transvene investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

IV. Summary of Additional Implants

A. Overview

This overview covers a total of 1335 implants in 1330 patients of the PCD Device with the Transvene Defibrillation Lead System. The patients included in this report includes the 757 patients described in the original PMA application and an additional 573 patients that have been implanted in the U.S. from 6/25/92 to 2/1/93. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990.

The mean implant duration for this patient population is 8.0 months and ranges from implant to 37.4 months. The cumulative implant duration is 10,653.7 months.

The patient population (N = 1330) enrolled in the clinical trial was predominately male (81.6%) with a mean age of 60.4 years. In half of the patients (54.5%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 34.7% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 10.8%. Coronary artery disease was the primary heart disease in 76.2% of the patient population with a mean reported ejection fraction of 34.3% Table IVA-1 provides a data summary on these patients. Although there is a slightly higher percentage of patients with the primary indication of VT, 54.5% vs 49.8% (PMA patient population), there are no substantial differences or trends noted from the original PMA population.

PCD Transvene System Data Summary of Updated Population N = 1330			
Number of Patients	757	573	1330
Device Months Follow-up	8894.8	1758.9	10,653.7 mo

Overall Survival	93.3%	93.4%	93.0%

Table 8-1: PCD Transvene System: Data Summary - Updated Pts. (1330) - 2/1/93

B. Complications and Observations

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following previously described definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Of the 1330 patients, as of February 1, 1993, there have been a total of 225 complications reported in 195 patients and 275 observations reported in 228 patients in the PCD Transvene System patient population. Thus, 14.7% (195/1330) of the patients had a clinical event which was categorized as a complication and 17.1% (228/1330) of the patients had a clinical event which was categorized as an observation.

Table IVB-2 and IVB-3 summarize the reported PCD Transvene System complications and observations by category, respectively. In almost all categories, the percentage of patients in which a complication or observation was reported has decreased compared to the original PMA patient population of 757. The percentage of patients with lead dislodgements reported has substantially decreased from 12% with a complication to 8.8% and 1.6% with an observation to 0.9%. No new categories of complications or observations were reported. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

PCD Transvene System Reported Complications By Category			
Category	757	573	1330

Total	**212**	**61**	**273**

Table 8-2: PCD Transvene System: Reported Observations - 2/1/93

Table IVB-4 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days. As noted earlier, the percentage of patients in which a complication or observation regarding lead dislodgement was reported has decreased from the original PMA patient population of 757.

PCD Transvene System
Reported Complications/Observations
Lead Dislodgements <30 and >30 days (N=1330)

Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=1314	19 (1.4%)	13 (1.0%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 387	19 (4.9%)	11 (2.8%)	2 (0.5%)	2 (0.5%)
SVC Lead Dislodgement n=989	16 (1.9%)	36 (3.6%)	1 (0.1%)	6 (0.6%)
Total Dislodgement n=1330	57 (4.3%)	60 (4.5%)	3 (0.2%)	9 (0.7%)

Table 8-3: PCD Transvene System: Lead Dislodgements <30/>30 days (n=1330) - 2/1/93

There have been a total of 60 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 60 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads

with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD Transvene System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed**.
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD System component, or as a result of a device induced arrhythmia, or an interaction between a PCD System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD Transvene System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 68 patient deaths reported in the PCD Transvene System patient population. Table IVC-1 summarizes how these patient deaths have been classified.

PCD Transvene System
Summary of Death Classifications
(n = 1330)

Classifications	n=757	n=573	Total # of Deaths
Sudden Cardiac	5	5	10
Non-Sudden Cardiac	31	7	38
Noncardiac	15	5	20
TOTAL	51	17	68

Table 8-4: PCD Transvene System - Summary of Death Classifications (n=1330) - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD Transvene System.

Actuarial survival analysis on the PCD Transvene System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat**. Those patients in whom the PCD Device was OFF at the time of death or in whom no device was implanted <u>are</u> included in the survival analysis. Those patients that were screened for a PCD Transvene System but failed to receive a Transvene system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table IVC-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.8% (10/1330) which is considerably less than the perioperative mortality for the PCD System with Epicardial leads (5.3% - 39/742).

PCD Transvene System One Year Actuarial Survival			
	757	**573**	**1330**
Sudden Cardiac Death	99.5%	98.3%	99.3%
Non-Sudden Cardiac	96.2%	97.7%	96.3%
All Cardiac	95.8%	96.0%	95.6%
Noncardiac	98.1%	98.3%	98.1%
Perioperative	0.7%	0.9%	0.8%
Overall	93.3%	93.4%	93.0%

Table 8-5: PCD Transvene System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD Transvene System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate the total patient group (n = 1330) is 99.3%. This is a marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

In conclusion, the data above for the 1330 patients implanted and followed through 2-1-93 is similar to the 757 PMA patient population as expected. Although lead dislodgement is not an unexpected complication and patients are routinely evaluated during follow-up procedures at follow-up visits, in order to minimize the incidence of lead dislodgement, the dual anchoring sleeve has been introduced and the incidence of lead dislodgement has drastically decreased. The one year actuarial survival results continue to be stable, above 99% for SCD and efficacy rates continue at greater than 98%.

Re: PMA Amendment to the Medtronic® TRANSVENE® Lead System (Document Control Number P920015) /A-2V1
Response to FDA Approvable Letter of September 23, 1993

The purpose of this PMA Amendment is to document additional modifications to the TRANSVENE® Lead System Labelling. These changes are the result of further discussions between FDA and Medtronic.

Copies of the final proposed labeling (technical manuals and package labels) for the TRANSVENE® lead system (reference Attachment A) and the PCD® Device (reference Attachment B) are provided. (Note: The PCD® Technical Manual is synonymous with the term Physician's Manual.)

Via this amendment, we are also informing the Agency that there is no new safety and effectiveness information learned about the device (system) from the ongoing clinical study that could reasonably affect the statement of contraindications, warnings, precautions and adverse reactions in the draft labeling.

Three copies of this submission are provided in accordance with 21 CFR Part 814.44(e)(2). It contains confidential and commercial trade secret information and we request that it be given the maximum protection provided by the law. If additional information is required, please contact Dennis Connolly at (612) 574-4696.

Sincerely,

MEDTRONIC, INC.

DESCRIPTION

The Medtronic® TRANSVENE®-SQ Model 6999 Unipolar, Subcutaneous, Oval Patch Lead is designed for the delivery of cardioversion and defibrillation therapies.

The lead features a low resistance conductor coil and platinum alloy electrode coils for cardioversion and defibrillation therapies. The outer edge of the lead is used for suturing. The lead also has a 6.5 mm unipolar connector.

There are 3 nodes on one side of the patch, and 2 nodes at the junction of the lead body and patch electrode. These nodes are intended to mark the insulated side of the patch electrode.

INDICATIONS FOR USE

modified

The Medtronic® TRANSVENE®-SQ Model 6999 is intended for single long-term use only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

added Remand

~~**NOTE:** The Model 6999 TRANSVENE®-SQ patch lead is not intended for epicardial or pericardial placement.~~

The lead has application for patients in which implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

modified

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the

safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the TRANSVENE® system.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE®-SQ lead
- End Cap
- Product literature

CONTRAINDICATIONS

The TRANSVENE® system is contraindicated for patients.

- with transient ventricular tachyarrhythmias due to reversible causes, e.g., drug intoxication, electrolyte imbalance, sepsis, or hypoxia.
- with transient ventricular tachyarrhythmias due to other factors, e.g., myocardial infarction and electrocution.

The TRANSVENE® system is contraindicated for the sole use of detection and treatment of atrial arrhythmias.

~~The TRANSVENE® lead system is contraindicated for use in any system other than a Medtronic implantable~~ tachyarrhythmia control device system for which it has been tested. Refer to the appropriate Medtronic technical manual for the contraindications to the ICD system.

WARNINGS

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning."

Do not attempt to use the TRANSVENE® lead system with any device other than a Medtronic implantable tachyarrhythmia control device for which it has been tested. While there has been no testing of the TRANSVENE® leads with a non-Medtronic device, the potential adverse consequences of using such a combination may include, but are not limited to, undersensing cardiac activity and failure to deliver necessary therapy.

The Model 6999 TRANSVENE® SQ patch lead is not intended for epicardial or pericardial placement since testing has not been performed to determine if epicardial or pericardial use is safe or effective.

Placement of a patch electrode over nerve tissue may result in nerve damage.

The Model 6999 TRANSVENE® leads have palpable nodes on the insulation side of the patch which must face the skin surface to assure the electrode surface is facing the heart. If the insulation side of the patch is facing the heart cardioversion/defibrillation energy maybe inadequate to reliably convert arrhythmias.

If patients do not meet the implant criteria (demonstration of a 10 Joule safety margin) for a transvenous lead system, physicians should consider implanting an epicardial cardioversion/defibrillation lead system. If an epicardial system is to be implanted after testing a transvenous system, consider performing the procedure at a later date. The Transvene® clinical study showed a 9.3% perioperative death rate for patients failing the implant criteria for a Transvene® system and receiving an epicardial system. This compares to 0.7% for those patients receiving a Transvene® system without the additional epicardial surgical procedure.

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, or whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile gloves that have been wiped with a sterile moist sponge or equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

Chronic Repositioning

Chronic repositioning or removal of the lead may be difficult because of the fibrotic tissue. **However, if a lead must be removed or repositioned, proceed with extreme caution.** If a lead is abandoned, it should be capped to avoid transmitting electrical signals. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section titled "Suggested Implantation Procedure."

Resterilization

For resterilization use ethylene oxide only. Do not resterilize more than one time.

Implant Technique

Do not use surgical instruments to grasp the lead or connector pin when tunneling.

6999 Rc 086cEN/MMC 10/8/93 11:05 AM Page 4

POTENTIAL ADVERSE EFFECTS

The potential adverse effects related to the use of subcutaneous patch leads include, but are not limited to, the following patient-related conditions: serous fluid accumulation around the patch; infection; and bleeding after placement, after repositioning, or if sutures tear out.

Other potential adverse effects related to the lead system, but are not limited to the following: lead displacement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of cardioversion and defibrillation therapies.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable bag and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55°C (130°F). Allow proper aeration of ethylene oxide residues prior to implantation. Use an acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

General Instructions

The implantation procedure generally includes selecting an insertion site; positioning the lead; taking electrical and defibrillation efficacy measurements; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Proper surgical procedures and sterile techniques are the responsibility of the medical professional. The implant procedures described in this manual are furnished for information only. Each physician must apply the information in these instructions according to professional medical training and experience.

Opening the Package

Open the package according to the instructions and inspect the lead.

Positioning a Lead

The recommended starting position for the TRANSVENE®-SQ subcutaneous patch lead is along the left chest near the heart. The patch may be repositioned, if necessary, to meet the implant defibrillation efficacy criteria.

The subcutaneous patch should be placed subcutaneously, submuscularly, or directly on the periosteum of the ribs.

Place sutures through the outer edge of the patch electrode. It is recommended that two or more sutures be used for fixation.

CAUTION: The patch must be placed such that the nodes are facing away from the heart (Figure 1).

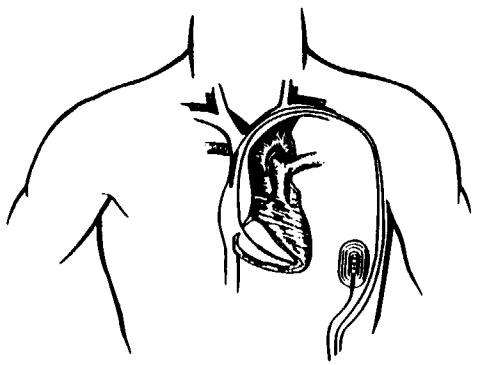

Figure 1. Positioning a Patch Lead

Taking Electrical Measurements and Defibrillation Efficacy Measurements

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

To demonstrate reliable defibrillation efficacy with acute or chronic leads, it is recommended that VF be initiated and terminated either two consecutive times at a stored energy of 24 joules or less, or 3 out of 4 times at a stored energy of 24 joules or less. If more than one of the four VF inductions are not terminated by the ETCD and lead system, the decision to implant the PCD device should be re-evaluated.

In order to keep patient morbidity and mortality to a minimum, patients should be rescued promptly with an external device if the lead system and ETCD fails to terminate the VF episode and at least 5 minutes should elapse between VF inductions.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold (at 0.5 ms pulse width)	≤ 1.0 V	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 2a and 2b for instructions and illustrations showing lead connections to the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Insert the lead connector into the connector block. Refer to the PCD® Tachyarrhythmia Control Device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillation Electrodes	Two-Electrode System Connection Diagram
Medtronic® Model 7217B PCD® Device	2	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE®-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE®-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the connector plug packaged with the pulse generator into the PULSE1 port. **PULSE2** Insert the lead connector of the TRANSVENE®-RV, -SVC, or -SQ lead into the PULSE2 port.

Figure 2a. Connections for two-electrode system leads (single pulse) into the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillation Electrodes	Three-Electrode System Connection Diagram
Medtronic® Model 7217B PCD® Device	3	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE®-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE®-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the lead connector of the TRANSVENE®-RV, -SVC, or -SQ lead into the PULSE1 port. **PULSE2** Insert the lead connector of the TRANSVENE®-RV, -SVC, or -SQ lead into the PULSE2 port.

Figure 2b. Connections for three electrode system leads (simultaneous or sequential pulse) into the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 3). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

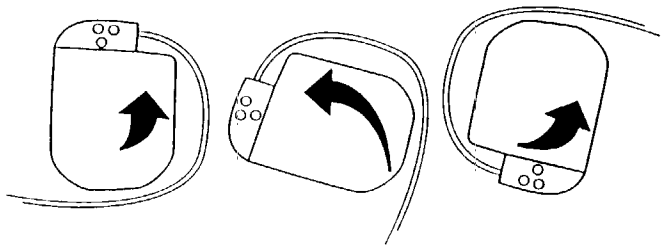

Figure 3. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended that the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 4).
- Do NOT grip the lead or pulse generator with surgical instruments.

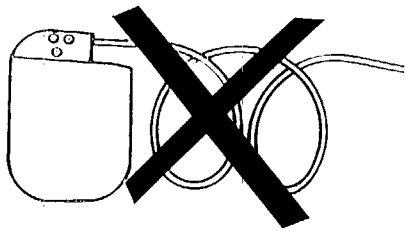

Figure 4. Do not coil or twist the lead body.

Post-Implant Evaluation

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

The patient should have X-rays and pacing/sensing thresholds taken every three months for the first year after implant and every six months thereafter to verify proper lead position and to check for conductor fractures.

In the event of a patient death, all implanted leads and devices should be explanted and returned to Medtronic with a completed PCD® Product Information Report. Any questions on product handling procedures can be addressed by calling 1-800-PCD-INFO.

SPECIFICATIONS (Nominal)

PARAMETER	MODEL 6999
Type	Unipolar
Position	Subcutaneous chest wall
Fixation	Sutures (may be placed through the outer edge of the patch body)
Length	50 cm
Connector	6.5 mm
Materials	Conductor: Multifilar MP35N Composite Insulator: Silicone Electrode: Platinum Alloy

PARAMETER	MODEL 6999
Number of Electrode Coils	4
Electrode Surface Area	660 mm^2
Body Diameter	2.5 mm
Patch Dimensions	8.0 cm x 11.0 cm
Silicone Patch Area	50 cm^2
Unipolar Resistance	1.2 ohms

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

For complete warranty information, see the accompanying card enclosed in the package.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

DESCRIPTION

The Medtronic® TRANSVENE®-SVC Model 6963 Unipolar, Endocardial, Superior Vena Cava or Coronary Sinus Lead is designed for the delivery of cardioversion and defibrillation therapies.

Silicone insulation surrounds the low resistance conductor coil and the coil electrode is a platinum alloy. The lead also has a 6.5 mm connector.

INDICATIONS FOR USE

The Medtronic® TRANSVENE®-SVC Model 6963 is intended for single long-term use in the superior vena cava or coronary sinus and is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the TRANSVENE® system.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE®-SVC lead with two non-radiopaque anchoring sleeves, stylet, and stylet guide
- 1 vein lifter
- Extra stylets
- Product literature
- End Cap

CONTRAINDICATIONS

The TRANSVENE® system is contraindicated for patients:

- with transient ventricular tachyarrhythmias due to reversible causes, e.g., drug intoxication, electrolyte imbalance, sepsis, or hypoxia.
- with transient ventricular tachyarrhythmias due to other factors, e.g., myocardial infarction and electrocution.

The TRANSVENE® system is contraindicated for the sole use of detection and treatment of atrial arrhythmias.

The TRANSVENE® lead system is contraindicated for use in any system other than a Medtronic implantable tachyarrhythmia control device system for which it has been tested. Refer to the appropriate Medtronic technical manual for the contraindications to the ICD system.

WARNINGS

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning."

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, or whenever arrhythmias are possible or intentionally induced during post-implant testing.

Do not attempt to use the TRANSVENE® lead system with any device other than a Medtronic implantable tachyarrhythmia control device for which it has been tested. While there has been no testing of the TRANSVENE® leads with a non-Medtronic device, the potential adverse consequences of using such a combination may include, but are not limited to, undersensing cardiac activity and failure to deliver necessary therapy.

Two anchoring sleeves are provided with the lead. Both anchoring sleeves should be used as described in the section of this manual "Anchoring the Lead" to assure adequate fixation.

If patients do not meet the implant criteria (demonstration of a 10 Joule safety margin) for a transvenous lead system, physicians should consider implanting an epicardial cardioversion/defibrillation lead system. If an epicardial system is to be implanted after testing a transvenous system, consider performing the procedure at a later date. The Transvene® clinical study showed a 9.3% perioperative death rate for patients failing the implant criteria for a Transvene® system and receiving an epicardial system. This compares to 0.7% for those patients receiving a Transvene® system without the additional epicardial surgical procedure.

Avoid placing the lead under extreme tension of angulation to prevent lead dislodgement and possible lead fracture. Do not grip the lead with surgical instruments.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile gloves that have been wiped with a sterile moist sponge or equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

Using an Anchoring Sleeve

Always use an anchoring sleeve with all leads to secure the lead from moving and to protect the lead insulation and conductor coil from damage. A second anchoring sleeve is provided for additional fixation.

Insertion Site
Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e. raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g. the cephalic vein.

Implant Technique
Avoid placing the lead under extreme tension or angulation to prevent dislodgement and possible lead fracture. Do not grip the lead with surgical instruments.

Do not use the anchoring sleeve for suturing.

Do not use surgical instruments to grasp the lead or connector pin when

Chronic Repositioning

Chronic repositioning or removal of the lead may be difficult because of the fibrotic tissue. **However, if a lead must be removed or repositioned, proceed with extreme caution.** If a lead is abandoned, it should be capped to avoid transmitting electrical signals. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section titled "Suggested Implantation Procedure."

POTENTIAL ADVERSE EFFECTS

The potential adverse effects related to the use of endocardial leads include, but are not limited to, the following patient-related conditions: fibrillation or other arrhythmias, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, infection, endocarditis, constrictive pericarditis, pneumothorax, hemothorax, and tissue necrosis.

Other potential adverse effects related to the lead system, but are not limited to the following: lead dislodgement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of detection, cardioversion, and defibrillation therapies.

Resterilization
For resterilization use ethylene oxide only. Do not resterilize more than one time.

Stylet Usage
To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end.

Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable bag and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55°C (130°F). Allow proper aeration of ethylene oxide residues prior to implantation. Use an acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

General Instructions

The implantation procedure generally includes using a stylet guide, stylets, and a vein lifter; selecting an insertion site; positioning the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Proper surgical procedures and sterile techniques are the responsibility of the medical professional. The implant procedures described in this manual are furnished for information only. Each physician must apply the information in these instructions according to professional medical training and experience.

Opening the Package

Open the package according to the instructions. Inspect the lead. Remove the disc from the distal end of the lead. Verify that two anchoring sleeves are present.

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 1).

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness for different lead and stylet flexibility. Each stylet knob is etched with the stylet diameter and length.

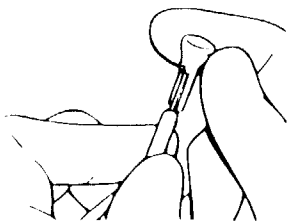

Figure 1. Stylet guide attachment.

If a slight curve is needed for the stylet, refer to instructions in the section titled "Positioning a Lead."

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein. In general, a left venous entry site will aid in maneuvering the lead into the coronary sinus orifice.

CAUTION: Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib (Figure 2). Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing

therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g., the cephalic vein.

Use fluoroscopy to facilitate accurate lead placement.

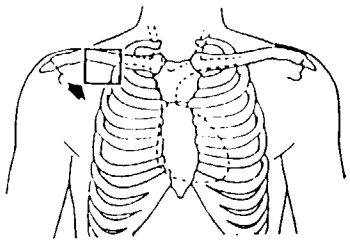

Figure 2. Insertion site.

Using a Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 3). During insertion of the lead into the vein, make sure the anchoring sleeves do not slide off the distal end of the lead.

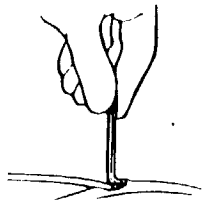

Figure 3. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Lead

For added control in maneuvering the lead tip, the distal end of the lead may be slightly curved by inserting a gently curved stylet as shown in Figure 4. A possible angle of curvature is illustrated in Figures 5 and 6.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 4).

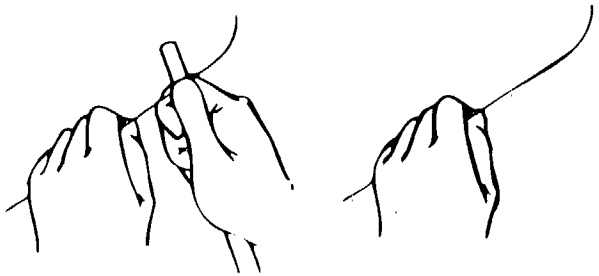

Figure 4. Imparting a curve to the stylet.

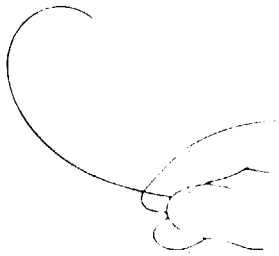

Figure 5. Bend the stylet into a gentle spiral. This gives the lead a gentle curve upward, to the left, and posterior.

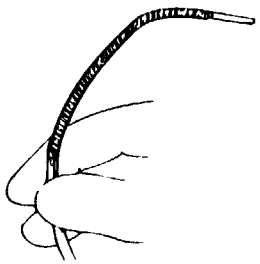

Figure 6. The curve in the stylet is designed to facilitate passage of the lead across the superior surface of the tricuspid valve. The second bend helps to position the lead to the left and posterior toward the coronary sinus ostium.

The electrode may be placed in either the superior vena cava or the coronary sinus.

If placing the electrode in the superior vena cava, advance the tip so that the distal portion of the electrode is approximately 3 to 5 cm proximal to the superior vena cava—right atrial junction.

If the electrode is to be placed in the coronary sinus, advance the lead into the right atrium and rotate the curved stylet to manipulate the tip over the tricuspid valve. Move the tip medially and posteriorly to the coronary sinus ostium and advance the lead into the coronary sinus. Continue advancing the lead through the coronary sinus to the desired position.

If the lead goes through the tricuspid valve opening, retract the lead with a gentle posterior rotation and then advance it toward the coronary sinus ostium.

The electrode for the TRANSVENE®-SVC must be as far as possible from other defibrillation electrodes. Also, the cardiac mass between the electrodes should be as large as possible. Insufficient separation between the electrodes may result in reduced defibrillation efficacy.

Proper positioning of the electrode is essential for defibrillation efficacy (Figure 7). Use fluoroscopy (P-A and lateral position) to ensure that the distal end of the electrode is properly positioned in the superior vena cava or is lodged in the coronary sinus with the proximal end of the electrode advanced beyond the coronary sinus ostium.

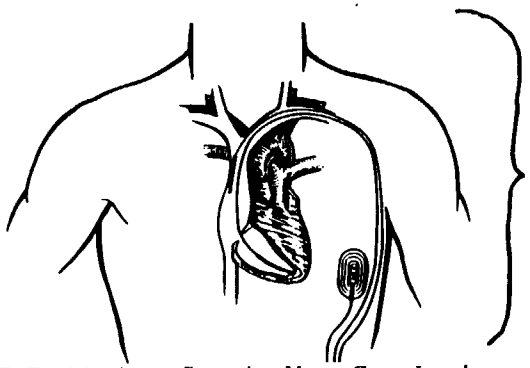

Figure 7. Positioning a Superior Vena Cava Lead

Bradycardia Pacemakers

Previously implanted bradycardia pacemakers, tachyarrhythmia devices and leads should be explanted. The output pulses of an implanted device may adversely affect the tachyarrhythmia detection capabilities of the PCD device. If leads must be abandoned rather than removed they should be capped to ensure they will not become a pathway for currents to or from the heart. If a patient requires a separate atrial or dual chamber pacemaker for hemodynamic reasons, either permanent or temporary, and allow adequate space between the pacing lead electrodes and the defibrillation lead electrodes.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

To demonstrate reliable defibrillation efficacy with acute or chronic leads, it is recommended that VF be initiated and terminated either two consecutive times at a stored energy of 24 joules or less, or 3 out of 4 times at a stored energy of 24 joules or less. If more than one of the four VF inductions are not terminated by the ETCD and lead system, the decision to implant the PCD device should be re-evaluated.

In order to keep patient morbidity and mortality to a minimum, patients should be rescued promptly with an external device if the lead system and ETCD fails to terminate the VF episode and at least 5 minutes should elapse between VF inductions.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold (at 0.5 ms pulse width)	≤ 1.0 V	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

CE 0344

Anchoring the Lead

Do not secure the ligatures so tightly that they damage the vein, lead, or anchoring sleeve. Do not tie a ligature directly to the lead body (Figure 8). During anchoring, take care to avoid dislodging the lead tip.

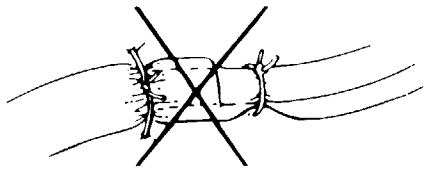

Figure 8. Do NOT secure the sutures too tightly and do NOT tie a suture to the lead body.

Use an anchoring sleeve to secure the lead from moving and to protect the lead insulation and conductor coil from damage caused by tight ligatures. A second anchoring sleeve should be placed in the tunnel entry site or in the pocket area for additional fixation.

Anchor the lead with nonabsorbable sutures.

The TRANSVENE®-SVC uses the triple groove anchoring sleeve illustrated in Figure 9. The triple groove anchoring sleeves are already situated at the connector end of the lead.

With a triple groove anchoring sleeve, all three grooves should be used with the following procedure (Figure 10).

- Partially insert the distal anchoring sleeve into the vein.
- **Use all three grooves to secure the anchoring sleeve (s) to the lead body.**
- Use the most distal suture groove to secure the anchoring sleeve to the vein.
- Use the middle groove to secure the anchoring sleeve to the fascia, vein, and lead body. First, create a base by looping a suture through the fascia underneath the middle groove and tying a knot. Continue by firmly wrapping the suture around the middle groove and tying a second knot.

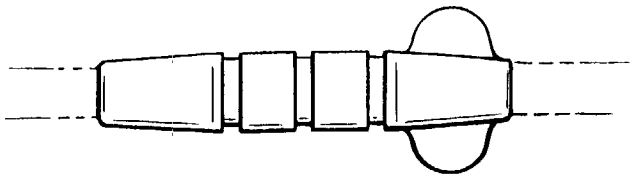

Figure 9. The triple groove anchoring sleeve.

CAUTION: Do not use the anchoring sleeve tabs for suturing.

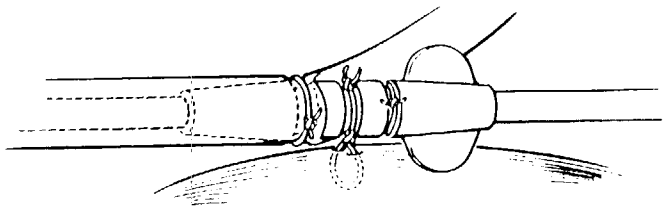

Figure 10. Triple groove anchoring sleeve secured to the lead and fascia using three grooves.

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 11a and 11b for instructions and illustrations showing lead connections to the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Insert the lead connector into the connector block. Refer to the PCD® Tachyarrhythmia Control Device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

CAUTION: Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

Figure 11b Connections for three-electrode system leads (simultaneous or sequential pulse) into the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 12). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

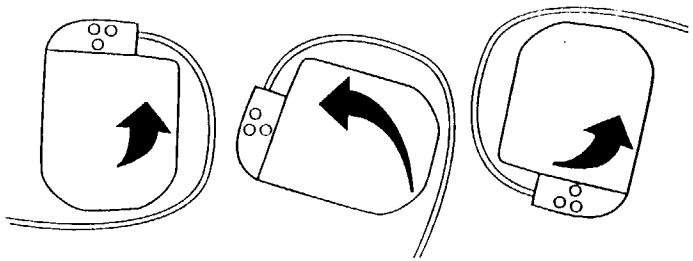

Figure 12. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended that the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 13).
- Do NOT grip the lead or pulse generator with surgical instruments.

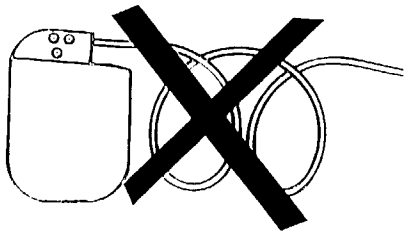

Figure 13. Do not coil or twist the lead body.

Post-Implant Evaluation

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

The patient should have X-rays and pacing/sensing thresholds taken every three months for the first year after implant and every six months thereafter to verify proper lead position and to check for conductor fractures.

In the event of a patient death, all implanted leads and devices should be explanted and returned to Medtronic with a completed PCD® Product Information Report. Any questions on product handling procedures can be addressed by calling 1-800-PCD-INFO.

SPECIFICATIONS (Nominal)

PARAMETER		MODEL 6963
Type		Unipolar
Position		Superior Vena Cava/ Coronary Sinus
Fixation		None. Tip lodges in the Superior Vena Cava or is placed in the Coronary Sinus
Length		110 cm
Connector		6.5 mm
Materials	Conductor:	Multifilar MP35N Composite
	Insulator:	Silicone
	Electrode:	Platinum Alloy

PARAMETER		MODEL 6963
Electrode Surface Area	Coil:	90 mm² (5 cm)
Diameters	Body:	1.7 mm
	Electrode:	2.3 mm
Unipolar Resistance		3.3 ohms
Lead Introducer (recommended size)		7.0 French

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications (including perforation of the heart) will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

For complete warranty information, see the accompanying card enclosed in the package.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

DESCRIPTION

The Medtronic® TRANSVENE®-RV Model 6966 Tripolar, Endocardial, Screw-In Ventricular Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation therapies.

The Medtronic® TRANSVENE®-RV lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool. Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be a potential problem.

The three electrodes of this lead are: coil, ring, and helix (Figure 1).

The defibrillating coil electrode is most proximal to the pulse generator and connects electrically to the connector PIN of the UNIPOLAR leg of the bifurcation. This UNIPOLAR leg will not accept a stylet.

The ring electrode is proximal to the helix and connects electrically to the connector RING of the BIPOLAR leg of the bifurcation.

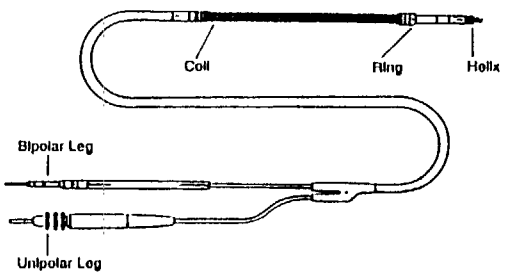

Figure 1. The three electrodes and two connector legs.

The helix tip electrode is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector PIN with a special fixation tool. The helix electrode connects electrically to the connector PIN of the BIPOLAR leg of the bifurcation. This BIPOLAR leg is the only one that will accept a stylet.

The lead's conductors are in a multifilar configuration and are insulated with polyurethane.

INDICATIONS FOR USE

The Medtronic® TRANSVENE®-RV Model 6966 is intended for single long-term use in the ventricle and is

The coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses.

The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; however, when used with the standard bipolar PCD® pulse generators, pacing occurs between the tip electrode and the coil electrode.

designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

The coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses. The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; however, when used with the standard bipolar PCD® pulse generators, pacing occurs between the tip electrode and the coil electrode.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in the TRANSVENE® Lead clinical study, the study objectives did not include stratification of this specific patient group.

Prior to TRANSVENE® implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the TRANSVENE® system.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE®-RV lead with two non-radiopaque anchoring sleeves, stylet, and stylet guide
- 2 fixation tools
- 1 vein lifter
- Extra stylets
- End Caps
- Product literature

CONTRAINDICATIONS

When tricuspid valvular disease or a mechanical heart valve is present, use of a ventricular endocardial lead is contraindicated.

The TRANSVENE® system is contraindicated for patients:

- with transient ventricular tachyarrhythmias due to reversible causes, e.g., drug intoxication, electrolyte imbalance, sepsis, or hypoxia.
- with transient ventricular tachyarrhythmias due to other factors, e.g., myocardial infarction and electrocution.

The TRANSVENE® system is contraindicated for the sole use of detection and treatment of atrial arrhythmias.

The TRANSVENE® lead system is contraindicated for use in any system other than a Medtronic implantable tachyarrhythmia control device system for which it has been tested. Refer to the appropriate Medtronic technical manual for the contraindications to the ICD system.

WARNINGS

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning."

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, and whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

new

Do not attempt to use the TRANSVENE® lead system with any device other than a Medtronic implantable tachyarrhythmia control device for which it has been tested. While there has been no testing of the TRANSVENE® leads with a non-Medtronic device, the potential adverse consequences of using such a combination may include, but are not limited to, undersensing cardiac activity and failure to deliver necessary therapy.

Two anchoring sleeves are provided with the lead. Both anchoring sleeves should be used as described in the section of this manual "Anchoring the Lead" to assure adequate fixation.

If patients do not meet the implant criteria (demonstration of a 10 Joule safety margin) for a transvenous lead system, physicians should consider implanting an epicardial cardioversion/defibrillation lead system. If an epicardial system is to be implanted after testing a transvenous system, consider performing the procedure at a later date. The Transvene® clinical study showed a 9.3% perioperative death rate for patients failing the implant criteria for a Transvene® system and receiving an epicardial system. This compares to 0.7% for those patients receiving a Transvene® system without the additional epicardial surgical procedure.

model 6966

New Warnings

Avoid placing the lead under extreme tension of angulation to prevent lead dislodgement and possible lead fracture. Do not grip the lead with surgical instruments.

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile gloves that have been wiped with a sterile moist sponge or equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

The maximum number of revolutions of the electrode fixation tool needed to extend or retract the helix is 20. **Exceeding the maximum revolutions may damage the lead.**

Using an Anchoring Sleeve

Always use an anchoring sleeve with all leads to secure the lead from moving and to protect the lead insulation and conductor coil from damage. A second anchoring sleeve is provided for additional fixation.

Chronic Repositioning

Chronic repositioning or removal of screw-in leads may not be possible because of blood or fibrotic tissue development into the helix mechanism. Removal of the lead could result in avulsion of the endocardium, valve, or vein. In addition, the lead junctions may separate, leaving the lead tip and bare wire in the heart or vein. In most clinical situations, it is preferable to abandon unused leads in place.

However, if a lead must be removed or repositioned, proceed with extreme caution. If a helix does not disengage from the endocardium by rotating the connector pin, rotating the lead body counterclockwise may withdraw the helix and decrease the possibility of damage to the cardiovascular structures during removal.

If a lead is abandoned, it should be capped to avoid transmitting electrical signals from the pin to the heart. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section "Suggested Implantation Procedure."

POTENTIAL ADVERSE EFFECTS

The potential adverse effects related to the use of endocardial leads include, but are not limited to, the following patient-related conditions: fibrillation or other arrhythmias, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, infection, endocarditis, constrictive pericarditis, pneumothorax, hemothorax, and tissue necrosis.

Resterilization
For resterilization use ethylene oxide only. Do not resterilize more than one time.

Rotating Helix
The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20. Exceeding the maximum number of revolutions may damage the lead.

Stylet Usage
To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end.

Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

Insertion Site
Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e. raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g. the cephalic vein.

Implant Technique
Avoid placing the lead under extreme tension or angulation to prevent dislodgement and possible lead fracture. Do not grip the lead with surgical instruments.

Do not use the anchoring sleeve for suturing.

Do not use surgical instruments to grasp the lead or connector pin when

Other potential adverse effects related to the lead system, but are not limited to the following: lead dislodgement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of detection, cardioversion, defibrillation, or pacing therapies.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable package and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55°C (130°F). Allow proper aeration of ethylene oxide residues prior to implantation. Use an acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

The implantation procedure generally includes checking the mechanical functioning of the lead electrode before it is inserted; using a stylet guide, stylets, and vein lifter; selecting an insertion site; positioning the lead; securing the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Proper surgical procedures and sterile techniques are the responsibility of the medical professional. The implant procedures described in this manual are furnished for information only. Each physician must apply the information in these instructions according to professional medical training and experience.

modified

Opening the Package

Open the package according to the instructions. Inspect the lead. Remove the disc from the distal end of the lead. Verify that two anchoring sleeves are present.

Verifying the Mechanical Functioning of the Helix Electrode

Before implantation, verify the mechanical functioning of the electrode, as described below.

1. Within the sterile field, remove the lead and the accompanying stylets from the sterile packaging. The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin that accepts the stylet controls the helix mechanism.
2. To attach the fixation tool, first remove the stylet guide. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).

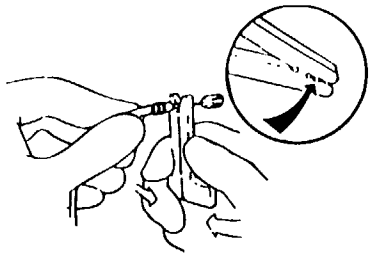

Figure 2. Attachment of the fixation tool to the connector pin.

3. Rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

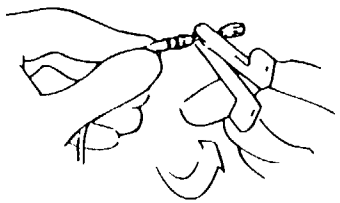

Figure 3. Rotating the fixation tool.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions may damage the lead.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the lead and its conductor coil to unwind.
5. After allowing the lead and its conductor coil to unwind, reattach the fixation tool and turn it counterclockwise until the helix tip is retracted in the sheath.

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin with the stylet in it controls the helix mechanism. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 4).

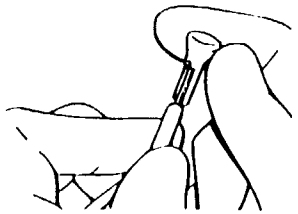

Figure 4. Stylet guide attachment.

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness for different lead and stylet flexibility. Each stylet knob is etched with the stylet diameter and length.

If a slight curve is needed for the stylet, refer to instructions in the section titled "Positioning a Lead."

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

6966 Reg/ 14CEN/MMC 10/8/93 1:24 PM Page 8

Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein.

CAUTION: Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib (Figure 5). Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g., the cephalic vein.

Use fluoroscopy to facilitate accurate lead placement.

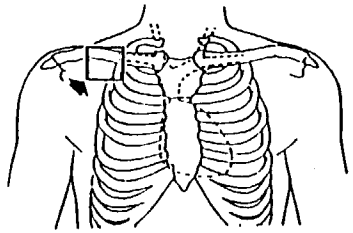

Figure 5. Insertion site.

Using the Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 6).

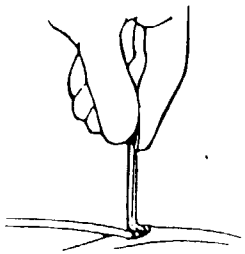

Figure 6. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Lead

Advance the lead into the right atrium. For added control in maneuvering the lead tip through the tricuspid valve, the distal end of the lead may be slightly curved by inserting a gently curved stylet (Figure 7). After the lead tip is passed into the ventricle, the curved stylet may be replaced with a straight stylet. The lead tip may then be advanced to the right ventricular apex while care is taken to avoid perforation of the ventricular wall.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 7).

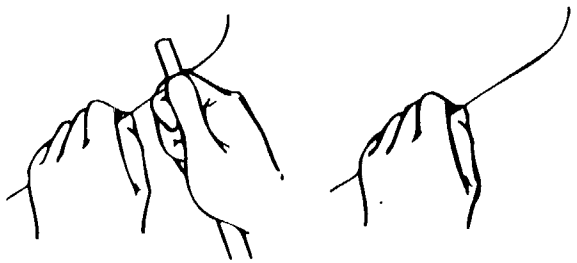

Figure 7. Imparting a curve to the stylet.

6966 Reg 14CEN/MMC 10/8/93 1:24 PM Page 10

Accurate positioning of the electrode is essential for stable endocardial pacing. A satisfactory position is usually achieved when the lead tip points straight toward the apex, or when the distal end dips or bends slightly (Figure 8).

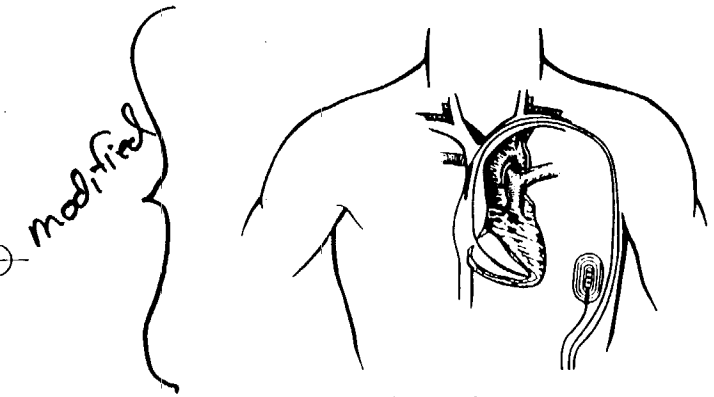

Figure 8. Positioning the Lead

Use fluoroscopy (lateral position) to ensure that the tip is not in a retrograde position or is not lodged in the coronary sinus.

After the stylet is inserted, gently remove the stylet guide so that it rests alongside the stylet knob.

Securing the Electrode into the Endocardium

The following procedure is recommended for electrode fixation:

1. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).
2. Gently press the lead tip against the endocardium by pushing the stylet and the lead at the vein entry site. Then, rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions to extend or retract the helix may damage the lead.

3. Use fluoroscopy to verify helix electrode exposure. Closing of the space between the conductor (A) and the indicator ring (B) implies complete exposure of the helix electrode (Figure 9).

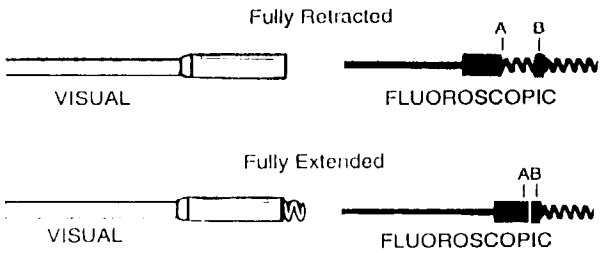

Figure 9. Possible views of the electrode.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the residual torque in the lead to be relieved.
5. After allowing the residual torque in the lead to be relieved, rotate the whole lead body clockwise approximately one revolution to ensure that the helical electrode is secured to the endocardium.
6. Carefully withdraw the stylet partially.
7. Obtain electrical measurements to verify satisfactory placement and electrode fixation. Refer to the following section, Taking Electrical and Defibrillation Efficacy Measurements, for recommended procedures and values.
8. Verify that the helix is affixed by gently pulling back on the lead and checking for resistance. A properly affixed helix will remain in position. If the helix is not properly affixed, the lead tip may become loose in the right ventricle.
9. If repositioning is required, reattach and rotate the fixation tool counterclockwise until the electrode is withdrawn. Use fluoroscopy to verify withdrawal. Repeat the procedure above.

CAUTION: When retracting the helix, do not rotate the fixation tool more than 20 revolutions. When the electrode is fully retracted, 2 coils of the helix will be visible between the indicator ring and the conductor.

10. Remove the stylet guide and stylet completely. When removing the stylet guide, grip the lead firmly just below the connector pin; this will help prevent possible lead dislodgement.

Bradycardia Pacemakers

Previously implanted bradycardia pacemakers, tachyarrhythmia devices and leads should be explanted. The output pulses of an implanted device may adversely affect the tachyarrhythmia detection capabilities of the PCD device. If leads must be abandoned rather than removed they should be capped to ensure they will not become a pathway for currents to or from the heart. If a patient requires a separate atrial or dual chamber pacemaker for hemodynamic reasons, either permanent or temporary, and allow adequate space between the pacing lead electrodes and the defibrillation lead electrodes.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

To demonstrate reliable defibrillation efficacy with acute or chronic leads, it is recommended that VF be initiated and terminated either two consecutive times at a stored energy of 24 joules or less, or 3 out of 4 times at a stored energy of 24 joules or less. If more than one of the four VF inductions are not terminated by the ETCD and lead system, the decision to implant the PCD® device should be re-evaluated.

In order to keep patient morbidity and mortality to a minimum, patients should be rescued promptly with an external device if the lead system and ETCD falls to terminate the VF episode and at least 5 minutes should elapse between VF inductions.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold		
(at 0.5 ms pulse width)	≤ 1.0 V	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Anchoring the Lead

Do not secure the ligatures so tightly that they damage the vein, lead, or anchoring sleeve. Do not tie a ligature directly to the lead body (Figure 10). During anchoring, take care to avoid dislodging the lead tip.

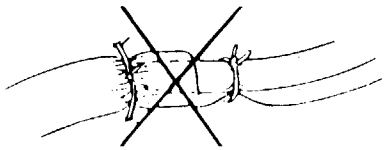

Figure 10. Do NOT secure the sutures too tightly and do NOT tie a suture to the lead body.

Use an anchoring sleeve to secure the lead from moving and to protect the lead insulation and conductor coil from damage caused by tight ligatures. A second anchoring sleeve should be placed in the tunnel entry site or in the pocket area for additional fixation.

Anchor the lead with nonabsorbable sutures.

TRANSVENE® RV uses a triple groove anchoring sleeve illustrated in Figure 11. The triple groove anchoring sleeves are situated at the connector end of the lead.

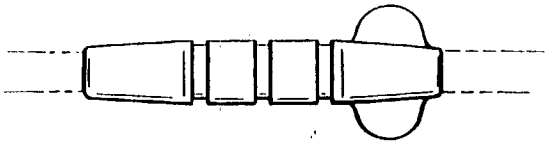

Figure 11. The triple groove anchoring sleeve.

With a triple groove anchoring sleeve, all three grooves should be used with the following procedure (Figure 12):

- Partially insert the distal anchoring sleeve into the vein.
- **Use all three grooves to secure the anchoring sleeve (s) to the lead body.**
- Use the most distal suture groove to secure the anchoring sleeve to the vein.
- Use the middle groove to secure the anchoring sleeve to the fascia, vein, and lead body. First, create a base

by looping a suture through the fascia underneath the middle groove and tying a knot. Continue by firmly wrapping the suture around the middle groove and tying a second knot.

CAUTION: Do not use the anchoring sleeve tabs for suturing.

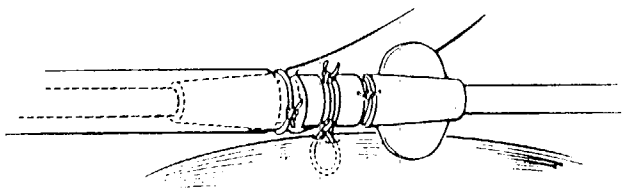

Figure 12. Triple groove anchoring sleeve secured to the lead and fascia using three grooves.

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 13a and 13b for instructions and illustrations showing lead connections to the Medtronic® PCD® Tachyarrhythmia Control Device Model 7217B.

Insert the lead connector into the connector block. Refer to the PCD® Tachyarrhythmia Control Device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

CAUTION: Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillation Electrodes	Two-Electrode System Connection Diagram
Medtronic® Model 7217B PCD® Device	2	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE®-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE®-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the connector plug packaged with the pulse generator into the PULSE1 port. **PULSE2** Insert the lead connector of the TRANSVENE®-RV, -SVC, or -SQ lead into the PULSE2 port.

6966 Reg. .14cEN/MMC 10/8/93 1:24 PM Page 18

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 14). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

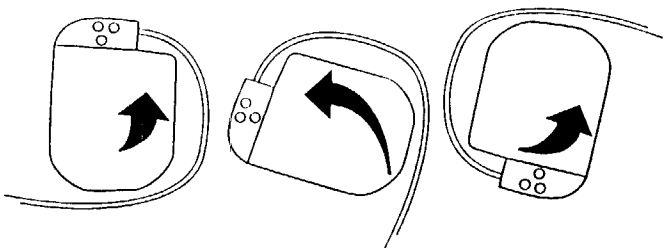

Figure 14. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended that the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 15).
- Do NOT grip the lead or pulse generator with surgical instruments.

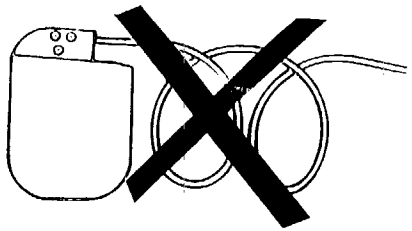

Figure 15. Do not coil or twist the lead body.

63

Post-Implant Evaluation

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

The patient should have X-rays and pacing/sensing thresholds taken every three months for the first year after implant and every six months thereafter to verify proper lead position and to check for conductor fractures.

In the event of a patient death, all implanted leads and devices should be explanted and returned to Medtronic with a completed PCD® Product Information Report. Any questions on product handling procedures can be addressed by calling 1-800-PCD-INFO.

SPECIFICATIONS (Nominal)

PARAMETER		MODEL 6966
Type		Tripolar
Position		Ventricle
Fixation		Screw-In
Length		110 cm
Connectors	Unipolar:	6.5 mm
	Bipolar:	3.2 mm
Materials	Conductors:	Multifilar MP35N Composite
	Insulator:	Polyurethane
	Electrode:	Platinum Alloy
Electrode Surface Area	Helix:	10 mm^2
	Ring:	37 mm^2
	Coil:	426 mm^2 (5 cm length)

PARAMETER		MODEL 6966
Diameters	Body:	3.3 mm
	Helix:	1.6 mm
	Maximum Head:	3.5 mm
Helix Length (fully extended)		2 mm
Conductor Resistances	Pacing:	45 ohms (unipolar) 190 ohms (bipolar)
	Defibrillation:	3.5 ohms
Lead Introducer (recommended size)		11 French
Maximum Revolutions that can be used to extend or retract the helix when using a straight style		20

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications (including perforation of the heart) will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

For complete warranty information, see the accompanying card enclosed in the package.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

Before implanting a Model 7217B PCD device, it is strongly recommended that the physician do the following:

- Thoroughly read this manual, the systems applications manual for the programmer MemoryMod® cartridge, the External Tachyarrhythmia Control Device (ETCD™) technical manual, and the technical manuals for the leads used with the device.
- Provide a copy of the patient manual to the patient and discuss it with him or her and any other interested parties.
- Medtronic requires physicians to attend an education seminar on the complete PCD system. This includes the following topics:
  - Indications for use
  - Overview of the PCD system functions
  - Implant procedure
  - Patient management

Automatic defibrillation was invented and patented in 1953 by Dr. F. Zacouto, who designed an external device that delivered a defibrillation impulse to the heart upon detection of very rapid ECG activity in combination with the absence of arterial pulsations.

Certain antitachycardia pacing modes of this device, invented by Dr. Fred Zacouto of Paris, France, fall under one or more patent claims of U.S. Patents 3,857,399 and 4,052,991 and corresponding patents in other countries, which are licensed exclusively to Medtronic, Inc.

GENERAL DESCRIPTION

The Medtronic Model 7217B PCD® (Pacer-Cardioverter-Defibrillator) Device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD device is designed to automatically detect episodes of ventricular tachycardia (VT) or ventricular fibrillation (VF) and, upon detection, deliver the appropriate programmed pacing, cardioversion, or defibrillation therapies. The device has two independently programmable detection and therapy procedures, one for VT and a second for VF.

The VT Detection circuitry can use up to four separately programmable detection modes as it monitors the cardiac cycle length to identify the presence of a tachycardia. Upon detection, the PCD device delivers its first programmed VT therapy. If the VT episode persists and is again detected, up to three additional independently programmable VT therapies may be delivered to restore the patient's normal cardiac rhythm. This progression of four VT therapies can be tailored to each patient's needs. The therapies may be selected from two methods of overdrive pacing (Burst and Ramp) and synchronized Cardioversion.

The VF Detection circuitry uses three programmable parameters as it monitors the cardiac cycle length to identify a VF episode. Upon detection, VF therapy provides a programmable high-energy defibrillation shock. Up to a maximum of four VF therapies may be delivered for ongoing detected VF episodes. Each defibrillation therapy consists of a single shock or two simultaneous or sequential high-voltage pulses designed to restore the normal cardiac rhythm.

The PCD device provides bradycardia therapy via ventricular inhibited (VVI) pacing.

The PCD device requires an appropriate lead system, consisting of up to five electrodes. Cardioversion and defibrillation occur between the **PULSE1** and/or **PULSE2** and **COMMON** electrodes[1]. The optional **PULSE1** electrode and the **PULSE2** electrode serve as anodes for the cardioversion and defibrillation therapies. Pacing stimuli occur between the **PACE/SENSE** (pacing cathode) and **COMMON**. Sensing of cardiac activity occurs between the **PACE/SENSE** and **SENSE2** electrodes.

The PCD device is to be programmed with an appropriate Medtronic programmer (e.g., the Model 9710 or other equivalent unit). Instructions for programming the PCD device may be found in the Model 9788 MemoryMod® Software Cartridge Technical Manual (or equivalent). Programmers from other manufacturers are **NOT** compatible.

The physician may use the PCD device to conduct noninvasive electrophysiologic studies (EPS) via the Programmer and appropriate MemoryMod cartridge. The physician can also manually deliver various therapies via the Programmer to manage an induced or spontaneous tachyarrhythmia.

The PCD device will provide the physician with information, via the Programmer, about its present programmed parameters, status, and data on its operation accumulated between office visits. This information may be printed and retained in the patient's file.

1. See the Lead Technical Manuals for details on the lead system.

7217B NTL p1-38/MMC 10/8/93 6:36 PM Page 2

PRESCRIBING THE MODEL 7217B PCD DEVICE

Intended Uses

The Model 7217B PCD device is intended for use in patients who are at high risk of sudden death due to ventricular tachyarrhythmia. Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; OR
- in the absence of a prior cardiac arrest, have poorly tolerated sustained VT and/or VF, which occurs spontaneously or can be induced despite the best antiarrhythmic drug therapy.

modified

The natural history of patients with hemodynamically stable sustained VT is not well defined. While this patient population was included in PCD clinical studies the study objectives did not include stratification of this specific patient group.

The PCD device may be used as a replacement for a previously implanted, commercially-available Automatic Implantable Cardioverter Defibrillator. The PCD device is intended for use only with the defibrillation lead systems with which it has been tested, which are Medtronic epicardial patch leads and Cardiac Pacemakers, Inc., patch leads.

Prior to implant, it is strongly recommended that patients undergo a complete cardiac evaluation, which should include extensive electrophysiologic testing. Also, extensive electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Model 7217B PCD device.

Before permanently programming the PCD device to the automatic detection and delivery of the VT and/or VF therapies, the patient should have demonstrated a satisfactory response to the proposed therapy. For more information, see "Programming Considerations" and "Pre-Hospital Discharge" in "Post-Implant Information."

Contraindications

The Model 7217B PCD device is contraindicated for patients:

- with transient ventricular tachyarrhythmias due to reversible causes, e.g., drug intoxication, electrolyte imbalance, sepsis, or hypoxia.
- with transient ventricular tachyarrhythmias due to other factors, e.g., myocardial infarction and electrocution.

The Model 7217B PCD device is contraindicated for the sole use of detection and treatment of atrial arrhythmias.

Because of the potential for damage to the PCD device and/or induction of life-threatening arrhythmias, the use of the following techniques and/or therapies is contraindicated in patients who have an implanted Model 7217B PCD device:

- Magnetic Resonance Imaging (MRI) and
- Hydraulic Shock-wave Lithotripsy

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 3

LONGEVITY EXPECTATIONS

The longevity of the Model 7217B PCD device depends upon several factors including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the pacing load, and the frequency of high-voltage capacitor charging. The longevity projections found in Table 1 apply under the following conditions:

- 65 ppm pacing rate,
- 5.4 V pacing pulse amplitude,
- 0.49 ms pacing pulse width, and
- 500 ohm pacing load.

Table 1. Projected Longevity[1]

Pacing/Sensing	34-Joule Charging Frequency	Average Longevity
100% sensing	Quarterly	5.0 years
15% pacing	Monthly	4.2 years
100% pacing	Monthly	3.4 years

The longevity of the device decreases with the following:

- an increase in pacing rate,
- an increase in pacing amplitude,
- a decrease in pacing impedance,
- an increase in pacing pulse width,
- an increase in the percentage of bradycardia paced to sensed events, or
- an increase in the charging frequency.

Each 34-joule charging cycle will typically decrease the longevity of the device by approximately six days.

For information on when to replace the PCD device, see "Elective Replacement and Potential Loss of Function Indicators" in "Post-Implant Information."

1. These preliminary longevity projections are based upon accelerated battery discharge data and device modeling. They include an estimate of five months between time of manufacture of a PCD device and its implant. If a device was stored for the full twelve-month shelf life, the average longevity would be reduced an estimated 4.3 to 5.9 months, depending on device use. With the stated conditions, 100% pacing and monthly 34-joule charging cycles, the minimum longevity of the device will be 2.5 years. Average refers to the projected mean longevity of the modeled run of PCD devices at the stated conditions. Minimum longevity means that virtually all (i.e. 99.9%) of all modeled production runs of PCD devices will attain the value given.

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 4

PRINCIPLES OF OPERATION

Overview

The Model 7217B PCD device is designed to detect two types of sustained ventricular tachyarrhythmia: ventricular tachycardia (VT) and ventricular fibrillation (VF). The sensing circuitry used for detection employs a bipolar electrode configuration (**PACE/SENSE** to **SENSE2**) to maximize rejection of myopotentials, far-field P-waves, and other electrical signals. Separately programmable detection criteria are designed to allow the PCD device to differentiate between VT and VF.

Once either VT or VF is detected, the PCD device will deliver the first programmed VT or VF therapy and up to three additional programmed therapies if the episode persists and is repeatedly detected. Three kinds of VT therapy are available: two different types of overdrive pacing therapy and a synchronized cardioversion therapy. VF therapy consists of high-energy defibrillation shocks; the stored energy level is separately programmable for all four VF therapies.

If required, the PCD device will provide bradycardia therapy with pacing (**PACE/SENSE** to **COMMON**) at the programmed lower rate in the VVI mode.

Figure 1 summarizes the detection and therapy features of the PCD device.

Complete details of these operations are found in the sections that follow:

- Features Used in Sensing and VT/VF Detection
- Ventricular Tachycardia (VT) Detection
- Ventricular Tachycardia (VT) Therapy
- Ventricular Fibrillation (VF) Detection
- Ventricular Fibrillation (VF) Therapy
- VVI Therapy

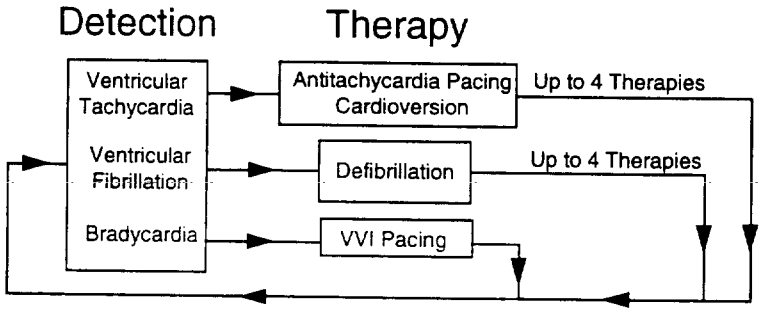

Figure 1. Detection and Therapy in the PCD Device

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 5

Features Used In Sensing and VT/VF Detection

Proper sensing is essential for the safe and effective use of the PCD device. The device's sensing function should be regularly verified by means of Marker Channel™ telemetry (see "Telemetry Reports" and Figure 26). If sensing or detection are inappropriate, VT and VF Detection should be programmed OFF until verification studies are performed.

Auto-Adjusting Sensitivity Threshold

The Model 7217B PCD device automatically adjusts its sensitivity following signal detection on the bipolar electrogram (between the **PACE/SENSE** and **SENSE2** electrodes). This feature is designed to prevent the sensing of T-waves when very low sensing threshold levels are used. When the amplitude of the sensed event exceeds the programmed setting, the PCD device notes that a sensed event has occurred. The sensing level is raised to about 75% of the electrogram peak (or about 6 times the programmed setting, whichever is less) and gradually returns to the programmed value with a 560 ms exponential decay time constant. Figure 2 illustrates how the sensing level is changed by increasing or decreasing the Auto-Adjusting Threshold.

NOTE: The Auto-Adjusting Sensitivity level is not increased by pacing, VT therapy, or VF therapy outputs. The physician should be aware that the programmed sensitivity setting and the associated blanking periods are also used to detect a VT or VF episode and, therefore, Auto-Adjusting Sensitivity is active during VT and VF detection.

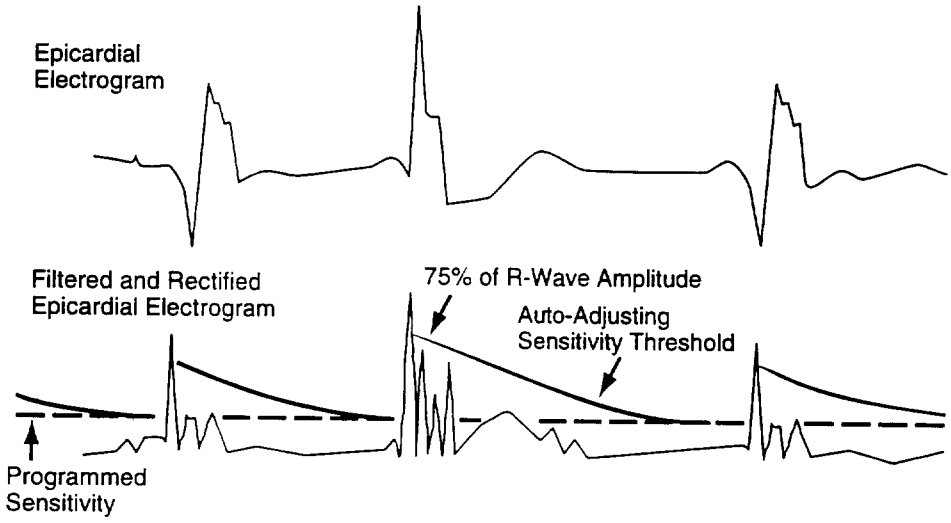

Figure 2. Auto-Adjusting Sensitivity Threshold

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 6

Blanking Periods

Nonprogrammable blanking periods follow paced and sensed events, capacitor charging periods, and therapy deliveries. These blanking periods prevent the sensing of device outputs or multiple sensing of the same event. Signals on the sensing electrodes during a blanking period are not used by the PCD device. The blanking period following a pacing output is longer than that following a sensed event. This feature is designed to avoid sensing the polarization signal on the electrodes. There are four blanking periods:

- 120 ms after a sensed event,
- 320 ms after a paced event (i.e., either VVI bradycardia pacing or VT pacing level Burst or Ramp stimuli),
- 300 ms after a cardioversion or defibrillation charging period and also after delivery of a cardioversion or defibrillation therapy, and
- During a charging period.

Refractory Periods

Refractory periods follow some events. The PCD device assumes that signals detected on the sensing electrodes during a refractory period are caused by noise, lead polarization, the trailing edge of an R-wave, or a T-wave. There are five refractory periods:

- 400 ms after a cardioversion or defibrillation charging period,
- 200 ms following sensed events in the automatic cardioversion synchronization period,
- 520 ms following the delivery of any VT or VF therapy,
- 320 to 520 ms after a therapy is aborted, and
- 320 to 480 ms (programmable) after paced events (Refractory After Pace).

No additional refractory period extends beyond the blanking period after sensed events. During VVI operation, **the PCD device will not revert to asynchronous operation in the presence of noise.**

Both the VT and VF detection criteria ignore an event sensed within a refractory period. An event sensed in the refractory period will not inhibit a pacing output. Such an event, however, does restart the sensed event blanking period of 120 ms.

Programming the Refractory After Pace to more than 320 ms may impair the PCD device's ability to detect VT or VF. Events sensed within the refractory period restart a 120 ms blanking period but are ignored by both VT and VF detection criteria and for bradycardia pacing inhibition. Therefore, a short bradycardia escape interval (i.e., a pacing rate greater than 50 ppm) combined with a long Refractory After Pace (360 ms or longer) may prevent a VT event from inhibiting a pacing output. **In such circumstances, the VT could remain undetected.**

To avoid this possibility when the Refractory After Pace is programmed to 360 ms or longer, ensure that at least one of the following is true: (1) the difference between the bradycardia escape interval and the effective refractory period should be greater than the

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 7

Tachycardia Detection Interval (TDI); or (2) the bradycardia escape interval must be greater than twice (2X) the effective refractory period. (The effective refractory period for a programmed refractory of 360 ms or longer is the programmed value plus 120 ms.) The following example and table show how programmed refractory periods of 360 ms and greater affect VT detection at various pacing rates above 50 ppm.

For example, if the Refractory After Pace equals 360 ms, then the effective refractory period could be 480 ms. If the escape interval equals 670 ms (90 ppm), then intrinsic rhythms with 190–480 ms intervals may not be detected if the rhythm initiates during VVI pacing.

Programmed Refractory After Pace	VT or VF Interval Lengths That Could Remain Undetected –At 70 ppm (860 ms)	–At 90 ppm (670 ms)
360 ms	380 - 480 ms	190 - 480 ms
400 ms	340 - 520 ms	150 - 520 ms
440 ms	300 - 560 ms	110 - 560 ms
480 ms	260 - 600 ms	70 - 600 ms

In order for the programmed refractory period to have **any** effect on VT detection, the VT episode must initiate during VVI pacing at rates **over** 50 ppm and with the Refractory After Pace **greater** than 320 ms.

Measurement of Intervals

The PCD device measures cardiac cycle lengths in multiples of 10 ms. Intervals are rounded down to the nearest 10 ms multiple (e.g., 457 ms becomes 450 ms). The PCD device uses this rounded interval value when applying the programmed criteria and calculating interval averages.

7217B NTL p1-38/MMC 9/25/93 12:10 AM Page 8

Ventricular Tachycardia (VT) Detection

Overview of VT Detection

With VT Detection enabled, the PCD device monitors the cardiac cycle length for the fulfillment of the programmed VT detection criteria. When the programmed criteria are fulfilled, the PCD device detects a VT episode and delivers the first programmed VT therapy. If this therapy is ineffective and the VT is again detected, the next programmed VT therapy is delivered. This progression continues until the PCD device confirms VT termination or delivers all programmed VT therapies. VT Detection is suspended if all programmed therapies are ineffective in terminating the arrhythmia. VT Detection is re-enabled when VT termination is confirmed or if VT Detection is manually reprogrammed ON.

All programmed VT detection criteria must be fulfilled for a rhythm to be detected as a VT episode. Whenever VT Detection is enabled (ON) there are three available criteria: the **Interval Criterion** is automatically enabled, the **Interval Stability Criterion** and the **Onset Criterion** are optionally programmable. The number of detected episodes is stored in the device's memory. The data for previously detected VT episodes may be accessed with the programmer.

NOTE: VF Detection must be programmed ON before VT Detection can be programmed ON.

VT and VF Detection may be programmed ON to permit the PCD device to function solely as a tachyarrhythmia monitor with all tachyarrhythmia therapies programmed OFF.

VT Detection Criteria

Interval Criterion

The Interval Criterion is designed to detect a sustained high ventricular rate by measuring each cardiac cycle length and comparing it to the **Tachycardia Detection Interval (TDI)**. If an interval is less than the TDI, then that cycle is potentially a count toward the fulfillment of the **Number of Intervals to Detect (VT NID)**. The Interval Criterion is activated when VT Detection is enabled and, therefore, requires programming both the TDI and VT NID parameters.

The Interval Criterion requires that the measured cardiac cycle length be less than the programmed TDI value and greater than or equal to the programmed Fibrillation Detection Interval (FDI). The VT event counter counts the number of intervals that meet the Interval Criterion. The VT event counter is reset to zero if an interval is greater than or equal to the TDI. The count is not increased nor reset if an interval is less than the FDI. When the cumulative VT event count is equal to the VT NID, the Interval Criterion for VT detection is fulfilled.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 9

Thus, fulfillment of VT Detection when only the Interval Criterion is enabled requires both of the following:

- Measured cardiac cycle lengths be **less than** the programmed Tachycardia Detection Interval (**TDI**), and **greater than or equal** to the programmed Fibrillation Detection Interval (**FDI**), and
- The cumulative number of these intervals be **equal to** the programmed Number of Intervals to Detect (**VT NID**).

Counting is reset to zero when an interval is greater than the programmed TDI and is interrupted when the interval is less than the FDI.

The Relationship Between the TDI and FDI

Figure 3 illustrates how the relationships between the blanking period (120 ms) after a sensed event, FDI, TDI, and bradycardia escape interval determine whether a sensed event is a VF event (B), a VT event (C), or a normal sensed event (D). In addition, all these events inhibit the bradycardia output pulse.

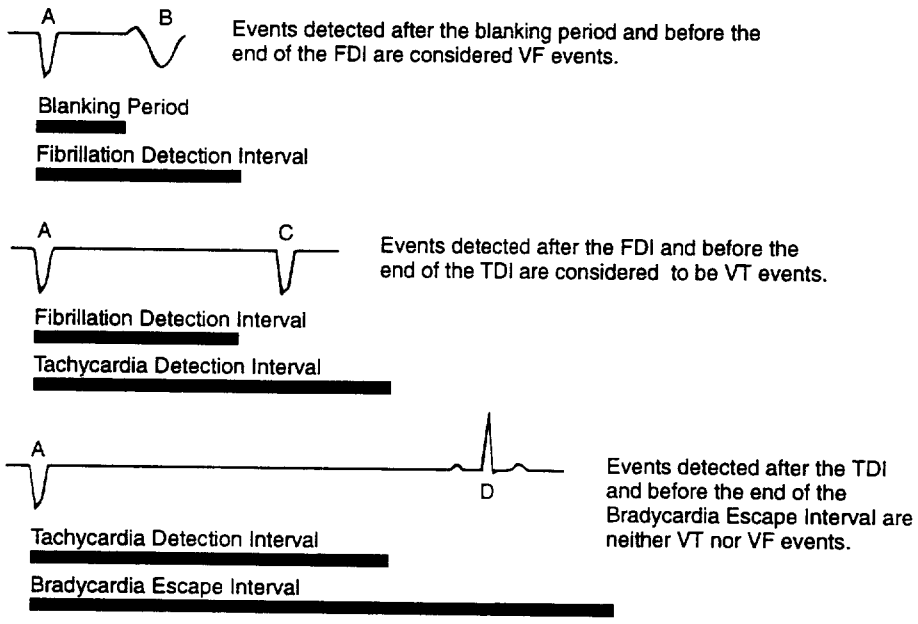

Figure 3. The Relationship of the TDI and FDI

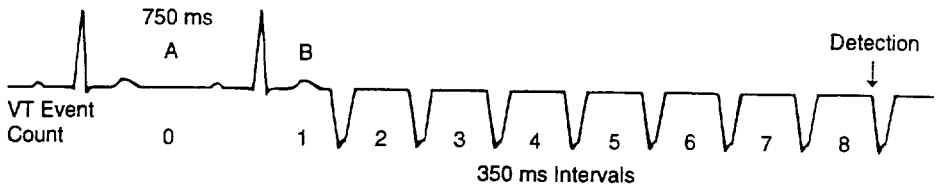
NOTE: Programming the FDI to a value greater than or equal to the TDI effectively disables VT Detection. **When programming these two values, the physician should keep the TDI at least 40 ms longer than the FDI to allow for variability of the clinical VT cycle length.**

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 10



Programmed to: TDI = 400 ms; FDI = 250 ms; VT NID = 8

In this example, Interval "B " and the intervals following B increment the VT event counter.

Figure 4. Interval Criterion (Example)

Figure 4 illustrates how the PCD device could use the Interval Criterion to detect a tachycardia. The interval at "B" is 350 ms, i.e., 50 ms less than the programmed TDI value of 400 ms. Because it is less than the TDI and greater than the FDI and since no other VT Detection Criteria are programmed, the VT event count, in this example, begins. When the VT event count reaches 8, VT detection occurs.

NOTE: Some of the timing diagrams provided in this manual depict representative surface ECGs and are illustrative of the operation being discussed. The PCD device actually uses epicardial or intracardiac electrograms (EGMs) for measurement and analysis of the cardiac cycle lengths. Detection and delivery of therapies are based on EGMs, not on surface ECGs.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 11

Interval Stability Criterion

The Interval Stability Criterion is a programmable option that provides an additional restriction to the Interval Criterion. It is intended, for example, to prevent VT detection when rapid ventricular rhythms with irregular intervals due to conduction of atrial fibrillation or flutter would otherwise fulfill the Interval Criterion.

When enabled, this criterion analyzes only those measured cardiac cycle lengths that fulfill the Interval Criterion. A measured cardiac cycle length is considered unstable when the difference between the current measured cycle length and any of the three previous cycle lengths is greater than the programmable Interval Stability value (in milliseconds). Note that the VT event count must be at least "3" before the PCD device can apply the Interval Stability Criterion. If the current cardiac cycle length varies more than the programmed Interval Stability value, then the VT event count is reset to zero. The measurement and counting of cardiac cycle lengths then begins anew.

Thus, with Interval Stability and Interval Criteria enabled, VT Detection requires all of the following:

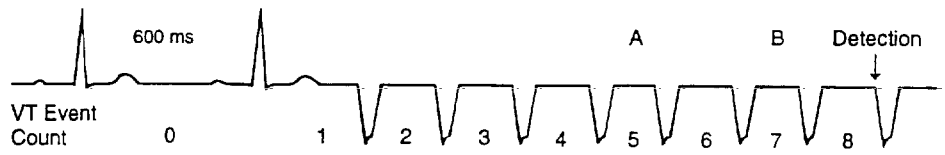
- Measured cardiac cycle lengths be **less than** the programmed Tachycardia Detection Interval (**TDI**) and **greater than or equal to** the programmed Fibrillation Detection Interval (**FDI**),
- **Each of these measured cardiac cycle lengths** vary from each of the three previous cycles by a value **less than or equal to** the programmed Interval Stability value, and
- The cumulative number of these intervals be **equal to** the programmed Number of Intervals to Detect (**VT NID**).

Counting is reset to zero when an interval is greater than the programmed TDI or is considered "unstable." The count is suspended when the interval is less than the FDI. When this criterion is enabled and a VT therapy is unsuccessful in treating a detected VT, Interval Stability must be fulfilled before the episode can be redetected.

NOTES: Choosing a small Interval Stability value may not allow for normal variation in a VT cycle length.

Decreasing the programmed interval stability increases the specificity of the Interval Stability Criterion to detect the targeted stable tachycardia, but may also decrease the sensitivity of the detection algorithm.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 12

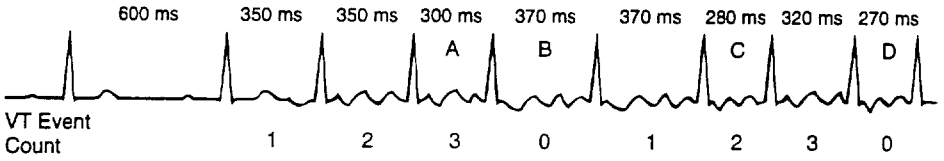


All VT intervals above are 350 ms, except "A" and "B", which are 300 ms.

Programmed to: TDI = 400 ms; FDI = 250 ms;
VT NID = 8; and Stability = 60 ms

Figure 5. Interval Stability Criterion Fulfilled (Example)

Figure 5 illustrates how the Interval Stability Criterion may be fulfilled. Interval "A" is a "stable" interval, i.e., only 50 ms shorter than the three previous intervals and less than the programmed Stability of 60 ms. Interval "B" similarly qualifies as a stable interval, because it is equal to one of the three previous intervals and is 50 ms shorter than the other two. VT detection occurs when the VT event count reaches the programmed VT NID value (8).



Programmed to: TDI = 400 ms; FDI = 250 ms;
VT NID = 8; and Stability = 60 ms

Figure 6. Interval Stability Criterion Not Fulfilled (Example)

Figure 6 illustrates how an "unstable" interval is identified. Interval "B" is 70 ms longer than "A" and therefore exceeds the programmed Stability value by 10 ms. As a result, the VT event count is reset to zero. Interval "C", though 90 ms less than the previous interval and greater than the programmed Stability of 60 ms, does not reset the VT event count, because the counter has not yet reached "3". Interval "D", however, is an unstable interval; it occurs after the event count reaches "3", and thus also resets the VT event count to zero.

90

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 13

Onset Criterion

The Onset Criterion, a programmable option, monitors the cardiac cycle length for a sudden onset of a high ventricular rate. It is intended to avoid VT detection of an episode of sinus tachycardia with gradually increasing (e.g., exercise-induced) high ventricular rates.

This criterion, when enabled, **must first be satisfied** before the device begins counting VT events that otherwise satisfy the Interval Criterion and, if programmed, the Interval Stability Criterion. When the Onset Criterion is enabled, the PCD device evaluates each cardiac cycle for a decrease in cycle length from previous intervals. The Onset Criterion is fulfilled when both of the following conditions are met:

- If the current interval is **less than** a programmed percentage of the average of the previous four intervals, and
- Either the second and/or third interval preceding the current interval is **equal to or greater than** the programmed TDI.

If two consecutive intervals after the Onset Criterion is satisfied are greater than or equal to the TDI, the Onset Criterion is reset and must again be satisfied before a VT can again begin to be detected. When a VT is detected, however, the Onset Criterion is not required again for redetection until the PCD device confirms VT episode termination.

NOTES: If the Onset Criterion is ON and not met at the beginning of a ventricular tachycardia, the VT episode could remain "undetected", such as with an exercise-induced VT. For example, if VT Detection uses the Onset Criterion and is enabled after the start of a VT, the VT may not be detected.

A low programmed onset percentage value will increase the specificity of the Onset Criterion to detect the targeted tachycardia, but may also decrease the sensitivity of the detection algorithm.

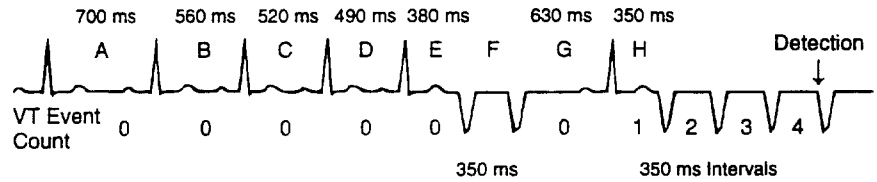
Intervals that are shorter than the programmed FDI may also fulfill the Onset Criterion, even though they are not VT events. Such an interval does not increase nor reset the VT event counter.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 14

Programmed Values: TDI = 400 ms; FDI = 250 ms; VT NID = 4; and Onset = 81%

Figure 7. Onset Criterion Fulfilled (Example)

Figure 7 illustrates how the PCD device uses the Onset Criterion to identify a VT episode. Interval "E" meets the programmed Onset Criterion because it is less than 81% of the average of intervals A through D and because B (and/or C) is greater than the TDI. The VT event count begins with the next interval because it is less than the programmed TDI.



Programmed Values: TDI = 400 ms; FDI = 250 ms; VT NID = 4; and Onset = 81%

Figure 8. Onset Criterion Fulfilled (Example)

In Figure 8, interval E satisfies the Onset Criterion, i.e., it is less than the programmed 81% of the average of intervals A through D, with interval B (and/or C) greater than the TDI. Interval G by itself, though longer than the TDI, does not reset the Onset Criterion, since two such consecutive intervals are required for a reset of the Onset Criterion. Interval G, however, does reset the VT event count; thus, the event count begins at F, resets to zero at G, and then begins again at H.

92

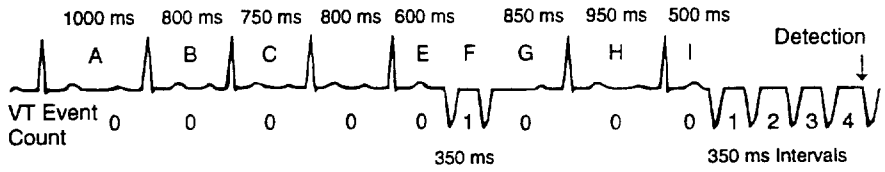


Figure 9. Onset Criterion Reset and Fulfilled (Example)

In Figure 9, a situation occurs that resets the Onset Criterion, which is first satisfied by Interval E. Two intervals (G and H), longer than the TDI, reset both the Onset Criterion and the VT event count. Thus, a second interval (I) must fulfill the Onset Criterion before the VT event count can begin counting toward VT detection.

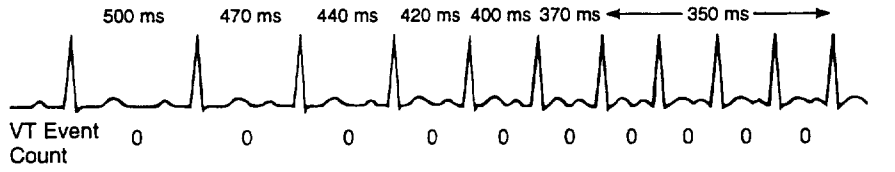

Figure 10. Onset Criterion Not Fulfilled (Example)

Figure 10 illustrates a sinus rhythm with a gradually accelerating rate. No interval is less than 81% of the average of the four previous intervals. Thus, this rhythm would not be detected by the PCD device as a VT. This example demonstrates how the Onset Criterion may be used to help differentiate between a sinus tachycardia (possibly exercise-induced) and a pathological VT.

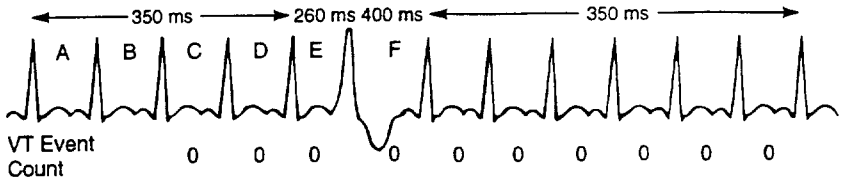

Figure 11. Onset Criterion Not Fulfilled (Example)

In Figure 11, all intervals, except "E" and "F", are 350 ms. Interval E, which is 260 ms, appears to satisfy the Onset Criterion. Although Interval E is indeed less than 81% of the average of Intervals A through D, neither Interval B or C is greater than the TDI. Both requirements must be satisfied to fulfill the Onset Criterion.

Subsequent Reconfirmation/Redetection of an Ongoing VT Episode

After initially detecting a VT episode and delivering the first programmed therapy, the PCD device monitors the cardiac cycle length for the continued fulfillment of the programmed detection criteria. Reconfirmation, i.e., redetection, is required before the next programmed therapy is delivered. **The Onset Criterion is only used for the initial detection of a VT episode and is not used for redetection of the same VT episode.**

VT detection begins immediately with the first cardiac cycle after VT therapy delivery. However, the first event detected may have a longer cycle than the programmed TDI due to the 520 ms refractory period following VT therapy.

NOTE: Programming high VT NID counts will result in correspondingly longer delays between VT therapies (when the previous therapy is ineffective in terminating the VT episode), due to the need to reconfirm the VT episode between therapies. The physician should understand that the programmed VT NID count applies to both initial detection and redetection of an ongoing episode after therapy delivery.

VT Episode Termination and Determination of Therapy Efficacy

The PCD device defines a VT episode as **terminated** when **eight consecutive** cardiac cycles (paced or sensed) all have intervals **greater than or equal to** the TDI.

The PCD device defines a VT therapy "effective" if VT termination occurs prior to any further VT detection. The PCD device is considered "ineffective" if, after **all** programmed therapies, VT detection occurs before VT termination. Once the PCD device detects a VT, it considers the episode as ongoing until a termination occurs. After episode termination, a subsequent VT detection marks the start of a new VT episode. See "Device Reporting Features" in "General Device Information" for information about how effectiveness is reported.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 17

NOTE: A rhythm following a therapy that does not satisfy the VT termination definition is considered part of an ongoing episode. However, the next VT therapy will not be delivered unless the programmed VT detection criteria are again fulfilled.

If all programmed therapies prove ineffective in terminating the arrhythmia, **only a later VT termination (either spontaneous or via a programmer-activated therapy) or manually programming VT Detection ON will restart** the programmed VT detection criteria and automatic therapy delivery.

Suspending and Disabling VT Detection

When the PCD device is "suspended," its detection functions are temporarily inactivated. "Disabled" is a permanently programmed state in which detection and/or therapies are not available (OFF condition). These functions can only be re-enabled via a programming sequence.

The programmed VT Detection criteria are temporarily **suspended** during

- Magnet application (unless a "Cancel Magnet" is programmed),
- Delivery of high rate pacing,
- Capacitor charging, in preparation for the delivery of a cardioversion or defibrillation shock or during a programmed charge period,
- Delivery of VT therapies,
- The period after all programmed VT therapies have proved ineffective (i.e., until VT episode termination is confirmed or VT Detection is again programmed ON),
- Delivery of VF therapies,
- The first 64 ventricular events (pace, sense, and therapy) after VF detection, and
- The period following VT and VF therapies that are manually initiated via the programmer, e.g., following programmed emergency or manual therapies (removing the programming head enables VT Detection).

The programmed VT Detection criteria are **disabled** whenever

- Three consecutive 35-second charge intervals have failed to reach the programmed energy level and the "Charge Circuit Inactive" condition occurs,
- Nominal or VVI option under Emergency VVI is programmed, and
- Power-on reset (an electrical reset) or a detected memory error occurs.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 18

Ventricular Tachycardia (VT) Therapy

The PCD device has three programmable VT therapy types: **Burst, Ramp, and Cardioversion.** Up to four separate therapies may be programmed **in any combination** of the three types. Here are four examples (read across):

Example	Therapy One	Therapy Two	Therapy Three	Therapy Four
No. 1	Ramp	Burst	Cardioversion	Cardioversion
No. 2	Ramp	Ramp	Burst	OFF
No. 3	Cardioversion	Cardioversion	Cardioversion	Cardioversion
No. 4	Cardioversion	OFF	OFF	OFF

NOTES: Programming a therapy OFF disables all subsequent therapies. For example, if the PCD device is programmed to Therapy #1 OFF, Therapy #2 Ramp, Therapy #3 Burst, and Therapy #4 Cardioversion, none of the VT therapies is enabled, and none will be delivered.

The PCD device cannot be programmed to deliver automatic VT therapies without VF detection and therapies programmed ON.

The physician may elect not to program any VT therapy. If VT Detection alone is enabled, the PCD device will only monitor the cardiac rhythm and record the number of detected VT episodes for subsequent interrogation via the programmer.

Burst Therapy[1]

A Burst sequence consists of a **rate-adaptive**, equal-interval set of pulses. A single Burst Therapy consists of one to 15 burst sequences. The physician programs the following: number of S1 pulses, adaptive percentage, number of sequences, millisecond decrement per sequence, and minimum pulse interval.

Burst Therapy is rate-adaptive. The PCD device determines the pulse interval of the first burst sequence as a programmable percentage of the tachycardia cycle length. The cycle length is determined by calculating the average of the last four intervals preceding VT detection.

The first pulse of the Burst sequence is delivered at the calculated "percentage", and is timed from the sensed event at which the VT event count equaled the programmed VT NID. Subsequent pulses in the same sequence are delivered at the same interval.

If a Burst sequence is ineffective in terminating the VT, and VT detection is reconfirmed, the pulse interval for the next sequence will be determined by calculating a percentage of the newly measured tachycardia cycle length and shortening that interval by a programmable value.

1. Certain antitachycardia pacing modes of this device, invented by Dr. Fred Zacouto of Paris, France, fall under one or more patent claims of U.S. Patents 3,857,399 and 4,052,991 and corresponding patents in other countries, which are licensed exclusively to Medtronic, Inc.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 19

The calculated pulse interval can never be less than a programmed "minimum" interval.[1] If the calculated interval is shorter than the programmed minimum, then the pulses will be delivered at the programmed minimum interval.

If the last programmed sequence of a Burst Therapy is ineffective in terminating the VT and the VT is again detected, the PCD device initiates the next therapy (if programmed).

During Burst Therapy, the PCD device operates in the VVI mode, although the programmable Refractory After Pace may affect this operation. R-waves, sensed outside the Refractory After Pace, are counted as individual pulses of the burst train (even though they are not output pulses). Whenever a sensed R-wave inhibits the scheduled pulse, the next pulse is scheduled at the calculated or minimum interval from the time of the sensed event.

A Burst sequence has the following characteristics:

- The pulse width and amplitude for an individual Burst pulse are the same as those programmed for bradycardia pacing output pulses.
- Burst sequences can be programmed as to the number of pulses, from one to 15 (in steps of one).
- The average of the last four intervals leading to VT detection and the resultant rate-adapted burst interval are both rounded to the nearest 10 ms (e.g., 387 ms is rounded to 390 ms).
- Following a Burst sequence, a 300 ms blanking period, a 520 ms refractory period, and a bradycardia escape interval of 1000 ms begin. The circuitry resumes monitoring the cardiac cycle for detection of a new/old VT episode, a VF episode, or bradycardia.

1. The "minimum" pulse interval is the same for all Burst and Ramp therapies.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 20

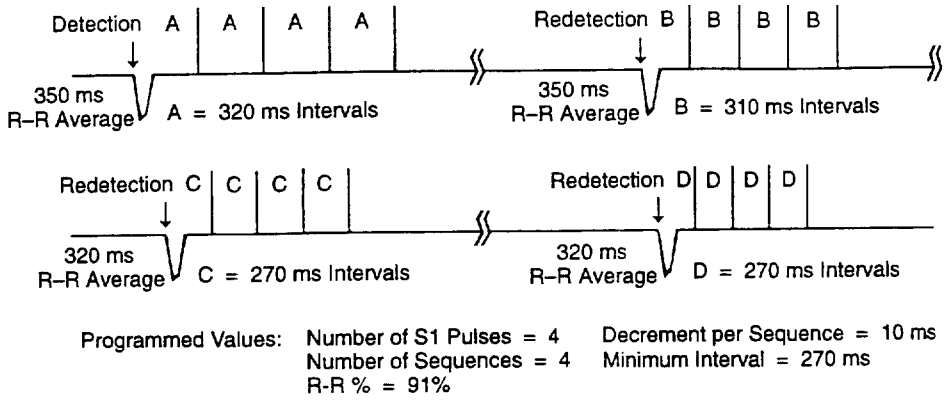

Figure 12. Burst Therapy (Example)

In the example in Figure 12, a VT episode is detected in which the R–R average interval is 350 ms. Note the programmed settings for the example.

The PCD device determines that the calculated pulse interval for the **first Burst sequence (A)** should be 320 ms, i.e., the R–R average interval of 350 ms X 91% (rounded). The first pulse is delivered at 320 ms from the R-wave that fulfilled the programmed VT NID. All subsequent pulses of this sequence are separated by 320 ms intervals.

Assuming the VT is redetected and that the R–R average interval remains at 350 ms, the calculated pulse interval for the **second Burst sequence (B)** is 310 ms (320 ms minus the 10 ms programmed decrement).

Before the **third Burst sequence (C)**, the average R-R interval shortens to 320 ms. Thus, the calculated pulse interval is 270 ms, i.e., (320 X 91%) – 20 ms = 290 – 20 ms = 270 ms (rounded).

The R-R average for the detected VT prior to the **fourth and final Burst sequence (D)** remains at 320 ms. The calculated pulse interval (with a decrement of 30 ms) would have been 260 ms; but, by definition, it cannot be shorter than 270 ms (the programmed minimum interval). Therefore, the pulse interval is 270 ms.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 21

Ramp Therapy

A Ramp sequence consists of a rate-adaptive, set of pulses delivered at decreasing intervals. A single Ramp Therapy consists of from 1 to 15 Ramp sequences.

Ramp Therapy is **rate-adaptive**. The PCD device calculates the interval for the first pulse of the Ramp sequence as a programmable percentage of the average cycle length of the last four cycles prior to VT detection. **Each subsequent interval in the Ramp sequence is shortened from the preceding interval by a programmable value.**

The number of pulses in the first ramp sequence is programmable (up to 15). If additional sequences are programmed and the VT is redetected, the PCD device **automatically increases the number of pulses by one in each successive sequence (to a maximum of 29 in the fifteenth sequence, if programmed to 15 pulses for the first sequence and to the maximum 15 sequences)**.

If a Ramp sequence is ineffective in terminating the VT and the VT is again detected, the first interval of the next sequence will be a programmed percentage of the newly measured tachycardia cycle length. As described above, each subsequent interval is shortened from the preceding interval by a programmable value. After each VT detection that initiates a Ramp sequence, the initial interval of the sequence is recalculated.

NOTE: If the tachycardia cycle length has not changed, the first interval of the next programmed sequence will be the same as the previous sequence. This is in contrast to Burst Therapy, in which the intervals of each sequence are shortened by a programmed value, even when the tachycardia cycle length is unchanged.

If the last programmed Ramp sequence proves ineffective in terminating the VT and the VT is redetected, the PCD device will deliver the next therapy (if programmed).

During Ramp Therapy, the PCD device operates in the inhibited mode, although the programmable Refractory After Pace may affect this operation. This means that R-waves, sensed outside the Refractory After Pace, are counted as individual pulses of the ramp sequence (even though they are not output pulses). Whenever a sensed R-wave inhibits the scheduled pulse, the next pulse is scheduled at the calculated or minimum interval from the time of the sensed event i.e., the interval is shortened (if possible) as if the sensed R-wave was an output pulse. A Ramp Therapy has the following characteristics:

- Each Ramp Therapy can be programmed from 1 to 15 pulses (in steps of one) for the initial sequence. Each successive sequence adds one pulse.
- The pulse width and amplitude for an individual Ramp pulse are the same as those programmed for the pacing output pulses.
- The average of the last four detected intervals and the resultant rate-adapted Ramp interval are both rounded to the nearest 10 ms (e.g., 387 ms is rounded to 390 ms).
- The calculated pulse interval during any Ramp sequence can never be less than the programmed "minimum" interval. If the calculated interval is shorter than the

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 22

programmed "minimum", the pulses will be delivered at the programmed "minimum" interval.

- The PCD device operates in the VVI mode during Ramp Therapy. This means that sensed R-waves are counted as individual pulses of the Ramp sequence (even though they are not output pulses). A sensed R-wave inhibits the scheduled pulse, and the next pulse is scheduled at the calculated or minimum interval from the time of the sensed event.
- Following a Ramp sequence, a 300 ms blanking period, a 520 ms refractory period, and a bradycardia escape interval of 1000 ms begin. The circuitry resumes monitoring the cardiac cycle for detection of a new/old VT episode, a VF episode, or bradycardia.

Figure 13 shows a detected tachycardia episode with an R–R interval of 350 ms.

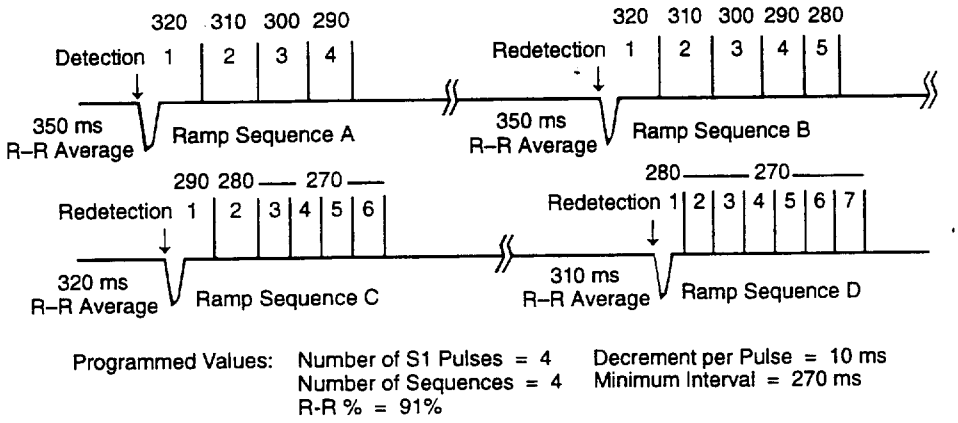

Figure 13. Ramp Therapy (Example)

The PCD device determines that the calculated pulse interval for the **first Ramp sequence (A)** should be 320 ms (i.e., 350 ms X 91% rounded). The first pulse is delivered at 320 ms from the R-wave that fulfilled the programmed VT NID, with each interval thereafter shortened by 10 ms so that the fourth interval equals 290 ms.

Assuming that the VT is redetected and the R–R average interval remains at 350 ms, the calculated initial pulse interval for the **second Ramp sequence (B)** is again 320 ms. Subsequent intervals are shortened as described above. In this sequence, however, a fifth pulse is delivered at 280 ms.

Before the **third Ramp sequence (C)**, the average R-R interval shortens to 320 ms. Thus, the initial interval is 290 ms (320 ms X 91% rounded); due to the 10 ms decrement, intervals three, four, five, and the additional sixth are all delivered at the programmed minimum of 270 ms.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 23

The R–R interval shortens to 310 ms prior to the **fourth Ramp sequence (D)**. In this case, the initial interval is 280 ms. All subsequent intervals (including the additional seventh) are delivered at 270 ms, since this is the programmed minimum value.

VT Acceleration During a Burst or Ramp Therapy

If, after the delivery of a Burst or Ramp sequence, the average cycle length for the four intervals preceding redetection has decreased by a value equal to or greater than 60 ms compared to the average cycle length for the initial VT detection of the episode, the PCD device determines that the VT has accelerated. Subsequent sequences (of a Burst or Ramp therapy) will not be delivered.

For example, assume the programmed therapies were Burst (with multiple sequences), Ramp (with multiple sequences), Cardioversion, and Cardioversion. If the VT were to accelerate after the first sequence of the Burst therapy, the PCD device would cancel the remaining sequences and initiate the programmed Ramp therapy. Similarly, if the VT was still considered accelerated after the initial sequence within the Ramp therapy, the PCD device would go immediately to the next programmed therapy, Cardioversion.

NOTE: This progression to the next therapy applies only when two or more sequences are programmed for a Burst or Ramp therapy. If at any time the detected rhythm satisfies the programmed VF criteria, the PCD device will deliver the first (or next) programmed VF therapy.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 24

Cardioversion Therapy

Overview

Cardioversion therapy may be programmed as any one of the four VT therapies. The pathway for the Cardioversion pulse(s) may be separately programmed for each of the four therapies as:

- a **SINGLE** pulse delivered over one pathway, i.e., from the PULSE2 anode to the COMMON cathode;
- two **SIMULTANEOUS** pulses delivered over two pathways, i.e., one from the PULSE1 anode and the other from the PULSE2 anode, with both flowing to the COMMON cathode;
- two **SEQUENTIAL** pulses, separated by a very short period and delivered over the same two pathways as the **SIMULTANEOUS** pulses.

In all three pathway options, the Cardioversion pulse(s) must be synchronized to a ventricular sensed event.

The physician also separately programs the stored energy[1] and pulse width of the pulse(s) for each of the programmed cardioversion therapies.

When a VT is detected and Cardioversion is the next programmed therapy, the PCD device will initiate a **Charging Period**. During this period, the device charges the high voltage capacitors to the programmed stored energy.

NOTE: The Cardioversion pulse may be programmed to the same range of stored energies as a defibrillation shock used in VF therapy.

Following the completion of charging, the device initiates a **Synchronization Sequence**. During this period the device attempts to confirm the continued presence of the VT (by ensuring that the first interval is less than the TDI) and to synchronize the delivery of the Cardioversion pulse(s) to an R-wave.[2]

1. The Programmer displays stored energy in "Joules" as the programmable value. The cardioversion/defibrillation output capacitors are charged in the PCD device to a corresponding voltage value. See Table 4 for the conversion of stored energy to volts. The physician should be aware that the delivered energy for both cardioversion and VF therapies depends on the total impedance (of the system and cardiac interface) and the programmed pulse width.
2. Since the Model 7217B cardioversion pulses are synchronized to events sensed on the PACE/SENSE to SENSE2 electrodes, monitoring by surface ECGs will exhibit morphologies and timing that do not necessarily coincide exactly with those taking place at the electrode sites.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 25

The differences between cardioversion and defibrillation in the PCD device are:

- A cardioversion pulse is delivered in response to VT detection, whereas a defibrillation shock is delivered only when VF detection criteria are fulfilled.
- Following the VT charging period, the PCD device reconfirms that the rhythm still has an interval defined as VT. After the VF charging period, no such reconfirmation is attempted.
- Cardioversion requires synchronization to a sensed R-wave for delivery to occur. In VF therapy, the PCD device attempts to deliver the defibrillation shock in synchrony with a sensed event, but does not require such synchronization.
- Current pathways are separately programmable for each programmed cardioversion therapy. All VF therapies must be programmed to the same current pathway.

Charging Period

After a VT detection that is to be followed by cardioversion therapy, there is a Charging Period during which the high-voltage capacitors in the PCD device are charged to the programmed stored energy (leading edge voltage).

Several points should be noted about the Charging Period:

- Electrogram sensing does not occur during this time.
- Bradycardia therapy does not take place.
- Marker Channel and electrogram telemetry are not available.
- Programming is disabled during this period. However, if a magnet is placed over the PCD device and is kept in position until the end of the charging period, the device will recognize the presence of the magnet and the Cardioversion therapy will not be delivered.

The capacitor charging period usually varies from less than one second to ten (10) seconds at beginning-of-life power source status, depending on the programmed stored energy. This time will lengthen as the power source is depleted or as time increases from the last charging period. **If the Charging Period reaches a maximum duration of 35 seconds, charging is terminated**, the cardioversion therapy attempt is aborted, and the device returns to its programmed mode. This situation presents a potential loss of device function (see "Potential Loss of Function Indicators").

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 26

Synchronization Sequence

The Synchronization Sequence is designed to ensure the continued presence of the VT after completion of the Charging Period and to synchronize the delivery of the cardioversion pulse(s) to an R-wave, sensed on the implanted electrodes. To do this, the PCD device monitors the cardiac cycle for a sensed R-wave within the timing requirements described below. When these timing requirements are met, the VT is confirmed and the delivery of the cardioversion shock is synchronized to the sensed event.

Following completion of the Charging Period, the Synchronization Sequence requires that the interval from the first non-refractory sensed event to the next sensed event be (1) less than the programmed TDI plus 60 ms and (2) greater than 200 ms.[1]

VT detection is not confirmed and the cardioversion therapy is aborted under the following conditions:

- The timing requirements are not met,
- The initial three events after the Charging Period are sensed during refractory periods, or
- No sensed event occurs within a synchronization period following completion of capacitor charging.

If, after an aborted cardioversion therapy, there is a subsequent VT detection within the same VT episode, the PCD device will again attempt to deliver the same therapy.

If some energy remains on the capacitors after a therapy or because a therapy was aborted, the capacitors are discharged internally when VT episode termination is identified unless they were charged by a programmer-initiated charge command or a VF episode is ongoing.

Timing Periods After Non-Confirmation of VT

If no R-wave is sensed during a synchronization period, the PCD device returns to the programmed settings after a single cycle with a 300 ms blanking period, a 520 ms refractory period, and a 1000 ms escape interval.

If the Synchronization Sequence is terminated by three consecutive refractory sensed events, the PCD device returns to the programmed settings after a single cycle. The single cycle has a 320 ms blanking period, a programmed Refractory After Pace, and the programmed pacing escape interval.

1. When cardioversion is manually initiated via the programmer, the Synchronization Sequence timing requirement simply requires the period from the first non-refractory sensed event to the next sensed event to be less than the programmed bradycardia escape interval.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 27

Cardioversion Timing

Figures 14 through 17 are timing diagrams that illustrate what may occur during the Synchronization Sequence.

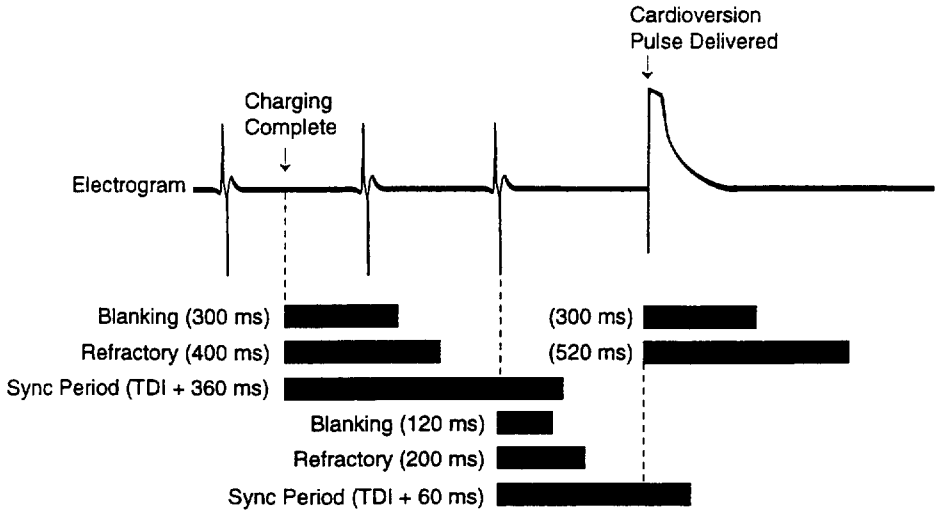

Figure 14. Cardioversion (Scenario "A")

Figure 14 depicts the simplest scenario in which the PCD device delivers the programmed cardioversion pulse(s) at the time of the second non-refractory sensed ventricular event following the Charging Period. The Synchronization Sequence consists of both sets of blanking, refractory, and synchronization periods. During the Synchronization Sequence, the PCD device confirms the continued presence of the tachycardia and identifies the R-wave to which it synchronizes delivery of the programmed cardioversion pulse(s).

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 28

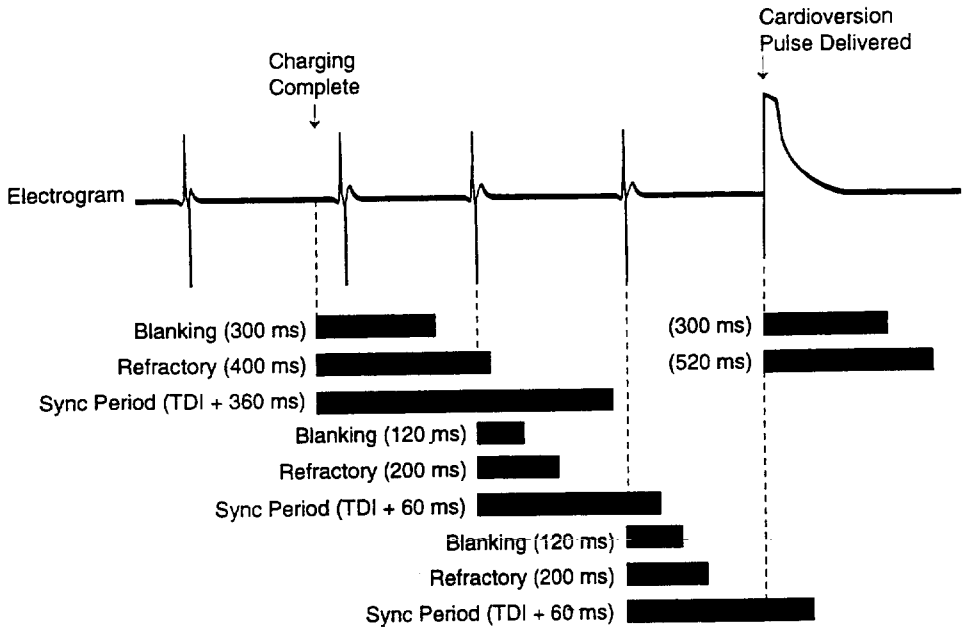

Figure 15. Cardioversion (Scenario "B")

In Figure 15, the first ventricular event after the end of the first blanking period is a refractory sensed event. As a result, the PCD device initiates a second set of periods in an attempt to identify an initial event outside the refractory period. Such an event is sensed and the resulting operation is the same as that in Figure 14. In this case, all three sets of periods comprise the Synchronization Sequence.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 29

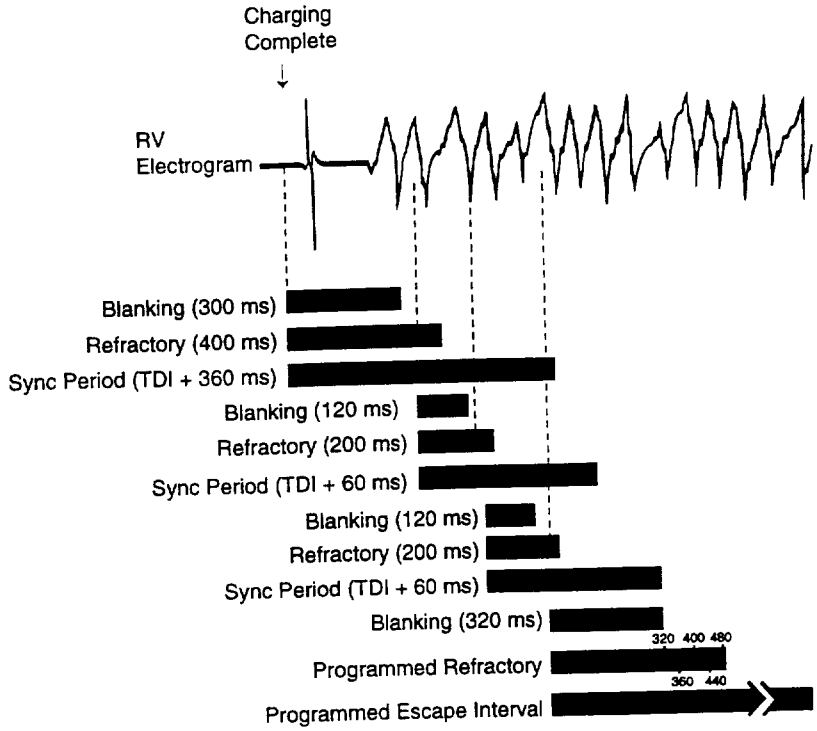

Figure 16. Cardioversion (Scenario "C")

In Figure 16, the PCD device fails to sense any ventricular events outside of a refractory period and, therefore, the VT cannot be confirmed. Thus, the cardioversion cannot be synchronized to a known R-wave. The therapy is aborted. After the third refractory sensed event, a pacing escape interval starts.

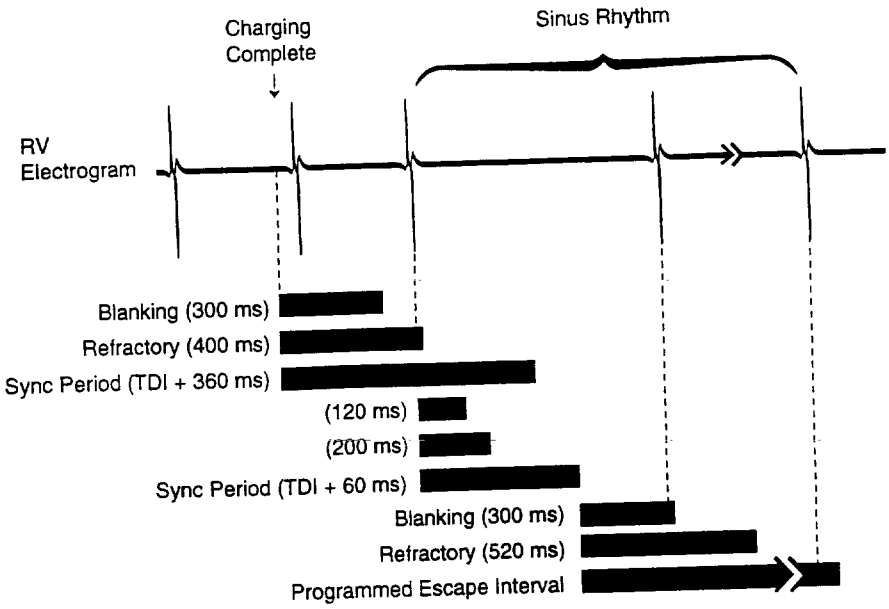

Figure 17. Cardioversion (Scenario "D")

Figure 17 depicts a situation in which the tachycardia terminates spontaneously sometime between VT Detection and completion of the Charging Period. Since the PCD device could not identify two non-refractory sensed ventricular events during the synchronization sequence, it aborted the VT therapy and initiated a bradycardia escape sequence. A sensed R-wave inhibits the bradycardia output.

Delivery of the Cardioversion Pulse

Delivery of the programmed cardioversion pulse(s) is synchronized to the second non-refractory sensed event following completion of charging. The current pathways for the cardioversion therapy are programmable, i.e., single, simultaneous, or sequential.

Following the cardioversion pulse, a 300 ms blanking period, a 520 ms refractory period, and a bradycardia escape interval of 1000 ms begin. The circuitry resumes monitoring the cardiac cycle for detection of a new VT episode, a VF episode, or bradycardia.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 31

Ventricular Fibrillation (VF) Detection

Overview

The PCD device detects ventricular fibrillation using three programmable parameters: Sensitivity of the ventricular sensing circuit, the Fibrillation Detection Interval (FDI), and the Number of Intervals to Detect (VF NID) that must be attained by the VF event counter. Up to four Defibrillation Therapies may be delivered in an attempt to terminate a single VF episode. If the first therapy is ineffective in terminating the arrhythmia and VF is detected again, a second defibrillation shock is delivered. Similarly, a third and fourth shock will be delivered if VF continues to be detected. If all the programmed VF therapies are ineffective, additional VF therapies will not be delivered until the PCD device identifies termination of the VF episode, or if VF detection is manually programmed ON.

NOTE: VT detection must be programmed OFF before VF detection can be programmed OFF.

VF Detection

The VF Detection Criterion is designed to detect a very fast ventricular rate. This criterion requires that 75% or more of the previous intervals are shorter than the programmed FDI. This is done to ensure detection for two reasons: (1) the signal amplitude of events within a VF episode may vary and (2) some intervals may be longer than others.

The Detection Criterion for VF requires that a programmed number of cardiac cycle lengths are less than the programmed FDI. This required number is called the Number of Intervals to Detect (VF NID). The PCD device continuously monitors a number of previous intervals equal to 133% of the programmed VF NID. It analyzes each cycle length to determine if it is shorter than the FDI. If the number of intervals shorter than the FDI equals the number required for VF detection (the VF NID), VF detection occurs.

VF NID	VF Detection Window
6	8
12	16
18	24
24	32
30	40

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 32

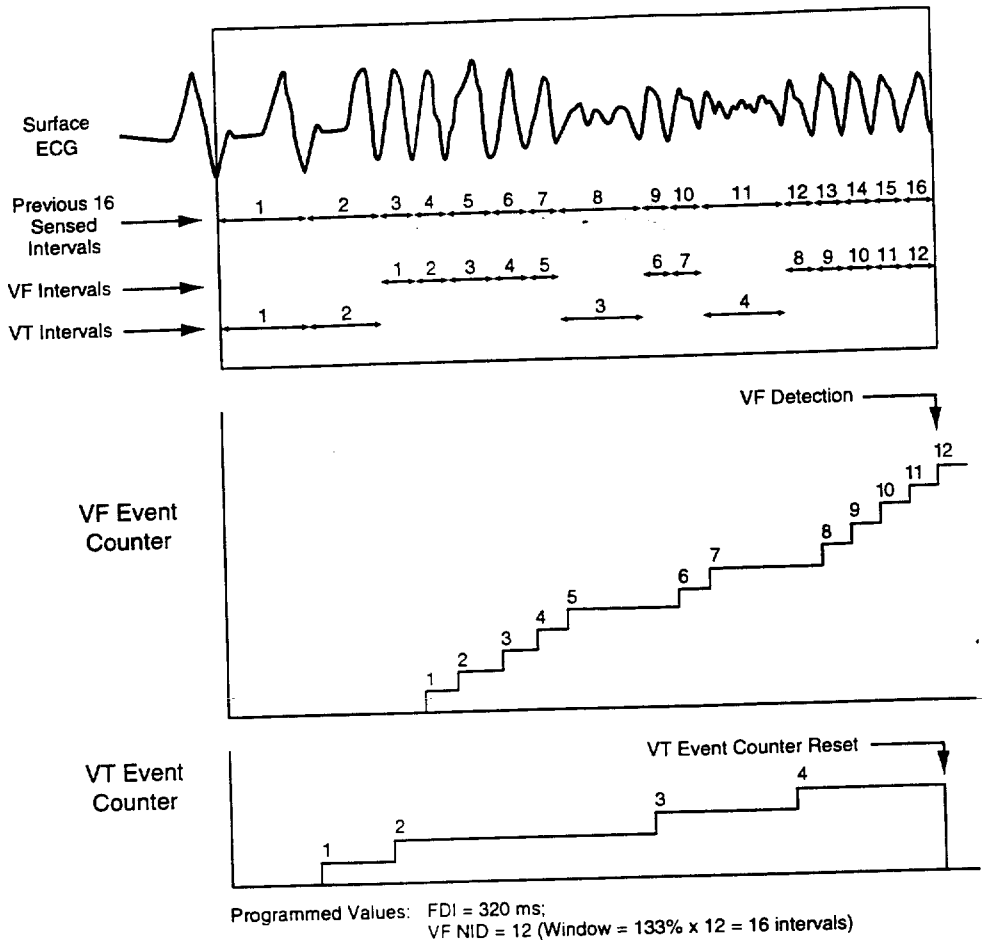

Figure 18. VF Detection (Example)

Figure 18 illustrates how VF Detection may be fulfilled. The PCD device is programmed to a VF NID of 12, which means it will evaluate the 16 intervals preceding the current interval (133% of 12). Since 12 of the intervals within the 16-interval "window" of detection are shorter than the FDI, VF detection occurs.

Relationship of VT and VF Detection

The PCD device separately processes the measured cardiac cycle lengths against the programmed VT and VF Detection Criteria. It is possible that, while a detected VT episode is in progress, a VF episode begins (i.e., to have both an active VT and an active VF episode). In such cases, when VF detection occurs, the PCD device will deliver the next programmed VF therapy.

110

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 33

When VT detection occurs, the fibrillation event count is not reset and interval data that occurred prior to the VT therapy will be used. However, when VF is detected, the VT event count is reset.

VF Episode Termination and Efficacy Determination

The PCD device defines a VF episode as **terminated** when eight consecutive cardiac cycles (sensed or paced) have intervals **greater than or equal to** the FDI.

The PCD device defines a VF therapy "effective" if VF termination occurs prior to any further VF detection. The PCD device is considered "ineffective" if after delivery of the last programmed VF therapy, VF detection occurs before VF termination is detected. See "Device Reporting Features" in "General Device Information" for information about how effectiveness is reported.

NOTE: A rhythm following a therapy that does not satisfy the VF termination definition is considered part of an ongoing episode. However, additional VF therapies will not be delivered unless the VF Detection Criterion is again fulfilled.

If all programmed therapies proved ineffective in terminating the arrhythmia, **only a later VF termination (either spontaneous, or via a programmer-activated therapy or transthoracic defibrillation) or manually programming VF Detection ON** will restart VF detection and automatic therapy delivery.

Suspending and Disabling VF Detection

When the PCD device is "suspended," its detection functions are temporarily inactivated.

"Disabled" is a permanently programmed state in which detection and/or therapies are not available (OFF condition). These functions can only be re-enabled via a programming sequence.

The VF Detection Criterion is temporarily **suspended** during

- Magnet application (unless a "Cancel Magnet" is programmed),
- Capacitor charging (i.e., in preparation for the automatic delivery of a cardioversion or defibrillation shock or during a programmed charge period),
- Delivery of high-rate pacing,
- Delivery of VT therapies,
- Delivery of VF therapies,
- The period after all programmed VF therapies are proved ineffective (i.e., until VF termination is confirmed or VF Detection is programmed ON), and
- The period following VT and VF therapies that are manually initiated via the programmer, e.g., following programmed emergency or manual therapies (removing the programming head enables VT and VF Detection).

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 34

The VF Detection Criterion is **disabled** whenever

- Three consecutive 35-second charge intervals have failed to reach the programmed energy level and the "Charge Circuit Inactive" condition occurs,
- Nominal or VVI option under Emergency VVI is programmed, and
- Power-on reset (an electrical reset) or a detected memory error occurs.

Ventricular Fibrillation (VF) Therapy

Overview

For each detected VF episode, the PCD device can deliver up to four defibrillation therapies. Each therapy consists of a high-energy defibrillation shock separately programmable as to stored energy and pulse width. The current pathway (i.e., single, simultaneous, or sequential) is programmable but must be the same for all VF therapies.

NOTES: A therapy programmed OFF disables all subsequent therapies. For example, if the first VF therapy is programmed OFF, all therapies are effectively disabled.

VF therapy cannot be programmed OFF if the PCD device is programmed to deliver automatic VT therapies.

After detection of a VF episode, the PCD device initiates a charging period for the first programmed therapy. During this period the device charges the high voltage capacitors to the programmed stored energy level. After completion of the charging, the device initiates the Synchronization Sequence. During this sequence, the device attempts to synchronize the defibrillation shock to the leading edge of a sensed event. If synchronization is not possible, an asynchronous shock will be delivered. Defibrillation Therapy, unlike Cardioversion, is "committed", i.e., once the charging cycle has begun, a shock will be delivered[1].

If the first and/or subsequent VF therapies prove ineffective and the VF arrhythmia is again detected after each therapy, the PCD device repeats the above operation up to a total of four times.

NOTE: It is recommended that the physician program the second, third, and fourth VF therapy to the maximum stored energy of 34 joules.

Charging Period

After a VF detection, the high-voltage capacitors are charged to the programmed stored energy (leading edge voltage) level for the next VF therapy. This period has the same function and range of durations as the cardioversion charging period.

1. See the section titled "Cardioversion and Defibrillation Charging Periods" under "Programming Considerations" for a complete description of charging periods.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 35

NOTE: If a cardioversion shock is programmed to a stored energy level higher than that for VF therapy and cardioversion is aborted, leaving the energy stored on the capacitors, the delivered energy of a subsequent VF shock could be higher than the programmed value, if VF is detected prior to the end of the VT episode.

The capacitor charging period usually varies from less than one second to ten (10) seconds at beginning-of-life power source status, depending on the programmed stored energy and the elapsed time since the previous charging cycle. This time will lengthen as the power source is depleted or as time increases from the last charging period. **If the charging period reaches a maximum duration of 35 seconds, charging is terminated,** the VF therapy attempt is aborted, and the device returns to its programmed mode. This situation presents a potential loss of device function (see "Potential Loss of Function Indicators").

Synchronization Sequence

Upon completion of the capacitor charging period, the Synchronization Sequence follows during which the device attempts to synchronize the defibrillation shock to a sensed cardiac event. The defibrillation shock is delivered at the time of the first non-refractory sensed event following completion of the charging period. If there is no non-refractory sensed event within the Synchronization Sequence, then the defibrillation shock is delivered at the end of the Synchronization Sequence.

In Figure 19, a non-refractory event is sensed during the first synchronization period. As a result, the PCD device synchronizes the delivery of the VF therapy to this event.

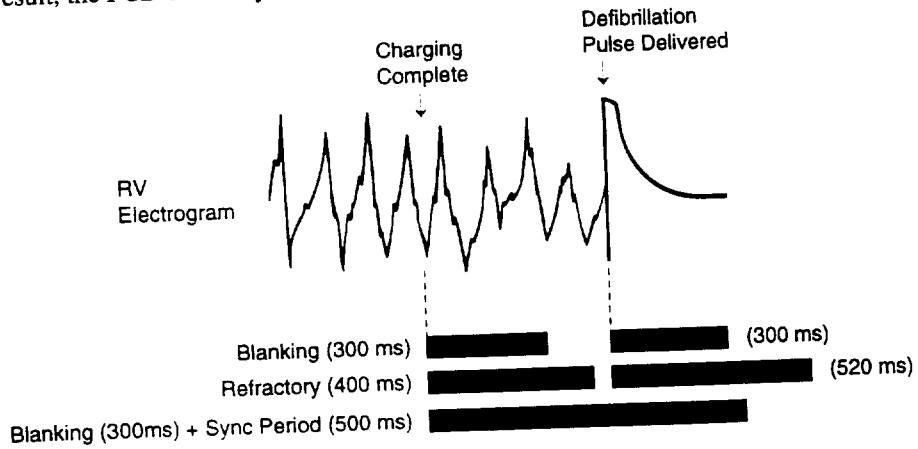

Figure 19. Defibrillation (Scenario "A")

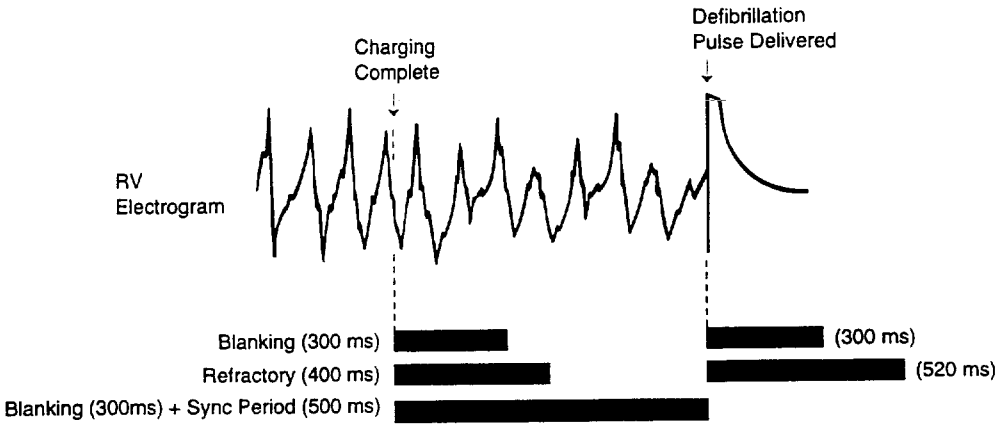

Figure 20. Defibrillation (Scenario "B")

Figure 20 illustrates an absence of sensed events during the synchronization period. As a result, the PCD device delivers the VF therapy at the end of the synchronization period.

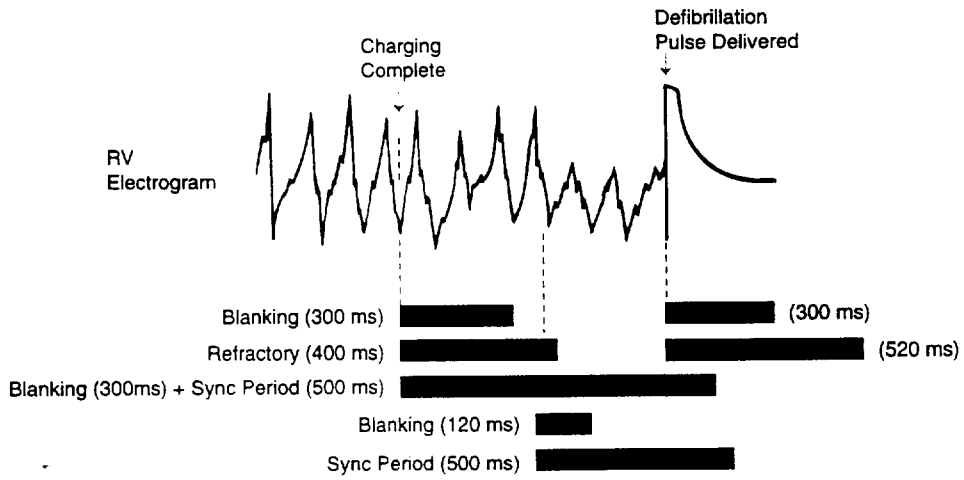

Figure 21. Defibrillation (Scenario "C")

Figure 21 shows how the PCD device might synchronize the delivery of a VF therapy to the second of two sensed events, the first of which is a refractory sensed event. Note the Synchronization Sequence that starts after the charging period. The refractory sensed event starts a second synchronization period as the PCD device attempts to synchronize the VF therapy to a non-refractory sensed event.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 37

Programmable Current Pathways

All four VF therapies must have the same pathway, programmable between:

- a SINGLE pulse delivered over one pathway, i.e., from the PULSE2 anode to the COMMON cathode;
- two SIMULTANEOUS pulses delivered over two pathways, i.e., one from the PULSE1 anode and the other from the PULSE2 anode, with both flowing to the COMMON cathode; or
- two SEQUENTIAL pulses, separated by a very short period and delivered over the same two pathways as the SIMULTANEOUS pulses.

The PCD device delivers sequential and simultaneous pulses with three cardioversion/ defibrillation electrodes. Single pulses can be delivered with two or three electrodes.

The physician also programs the stored energy and pulse width of the pulse(s) for each of the four VF therapies (or as many as are programmed ON).

Operation Following VF Therapy

After a VF therapy, there is a 300 ms blanking period, a 520 ms refractory period, and an escape interval of 1000 ms for one cycle. The device returns to the programmed settings and, if enabled, automatically begins to evaluate the cardiac cycle for the possible detection of VF or bradycardia.

VT detection is automatically suspended[1] for 64 events (including paced events, sensed events, and therapy, except during a Charging Period) after each VF detection that initiates a VF therapy. This operation is designed to avoid detection of a transient VT which may follow such a VF therapy. After 64 events have occurred, the VT detection process is re-enabled and, if the Onset Criterion is programmed ON, then this criterion is considered fulfilled.

If some energy remains on the capacitors after a therapy, the capacitors are internally discharged when VF episode termination is detected, unless they were charged by a programmer-initiated command or a VT episode is ongoing.

1. During the 64 events following an automatic defibrillation therapy, the algorithm for detecting VT episode termination is also suspended.

7217B NTL p1-38/MMC 9/25/93 12:11 AM Page 38

VVI Therapy

The Model 7217B PCD device provides backup bradycardia therapy, i.e., pacing in the ventricular inhibited (VVI) mode. Thus, unless a sensed event occurs and resets the pacing interval (the bradycardia escape interval), the PCD device will pace at the programmed rate.

These parameters are programmable:

- **Rate:** rates from 30 to 90 ppm for backup bradycardia pacing.
- **Pulse width:** keep in mind that this programmed setting also applies to VT Burst and Ramp therapies. When programming this parameter, ensure an adequate safety margin above the stimulation threshold.
- **Pulse Amplitude:** choose one of two settings that ensures an adequate safety margin above the stimulation threshold. The setting selected also applies to VT Burst and Ramp therapies.
- **Sensitivity:** this programmed setting will also be used to detect VT or VF. Therefore, program a setting that will sense R-wave and VF wave amplitudes, but not sense P- or T-waves or electromagnetic interference. Sensitivity should be programmed to 0.3 mV to maximize the probability that VF will be detected. A value greater than 1.2 mV may be too insensitive for VF detection. Values less sensitive than 1.2 mV are not recommended except for testing and troubleshooting. If undersensing is observed in normal sinus rhythm, verify that VF sensing and detection are appropriate. Repositioning the lead or implanting a new pacing/sensing lead may be necessary.
- **Refractory period:** the PCD device has a blanking period and Refractory After Pace after a paced event, and only a blanking period after a sensed event. (See "Refractory Periods.") The Refractory After Pace is usually the same duration as the 320 ms blanking period but may be programmed to a longer duration. Events sensed after the 320 ms blanking period are noted on Marker Channel telemetry as refractory sensed events. There is a 120 ms blanking period (nonprogrammable) after sensed events.

Events sensed within the programmed refractory period do not inhibit the pacing output. The PCD device does not revert to asynchronous operation (VOO) in the presence of continuous electrical "noise." Also, placing a magnet over the device does not inhibit VVI therapy.

A combination of wide pacing pulse width, high pacing amplitude, and high sensitivity (low sensing threshold) may cause inappropriate sensing after pacing. Programming a narrower pulse width, a lower amplitude pulse, a longer refractory period after pace, or a higher sense threshold may eliminate this inappropriate sensing. If sensitivity is reprogrammed to eliminate inappropriate sensing, VF should be reinduced and the PCD device should be allowed to automatically detect and treat the arrhythmia to ensure proper sensing and detection.

A long refractory period, coupled with a high programmed pacing rate, may impair the PCD device's ability to detect VT or VF and may cause asynchronous pacing.

7217B NTL p39-52/MMC 9/25/93 12:17 AM Page 39

IMPLANTING THE PCD DEVICE

Handling and Storage

Dropping the PCD device onto a hard surface (e.g., dropped from a height of 12 inches (30 cm) or more onto a concrete floor) could damage the device. Should this occur, the unit should not be implanted.

Environmental temperature limits for transportation and storage are:

Maximum: +52° C (125° F)
Minimum: –18° C (0° F).

Resterilization

Medtronic has sterilized the PCD device with ethylene oxide prior to shipment. The sterile package is designed to maintain the device in a sterile condition. If the device was not used, it may be resterilized in ethylene oxide.

DO NOT AUTOCLAVE OR STERILIZE THE PCD DEVICE BY GAMMA IRRADIATION. DO NOT ATTEMPT TO CLEAN THE DEVICE IN ULTRA-SONIC CLEANERS.

Avoid the application of certain organic cleaning agents (e.g., alcohol and acetone) prior to resterilization, because they may have a detrimental effect on the device's connector assembly.

When resterilizing, place the device in an ethylene oxide permeable package. Due to the variability between sterilizers, precise resterilization instructions must come from the sterilizer manufacturer. However, the process should not exceed temperatures of 55° C (130° F) nor 15 psi. Use some acceptable method for determining sterility, such as biological indicators.

Prior to implantation of the PCD device, aerate the packaged device to ensure that ethylene oxide residues are no longer present.

Resterilization of a PCD device does not change the "use before" date established at the time of manufacture.

7217B NTL p39-52/MMC 10/5/93 9:17 PM Page 40

Implantation Procedure

Overview

Patients should undergo the following procedures before implant of the PCD device to help determine if they are appropriate candidates for a PCD system:

- Electrophysiologic evaluation to determine the patient's ventricular arrhythmia and how it responds to different therapies,
- Exercise stress test to determine the patient's maximum sinus rate, and
- Cardiac catheterization to determine if there is a need for concomitant surgery.

modified

If patients do not meet the implant criteria (demonstration of a 10 Joule safety margin) for a transvenous lead system, physicians should consider implanting an epicardial cardioversion/defibrillation lead system. If an epicardial system is to be implanted after testing a transvenous system, consider performing the procedure at a later date. The Transvene® clinical study showed a 9.3% perioperative death rate for patients failing the implant criteria for a Transvene® system and receiving an epicardial system. This compares to 0.7% for those patients receiving a Transvene® system without the additional epicardial surgical procedure.

Implanting the PCD device and corresponding lead system involves seven main steps:

- Operative Set-Up
- Lead System Implantation and Evaluation
- Defibrillation Efficacy Testing
- Connecting the Leads to the PCD Device
- Placing the PCD Device
- PCD System Evaluation
- Closing

During implantation, the PCD system requires an appropriate Medtronic programmer and MemoryMod cartridge and the Medtronic External Tachyarrhythmia Control Device (ETCD) to evaluate and monitor the implanted lead system and therapy efficacy.

Each of the above steps is explained in the following sections. At the end of this chapter, instructions for replacing a PCD device and implanting a PCD device with a chronically implanted lead system are also given.

7217B NTL p39-52/MMC 9/25/93 12:17 AM Page 41

Operative Set-Up

The preparation and procedures before implanting the lead system are grouped into four main steps: assembling the necessary equipment, setting up the equipment, pre-programming and testing the PCD device, and pre-programming and testing the ETCD and auxiliary equipment.

Necessary Equipment

The equipment listed below should be available for each implant. Duplicates of sterile items should also be on hand.

- Model 7217B PCD device
- External Tachyarrhythmia Control Device (ETCD)
- Appropriate Medtronic programmer and printer
- Appropriate MemoryMod software cartridge
- Cardioversion/defibrillation and pacing/sensing leads
- Appropriate adaptors
- External defibrillator
- Pacing system analyzer (PSA)
- Patient cable for connecting lead system to the ETCD
- EGM cable to connect the programmer to the ETCD
- Cable (and connector pins if necessary) to connect a pacing system analyzer to the ETCD or a surgical cable to connect the PSA directly to the leads
- Test load for discharging high-voltage shocks from the ETCD
- Cables for connecting the EGM output of the ETCD and Marker Channel output of the programmer to a hospital monitor/recorder
- Appropriate batteries for the pacing system analyzer and ETCD
- Extra printer paper for the pacing system analyzer and programmer/printer
- Sterile bag to place over programming head and cable
- Implant documentation forms

Some optional equipment includes an external fibrillation source or stimulator, tape or multi-channel recorder, dual-channel oscilloscope, and appropriate cables.

Equipment Set-Up

Set up the ETCD/programmer with the appropriate MemoryMod cartridge, an external defibrillator, and auxiliary equipment such as monitors, recorders, a fibrillator, and their related cabling. Also, connect the test load to the ETCD.

7217B NTL p39-52/MMC 9/25/93 12:17 AM Page 42

Pre-Programming and Testing the PCD Device

Check the "use before" date printed on the package. It is recommended that you do not use the product after its expiration date.

Prepare the PCD device for implant by doing the following:

1. Interrogate the device while it is still in its sterile package and print out a full report.
2. Review the battery status. Devices with an initial battery voltage less than 6.1 volts before charging should not be implanted. If the device is charged without obtaining the initial voltage, it should be implanted only if the battery voltage reaches 6.1 volts or more within thirty minutes after charging.
3. Test the charge circuit by charging the capacitors to the maximum output. The charge time must meet the following requirements:
   - If the charge time is less than or equal to 10 seconds, implant the device. If it is greater than 10 seconds, wait 5 minutes, discharge (dump) the capacitors, and then perform a second charge.
   - If the second charge time is less than or equal to 10 seconds, implant the device. If it is greater than 10 seconds, do not implant the device.
4. While still in the sterile package set the device parameters for implant as appropriate for the patient.
5. Ensure that VT and VF Detection are programmed OFF.

Pre-Programming and Testing the ETCD & Auxiliary Equipment

To prepare for lead system evaluation and defibrillation efficacy testing, do the following:

1. Verify that the ETCD's battery status is acceptable.
2. While recording the ETCD's output signals and the Marker Channel output from the printer, calibrate the hospital's monitoring/recording equipment.
3. Test the ETCD's high-energy output capability using the test load.

Lead System Implantation and Evaluation

The PCD lead system uses electrodes designed to carry high current for cardioversion or defibrillation. The cardioversion/defibrillation electrodes (PULSE1, PULSE2, and COMMON) must be specifically suited for this purpose and have a large electrode surface area to reduce cardioversion/defibrillation thresholds and minimize tissue damage possibly caused by the high cardioversion/defibrillation currents.

While the PCD is connected to the leads, no metal portion of any electrode should contact the metal of any other electrode. If the electrodes are in contact during a cardioversion or defibrillation therapy, the current will bypass the heart and may also damage the PCD device.

7217B NTL p39-52/MMC 10/8/93 6:38 PM Page 43

Pacing occurs between a pacing/sensing lead and one of the cardioversion/defibrillation leads (COMMON). Sensing is accomplished through two pacing/sensing electrodes. Either epicardial or endocardial leads may be used. To reduce the effects of electromagnetic interference (EMI), the PACE/SENSE and SENSE2 electrodes should be positioned adjacent to each other, and where separate leads are used, the lead wires should be routed together with several loose twists.

Depending on what kind of operative approach is used to implant the leads, the PCD Device can use two different kinds of lead systems: an epicardial lead system or a Transvene® lead system. Each system is described briefly below. See the appropriate Lead Technical Manual for more details.

The physician chooses the lead system that best meets the patient's needs. Patient factors that affect the decision include the following:

- Overall size of the patient's heart,
- Size and location of previous infarcts, aneurysms, or bypass grafts, and
- Surgical approach.

The epicardial lead system uses two or three epicardial patch leads for cardioversion/defibrillation. Three patch sizes allow the physician the flexibility to meet the varying patient conditions. Clinical experience has shown that approximately half of all patients receive a three-patch system; the other half receives two patches. Three patches may be required initially if the physician expects difficulty in meeting defibrillation implant criteria. Adding a third patch to a two-patch system may be required if the implant criteria cannot be met with the two-patch system.

The Transvene® non-thoracotomy lead system can use two or three leads in four different areas:

- A tripolar lead in the right ventricle (RV).
- A unipolar lead in the coronary sinus (CS) and/or superior vena cava (SVC).
- A subcutaneous (SQ) patch lead.

addition

Clinical experience with the Transvene® lead system has shown that most patients (65.6%) received an RV-SVC-SQ system; an additional 29.3% received an RV-CS-SQ system, and the remaining 5.1% recieved an RV-CS-SVC system. The majority of patients were programmed to Sequential Pulse (75.3%), 23.4% were programmed to the Simultaneous Pulse, and 1.3% were programmed to Single Pulse.

Cardioversion/defibrillation occurs between the COMMON electrode (cathode) and one or two anodes. These electrodes can be any of the following: the CS lead, the SVC lead, the RV coil, or the SQ patch. Sensing occurs between the tip and ring of the tripolar RV lead. Pacing occurs between the tip of the RV lead and the COMMON electrode.

addition

The RV electrode was COMMON in the majority (75.3%) of the clinical implants, the SQ patch in 13.9%, the CS in 7.6%, and the SVC electrode in 2.4% of the clinical implants. The overall efficacy in terminating spontaneous episodes of VF was approximately 98% for all pathways, pulsing techniques and choice of cathode.

21

7217B NTL p39-52/MMC 10/6/93 4:07 PM Page 44

Lead system implantation and evaluation consists of placing the lead system, connecting the leads for pacing and sensing measurements, performing pacing and sensing measurements, and verifying lead connections. Each step is explained in the following sections. See the appropriate lead technical manual for more details.

Placing the Lead Systems

Placing the Epicardial Lead System

Depending on the physician's preference, a variety of surgical approaches can be used to implant the lead system, such as a limited thoracotomy or median sternotomy.

Placing Pacing/Sensing Leads:
The pacing/sensing leads should be placed close to the ventricular apex to avoid sensing P-waves. Approximately 1 cm should separate the electrodes from each other.

Placing Epicardial Patch Leads:
Suture two or three patch leads to the epicardium or pericardium in locations that produce optimal defibrillation, pacing, and sensing. In all locations, place the leads so that they encompasses the maximum amount of cardiac mass and they have approximately equal amounts of mass between them.

For a two-patch system, a typical approach is to use an anterior right ventricular patch as COMMON and a posterolateral left ventricular patch as PULSE2. For a three-patch system, a typical approach is to use a posterior ventricular septal patch as COMMON, an anterior right ventricular patch as PULSE1, and an anterolateral left ventricular patch as PULSE2. The PULSE1 and PULSE2 patches should be the same size.

Placing Transvene Leads

CAUTION: Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g. the cephalic vein.

There are several possible lead systems that can be evaluated depending on the desired pathway and physician placement preference.

7217B NTL p39-52/MMC 10/5/93 7:51 PM Page 45

Two Lead System

- Right ventricle, coronary sinus.
- Right ventricle, superior vena cava.
- Right ventricle, subcutaneous patch.

Figure 23 shows a flowchart for lead system evaluation that begins with the two lead system and adds an additional lead if the implant criteria is not met with the two lead system. The decision to evaluate a two lead system is based on the desire to achieve the simplist transvenous defibrillation system.

modified

Three Lead System:

- Right ventricle, superior vena cava, and subcutaneous patch.
- Right ventricle, coronary sinus, and subcutaneous patch.
- Right ventricle, coronary sinus, and superior vena cava.

Clinical results do not indicate superiority of any pulsing technique, lead system, or choice of cathode for transvenous defibrillation. The choice of lead system for initial evaluation can therefore be based on other factors including simplicity (SVC vs CS lead placement) and physician preference.

The RV, CS, and SVC lead should be implanted using standard transvenous implant techniques. Follow the general guidelines below for initial positioning of the Transvene lead system (the final positions will be determined by defibrillation threshold tests):

- Position the RV lead tip in the right ventricular apex.
- Advance the CS lead tip to just under the left atrial appendage, if possible.
- Place the SVC lead tip approximately 5 cm proximal to the right atrium and SVC junction.
- Place the SQ patch lead along the left midaxillary with the center over the fourth-to-fifth intercostal space.

Other positioning recommendations to consider:

- The CS lead position should be considered unacceptable if the proximal end of the CS defibrillation coil is at or outside the CS ostium.
- A cutaneous patch electrode may also be used during acute testing to minimize invasive procedures. Once defibrillation efficacy has been demonstrated, a permanent subcutaneous can be implanted.
- The subcutaneous patch may be placed subcutaneously, submuscularly, or directly on the periosteum of the ribs. The patch may be repositioned on the left lateral chest wall, if necessary, to meet the implant defibrillation efficacy criteria.
- If the Transvene lead system implant criteria cannot be met, an epicardial lead system may be evaluated, as described in this section.
- If the CS lead is proving difficult to position, a temporary pacing catheter can be positioned in the coronary sinus ostium. This can be used as a guide to cannulate the coronary sinus with the permanent lead.

7217B NTL p39-52/MMC 10/5/93 7:51 PM Page 46

Connecting the Leads for Pacing and Sensing Measurements

Depending on the physician's preference, two approaches can be used to connect a pacing system analyzer (PSA) to the implanted leads: passing through the ETCD or by direct connection. See the appropriate ETCD or PSA technical manual for connecting instructions.

Performing Pacing and Sensing Measurements

For a Transvene lead system, the pacing connections should be the RV tip electrode as cathode (-) and the defibrillation COMMON electrode as anode (+). Sensing measurements should be made between the RV tip and RV ring electrodes.

For an epicardial lead system, the PACE/SENSE electrode serves as the cathode (-) for pacing and the COMMON patch electrode serves as the anode (+). Measure between this patch electrode and each pacing/sensing electrode to obtain the best pacing threshold. Designate the best pacing/sensing electrode as PACE/SENSE. The other electrode should be SENSE2.

Listed below are the acceptable PCD system implant values for acute and chronically implanted lead systems.

	Acceptable Implant Values	
Measurements Required	**Acute Lead System**	**Chronic Lead System**
Capture threshold (at 0.5 ms pulse width)	≤ 1.5 V - epicardial ≤ 1.0 - endocardial	≤ 3.0 V - epicardial ≤ 3.0 V - endocardial
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≥ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Also, check that P- and T-wave oversensing are not occurring by pacing at the maximum output (5.4 V, 1.59 ms) and sensing at the maximum sensitivity (0.3 mV).

Defibrillation Efficacy Testing

Verifying Lead Connections

After connecting all of the leads to the ETCD, confirm that the sensing leads are connected properly by observing sensed events on the Marker Channel telemetry. Verify the cardioversion/defibrillation lead connections to the ETCD by delivering a low-energy shock (0.6 joules) synchronously into sinus rhythm.

The path resistance should be approximately 20 to 100 ohms for epicardial leads, or 40 to 150 ohms for Transvene leads.

If the path resistance measurements (ohms) do not fall within these ranges, check the lead connections and lead placements and tighten or reposition if necessary.

CAUTION: Implanting the PCD device when the path resistance is less than 20 ohms may damage the device.

7217B NTL p39-52/MMC 10/6/93 5:01 PM Page 47

Performing Defibrillation Efficacy Testing

After checking the lead connections, test defibrillation efficacy to show the ability to properly treat ventricular fibrillation. Before testing defibrillation efficacy, ensure an external defibrillator is charged for a rescue shock. Use the ETCD to perform the following:

1. Program the ETCD to properly detect VF with an adequate safety margin (sensitivity = 1.2 mV, VF NID = 18, FDI = 320 ms).
2. Program the VF therapy parameters (energy, pathway, and pulse width) to the desired settings. See Table 5 in "General Device Information" for information on choosing optimal pulse widths.
3. Induce VF using AC stimulation or the fibrillation induction feature present in the ETCD. See the appropriate programmer manual for specific instructions on inducing VF with the ETCD.
4. Convert the arrhythmia using the ETCD and lead system.

To demonstrate reliable defibrillation efficacy with acute or chronic leads, it is recommended that VF be initiated and terminated three out of four times at a stored output energy of 24 joules or less. The protocol shown in Figures 22 and 23 are suggested. If more than one of the four VF inductions are not terminated by the ETCD and lead system, the decision to implant the PCD device should be re-evaluated.

add, 4 ron

In order to keep patient morbidity and mortality to a minimum, patients should be rescued promptly with an external device if the lead system and ETCD fails to terminate the VF episode and at least 5 minutes should elapse between VF inductions.

At their option, physicians may also test for ventricular tachycardia therapy efficacy after testing for defibrillation efficacy.

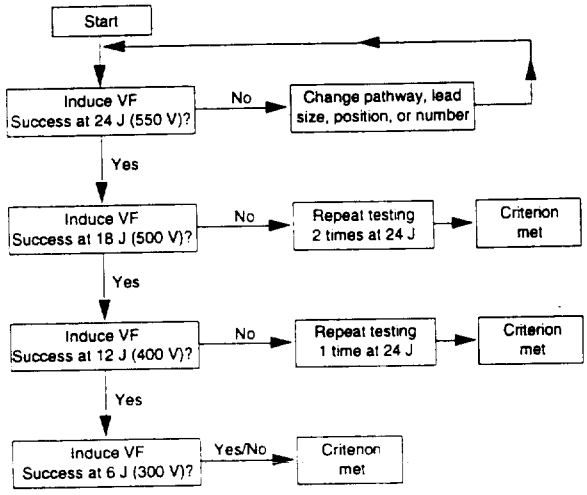

Figure 22. Defibrillation Efficacy Protocol Flowchart

7217B NTL p39-52/MMC 10/6/93 4:14 PM Page 48

Evaluating VF Sensing

While testing for defibrillation efficacy, evaluate VF sensing by reviewing the Marker Channel symbols and electrograms and checking for post-shock T-wave sensing. If VF sensing is not appropriate, it may be necessary to reposition the leads and repeat the VF inductions.

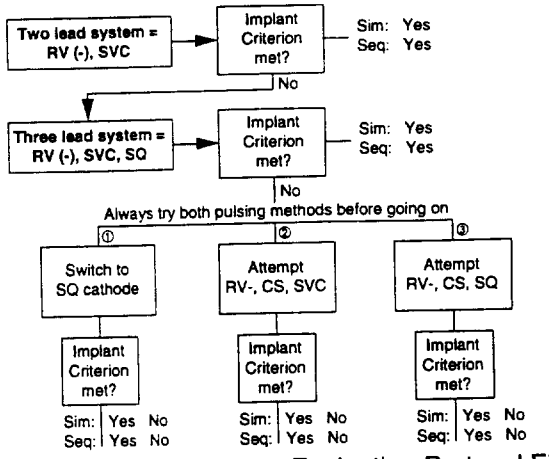

Figure 23. Transvene Lead System Evaluation Protocol Flowchart

CAUTION: Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. DO NOT use surgical instruments to grasp the lead or connector pin when tunneling.

Connecting the Leads to the PCD Device

The Model 7217B PCD device is connected to a lead system consisting of either two or three cardioversion/defibrillation electrodes. Figures 24 and 25 illustrate these two connection configurations. Both the PULSE2 and COMMON electrodes are used in either configuration. The PULSE1 electrode is required in a lead system that uses the sequential or simultaneous therapy current pathway, but it is not required when the single pulse therapy is used. When the PULSE1 electrode is not used, the 6.5 mm plug provided with the PCD device must be positioned in the lower left port of the connector block.

The COMMON, PULSE2 and PULSE1 lead connectors must be of the 6.5 mm style. If the lead connector is not the correct size, an adaptor designed for use in a 6.5 mm port must be positioned on the lead connector.

In either configuration shown in Figures 24 and 25, both a PACE/SENSE and a SENSE2 electrode are required. The PACE/SENSE and SENSE2 lead connector must be either the Medtronic low-profile bipolar or the IS-1[1] bipolar style. The PACE/SENSE electrode must be on the pin of the lead connector and the SENSE2 electrode must be on the ring of the lead connector. If two unipolar myocardial leads are used for pacing and sensing, insert their connectors into an appropriate adaptor that will fit into the PCD device's bipolar pacing/sensing port. See the appropriate lead technical manual for more details.

1. IS-1 refers to the International Connector Standard (ISO 5841-3: 1992) whereby generators and leads so designated are assured of a basic mechanical fit.

7217B NTL p39-52/MMC 10/6/93 4:14 PM Page 49

CAUTION: For questions about lead—pulse generator compatibility, consult your Medtronic representative or call Medtronic Technical Services at our 24-hour toll-free number, 1-800-328-2518.

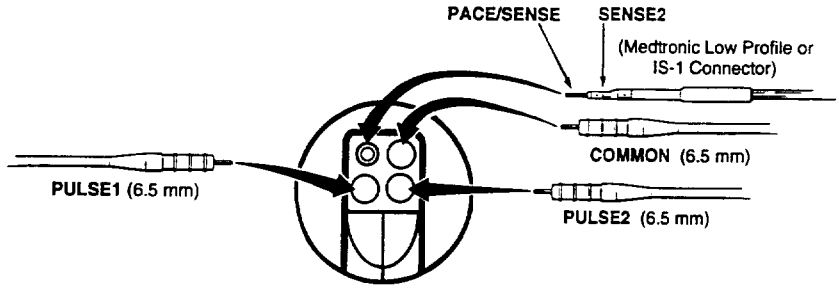

Figure 24. The Three Cardioversion/Defibrillation Electrode System

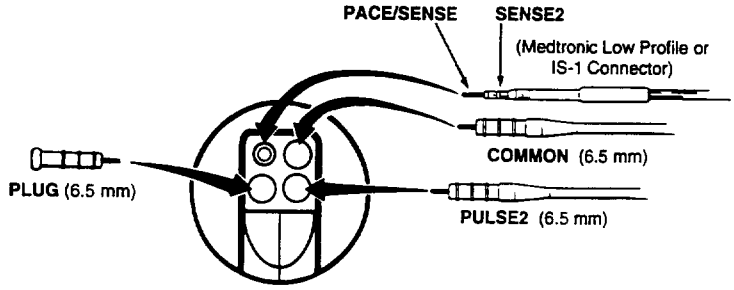

Figure 25. The Two Cardioversion/Defibrillation Electrode System

It should be noted that the insertion depth of an IS-1 lead pin is less than the insertion depth of a low-profile lead pin. The insertion mark for the IS-1 lead connector on the connector module (Figure 26) indicates that the IS-1 lead pin may not be inserted any further than the bar. Since the pin cavity is longer than the IS-1 requirement, the front part of the pin cavity will be empty when using an IS-1 lead.

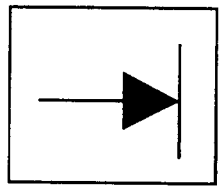

Figure 26

To connect each of the leads and plug, if required, to the PCD device:

1. Place a lead or plug into the appropriate port as shown in Figure 24 or 25.
2. Ensure full insertion of the connector pin by observing it protrude into the pin viewing area (i.e., beyond the metal block of the connector).

7217B NTL p39-52/MMC 10/6/93 4:17 PM Page 50

3. Pass the hex wrench through the associated grommet and tighten the setscrew securely by turning clockwise until tight. For the PACE/SENSE and SENSE2 connector, tighten both setscrews.

If there is difficulty with lead insertion due to the setscrew obstructing the port, turn the setscrew counterclockwise—but only until the port becomes clear.

CAUTION: Counterclockwise rotation beyond this point may disengage the setscrew from the connector block.

The setscrews must be tightened securely using the hex wrenches provided with the PCD device. The hex wrenches are designed to yield at the handle when overtorqued, thus preventing damage to the socket of the setscrew. **Do not use Medtronic blue handled, right angle, or allen-type wrenches** since they possess torque capabilities far greater than intended for this device.

PCD System Evaluation

After connecting the leads to the PCD device, test the defibrillation efficacy of the PCD system. Before testing defibrillation efficacy, ensure an external defibrillator is charged for a rescue shock. Perform the following:

1. Program the PCD device to appropriately detect and treat the VF episode.
2. If using external fibrillation equipment, place the PCD device in magnet mode (VT and VF Detection are suspended).
3. Induce VF using external fibrillation equipment or the fibrillation feature present in the PCD device. If using external fibrillation equipment, apply the signal between the PACE/SENSE terminal of the PCD and an indifferent electrode attached to body tissue. The SENSE2 terminal may be used instead of the PACE/SENSE terminal with an indifferent electrode. See the appropriate programmer manual for specific instructions on inducing VF with the PCD device.

   CAUTION: When using external fibrillation equipment, make only one connection to the PCD lead system. This connection should be disconnected immediately after VF is induced.

   CAUTION: DO NOT MOVE THE PROGRAMMING HEAD from the beginning of detection through delivery of the shock. If the head is moved, remove it from the PCD device to allow the device to operate automatically. Replacing the head during the sequence may suspend VF Detection or abort the therapy.

4. After verifying sustained VF, press the CANCEL MAGNET key and then the PROGRAM key to allow automatic VF detection and therapy delivery to convert the arrhythmia.[1]

1. When using the fibrillation feature present in the PCD device, pressing the CANCEL MAGNET key and then the PROGRAM key prior to induction of VF will cause VF Detection to be enabled immediately after the end of the fibrillation sequence.

7217B NTL p39-52/MMC 10/6/93 4:17 PM Page 51

5. Observe the ECG signal and Marker Channel symbols for proper detection and therapy. Proper sensing following therapy delivery must be observed. Wait ten seconds after VF has been terminated before interrogating the device and printing a partial summary report of the data.
6. Program VT and VF Detection OFF before closing.

Placing the PCD Device

To ensure telemetry and programming function post-implant, the Model 7217B PCD device must be placed within 5 cm of the skin and with the engraved side facing toward the skin.

The Model 7217B PCD device has two suture holes located in the connector assembly. Use of these suture holes may help secure the device in the subcutaneous pocket, thus minimizing rotation and/or migration of the device post-implant. Penetration of the holes can be achieved with normally available surgical needles.

Closing

At closing perform or verify the following:

- All leads are sutured or positioned for chronic implant.
- All leads are fully inserted into the PCD device connector and all setscrews are tight.
- Place the PCD device in the pocket within 5 cm of the skin and with the **engraved side toward the skin**.
- Ensure that there are no kinks in the leads.
- Close the pocket.
- Program VF Detection and Therapies ON.
- Interrogate the device and print a full summary to document the post-operative programmed status of the PCD device.

7217B NTL p39-52/MMC 9/25/93 12:17 AM Page 52

Replacing a PCD Device

To replace a Model 7217B PCD device:

1. Program VT and VF Detection OFF.
2. Carefully dissect the leads and the PCD device free from the surrounding tissues in the pocket. Be especially careful not to nick or breach the lead insulation inadvertently during the process of exposing the PCD system.
3. Insert the proper hex wrench through the slits in the rubber grommet and loosen the setscrew by turning counterclockwise.
4. Gently retract the lead connectors from the connector ports.
5. If any lead pin shows signs of pitting or corrosion, the entire lead should be evaluated and tested to assure the integrity of the system.
6. Take pacing, sensing, and defibrillation efficacy measurements.
7. Connect the leads to the replacement device.
8. Evaluate the defibrillation efficacy of the PCD system.
9. Place the PCD device and close.
10. Interrogate the device and print a full summary to verify and document that the programmed status of the device is as desired.
11. Return the explanted device after cleaning/gas sterilizing to your Medtronic representative for device evaluation.

Implanting a PCD Device With a Chronic Lead System

When implanting a PCD device that connects to a chronically implanted lead system, evaluate the following to ensure the device will detect and treat ventricular arrhythmias appropriately:

1. Integrity of the chronic patch leads. Evaluate by chest X Ray, inspection, or test shock.
2. Chronic pacing and sensing measurements (see "Performing Pacing and Sensing Measurements" in "Implantation Procedure"). Repositioning the chronic leads or implanting new pacing/sensing or patch leads may be necessary.
3. Defibrillation efficacy (see "Defibrillation Efficacy Testing" in "Implantation Procedure"). Repositioning the chronic leads or positioning a third patch lead may be necessary to meet the defibrillation efficacy protocol (Figure 22).
4. VF sensing (see "Evaluating VF Sensing" in "Defibrillation Efficacy Testing"). Repositioning the chronic leads or implanting new pacing and sensing leads may be required.
5. Fit of the connectors in the PCD device (see "Connecting the Leads to the PCD Device" in "Implantation Procedure"). The leads must be properly inserted into the connector block for the device to function properly.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 53

POST-IMPLANT INFORMATION

Programming Considerations

The following suggestions have been developed to assist the physician in programming the Model 7217B PCD device. These suggestions should be used to help program the proper detection and therapy parameters for the patient's clinical arrhythmias. They are **only** considerations based on the review of the clinical experience and are not the result of unanticipated adverse results or complications. The programming choices will also depend on the patient's specific clinical arrhythmia and the results of pre- and post-implant electrophysiologic testing.

NOTE: Always interrogate the device at the beginning and end of each follow-up session and print a full summary to verify and document that the programmed status of the PCD device is as desired.

The suggestions are divided into six main areas: VT Detection, VT Therapy, VF Detection, VF Therapy, VVI Therapy, and General.

VT Detection

The PCD device uses two primary parameters to detect ventricular tachycardia: the Tachycardia Detection Interval (TDI) and the Number of Intervals to Detect (VT NID). The two optional detection methods are the Onset and Stability Criteria. Keep in mind the following when programming VT Detection:

Tachycardia Detection Interval (TDI)

The choice of the TDI is based on the cycle length of the patient's clinical ventricular tachycardia. To provide a safety margin that allows the VT cycle length to vary somewhat and still be appropriately detected, the TDI should be programmed at least 40 ms longer than the clinical VT cycle length (since a single cycle length greater than or equal to the TDI resets the VT event counter to zero). However, it must also be short enough to avoid inappropriate detection of sinus tachycardia and atrial fibrillation or flutter with rapid ventricular response.

Programming the FDI to a value greater than or equal to the TDI effectively disables VT Detection. **When programming these two values, the physician should keep the TDI at least 40 ms longer than the FDI to allow for variability of the clinical VT cycle length.**

Number of Intervals to Detect (VT NID)

The choice of the VT NID is based on the hemodynamic consequences of the clinical VT. Smaller VT NIDs will allow rapid detection of hemodynamically unstable VT. Larger VT NIDs may be indicated in patients with a history of non-sustained but well-tolerated VT. For patients other than these, programming an initial VT NID of 16 is appropriate.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 54

Programming larger VT NID counts will result in correspondingly longer delays between VT therapies (when the previous therapy is ineffective in terminating the VT episode), due to the need to redetect the VT episode after each unsuccessful VT therapy.

The physician should understand that the programmed VT NID applies to both initial detection and redetection of an ongoing episode after each therapy is delivered.

Onset Criterion

Onset Criterion is indicated only if inappropriate detection of sinus tachycardia resulting in inappropriate VT therapy delivery has occurred. Treadmill testing, beginning at 81% Onset, is suggested to evaluate the appropriate function of this algorithm.

This algorithm was used safely in 8.5% of 434 patients in the clinical study. Its use has demonstrated its safety and effectiveness.

If the Onset Criterion is ON and is not met at the beginning of a spontaneous ventricular tachycardia, the VT episode could remain "undetected", such as with an exercise-induced VT. If VT Detection uses the Onset Criterion and detection is enabled after the start of a VT, the VT may not be detected.

A low programmed onset percentage value will increase the specificity of the Onset Criterion to detect the targeted tachycardia, but will also decrease the sensitivity of the overall VT detection algorithm.

Stability Criterion

Stability Criterion is indicated if atrial fibrillation or atrial flutter with a rapid ventricular response has caused inappropriate detection and therapy delivery. A stability value of 60 ms is suggested initially.

This algorithm was used safely in 17.9% of 434 patients in the clinical study. Its use has demonstrated its safety and effectiveness.

Decreasing the programmed interval stability value increases the specificity of the Interval Stability Criterion to detect the targeted stable tachycardia, but may also decrease the sensitivity of the detection algorithm.

Programming VT Detection ON

VT Detection can be programmed ON only after VF Detection has been programmed ON.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 55

VT Therapy

VT Therapy consists of four independently programmable therapies that can be delivered to restore the patient's normal cardiac rhythm. The physician can tailor these four therapies to each patient's needs by choosing from two methods of overdrive pacing (Ramp and Burst) and synchronized Cardioversion. Since the actual programmed parameters used will be patient dependent, the suggestions below may help in programming them appropriately.

The physician should be aware that even when there has been a satisfactory response to VT therapies (i.e., Burst, Ramp, or Cardioversion) during clinically conducted EP studies, underlying or accompanying disease may over time alter the heart's electrophysiologic characteristics. Thus, over time, the programmed automatic therapies may not only be ineffective but also deleterious to the patient (e.g., initiate an atrial tachyarrhythmia or accelerate a ventricular tachycardia to flutter or fibrillation).

Ramp and Burst Therapy

Clinical experience has shown that the most commonly programmed values for Ramp Therapy are the following:

Initial # of S Pulses:	5
First R-S Interval	91%
Per Pulse Decrement	10 ms
# of Sequences	5
Minimum Interval	250 ms

Clinical experience has shown that the most commonly programmed values for Burst Therapy are the following:

# of S1 Pulses:	6
First S1-S1 Interval	84%
Per Sequence Decrement	10 ms
# of Sequences	5
Minimum Interval	250 ms

The values selected for Ramp and Burst Therapies will depend on the patient's clinical VT cycle length, electrophysiologic testing results, and antiarrhythmic drug therapy.

Evaluating VT Therapies

For evaluation of VT therapies, the exact number of inductions and successful terminations that should be completed is primarily dependent on a patient's hemodynamic response to their ventricular tachycardia. In patients with poorly-tolerated VT, it is recommended that at least **ONE** episode of VT be induced and successfully terminated using any of the VT therapies selected. For patients with well-tolerated VT, it is recommended that at least **FOUR** episodes of VT be induced and successfully terminated. This testing should be conducted whenever the following are performed:

- Initial selection of VT therapies,
- Permanent reprogramming of VT therapies, and
- Modification of antiarrhythmic drug therapy.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 56

Detecting VF as VT

In cases where VF may be detected as VT, consider using one pacing sequence and three high-energy cardioversion shocks for the VT therapies.

VT Therapy #4

The last VT therapy should be high-energy cardioversion.

Programming VT Therapies ON and OFF

VT Therapy cannot be programmed ON unless VF Therapy is also programmed ON. Also, programming one of the four VT therapies OFF will disable all subsequent VT therapies. For example, if VT Therapy #1 is programmed OFF, all VT therapies are effectively disabled.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 57

VF Detection

The PCD device detects ventricular fibrillation using three programmable parameters: the Sensitivity of the ventricular sensing circuit, the Fibrillation Detection Interval (FDI), and the Number of Intervals to Detect (VF NID) that must be attained by the VF event counter. The programming suggestions for VF Detection are the following:

Sensitivity

Sensitivity should be programmed to 0.3 mV to maximize the probability that VF will be detected. Values of 0.6 or 0.9 mV should be used **only** if oversensing (such as P- and T-waves) would cause inappropriate shocks or inhibit pacing therapies. If sensitivity is reprogrammed to eliminate inappropriate sensing, VF should be reinduced and appropriately treated to ensure proper sensing and detection. Repositioning or implanting new pacing/sensing leads may be necessary. Use of values less sensitive (higher threshold) than 1.2 mV are not recommended except for testing and troubleshooting.

In the event of post-pace oversensing, consider increasing the Refractory After Pace if it does not interfere with VT Detection or reducing the pacing pulse width or amplitude if it does not affect proper pacing capture. See "Refractory Periods" in "Principles of Operation" for more information on programming the Refractory After Pace.

Fibrillation Detection Interval (FDI)

FDI should generally be programmed to **at least** 320 ms. If VT therapies are required for faster VTs, then a shorter FDI should be programmed **only** if repeated inductions of true VF are detected as VF at the shorter FDI. Using the Last Episode Detection Sequence memory, the FDI should be lengthened if 3 or more of the intervals from the start of VF detection are greater than or equal to the programmed FDI. Some drugs, such as Amiodarone, may slow the VF intervals to greater than 320 ms, which would require the FDI to be increased.

Number of Intervals to Detect (VF NID)

For most patients a programmed VF NID of 18 should be used. VF NIDs greater than 18 may be indicated for some patients, for example, those with non-sustained rapid tachyarrhythmias. However, in general, VF NIDs greater than 18 should be avoided to prevent prolonged detection and redetection times.

Programming VF Detection OFF

VT Detection must be programmed OFF before VF Detection can be programmed OFF.

VF Therapy

VF Therapy delivers up to four high-energy defibrillation shocks to treat ongoing detected VF episodes. The stored energy and pulse width for each therapy is separately programmable (see Table 5 in "General Device Information" for information on how to program the optimal pulse width); the electric current pathway is also programmable but must be the same for all VF therapies.

Current Pathways

The multiple pathway options the PCD device offers (sequential, simultaneous, and single) allow the physician to provide an adequate defibrillation efficacy safety margin for most patients. For example, the simultaneous pathway may be indicated for patients who have difficulty meeting the defibrillation implant criteria with a different pathway.

Stored Energy

modified

Although the Transvene clinical study provided evidence that defibrillation thresholds remain stable in the study population, individual patients may experience threshold changes relative to changes in their underlying disease state. Therefore, VF therapy number 1 should be programmed to at least twice the lowest energy of defibrillation or 34 Joules.

The second, third, and fourth VF therapies should be programmed to the maximum stored energy of 34 joules.

Programming VF Therapies OFF

VF Therapy cannot be programmed OFF unless VT Therapy is programmed OFF. Also, programming one of the four defibrillation therapies OFF will disable all subsequent defibrillation therapies. For example, if VF Therapy #1 is programmed OFF, all defibrillation therapies are effectively disabled.

316

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 59

VVI Therapy

Pacing Parameters

Rate: VVI pacing may be required for underlying conduction disease and after delivery of cardioversion/defibrillation therapy. Program the rate for appropriate bradycardia support, but allow for contribution of the patient's intrinsic rate.

Pulse Width: keep in mind that this programmed setting also applies to VT Burst and Ramp therapies. When programming this parameter, ensure an adequate safety margin above the stimulation threshold.

Pulse Amplitude: choose from two settings. The setting selected also applies to VT Burst and Ramp therapies; the value selected should ensure an adequate safety margin above the stimulation threshold.

Sensitivity: this programmed setting will also be used to detect VT or VF. Therefore, sensitivity should be programmed to 0.3 mV to maximize the probability that VF will be detected. A threshold greater than 1.2 mV may be too insensitive for VF detection. Values less sensitive than 1.2 mV are not recommended except for testing and troubleshooting. If undersensing is observed in normal sinus rhythm, verify that VF sensing and detection are appropriate. Repositioning or implanting new pacing/sensing leads may be necessary. See also the programming considerations for VF Detection above.

A combination of wide pacing pulse width, high pacing amplitude, and high sensitivity (low sensing threshold) may cause inappropriate sensing after pacing. Programming a narrower pulse width, a lower amplitude pulse, a longer refractory period after pace, or a higher sense threshold may eliminate this inappropriate sensing. If sensitivity is reprogrammed to eliminate inappropriate sensing, VF should be reinduced and the PCD device should be allowed to automatically detect and treat the arrhythmia to ensure proper sensing and detection.

Long Refractory After Pace

A long refractory period (more than 320 ms), coupled with a high programmed pacing rate, may impair the PCD device's ability to detect VT or VF and may cause asynchronous pacing. Events sensed within the refractory period restart a 120 ms blanking period but are ignored by both VT and VF detection criteria and for bradycardia pacing inhibition. Therefore, a short bradycardia escape interval (i.e., a pacing rate greater than 50 ppm) combined with a long Refractory After Pace (360 ms or longer) may prevent a VT event from inhibiting a pacing output. **In such circumstances, the VT could remain undetected**.

To avoid this possibility when the Refractory After Pace is programmed to 360 ms or longer, ensure that at least one of the following is true: (1) the difference between the bradycardia escape interval and the effective refractory period should be greater than the Tachycardia Detection Interval (TDI); or (2) the bradycardia escape interval must be greater than twice (2X) the effective refractory period. (The effective refractory period

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 60

for a programmed refractory of 360 ms or longer is the programmed value plus 120 ms.) See "Refractory Periods" in "Principles of Operation" for more information.

General

Estimates of Time to Device Therapy

The time to device therapy depends on several factors including programmed detection parameters, the PCD device's remaining battery life, and the time since the last charge of the device capacitors. For all therapies, the time to device therapy increases with higher programmed NIDs. For cardioversion and defibrillation therapies, the time also increases as the device's battery voltage decreases and as the time since the last charge of the capacitors increases.

The time to device therapy projections found in Table 2 apply under the following conditions:

- The episode interval lengths to be detected are all less than the programmed TDI for VT episodes or FDI for VF episodes,
- A programmed TDI of 400 ms and VT NID of 16,
- A programmed FDI of 320 ms and VF NID of 18
- A beginning-of-life charge time to 34 J of 6.00 seconds,
- A cardioversion or defibrillation therapy of 34 J.

Table 2. Estimated Time to Device Therapy from Onset of Episode

Therapy	Time to Therapy
Ramp or Burst	6.4 seconds
Cardioversion	12.4 seconds
Defibrillation	11.8 seconds

Cardioversion and Defibrillation Charging Periods

The PCD device cannot be programmed during the cardioversion or defibrillation charging periods or during delivery of VT and VF therapies. Positioning (i.e., applying or removing) the programming head during a charging period has no immediate effect on the operation of the PCD device. However, if such positioning changes between the time the charging period begins and ends, the PCD device will abort the scheduled cardioversion or VF therapy.[1]

If the capacitors are not fully charged after three consecutive 35-second charging periods, the PCD device disables all VT and VF detection parameters and charging cycles and all VT pacing therapies.

1. VF therapy is aborted only if a refractory event is sensed at the end of charging.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 61

Permanent Telemetry Enable

This feature, which appears on the 9710 Programmer, is designed for future applications. At that time, it may be used to provide continuous telemetry (after removal of the programming head) for a programmable number of hours, or continuously. **This feature is normally programmed OFF.**

Conditioning the PCD Device Output Capacitors

The cardioversion/defibrillation output capacitors function more efficiently if they periodically receive an electrical charge. The charge conditions and helps maintain the efficiency of the capacitor function. The electrical charge should be used to condition the capacitors at every PCD follow-up visit. See the appropriate MemoryMod cartridge technical manual for charging instructions.

Elective Replacement and Potential Loss of Function Indicators

See Table 3 on the next page for a summary of voltage and charge time requirements at implant, elective replacement, and potential loss of function.

Elective Replacement Indicators

Replacement of the Model 7217B PCD device is recommended when any of the following occur:

- The telemetered voltage for the battery is 4.97 V or less, or
- The capacitor charging time is greater than or equal to 11.00 seconds.

These are elective replacement indicators only. They do not indicate that the PCD device has altered its operation in any way.

Potential Loss of Function Indicators

Whenever any of the following are observed an **immediate replacement** of the PCD device is recommended:

- The potential for altered or loss of function is present when the telemetered voltage for the **Battery** is 4.74 V or less.

  When the telemetered battery voltage is less than this value, the PCD device may be unable to successfully complete a charging cycle to the programmed energy. That is, a charging period may terminate prematurely and result in the "Reset Parameter Value" (see Table 4).

- As the battery depletes, the charging time will generally increase (typically less than 25 seconds), but a single charging period should not exceed 35 seconds. If the output capacitors have not reached their full programmed charge in this time, the charge circuit "times out." (This data is available via telemetry.) After such a timeout, the PCD device will again attempt to confirm VT/VF detection before resuming with an

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 62

additional 35-second charging period. If after three successive charging periods the capacitors do not reach their programmed level, the PCD device identifies a "Charge Circuit Inactive" state. (This data is also available via telemetry.) In this state, the PCD device disables the following:

All automatic VT and VF detection and therapies
Programmer-initiated therapies (except emergency Burst Pacing)
Programmer-initiated charging periods

Table 3. Voltage and Charge Time Requirements

	Requirements		
Event	**Voltage**		**Charge Time**
Implant	≥ 6.10 V	and	≤ 10.00 seconds
Elective Replacement	≤ 4.97 V	or	≥ 11.00 seconds
Potential Loss of Function	≤ 4.74 V		*

*Not applicable

Time from Elective Replacement Indicator to Potential Loss of Function

The time from the Elective Replacement Indicator to potential loss of function should be used to determine the frequency of follow-up and the schedule for replacement of the unit.

The time from the Elective Replacement Indicator to potential loss of function is four months (minimum)[1], based on the following conditions:

- 100% pacing at 65 ppm,
- 5.4 V pulse amplitude,
- 0.49 ms pulse width,
- 500 ohm pacing load, and
- two 34-joule high-voltage capacitor charging cycles per month.

This time may be shorter with increased pacing rates, increased pacing pulse widths, lower pacing impedances, or an increase in high-voltage capacitor charging frequency. Potential loss of function means the PCD device may be unable to successfully complete a charging cycle to the programmed energy.

1. The preliminary projection of the time from Elective Replacement to potential loss of function is based on accelerated battery data and device modeling. Minimum projection means that virtually all (i.e. 99.9%) of the modeled production run of PCD devices will attain the values given at the stated conditions.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 63

Pre-Hospital Discharge

Monitor the patient appropriately post-implant and take X rays as soon as possible to document and assess the location of the leads.

While the patient is in the hospital, interrogate the device after each spontaneous episode to assess the appropriateness of the detection and delivered therapy. Depending on the physician's judgment, the clinical tachyarrhythmia should be induced and terminated if no spontaneous episodes have occurred to confirm the appropriateness of the programmed values. Induction can be performed using the noninvasive electrophysiologic study (EPS) features present in the PCD device. See the appropriate MemoryMod cartridge technical manual for instructions.

Pacing and sensing values should also be tested and adjusted if necessary.

CAUTION: The physician should be aware that even when there has been a satisfactory response to VT therapies (i.e., Burst, Ramp, or Cardioversion) during clinically conducted EP studies, underlying or accompanying disease may over time alter the heart's electrophysiologic characteristics. Thus, over time, the programmed automatic therapies may not only be ineffective but also deleterious to the patient (e.g., initiate an atrial tachyarrhythmia or accelerate a ventricular tachycardia to flutter or fibrillation).

7217B NTL p53-81/MMC 10/5/93 7:59 PM Page 64

Patient Follow-Up

Regular patient follow-up testing should be scheduled every three months post-implant to confirm that the programmed parameter values are appropriate and to monitor the condition of the implanted system and of the device's battery. After the battery voltage falls below 5.25 volts, patient follow-up should be scheduled every month.

Perform the following during each follow-up visit:

- Evaluate the patient's clinical status.
- Interrogate the device at the beginning and end of each follow-up session and print a full summary to verify and document that the programmed status of the PCD device is as desired.
- Observe the battery voltage before charging the device's capacitors.
- Review device experience and status.
- Evaluate pacing and sensing performance.
- Perform a programmer-initiated 34-joule charge of the capacitors and interrogate for the charge time[1]. Do not "dump" the energy from the capacitors so as to allow them to reform.

If the charge time is greater than or equal to 11.00 seconds, wait five minutes before dumping the energy on the capacitors and then perform another programmer-initiated 34-joule charge and interrogation. If the second charge time is again greater than or equal to 11.00 seconds or if the initial battery voltage is 4.97 volts or less, the device should be replaced.

If the battery voltage is not observed before the device's capacitors are charged, it must reach its required value within thirty minutes after charging.

modified

The patient should have X-rays and pacing/sensing thresholds taken every three months for the first year after implant and every six months thereafter to verify proper lead position and check for conductor fractures.

See the section titled "Elective Replacement and Potential Loss of Function Indicators" for more information about when to replace the PCD device.

1. Under unique conditions, a charge time of 2.33 seconds or its multiple may be reported as 2.33 seconds less than its actual value (e.g. a reported charge time of 0.00 seconds could actually be 2.33 seconds). If this occurs, wait five minutes before dumping the energy on the capacitors and perform another programmer-initiated 34 J charge and interrogation.

GENERAL DEVICE INFORMATION

Magnet/Programming Head Operation

Applying and holding a magnet (Part No. 174105) and/or programming head over the device temporarily suspends the automatic detection and therapy capabilities. Using the "Cancel Magnet" function on the programmer will restore these detection capabilities while the magnet/programming head is in position.

CAUTION: Telemetry communication with the PCD device may cause inappropriate sensed events resulting in brief inhibition of bradycardia therapy. These sensed events may also count toward detection of VT or VF. Removing the programming or transtelephonic monitor head restores the device to normal function.

Placing a magnet over the PCD device does **not** inhibit VVI therapy.

Turning Off the PCD Device

To turn OFF the VT and VF capabilities of PCD device, press the "Nominal VVI" key and then the "Program" key on the programmer. This turns OFF VT and VF Detection and programs other parameters to the values listed in Table 4 below. This programming takes effect after any therapies in progress are delivered. This keystroke sequence can be used at any time after the device model number has been selected or a successful interrogation has been performed. The physician should interrogate the device after pressing the key to ensure that VT and VF Detection have been turned OFF.

To turn the PCD device back ON, follow the usual programming steps.

The table below lists the settings the PCD device is programmed to at the following events:

- At factory shipping,
- When "Nominal VVI" is programmed,
- When the VVI option under "Emergency VVI" is programmed,and
- When a "power-on reset" (an electrical reset) occurs.

Table 4. Nominal VVI Settings, Reset Parameter Values, Emergency VVI Option Settings, and Factory Shipped Settings

Parameter	Value
Mode	VVI
Pulse Width	0.49 ms
Sensitivity	0.6 mV
Amplitude	5.4 V
Refractory After Pace	320 ms
Pacing Rate	65 ppm
VT Detection & Therapies	OFF
VF Detection & Therapies	OFF

Device Reporting Features

The PCD device has a number of reporting features that provide current programmed settings of pacing, sensing, and VT and VF Detection and Therapy. It also provides current functional status of the device and information about previous detected and treated VT and VF episodes.[1]

Programmed Parameters

Pacing and Sensing

The PCD device reports the pacing mode, rate, pulse width, and amplitude. It also gives the programmed sensitivity and refractory after pace.

VT Detection and Therapy

The PCD device reports the following about VT Detection and Therapy:

- VT Detection ON or OFF
- Interval Criterion settings (TDI and VT NID)
- Interval Stability Criterion ON or OFF
- Interval Stability Criterion settings
- Onset Criterion ON or OFF
- Onset Criterion settings
- Onset Counter ON or OFF
- VT Therapy types (Ramp, Burst, or Cardioversion) and their respective settings.

PACING AND SENSING

PACING MODE	VVI
PACING RATE	65 PPM
PACING PULSE WIDTH	0.49 MS
PACING AMPLITUDE	5.4 V
SENSITIVITY	0.3 MV
REFRACTORY AFTER PACE	320 MS

VT DETECTION AND THERAPIES

VT DETECT:	
VT DETECTION ENABLE	ON
# INTERVALS TO DETECT	16
VT DETECTION INTERVAL	400 MS
INTERVAL STABILITY	OFF MS
ONSET CRITERIA ENABLE	OFF
ONSET VALUE (R-R%)	81 %
ONSET COUNTER ENABLE	OFF
VT THERAPY #1:	
THERAPY TYPE	RAMP%
VT THERAPY ENABLE	ON
INITIAL # OF S PULSES	5
FIRST R-S INTERVAL	97 %
PER PULSE DECREMENT	10 MS
# OF SEQUENCES	8
MINIMUM INTERVAL	200 MS
VT THERAPY #2:	
THERAPY TYPE	BURST%
VT THERAPY ENABLE	ON
# OF S1 PULSES	6
S1-S1 INTERVAL	84 %
PER SEQUENCE DECREMENT	10 MS
# OF SEQUENCES	5
MINIMUM INTERVAL	200 MS
VT THERAPY #3:	
THERAPY TYPE	CARDIOVERSION
VT THERAPY ENABLE	ON
CV PULSE WIDTH	3.9 MS
CV ENERGY (JOULES)	3.0 J
CV CURRENT PATHWAY	SEQ
VT THERAPY #4:	
THERAPY TYPE	CARDIOVERSION

CV PULSE WIDTH	3.9 MS
CV ENERGY (JOULES)	34.0 J
CV CURRENT PATHWAY	SEQ

1. The data strips shown are examples.

7217B NTL p53-81/MMC 9/25/93 12:18 AM Page 67

VF Detection and Therapy

The PCD device reports the following about VF Detection and Therapy:

- VF Detection ON or OFF
- VF Detection settings (FDI and VF NID)
- Defibrillation Therapy settings

VF DETECTION AND THERAPIES

VF DETECT:	
VF THERAPY ENABLE	ON
VF DETECTION INTERVAL	320 MS
# INTERVALS TO DETECT	18
VF DEFIBRILLATION THERAPY #1:	
VF THERAPY ENABLE	ON
DEFIB PULSE WIDTH	3.9 MS
DEFIB ENERGY (JOULES)	34.0 J
DEFIB CURRENT PATHWAY	SEQ
VF DEFIBRILLATION THERAPY #2:	
VF THERAPY ENABLE	ON

Status and Data

These reports provide the physician with the capability to acquire data on the device's activities/operations between office visits.

- The PCD device will determine and report its own internal status, e.g., what it has retained in memory, error messages, battery status, last charging time, and charging circuit status.
- The **VT Onset Counter** reports the number of instances when the Onset Criterion associated with VT detection was fulfilled. It only counts when VT Detection is also ON and either the Onset Criterion or Onset Counter is enabled.
- Following detection of a VT episode, the PCD device's **VT Episode Counter** adds one. This counter does not increase for subsequent detection(s) of the same VT episode. It keeps track of the number of detected VT episodes.
- If the PCD device determines the VT therapy was effective (see "VT Episode Termination and Determination of Therapy Efficacy"), the **VT Therapy Success Counter** (corresponding to the last delivered therapy) is increased by one. A counter exists for each of the four possible programmed therapies.[1]
- The **Number of VTs That the PCD was Ineffective** (in terminating) increases by one each time all programmed VT therapies are ineffective in terminating a detected VT episode.

DATA

PCD STATUS:	
MEMORY RETENTION	OK
CHARGE CIRCUIT	OK
LAST CHARGE TIME	3.12 SEC
BATTERY VOLTAGE	6.19 V

:
:
+10. R-R INTERVAL-920 MS
+10. THERAPY WAS SUCCESSFUL

1. This counter is also incremented if the VT therapy accelerated the rhythm to VF and the corresponding VF therapy is successful in terminating the VT episode prior to the next VT detection.

7217B NTL p53-81/MMC 9/25/93 12:19 AM Page 69

The number of effective therapies plus the number of VT episodes in which the PCD was ineffective should equal the VT episode count. Exceptions to this may occur if a therapy is aborted (e.g., by a magnet application or by spontaneous termination of the VT episode during the first therapy's charging period), if therapies are initiated by the programmer during the episode, or if the device is interrogated prior to identification of VT termination.

- The **PCD Efficacy on the Last VT Episode** is also available, that is, whether the device was successful (8 consecutive paced or sensed beats greater than or equal to the TDI) on the last detected VT episode.
- The **Last VT Therapy Used** notes which programmed therapy was delivered last.
- The **Number of Sequences in the Last Pacing Therapy** reports which sequence within the last Burst or Ramp Therapy was delivered last. This information is useful because, from it (and with the next report), the physician can determine the interval and number of pulses of the last delivered therapy.[1]
- The **R–R Average for the Last Pacing Therapy** discloses the average of the last four intervals prior to delivery of the last Burst or Ramp sequence. When this information is coupled with knowledge of the programmed settings for the last pacing therapy and sequence counter of the therapy, the physician can determine the pulse intervals delivered during the last pacing therapy.[1]
- Following detection of a VF episode, the PCD device's **VF Episode Counter** is increased by one. This counter does not increase for each detection within the same VF episode.
- If the PCD device determines a VF therapy was effective (see "VF Episode Termination and Efficacy Determination"), **the Successful VF Therapy Counter** corresponding to the last delivered therapy is incremented by one. A counter exists for each of the four possible therapies.
- The **Number of VF Episodes in which the PCD device was Ineffective** is incremented by one each time all programmed VF therapies are delivered and determined to be ineffective in terminating a detected VF episode.

  The number of effective therapies plus the number of VF episodes in which the PCD device was ineffective should equal the total VF episode count. Exceptions to this may occur if a therapy is aborted by a magnet application, if therapies are initiated manually by the programmer during a VF episode, or if the device is interrogated prior to identification of VF termination.
- The **PCD Efficacy on the Last VF Episode** is also available from the PCD device.
- The **Last VF Therapy Used** notes which programmed VF therapy was last delivered.
- The **Last Episode Detection Sequence** retains data from 20 intervals just prior to the last detected VT/VF episode.
- The **Events After Last Therapy** section retains data from 10 intervals following the last VT/VF therapy of the last VT/VF episode.

1. These two counters are also updated by a manually-programmed Burst or Ramp therapy.

7217B NTL p53-81/MMC 9/25/93 12:19 AM Page 70

Electrophysiological Study (EPS) Features

With programmer-initiated commands, the PCD device will produce up to four independently programmable premature stimuli. These stimuli may be used to induce a tachycardia for determining the patient's susceptibility to ventricular tachyarrhythmias and the efficacy of the device's programmed therapies (i.e., Burst, Ramp, or Cardioversion) to treat the induced tachycardia.

Also, a ramp or burst pacing sequence with very short intervals for more aggressive stimulation may be used to establish the efficacy of Defibrillation Therapy.

The PCD device has these manually controllable therapies:

- **Emergency therapies,** including Defibrillation, Cardioversion, Burst, and VVI nominal pacing parameters,
- Defibrillation therapy (**VFRx**), programmable as to pulse width, stored energy, and current pathway, and
- VT therapies (**VTRx**), programmable as to Burst, Ramp, or Cardioversion.

7217B NTL p53-81/MMC 10/6/93 6:37 PM Page 71

Telemetry Features

The physician can acquire information about the present and past operation of the PCD device.

- Programmed Parameter Report, i.e., the programmed values to which the PCD device is currently set. See "Device Reporting Features" in "General Device Information" for more information on reports.
- Continuous, Real-Time Marker Channel™ telemetry, including the timing and categorization of sensed, paced, and therapeutic events (i.e., VF/VT/Normal). Refer to Figure 27 and the programmer technical manual for additional details.
- Continuous, Real-time Electrograms from either of two different sets of leads. EGM-Near-Field is taken from the PACE/SENSE to SENSE2 leads and EGM-Far-Field is taken from the PULSE1 to COMMON leads. (Far-Field electrograms are not available in two-electrode cardioversion/defibrillation systems because a plug is used in the PULSE1 connector port.)

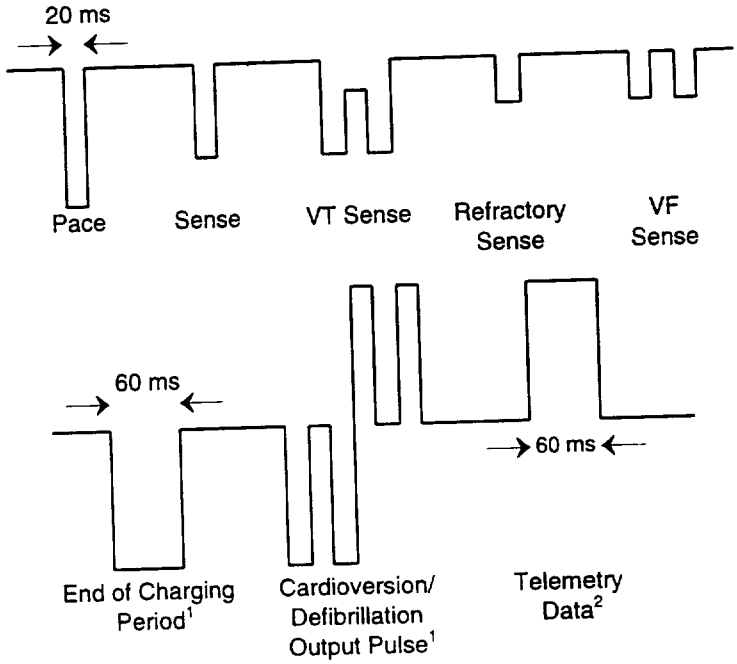

Figure 27. Representative Marker Channel Symbols

1. Interference generated during charging or pulse delivery may occasionally prevent these markers from appearing.

2. This indicates data transmission other than Marker Channel telemetry. Other markers may not appear or may falsely appear within 300 ms either side of this Telemetry Data marker.

7217B NTL p53-81/MMC 9/25/93 12:19 AM Page 72

Permanent Telemetry Enable

This feature, which appears on the 9710 Programmer, is designed for future applications. At that time, it may be used to provide continuous telemetry (after removal of the programming head) for a programmable number of hours, or continuously. **This feature is normally programmed OFF.**

Radiopaque Identification

A radiopaque code block is visible on a standard X Ray as black characters on a white background. This code block may be used to identify the PCD device, Model 7217B, as follows:

Manufacturer:	Medtronic
Model Identification:	ZB (Model 7217B)
Engineering Series Number:	Follows the Model Identifier

Figure 28. Radiopaque I.D.

7217B NTL p53-81/MMC 9/25/93 12:19 AM Page 74

Output Voltage and Delivered Energy

Programming Output Voltage For Cardioversion/Defibrillation

Table 5 converts stored energy (joules) to pulse amplitude (volts), based on a 75 ohm load.

Table 5. Converting Joules to Volts

Programmed Stored Energy (Joules)	Pulse Amplitude (Volts)	Programmed Stored Energy (Joules)	Pulse Amplitude (Volts)
34.0	753 (± 5%)	9.0	387 (± 5%)
32.0	732 (± 5%)	8.0	366 (± 5%)
30.0	708 (± 5%)	7.0	342 (± 5%)
28.0	684 (± 5%)	6.0	315 (± 5%)
26.0	660 (± 5%)	5.0	288 (± 5%)
24.0	633 (± 5%)	4.0	258 (± 5%)
22.0	606 (± 5%)	3.0	225 (± 5%)
20.0	579 (± 5%)	2.0	183 (± 5%)
18.0	549 (± 5%)	1.8	174 (± 16%)
16.0	516 (± 5%)	1.6	162 (± 16%)
15.0	501 (± 5%)	1.4	153 (± 16%)
14.0	483 (± 5%)	1.2	141 (± 16%)
13.0	465 (± 5%)	1.0	129 (± 16%)
12.0	447 (± 5%)	0.8	114 (± 16%)
11.0	429 (± 5%)	0.6	99 (± 16%)
10.0	408 (± 5%)	0.4	81 (± 16%)
		0.2	57 (± 16%)

Programming Pulse Width For Defibrillation

To achieve the most effective defibrillation therapy for the most patients, the output pulse should have approximately a 65% "tilt", which means the amplitude at the end of the pulse should drop 65% of the initial amplitude. Tilt values are dependent on the pulse width and pathway resistance. Table 6 below suggests what the pulse width should be programmed to as a function of the pathway resistance to obtain a 65% tilt. For example, when programming for SEQUENTIAL pulses where the two path resistances are 80 and 60 ohms, calculate the mean resistance (70 ohms) and use the SEQUENTIAL table to choose a pulse width of 4.4 ms. If programming for SIMULTANEOUS pulses where the path resistances are 90 and 70 ohms, approximate the resistance by using the product of the two path resistances divided by their sum ($6300 \div 160 \approx 39\ \Omega$). Then look at the SIMULTANEOUS/SINGLE table for 39 ohms and choose 4.9 ms. For a SINGLE pulse with a path resistance of 40 ohms, for example, use the SIMULTANEOUS/SINGLE table, look under 40 ohms, and choose 4.9 ms.

7217B NTL p53-81/MMC 9/25/93 12:19 AM Page 75

Clinical experience has shown that the most commonly used defibrillation pulse width is 3.9 ms for SEQUENTIAL pathway and 6.3 ms for SIMULTANEOUS and SINGLE pathways.

Table 6. Pulse Widths for 65% Tilt

SEQUENTIAL		SIMULTANEOUS/SINGLE	
Resistance (ohms)*	Pulse Width (ms)	Resistance (ohms)**	Pulse Width (ms)
20-34	2.0	<19	2.0
35-42	2.4	20-21	2.4
43-50	2.9	22-25	2.9
51-58	3.4	26-29	3.4
59-66	3.9	30-33	3.9
67-74	4.4	34-37	4.4
75-82	4.9	38-41	4.9
83-89	5.4	42-45	5.4
90-97	5.9	46-48	5.9
98-102	6.3	49-52	6.3
103-110	6.8	53-56	6.8
111-118	7.3	57-59	7.3
119-126	7.8	60-63	7.8
—	8.1	64-100	8.1

*Use the mean of the two path resistances.
**For simultaneous, approximate the resistance—use the formula $\frac{R_1 \times R_2}{R_1 + R_2}$

Stored and Delivered Energy

Cardioversion and defibrillation therapies have three programmable parameters: stored energy, pathway, and pulse width. The stored energy determines the pulse amplitude (as shown in Table 5). The percentage of programmed stored energy that is applied to the lead system (that is, the delivered energy) depends on the programmed pathway, the programmed pulse width, and the pathway impedance. The percentage of programmed stored energy that is delivered increases when the programmed pulse width increases or the pathway impedance decreases.

7217B NTL p53-81/MMC 10/6/93 6:38 PM Page 76

The percentage of delivered energy vs. programmed stored energy may be seen by referring to Figures 29 and 30. Increasing the programmed stored energy will have a proportional effect on the delivered energy. For example, if the pulse width, pathway, and pathway impedance are unchanged, doubling the stored energy doubles the delivered energy.

Figures 29 and 30 demonstrate the effect on the delivered energy with respect to the programmed stored energy, pulse width, pathway, and pathway impedance. One should not conclude, however, that two different settings delivering the same energy have the same effectiveness. Always verify the effectiveness of the new settings when reprogramming pulse width or current pathway.

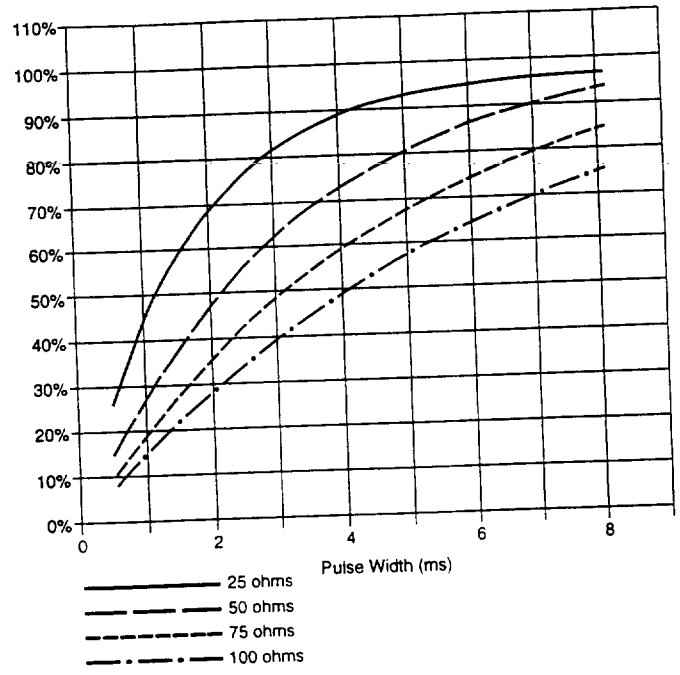

Figure 29. Percentage of Programmed Stored Energy Delivered Over a Single Pathway

If, for example, the programmed pulse width is 3.9 ms and the pathway impedance is 50 ohms, the percentage of delivered energy (compared to programmed stored energy), is about 72%. Increasing the pulse width to 6.3 ms with the same impedance will result in about an 88% delivered energy figure.

7217B NTL p53-81/MMC 10/6/93 6:38 PM Page 77

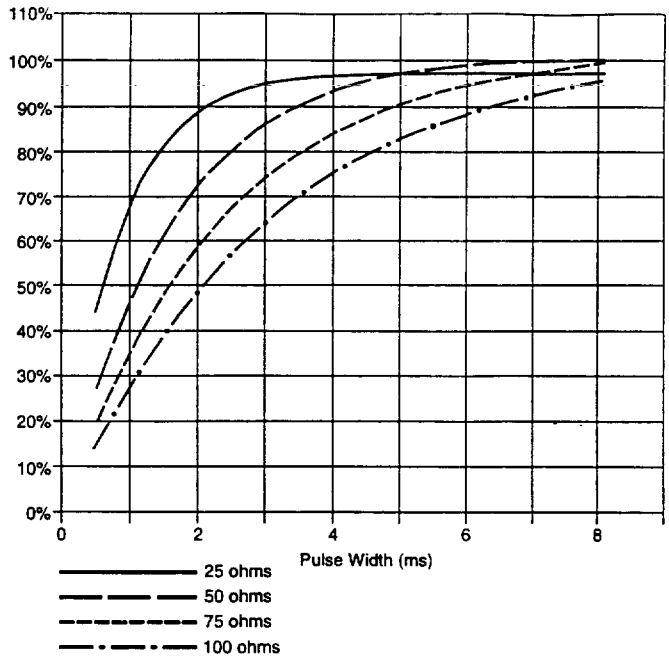

Figure 30. Percentage of Programmed Stored Energy Delivered Over Sequential or Simultaneous Pathways

Programming a sequential or simultaneous pathway may change the percentage of delivered energy. With the same examples as were used to illustrate Figure 29 where each pathway is 50 ohms, the percentages are about 93% and 99% respectively.

Output Waveforms

The illustrations that follow depict examples of waveforms that can be delivered by the PCD device during its programmable VT and VF therapies. Figures 31-33 represent the three programmable waveforms delivered during Cardioversion and Defibrillation Therapy. Figure 34 displays the waveform for Burst and Ramp therapies and bradycardia therapy, which are delivered at pacing energy levels. (Dashed voltage waveforms represent detected potentials generated from other leads. The examples assume 75 ohms as the resistance for cardioversion and VF pathways.).

7217B NTL p53-81/MMC 10/6/93 6:38 PM Page 78

WARNINGS AND PRECAUTIONS

Lead Systems

The Medtronic 7217B has been proven safe and effective when combined with Medtronic epicardial patch electrodes, Medtronic Transvene non-thoracotomy leads, or commercially available electrodes manufactured by Cardiac Pacemakers Incorporated (i.e. C10). No claims of safety and efficacy can be made with regard to other acutely or chronically implanted lead systems.

Disease Progression, Detection and Automatic VT and VF Therapies

The physician should be aware that even when there has been a satisfactory response to VT or VF therapies (i.e., Burst, Ramp, Cardioversion, or Defibrillation) during clinically conducted EP studies, underlying or accompanying disease or change in antiarrhythmic drug therapy may over time alter the heart's electrophysiologic characteristics. Thus, over time, the programmed automatic therapies may not only be ineffective but also deleterious to the patient (e.g., initiate an atrial tachyarrhythmia or accelerate a ventricular tachycardia to flutter or fibrillation). In addition, changing cardiac electrical characteristics may prevent detection of a tachyarrhythmia or may cause the pulse generator to misinterpret a normal rhythm as a clinically significant arrhythmia.

Implanted or Temporary Pacemakers

Previously implanted bradycardia pacemakers, tachyarrhythmia devices and leads should be explanted. The output pulses of an implanted device may adversely affect the tachyarrhythmia detection capabilities of the PCD device. If leads must be abandoned rather than removed they should be capped to ensure they will not become a pathway for currents to or from the heart. If a patient requires a separate atrial or dual chamber pacemaker for hemodynamic reasons, either permanent or temporary, consider the following to minimize potential interaction between the pacemaker and the PCD:

- Use only bipolar pacemakers that remain bipolar after exposure to high voltage shocks;
- Use pacemaker leads with close interelectrode spacing;
- Allow adequate space between the pacing lead electrodes and the defibrillation lead electrodes;
- Test the PCD device to determine if output pulses from the pacemaker are sensed by the PCD;
- Induce all the patients ventricular tachyarrhythmias and ventricular fibrillation with the pacemaker programmed to an asynchronous mode at maximum output to evaluate possible inhibition of detection by the PCD due to pacing artifacts;
- Program the pacemaker to the lowest amplitude allowable for capture chronically, the maximum sensitivity, and the minimum rate acceptable to the patient.

modified

7217B NTL p82-94/MMC 10/5/93 9:36 PM Page 83

Electromagnetic Interference (EMI)

Exposure to EMI may, under certain circumstances, prevent VT/VF detection or cause the PCD device to falsely detect a VT or VF and deliver an unneeded VT or VF therapy. The delivery of the therapy could, in turn, provoke an actual VT or VF. Additionally, since the PCD device communicates with the programmer by means of radio frequency telemetry, EMI may cause short telemetry interruptions. Under unique circumstances, EMI may cause an electrical reset of the device (see **Power On Reset**). **Keep PCD patients away from EMI sources, when and as long as any detection criteria are enabled.** Physicians should carefully weigh their decision to program the device to maximum sensitivity (0.3 mV), as it will increase the susceptibility to EMI sources. EMI sources include, but are not limited to, the following:

- Nuclear Magnetic Resonance Imaging (MRI) equipment
- Therapeutic diathermy
- Defibrillation equipment
- Electrocautery
- High-voltage systems
- Radio transmitters
- Theft prevention equipment
- Current-carrying conductors
- High-powered electromagnetic fields

Preventing Accidental Exposure to Maximum Voltage

To prevent an accidental discharge during implantation or explantation, the Model 7217B PCD device should be programmed so that VT and VF detection are both OFF.

In the event of a patient's death while the Model 7217B PCD device is implanted, the device should be explanted and returned to Medtronic. Prior to the explant procedure, **both VT and VF detection must be programmed OFF** to prevent the delivery of potentially hazardous shocks to medical or mortuary personnel. Medtronic requests that such individuals INTERROGATE THE PCD DEVICE AND PRINT A FULL REPORT BEFORE TURNING OFF DETECTION AND EXPLANTING THE DEVICE.[1]

Supraventricular Tachyarrhythmias

Depending on programmed detection and therapy settings, patients with supraventricular tachyarrhythmias (despite a drug regimen) may be inappropriately paced, cardioverted, or defibrillated. If the PCD device cannot distinguish such rhythms from ventricular tachyarrhythmias with available criteria, the physician must judge whether the use of the PCD device is advisable.

1. Consult the Technical Manuals for the Programmer and MemoryMod for details on turning OFF VT and VF detection.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 84

Because of the nature or frequency of conducted rapid atrial rhythms, the physician should carefully evaluate such rhythms and weigh the patient's needs against the benefits before implanting the PCD device. If the determining factor hinges on which therapies must be used, the physician should be aware that the total designed capacity for cardioversion and VF therapies is finite. The use of pacing level therapies, i.e., Burst and Ramp, will not appreciably alter the device's longevity.

Repeated, Multiple VT/VF Episodes

The physician must weigh the risks versus the benefits for patients who display a history of repeated and multiple VT episodes. Use discretion in the treatment of such episodes, since it may quickly deplete the battery of the PCD device.

The PCD device has a finite capacity for its high-energy therapies, i.e., cardioversion and defibrillation. The use of pacing level therapies, i.e., Burst and Ramp, will not appreciably alter the device's longevity.

Diathermy

Therapeutic diathermy should not be used at the implant site on patients who have a PCD device because of possible damage to the circuitry due to heating effects on the device.

Defibrillation

The Model 7217B PCD device may be damaged by direct or transthoracic defibrillatory discharges. When performing direct heart defibrillation, do not directly contact the exposed metal surface of any electrode with the paddles. When performing transthoracic defibrillation, do not place a paddle directly over the PCD device. Interrogate the PCD device after the use of direct or transthoracic defibrillation to determine the functional integrity of circuits and programmed parameters. Reprogramming may be necessary.

Patch electrodes, because they "insulate" a portion of the heart tissue, may unavoidably reduce the effectiveness of transthoracic defibrillation.

Use of a Magnet

Use only a Medtronic magnet (Part No. 174105) or programming head over the PCD device.

Positioning a magnet or the programming head of the Programmer over the Model 7217B PCD device temporarily suspends VT and VF Detection and makes the device subject to programming. Placing a magnet over the PCD device does **not** inhibit VVI therapy.

Electrocautery

Electrosurgical units should **never be used in the vicinity (i.e., six inches [15 cm] or closer)** of a Model 7217B PCD device and its associated lead system. Currents generated from electrosurgical units may cause permanent loss of output, induce ventricular

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 85

fibrillation, or reset programmed parameters in these units (see "Effects of Electrosurgical Cautery and Defibrillation"). Where alternatives to electrocautery are available, these should be used.

Power On Reset

Certain conditions, (including but not limited to: exposure to EMI, electrocautery or transthoracic defibrillation) may lead to an electrical reset of the device. The table below lists the settings the PCD is reset to when a "power on reset" (POR) occurs. **Always interrogate the PCD device at the beginning and end of each follow-up session to verify and document that the programmed status of the device is as desired.** The device may be reprogrammed to desired parameters after the source of interference is removed.

If a POR has occurred, then the POWER ON RESET message should be cleared from the PCD device memory and the device reprogrammed to desired parameters. To clear the POWER ON RESET message, use the DATA key on the main menu of the programmer to display and clear the STATUS group.

Table 7. Power On Reset Parameter Values

Parameter	Value
Mode	VVI
Pulse Width	0.49 ms
Sensitivity	0.6 mV
Amplitude	5.4 V
Refractory After Pace	320 ms
Pacing Rate	65 ppm
VT Detection & Therapies	OFF
VF Detection & Therapies	OFF

Nonsterile Package

The sterile package should be inspected prior to opening. If the seal or package is damaged, contact your local Medtronic representative.

Damage to a PCD Device Prior to Implantation

The Model 7217B PCD device should not be implanted if dropped on a hard surface from a height of 12 inches (30 cm) or more.

Random Failures

All devices will ultimately cease to function due to normal depletion of the battery and may also fail at any time due to random component or battery failure which cannot be predicted prior to their occurrence. Also, the system may cease to function at any time due to lead-related problems such as dislodgement, fracture, fibrotic tissue formation, elevated thresholds, or medical complications.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 86

Infrequent Charging of the High-Voltage Capacitors

Infrequent charging of the high-voltage capacitors may cause the charging period to be longer than desired. **The use of the programmer-initiated charging command should be performed to 34 joules at every PCD follow-up visit.**

SIDE EFFECTS

Possible side effects include, but are not limited to, the following: body rejection phenomena including local tissue reaction; muscle and nerve stimulation; pericarditis; infection; lead dislodgement; erosion of the PCD device, leads, or adaptor through the skin; and adverse psychological effects, which may include psychologic intolerance to the PCD device, imagined pulsing, dependency, fear of inappropriate pulsing, and fear that pulsing capability may be lost.

POTENTIAL ADVERSE EFFECTS

The following potential adverse effects may arise during and after implantation of a PCD device: myocardial irritability at implant, which might cause premature ventricular contractions (PVCs), supraventricular tachycardia, or fibrillation; cardiac tamponade or loss of sensing due to perforation of the myocardium at implant; acute hemorrhage due to venous perforation; infection; thrombus formation and subsequent pulmonary embolization caused by the presence of intravascular leads; loss of system function due to battery failure or other component failure; inability to reprogram the pulse generator because of programmer failure; false sensing, inappropriate pulsing, and/or inhibition of normal electrical conduction due to dislodged or fractured leads, case fracture, or electronic component failure; interruption of desired function due to electrical or magnetic interference, including nuclear magnetic resonance (NMR) and diathermy and lithotripsy when used near the site of the pulse generator and leads, and system failure due to ionizing radiation; erosion or extrusion of the pulse generator; fibrotic tissue growth; fluid accumulation; keloid formation; and formation of hematomas or cysts.

EFFECTS OF ELECTROMAGNETIC INTERFERENCE

The Model 7217B PCD device is designed to limit the effects from most common sources of electromagnetic interference (EMI). Because many forms of EMI exist, it is impossible to characterize all of them here. In general, VT and VF Detection should, if possible, be programmed OFF before subjecting the patient to procedures that induce strong electromagnetic fields.

Paired sensing between the PACE/SENSE and SENSE2 leads makes the Model 7217B PCD device relatively insensitive to signals of non-cardiac origin. It is important to maintain a distance no greater than one (1) cm between the two electrodes to minimize EMI effects. The patient should be advised to avoid strong electromagnetic fields such as those listed in Table 8. Such signals could be interpreted by the device as being of cardiac origin and be detected as a tachyarrhythmia with subsequent delivery of VT or VF therapies.

64

7217B NTL p82-94/MMC 10/5/93 9:39 PM Page 87

Table 8. Potential Complications

Source	Effects/Precautions
Standard fluoroscopy radiation for imaging	No Effect
Microwave diathermy/ovens	No Effect[1]
Therapeutic diathermy	Heating of circuitry. Must be avoided directly over the device; program VT/VF Detection OFF.
Transthoracic defibrillation	Effectiveness of transthoracic defibrillation may be affected by the implanted PCD system; possible circuit damage or loss of output if ≥ 400 J or < 15 cm from the PCD device; increased pacing threshold; decreased R-wave amplitude; resetting of programmed parameter values (see "Power On Reset" on page 82).
Direct defibrillation	Effectiveness of direct defibrillation may be affected by the implanted PCD system; potential circuit damage to the PCD device, loss of output, increased pacing threshold, decreased R-wave amplitude, resetting of programmed parameter values. Avoid direct contact of the paddles with the exposed coils of the patch electrodes.
Electrosurgical cautery	Possible triggering of VT/VF detection and/or therapies; within 15 cm of the PCD system, the complications may include: potential circuit damage to the PCD device, loss of output, increased pacing threshold, decreased R-wave amplitude, or resetting of programmed parameter values. Program VT/VF Detection OFF to avoid inadvertent detection.
Ionizing radiation	Possible damage to circuitry. Should be avoided or device shielded; see "Hospital or Medical Environment." May mimic R-waves and inhibit output or initiate VT/VF detection and therapies. Program VT/VF Detection OFF to avoid inadvertent detection.
Domestic electrical equipment, car engine, airport screening equipment	No adverse effect with conventional, properly grounded and operating devices. However, excessive levels of EMI may cause VT/VF detection.
Pulsed energy; leakage current	May mimic R-waves and inhibit output or cause VT/VF detection.

1. Up to 200 Volts peak/meter.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 88

Potential Complications (Continued)

Source	Effect/Precautions
Continuous strong interference	May mimic R-waves and inhibit output or cause VT/VF detection.
Continuous strong magnetic field	Undesired suspension of VT/VF detection; possible damage to PCD circuitry, if charging occurs.
Metal portions of the electrodes touching each other	A short circuit may occur during defibrillation or cardioversion resulting in permanent damage to the device's high-energy output circuitry.

Effects of Electrosurgical Cautery and Defibrillation

The use of electrocautery (within 15 cm) or direct defibrillation may cause permanent damage to the device.

Under certain conditions, the use of direct defibrillation or electrosurgical cautery in the vicinity of a Model 7217B PCD System (i.e., device and lead/electrodes) may cause the device to be set to its reset parameter values (see Table 4 in "General Device Information").

Program VT/VF Detection OFF during electrosurgical cautery to avoid triggering of VT/VF therapy.

Following the use of direct or transthoracic defibrillation or electrosurgical cautery, interrogate the device and print a full summary to verify and document that the programmed status of the device is as desired.

NOTE: Always interrogate the device at the beginning and end of each follow-up session and print a full summary to verify and document that the programmed status of the PCD device is as desired.

Hospital or Medical Environment

Exposure to normal diagnostic levels of x-ray and fluoroscopic radiation should not affect the Model 7217B PCD device.

The Model 7217B PCD device SHOULD NOT BE DIRECTLY IRRADIATED by therapeutic levels of ionizing radiation (such as produced by cobalt or linear accelerators used for cancer treatment) because of risk of permanent damage to the device's circuitry. If such therapy is required in the vicinity of the device, the device should be shielded (with VT/VF detection OFF) and its operation and various functions confirmed following treatment.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 89

Home or Job Environment

The Model 7217B PCD device should not be affected by the normal operation of electrical equipment such as household appliances, electrical machine shop tools, microwave ovens, spark-ignited internal combustion engines, radio frequency transmitting systems, or microwave frequency transmitting systems.

NOTE: Such effects will normally not be observed if proper electrode spacing (i.e., no greater than 1 cm between the PACE/SENSE and SENSE2 electrodes and with the corresponding leads routed together) is provided at implant.

- Medtronic should be consulted when device wearers will be in areas where contact with current-carrying conductors is possible or when they must come near high-powered, electromagnetic fields radiated by arc-welding units, induction furnaces, resistance welders, etc.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 90

GENERAL WARNING

The Medtronic® Implantable Pacer Cardioverter Defibrillator Device (the "Device") and the Medtronic Implantable Leads (the "Leads") are implanted in the extremely hostile environment of the human body. This environment places severe limitation on the design and function of the Device and Leads. These limitations unavoidably reduce the effectiveness and longevity of the Device and Leads despite the exercise of due care in design, component selection, manufacture, and testing prior to sale.

The Device includes a nonseparable power source that will ultimately cease to function due to exhaustion or premature failure thereby necessitating removal of the Device. The Leads are necessarily very small in diameter and very flexible, which unavoidably increases the likelihood of breakage or breach of their insulation. Other reasons for failure of the Device or Leads include, but are not limited to: body rejection phenomena; physiological variations in patients; medical complications, including antiarrhythmic drugs; Lead displacement; Lead fracture; fibrotic tissue formation; erosion of the Device or Lead through body tissue; infection; perforation of an artery or heart; random component failure; or interference from transmitters, tools, appliances, instruments, equipment, electrocautery, external defibrillators or other devices that use electricity, ionizing radiation, or electromagnetic wave transmission.

Complications that may be associated with the use of the Device and Leads include, but are not limited to: failure to detect ventricular tachycardia or ventricular fibrillation; failure to terminate ventricular tachycardia or ventricular fibrillation; delivery of a pacing or shock therapy when no ventricular arrhythmia is present, which could precipitate an episode of ventricular tachycardia or ventricular fibrillation; acceleration of a ventricular arrhythmia; failure to capture after a shock delivery; constrictive pericarditis; discomfort or pain during or following the delivery of electrical shock; or tissue or muscle burns at the site of the electrodes.

Consequently, no representation or warranty is made that failure or cessation of function of the Device or Leads will not occur, that the body will not react adversely to the implantation of the Device or the Leads, that medical complications will not follow the implantation of the Device or the Leads, that the Device and Leads will effectively restore adequate cardiac function, or that implantation of the Device and Leads will prevent sudden death. See the Medtronic Warranty packaged with the product for the terms and conditions of the warranty.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 91

GLOSSARY OF TERMS

The following definitions and/or descriptions are used in this manual.

Anode: Positive "pole" of the current pathway. PULSE1 and/or PULSE2 are the anodes for delivery of cardioversion and defibrillation therapies.

Auto-Adjusting Sensitivity: The device automatically adjusts the programmed sensitivity to a less sensitive value following signal detection on the sensing leads. This prevents the sensing of T-waves when sensitive thresholds are used.

Acceleration: The criteria for determination that a VT has accelerated after delivery of a therapy. Acceleration is defined as a decrease by 60 ms or more in the average cardiac cycle length from the initial VT detection cycle length.

Automatic: When the desired detection and therapy are programmed ON, the device delivers the therapy (without manual intervention) after all detection criteria are met.

Blanking Period: The period during which the PCD device does not sense events. Blanking periods occur after each paced, sensed, or therapy event and during and after a charging period is completed.

Burst: A VT therapy in which the device delivers a sequence of rate-adaptive, equal-interval pulses. The first pulse in the sequence is delivered at a programmable percentage of the tachycardia cycle length. Subsequent pulses in the same sequence are delivered at this same interval.

Cancel Magnet: A programming command that overrides the effect (on VT and VF Detection) of positioning a programming head over the device. This command reinstates automatic VT and VF Detection while the programming head is in place.

Cardioversion: Describes the VT therapy type in which the PCD device delivers a programmable pulse that is synchronized to a ventricular sensed event.

Cathode: Negative "pole" of the current pathway. COMMON is the cathode for delivery of cardioversion and defibrillation therapies.

Charge: A programming command that allows the manual initiation of the capacitor charging cycle. The length of this cycle is an indication of the condition of the PCD device battery.

Charge Circuit Inactive: A change in device function after three consecutive Charging Periods are equal to 35 seconds. In this state, the device disables:

- All automatic VT and VF Detection and Therapies,
- Programmer-initiated therapies (except Emergency Burst Pacing),
- Programmer-initiated EPS, premature stimuli, and fibrillation stimuli,
- Programmer-initiated Charging Periods.

Charging Period: The period during which the PCD device stores the programmed energy (charge) in capacitors so that it can rapidly deliver a cardioversion or defibrillation therapy.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 92

Committed: Once a charging cycle is initiated for defibrillation therapy, a shock will be delivered. The therapy may be aborted by applying a magnet; however, timing of magnet application will determine whether therapy is aborted.

COMMON: The electrode that serves as the cathode for cardioversion and defibrillation therapies, and as the anode for pacing therapies.

Current Pathway: The path followed by a Cardioversion or Defibrillation pulse(s) when discharged across cardiac tissue, i.e., between an anode and cathode.

Defibrillation: A therapy consisting of electrical shock to terminate ventricular fibrillation. The device attempts to synchronize the shock to a ventricular depolarization, and if unsuccessful, delivers the shock asynchronously. Automatic VF Therapy can be programmed up to a series of four attempts to terminate a VF episode.

Detection: The condition in which the device has determined the presence of electrical events that fulfill all programmed VT or VF criteria.

Disabled: A permanently programmed state in which detection and/or therapies are not available (OFF condition). These functions can only be re-enabled via a programming sequence.

Dump: A programming command that discharges the manually-charged capacitor into a load circuit in the device.

Effective Therapy: The PCD device considers a VT or VF therapy effective if, after the therapy, the device recognizes the termination of the episode prior to redetection, i.e., the continuation of the original arrhythmia.

EGM (Electrogram): The signal, transmitted via telemetry, of an electrogram taken from the device's lead system.

Elective Replacement Indicator: The telemetered battery voltage at which replacement of the device is recommended. It does not indicate that the device has altered its operation in anyway.

Emergency-VVI: A programming step that allows quick access to manual initiation of Defibrillation, Burst, Cardioversion, or VVI Nominal Therapy.

Enable: Allows or turns ON the function: e.g., allows VT and VF Detection and Therapies to carry out the designed capacity for detecting and terminating VT/VF episodes.

ETCD: External Tachyarrhythmia Control Device.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 93

Fibrillation Detection Interval (FDI): The interval in milliseconds that measured cardiac intervals must be less than or equal to in order to meet the ventricular fibrillation detection criteria.

Interval Criterion: The programmable VT Detection Criterion that is designed to detect a sustained high ventricular rate by measuring each cardiac cycle length and comparing it to the programmed Tachycardia Detection Interval.

Interval Stability Criterion: The programmable VT Detection Criterion that allows the PCD device to screen out irregular ventricular rhythms and/or unstable VTs.

Marker Channel: A programmer-generated set of symbols that allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

Number of Intervals to Detect (NID): The programmable number of measured cardiac intervals that must meet the FDI or TDI criteria for detection to occur. Displayed on the programmer screen as #INT.

Non-Committed: Post completion of charging for cardioversion, the device attempts to confirm the presence of VT and synchronize to an R-wave; if this is not possible, therapy will not be delivered.

Onset Criterion: The programmable VT Detection Criterion that permits the PCD device to differentiate between a sudden or abruptly starting tachycardia and one with a gradually increasing rate such as sinus tachycardia.

Paced Events: Output pulses (of pacing energy levels) from the PCD device.

Pacing Therapies: Two VT therapies, Burst and Ramp, are pacing therapies designed to deliver pulses at pulse widths and amplitudes the same as those programmed for bradycardia therapy.

PCD Ineffective: The PCD device is considered ineffective for VT or VF if, after all therapies have been delivered, the device redetects the arrhythmia prior to recognition of the episode's termination.

Potential Loss of Function Indicator: The telemetered voltage at which immediate replacement of the PCD device is recommended. In this situation the potential for altered or loss of function is present.

PULSE1, PULSE2: The defibrillation electrodes that serve as anodes for cardioversion and defibrillation therapy.

Ramp: A VT Therapy in which the device delivers a sequence of rate-adaptive, decreasing-interval pulses. The first interval is a programmable percentage of the detected VT cycle length. Each subsequent interval is decremented from the preceding interval by a programmable value. For each sequence the device automatically increases the number of pulses by one.

Redetection: After the delivery of VT/VF Therapy the device monitors the cardiac cycle length for continued fulfillment of the programmed detection criteria. Fulfillment of this criteria (redetection) is required before the next therapy will be delivered.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 94

Refractory Period: The period after paced, sensed, or therapy events during which events are not used for detection, synchronization, etc., but are used to restart a blanking period. The PCD device can sense events during this time, but not during the related blanking period. Events sensed during the refractory period are called "refractory sensed events."

Rounding: When attempting to detect a tachyarrhythmia, the PCD device rounds down to the nearest 10 ms while measuring the cardiac cycle length. However, it rounds up or down to the nearest 10 ms interval when using the measured interval to average or calculate percentages of intervals, e.g., during Burst or Ramp Therapies or when the Onset Criterion is active.

Sensed Event: The recognition by the PCD device circuitry of electrical activity on the paired leads (PACE/SENSE to SENSE2) that exceeds the programmed sensitivity threshold. Sensed events are either refractory sensed events or non-refractory sensed events, i.e., events sensed outside a refractory period. Non-refractory sensed events may also be categorized as VT, VF, or normal sensed events.

Sequence: The programmable feature that indicates the number of attempts that will be made by a given Ramp or Burst therapy to terminate the tachycardia.

Sequential Pulse Cardioversion or Defibrillation: The programmable therapy designed to terminate a VT/VF episode, consisting of two high-voltage pulses delivered one after the other across two different pathways.

Simultaneous Pulse Cardioversion or Defibrillation: The programmable therapy designed to terminate a VT/VF episode, consisting of two high-voltage pulses delivered at the same time across two different pathways.

Single Pulse Cardioversion or Defibrillation: The programmable therapy designed to terminate a VT/VF episode, consisting of one high-voltage pulse delivered across one pathway.

Suspend: Temporary inactivation of detection functions by placing the programming head over the device. Cancel Magnet or lifting the programming head reactivates detection if it was previously programmed ON. Detection functions are also suspended after all therapies are delivered.

Synchronization Sequence: In both Cardioversion and Defibrillation Therapy, the process conducted after the completion of charging when the PCD device attempts to identify the leading edge of an R-wave or ventricular event with which to synchronize the delivery of a high-energy output. In Cardioversion therapy, this period is also used to confirm the continued presence of the VT.

7217B NTL p82-94/MMC 10/5/93 9:03 PM Page 95

Tachycardia Detection Interval (TDI): The interval in milliseconds that measured cardiac intervals must be less than to meet the ventricular tachycardia detection criteria. Note: The intervals must also be greater than the FDI.

Termination: The PCD device considers a VT of VF episode "terminated" whenever it detects eight consecutive cardiac cycles longer than the TDI or FDI, respectively.

Therapy Type: Defines the kind of delivered therapy, i.e., Burst, Ramp, Cardioversion, or Defibrillation.

Therapy Sequence: A single attempt to terminate a VT with pacing level stimuli. The term applies to VT therapy types in which a single therapy can consist of a programmable number of Burst or Ramp sequences.

Therapy: The device operation to treat a detected VT or VF. A single therapy consists of a cardioversion or defibrillation shock or a sequence of pacing level treatments, i.e., Burst or Ramp.

VF Episode: The period during which the device considers VF in progress, i.e., from the time of initial VF detection until the criteria for VF termination are recognized by the PCD device.

VT Episode: The period during which the device considers VT in progress, i.e., from the time of initial VT detection until the criteria for VT termination are recognized by the PCD device.

SPECIFICATIONS[a,b]

Programmable Functions	Capability	Increments	Programmer Default[c]	Tolerance	Other Notes
Sensing/Pacing					
Mode	VVI				Only mode available
Pacing Rate[d]	30-64, 65, 66-82, 85, 86, 88, 90 ppm	2 ppm	65 ppm	± 1 ppm	
Pulse Width	0.03–1.59 ms	0.03 ms	0.49 ms	– 0.0, + .03 ms	
Sensitivity[e,f]	0.3–2.4 mV	0.3 mV	0.3 mV	± 0.15 mV ± 0.20 mV ± 0.25 mV ± 0.40 mV	For 0.3 mV For 0.6 mV For 0.9–1.5 mV For 1.8–2.4 mV
Pulse Amplitude	2.8 and 5.4 V		5.4 V	2.5 & 5.2 V min	
Refractory After Pace	320–480 ms	40 ms	320 ms	– 20, + 0 ms	
VT Detection					
Enable	ON/OFF		OFF		
VT Detection Interval[g]	280–600 ms	10 ms	400 ms	± 1 ms	TDI should be at least 40 ms longer than FDI
Number of Intervals to Detect	4-52	4	16		NID value applies to all VT Detections
Onset Criterion	ON/OFF		OFF		
R-R Percent[g]	56–62, 66–87, 91–97%	3%	81%	± 0.5%[h,i]	
Onset Counter	ON/OFF		OFF		
Interval Stability[g]	OFF, 30–130 ms	10 ms	OFF	± 1 ms[h]	

a. Due to Medtronic's continuing deveopment, it is not possible to list all currently available programming configurations. See the appropriate Medtronic programmer manual for specific details.
b. Parameter and tolerance values apply at 37° C and 510 ohm load at time of manufacture. Values may vary depending on the specific test procedures used.
c. Programmer default values are associated with the Model 9788 MemoryMod.
d. Escape interval equals pulse interval (–10, + 50 ms).
e. With a 40 ms sine^2 waveform.
f. When using the Cenelec waveform, the rated sensing threshold value will be 1.5 times the rated sine^2 sensing threshold value.
g. With a periodic (constant amplitude and wave shape) signal.
h. Does not include an additional (-0, +10 ms) rounding tolerance associated with each interval measurement.
i. Does not include an additional ± 5 ms rounding tolerance associated with an R-R average calculation.

Programmable Functions	Capability	Increments	Programmer Default	Tolerance	Other Notes
VF Detection					
Enable	ON/OFF		OFF		
VF Detection Interval[a,b]	240-400 ms	10 ms	320 ms	± 1 ms	FDI should be at least 40 ms less than TDI
Number of Intervals to Detect	6-30	6	18		
VT Therapies	0-4				
Burst					
Enable	ON/OFF		OFF		
Number of S_1 Pulses	1–15	1	6		
S_1–S_1 Interval	50–62, 66–87, 91–97%	3%	84%	± 0.5%[c]	
Number of Sequences	1–15	1	5		
Decrement per Sequence	0–40 ms	10 ms	10 ms	± 1 ms	
Minimum Pulse Interval[d]	150–300 ms	10 ms	200 ms	± 1 ms	
Ramp					
Enable	ON/OFF		OFF		
Initial Number of S_1 Pulses	1-15	1	5		
First R–S Interval	50–62, 66–87, 91–97%	3%	97%	± 0.5 %[c]	
Decrement per Pulse	0–40 ms	10 ms	10 ms	± 1 ms	
Number of Sequences	1–15	1	8		
Minimum Pulse interval[d]	150–300 ms	10 ms	200 ms	± 1 ms	

a. With a periodic (constant amplitude and wave shape) signal.
b. When VF Detection is enabled, the programmed setting for this parameter serves as the minimum interval to identify a VT event.
c. Tolerance does not include rounding tolerances associated with the R–R interval measurement (–0,+10 ms), R–R average calculation (± 5 ms), and the stimulation interval calculation (± 5 ms).
d. The Minimum Pulse Interval selected applies to both Burst and Ramp therapies and is used for all programmed therapies and sequences.

Re: Transvene Lead System, PMA Amendment
(Document Control Number P920015)

A031

The purpose of this submission is to respond to the deficiencies described in FDA's letter, dated March 17, 1993, see Attachment 1. Deficiency responses are presented in Attachment 2. An updated Summary of Safety and Effectiveness is provided in Attachment 3.

Information provided in this amendment includes clinical experience of 757 patients through February 1, 1993. Additional information is provided on virtually all clinical Transvene system implants, N = 1330, relative to patient complications and observations (including lead dislodgements), patient deaths and survival. This is provided in deficiency response #8. Again, the data cutoff date for these 1330 patients is February 1, 1993. A stand-alone, Clinical Summary Report is provided in Attachment 4 for convenient reference.

Clinical data presented in this amendment continues to demonstrate the PCD Transvene system performs as specified and is, therefore, safe and effective for its intended use. Results include 99.3 percent survival from SCD at one year. Additionally, Transvene system perioperative mortality and hospital stay compares dramatically to that of epicardial systems, 0.7% mortality and 7 days in hospital, versus 5.3 percent mortality and 11 days in hospital, respectively.

Copies of Transvene labeling (technical manuals) are provided in Attachment 5 for reference.

The existence of this PMA Amendment and the data and other information it contains are confidential, and the protection afforded to such confidential information by 18 USC 1905 and other applicable laws is hereby claimed.

Three copies of this PMA Amendment are provided. Should additional information be required by the Agency, please contact the undersigned.

Sincerely yours,

MEDTRONIC, INC.

RE: P920015
Transvene™ Lead System
Filed: April 1, 1992
Amended: September 21, 1992

Dear Ms. Marrone:

The Center for Devices and Radiological Health (CDRH) of the Food and Drug Administration (FDA) has completed an initial scientific review of the above referenced premarket approval application (PMA). We regret to inform you that on the basis of this review, we have concluded that the PMA lacks information needed to complete the review and determine whether there is reasonable assurance that the device is safe and effective for its intended use.

We recognize the potential public health significance of this device and acknowledge the separate discussions underway to expedite the review. However, because of this lack of information, review of the PMA cannot continue and, accordingly, we have listed the following significant deficiencies which require the responses as indicated:

1. To clearly establish the purpose of the clinical data in the PMA application, please provide the following:

   a. the hypothesis and the objectives of your clinical study;

   b. a discussion of (i) how your clinical study addresses the use of a control, which is relevant to all clinical studies, (ii) the appropriateness of the AICD™ as a historical control, and (iii) your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;

   c. the endpoints of your study; and

   d. how the data provided in the PMA application support the specified endpoints.

3

2. Based on data provided in your PMA application, please prepare table(s) which include a side-by-side comparison of the PCD® Transvene™ and the PCD® Epicardial System and the PCD® Transvene™ and Ventak P AICD™ populations. The table must also include the inclusion and exclusion criteria which were used for each study. You must include a discussion of how these data may or may not represent a valid comparison, and other comments which justify and support the use of these groups as controls.

3. An update of the PMA clinical study population must be provided. The update must include the data as presented in the PMA application, and must include the clinical experience in the use of the new anchoring sleeves, which are aimed at decreasing the incidence of dislodgement, and a summary of the clinical experience (spontaneous treatment efficacy of ventricular tachycardia (VT) and ventricular fibrillation (VF), observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.

4. Please provide a clear description of how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.

5. Of the 214 patients who did not meet the implant criteria and yet were implanted with the device, 170 patients had successful defibrillation with 24 Joules (J). Please provide an update of the clinical experience on these patients, as described in item 3 above. Also, please discuss how your proposed labeling will address this protocol deviation. Will implant criteria be changed?

6. There were 20 patients among the 214 who did not meet the implant criteria and were implanted without the 10 J safety margin. An update of the spontaneous episode experience in the treatment of VT and VF in these patients and the overall survival must be provided.

7. Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not meet the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.

8. Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update must include a summary of the clinical experience as referenced in item 3 above.

9. Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was

CC64

categorized as DFT and LED testing must be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.

10. There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. You must document that there were no significant differences between the scheme for performing DFT and LED testing between the Transvene™ and PCD® Epicardial patient populations, if that is the case.

11. Please elaborate on how the comparison of DFTs obtained from the PCD® Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (574 (75.3 percent)) in the Transvene™ study were programmed with the sequential pathway and 178 (23.4 percent) were programmed via the simultaneous pathway. The majority of the patients (496 (65.2 percent)) in the PCD® Epicardial study were programmed with the single pathway. Based on your PCD® Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ System versus the PCD® Epicardial System.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it is determined, and if the patients met the criteria.

14. Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes. What was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes per patient in this group?

15. On page 130, Table IF-4, you report that there were 5362 episodes of VT successfully terminated. On page 131, paragraph 2, you state that 25 patients experienced 45 (0.8 percent) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. You must clarify how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a table which includes a category of ineffective therapies with actual patient numbers and percentages. In addition, what assurance is there that an episode of supraventricular tachycardia or atrial fibrillation is not misinterpreted as VT or VF by the physician and considered a successful therapy?

16. Table IM-6, page 173 must be modified to include a column on inappropriate therapy or therapies delivered as the device was programmed so that the percentages add up to 100 percent.

17. On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8 percent. Please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The tables must include percentages with the representative numerical support.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

19. Please discuss how the 1 year sudden cardiac death survival, as reported in Table IF-2 page 128, was calculated. The numbers and an explanation of patient classification must be included. Was every patient included who had a prior cardiac arrest regardless of the arrhythmia?

20. On page 177, the number of patients must be provided so that the percentages and calculated p-values can be confirmed.

21. Table IV-C, page 649 of the original submission shows a comparison of patient variables for the three lead systems and provides p-values for the variables tested, but the hypothesis was not clearly stated. Please state the hypothesis and discuss the p-values obtained when reporting by primary indication, and the chi-square test of the data set and how it was computed.

22. For purposes of justification of data pooling and data analysis of Table IV-C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp.162-170).

23. You claim that confidence interval analysis was performed to compare the overall mortality of the PCD● and AICD™ populations. What was the confidence interval?

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

    a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

    b. a chi-square test of primary indication, using the StatXact computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD● and Ventak P populations are significantly different.

25. Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD® Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment of induced and spontaneous episodes with use of the algorithms must be discussed.

26. Please discuss the "device related" complications reported for the Transvene™ and the PCD® Epicardial System.

27. Please describe in detail the complications reported in the patients followed for a year.

28. There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the procedures for reduction in the number of infections? Please validate these procedures.

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads, and how your labeling assists in the selection of an entry site, must be provided.

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD® and Transvene™ leads) must be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices must be provided. The PMA application must document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD®.

31. Please discuss the circumstances surrounding the death of the patient who died (b)(4) months post implant. What did interrogation of the device reveal?

32. Of the perioperative deaths, how many devices were programmed OFF? Please discuss the circumstances surrounding each death. The number of perioperative deaths must be reported in a table and be identified as sudden cardiac, non-sudden cardiac or non-cardiac. Were there other deaths when the device was programmed OFF?

33. You state that there have been no reported patient deaths in the group with a 1 year sudden cardiac death survival and overall

actuarial survival of 100 percent. Does this include the perioperative deaths and the patients who have been followed out for a year?

34. Please provide an engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent.

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over a 12 month period would be sufficient? Describe how the full lead and different segments were flexed. Did you do a finite element stress analysis to validate the flex testing stress?

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.

37. A copy of the Summary of Safety and Effectiveness which includes the updated data must be provided.

This is to advise you that an amendment including the above requested information will be considered a major amendment and may extend the FDA review period up to 180 days. As provided by 21 CFR 814.37(c), you may decline to submit a major amendment requested by FDA in which case the review period may be extended for the number of days that elapse between the date of such request and the date that FDA receives the written response declining to submit the requested amendment.

As provided under 21 CFR 814.44(g), FDA will consider this PMA to have been voluntarily withdrawn if you fail to respond in writing within 180 days of the date of this request for a PMA amendment. You may, however, amend the PMA within the 180-day period to request an extension of time to respond. Any such request is subject to FDA approval and should justify the need for the extension and provide a reasonable estimate of when the requested information will be submitted. If you do not amend the PMA with in the 180-day period to (1) correct the above deficiencies, or (2) request an extension of time to respond and have the request approved, any amendment submitted after the 180-day period will be considered a resubmission of the PMA and will be assigned a new number.

You may amend the PMA to provide the above requested information (12 copies), voluntarily withdraw the PMA (3 copies), direct CDRH to complete processing the PMA without the submission of additional information (3 copies) or request an extension. The required copies of the amended PMA should include the FDA reference number for this PMA and should be submitted to the following address:

PMA Document Mail Center (HFZ-401)
Center for Devices and Radiological Health
Food and Drug Administration
1390 Piccard Drive
Rockville, Maryland 20850

Upon receipt of an amendment adequately addressing the above requests or a written response declining to submit the requested amendment, CDRH may schedule an advisory panel meeting at which your PMA will be reviewed. You will be notified of the location and date of this meeting should one be necessary. In order to provide adequate time for CDRH and advisory panel review, information received by FDA less than 6 weeks in advance of any scheduled advisory committee meeting will not be considered or reviewed at the meeting and may delay consideration of your PMA until a subsequent advisory committee meeting.

If you have questions concerning this deficiency letter, please contact Doris Terry at (301) 427-1018 or Arnold Alpert, Ph.D., at (301) 427-1186.

Sincerely yours,

F. Alan Andersen

F. Alan Andersen, Ph.D.
Acting Director
Office of Device Evaluation
Center for Devices and
Radiological Health

1. **To clearly establish the purpose of the clinical data in the PMA application, please provide the following:**

   a. **the hypothesis and the objectives of your clinical study;**

   RESPONSE:

   The hypothesis and objectives of the Medtronic Transvene clinical study are as follows. Note that this has been presented in each clinical summary report provided to FDA over the past two years including our previous deficiency responses provided on September 18, 1992.

   Hypothesis

   The objectives of the Transvene clinical study, described below, are intended to demonstrate the hypothesis that the Transvene PCD system is safe and effective in treating VT and VF, versus the null hypothesis that the system is not safe and effective in the treatment of VT and VF tachyarrhythmias.

   Objectives

   The safety and efficacy of the Transvene system is/was determined by:

   - Evaluating the sensitivity and specificity of the PCD device with Transvene lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms.

   - Monitoring the efficacy of the PCD device with Transvene lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (successful termination/number of detected episodes with therapy delivered). Investigators are able to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely.

   - Evaluating the performance of the Model 6966, 6963 and 6999 Transvene leads.

- Estimating the one year SCD and overall survival of the patients implanted with the PCD® Transvene™ System.

- Monitoring the patient selection criteria and patient management methods required by the PCD device and Transvene leads.

- Evaluating the safety and effectiveness of the Model 5355 ETCD device when used during the implant procedure. Specifically, tachyarrhythmia episode induction, detection, termination and ease of use are analyzed.

- Evaluating the safety and performance of the Model 9710 programmer and the Model 9788 MemoryMod software cartridge in programming sensing and therapy parameters and the appropriate delivery of noninvasive electrophysiologic stimulation.

b. **a discussion of (i) how your clinical study addresses the use of a control, which is relevant to all clinical studies, (ii) the appropriateness of the AICD™ as a historical control, and (iii) your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;**

RESPONSE:

i. **how your clinical study addresses the use of a control, which is relevant to all clinical studies,**

Background

The PCD Epicardial System, is a tiered therapy device that, combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as

the PCD Transvene System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD Epicardial System and PCD Transvene System are identical except for the implanted defibrillation lead system. Thus the performance of the PCD device, and associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the lead system implanted may impact clinical outcome. This would include spontaneous VT/VF episode efficacy, complication/observation rates and patient survival.

The Use of a Control

Medtronic provides a comparison of the PCD Transvene System clinical experience to the reported PCD Epicardial System clinical experience. **A historical control comparison was performed using the Medtronic clinical database on the PCD Epicardial System since patients were being enrolled in the two studies concurrently and the patient indications, implant criteria and clinical data requirements were identical for the two patient groups.**

At the start of the PCD® Transvene™ System clinical study a randomized controlled study was not performed since the investigators felt strongly that it was not clinically appropriate to randomize to a surgical procedure when a less invasive implant procedure was available. The investigators believed that the ability for Medtronic to do a historical control comparison between the PCD® Transvene™ and PCD® Epicardial System would provide sufficient data to allow a comparison of the clinical outcome of the two patient groups. A historical comparison would be appropriate

A historical comparison to the Ventak-P Epicardial System was also feasible since it was the most similar system that was market released and the patient indications were similar to that of both the PCD® Transvene™ and PCD® Epicardial Systems.

The premise of the PCD® Epicardial and Transvene™ studies was to demonstrate that if a patient was evaluated at

implant and shown to meet implant criteria, that they would be reliably defibrillated over time, and therefore, have a high probability of survival from SCD regardless of which lead system or defibrillation pathway was chosen. The Epicardial System is a valid comparison since the same PCD® was used in both systems, the same indications were used, the same implant criteria, the same protocol and data requirements and the studies were performed concurrently at the same centers. There is no other system that is currently market released that is a better, or more applicable control. We have shown for both studies that freedom from SCD at one year is at least equivalent to that afforded by the commercially available AICD for patients who meet the implant criteria regardless of lead system. All of the transvenous defibrillation systems that are available are currently under investigation and, as such, limited or no data exists with which to compare our performance.

The investigators believe that there is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. For these patients, the PCD Transvene System is the only therapy available. Because of the surgical risks and postsurgical complications associated with epicardial lead system, implantation in the following patient groups may not be possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD System implant;

(2) patients with severe pulmonary disease who cannot tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection < 40%) who are at increased risk for perioperative mortality post a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, the PCD Transvene System is the only therapy available. The PCD Transvene System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient

groups. Because there is no need to open the chest of these patients, options for future therapy remain available; e.g. CABG is associated with decreased morbidity and mortality if there has been no prior open chest surgery. **Thus randomization would not be feasible or clinically or ethically appropriate in these patient groups.**

ii. **the appropriateness of the AICD™ as a historical control, and**

The AICD clinical experience was compared to that of the Transvene system, i.e., the AICD served as a control of sorts, because the AICD system **was the only commercially available, FDA approved ICD system,** at the time of our analysis and documentation of the PCD® Epicardial and Transvene™ clinical experience. The Ventak-P System was chosen since it was the most similar to PCD® and the patient indications were similar. For purposes of comparison, the Ventak-P epicardial system patient population described in the (Ventak-P) Summary of Safety and Effectiveness, P890061, dated May 2, 1991, was used. A copy of this summary was obtained through the Freedom of Information Act.

A detailed comparison has been provided in the Transvene PMA application and subsequent amendments. It is also provided in this amendment, see Deficiency Response Number 2.

iii. **your rationale for not using a concurrent control during an implantable cardioverter defibrillator (ICD) study;**

A concurrent market release control was not used because of the reasons previously stated in Deficiency Response 1.b.(i) and because another transvenous defibrillation lead system was/is not commercially available. Other manufacturers simply do not allow their systems, clinical or market release, to be used by competitors due to the need to protect trade secrets. A concurrent control was also not used because an appropriate historical control was available, that is, the PCD Epicardial System. The PCD® Epicardial System is an appropriate historical control. Since patients were being enrolled in the two studies concurrently, the patient indications, implant criteria and clinical data requirements were identical for the two groups.

Specifically, the PCD Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD Epicardial System and PCD Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD device and associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

Analysis provided in this clinical update, and also provided in previous Transvene PMA documents, shows that the incorporation the of nonthoracotomy defibrillation system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

This analysis is thoroughly discussed in this amendment. See Deficiency Response Number 1 and the Clinical Update.

c. the endpoints of your study; and

d. **how the data provided in the PMA application support the specified endpoints.**

RESPONSE:

The following is a description of the endpoints of the Transvene clinical study and how the data collected support these endpoints.

Endpoint: Freedom from sudden cardiac death (SCD) and all cause mortality as shown through one-year survival.

Endpoint: Treatment efficacy of spontaneous VT/VF episodes.

Data supporting these endpoints are as follows. (See also the Clinical Update included in this PMA amendment.)

Patient Deaths

- The estimated one-year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD™ patient population 98.0%.

- There have been no deaths due to a PCD Device malfunction.

- Overall survival at 93.3% is better than that afforded by the Ventak-P Epicardial System.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD™ system in the categories of ineffective VT/VF therapy, pocket infection and pocket erosion, and was lower than the AICD™ in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8% of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria

are appropriate and that the PCD Transvene System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD Transvene System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD Transvene System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD Transvene System.

PCD Transvene System Performance

- The PCD Transvene System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

Clinical Experience Summary Conclusions

The PCD Transvene System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The PCD Transvene System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the

perioperative and overall patient mortality as compared to the PCD Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of 7.6 days as opposed to a mean of 10.6 days ($p = 0.001$) for the PCD Epicardial System.

Medtronic asserts and the PCD Transvene investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

2. **Based on data provided in your PMA application, please prepare table(s) which include a side-by-side comparison of the PCD® Transvene™ and the PCD® Epicardial System and the PCD® Transvene™ and Ventak P AICD™ populations. The table must also include the inclusion and exclusion criteria which were used for each study. You must include a discussion of how these data may or may not represent a valid comparison, and other comments which justify and support the use of these groups as controls.**

RESPONSE:

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The Ventak-P Epicardial System provides cardioversion and defibrillation therapy for VT and hemodynamically unstable VT. However, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing due to the pain associated with cardioversion shock therapy. The need to incorporate programmability, multiple detection and therapeutic options has lead to the development of the PCD® Device.

However the Ventak-P Epicardial System and PCD® Epicardial System are implanted only with a defibrillation lead system requiring a thoracotomy. The PCD® Transvene™ System allows the implantation of an ICD System without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy.

In the PCD® Transvene™ System PMA Application a comparison of the PCD® Transvene™ System clinical experience was made to both the Ventak-P Epicardial System and the PCD® Epicardial System. (Reference: Clinical Experience Report Section X, Comparison to AICD Clinical Results and Section XI, Comparison to PCD® Epicardial System Clinical Results). A comparison to the Ventak-P Epicardial System was done because this was the only FDA approved ICD System available at the time of the original submission. A comparison to the PCD® Epicardial System was done since this system incorporated the same tiered therapy ICD Device as well as being a concurrent clinical study.

The comparison between the Ventak-P Epicardial System and the PCD® Transvene™ System was limited in scope due to the availability of clinical data from the Ventak-P Epicardial System Summary of Safety and

Effectiveness but included patient characteristics, implant defibrillation thresholds, incidence of spontaneous VT/VF episodes, incidence of complications and one year actuarial survival.

The comparison between the PCD® Transvene™ System and the PCD® Epicardial System included patient characteristics, implant data, implant defibrillation thresholds, programmed parameter status, spontaneous VT/VF episode efficacy, incidence of complications and observations and one year actuarial survival.

At the start of the PCD® Transvene™ System clinical study a randomized controlled study was not performed since the investigators felt strongly that it was not clinically appropriate to randomize to a surgical procedure when a less invasive implant procedure was available. The investigators believed that the ability for Medtronic to do a historical control comparison between the PCD® Transvene™ and PCD® Epicardial System would provide sufficient data to allow a comparison of the clinical outcome of the two patient groups. A historical comparison would be appropriate since patients were being enrolled in the two studies concurrently and the patient indications, implant criteria and clinical data requirements were identical for the two patient groups.

A historical comparison to the Ventak-P Epicardial System was also feasible since it was the most similar system that was market released and the patient indications were similar to that of both the PCD® Transvene™ and PCD® Epicardial Systems.

The **indications for the Ventak-P Epicardial System** are:

1. Patients who have survived at least one episode of cardiac arrest presumably due to hemodynamically unstable ventricular tachycardia unassociated with acute myocardial infarction; and

2. Patients who have experienced recurrent ventricular tachyarrhythmias in the absence of previous arrest and are inducible into sustained hypotensive ventricular tachycardia or fibrillation despite conventional antiarrhythmia drug therapy.

The patient **indications for the PCD® Transvene™ and PCD® Epicardial System** are as follows:

1. Patients who have survived at least one episode of cardiac arrest presumably due to a ventricular tachyarrhythmia not caused by an acute myocardial infraction; or

2. Patients with recurrent sustained ventricular tachycardia that remain inducible via programmed electrical stimulation or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

The **Ventak-P Epicardial System is contraindicated** in the following patients:

1. Patients who ventricular tachyarrhythmias may have a reversible cause;
2. Patients who require a pacemaker that causes Ventak-P pulse generator nondetection or oversensing;
3. Patients whose ventricular tachyarrhythmias occur so frequently that device's batteries would be depleted soon after implantation; and
4. Patients who are prone to supraventricular tachyarrhythmias despite conventional drug therapy.

The PCD® Transvene™ and PCD® Epicardial System are contraindicated in the following patient groups:

1. Patients with transient ventricular tachyarrhythmias due to reversible causes;
2. Patients with transient ventricular tachyarrhythmias due to other causes such as acute myocardial infarction; and
3. Sole use of detection and treatment of atrial arrhythmias.

The following tables provide a side-by-side comparison of the PCD® Transvene™ System to both the Ventak-P Epicardial System and the PCD® Epicardial System. These tables are identical to those presented in the PCD® Transvene™ System PMA application but have been updated to reflect clinical experience with the PCD® Transvene™ System with a data cutoff of 2/1/93. The clinical experience with the PCD® Epicardial System reflects a data cutoff of 1/5/93 and the Ventak-P Epicardial System clinical experience is that presented in the Summary of Safety and Effectiveness that is available via the Freedom of Information Act.

A comparison of the Ventak-P Epicardial System clinical experience and the PCD® Transvene™ System clinical experience indicates that the devices are being used in patients with similar cardiovascular disease history. There is a statistical difference in the primary indication for implant between the two systems. There were more patients that had Sudden Cardiac Death as their primary indication in the PCD® Transvene™ System population than the AICD Epicardial System population ($p = 0.001$).

Cox regression analysis was performed to see what effect gender, primary indication and system implanted (PCD® Transvene™ or PCD® Epicardial) had on survival outcome. This analysis showed that for overall

survival at one year the system implanted had an influence on the probability of survival but gender and primary indication had no influence.

Thus, since primary indication has no impact on survival outcome, the PCD® Transvene™ System and Ventak-P Epicardial System can be compared. There was a statistical difference (Confidence Interval Analysis) in one year overall survival between the PCD® Transvene™ (94.2%) and AICD Epicardial System (90.8%). This difference is due to the implanted defibrillation lead system.

The mean DFT value at implant of the PCD® Transvene™ System falls well below the maximum output (34J) of the PCD® Device and is comparable to that reported with the Ventak-P Epicardial System.

The percentage of patients receiving therapy from the PCD® Transvene™ System is comparable to that reported with the Ventak-P Epicardial System. However, greater than 90% of the VT episodes are treated by antitachycardia pacing in the PCD® Transvene™ System versus cardioversion shocks in the Ventak-P Epicardial System experience. This reduction in shocks is a clinical benefit to the patients.

The reported incidence of most complications is comparable between the two systems. The incorporation of programmable VT/VF detection has decreased the delivery of inappropriate therapy for sinus tachycardia and/or atrial fibrillation with a rapid ventricular response. The incorporation of programmable VT/VF detection and therapy algorithms has not resulted in an increase in reported complications.

The reported Sudden Cardiac Death survival rates in the two patient groups is comparable (PCD® Transvene™ System - 99.7%; Ventak-P System - 98.6%). This indicates that the programmable features within the PCD® Transvene™ System have improved the types of therapy available for the treatment of recurrent VT and VF while maintaining a positive impact on sudden cardiac death survival.

More importantly, the overall one year actuarial survival for the PCD® Transvene™ System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD® Transvene™ System patient population.

The PCD® Transvene™ System incorporates additional detection and therapy features as compared to market released Ventak-P Epicardial System and has been used in a comparable patient population. In that patient population the PCD® Transvene™ System has allowed for fewer

shocks to be delivered because of the antitachycardia pacing features, fewer cases of inappropriate therapy delivery due to programmable detection and a comparable sudden cardiac death survival rate.

In addition, the elimination of a thoracotomy for implant in the PCD® Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

A comparison of PCD® Transvene™ System clinical experience and PCD® Epicardial System clinical experience indicates that the devices are being used in patients with similar cardiovascular disease history. There is a statistical difference in the primary indication for implant between the two systems. There were more patients that had Sudden Cardiac Death as their primary indication in the PCD® Transvene™ System population than the PCD® Epicardial System population ($p = 0.002$). However, as with the Ventak-P Epicardial System analysis indicated that this difference in indication did not have an impact on patient outcome.

The mean DFT value at implant of the PCD® Transvene™ System falls well below the maximum output (34J) of the PCD® device and are comparable to those obtained with the PCD® Epicardial System.

The differences in PCD® device programmed status in the two groups is a reflection of the patients receiving the PCD® Transvene™ System and the defibrillation energy requirements of a nonthoracotomy lead system. However, despite differences in the programmed status, the PCD® device performed safely and effectively in both patient groups.

The spontaneous VT episode efficacy for the PCD® Transvene™ System was 98.4% which was comparable to that reported with the PCD® Epicardial System, 98.3%. The spontaneous VF episode efficacy for the PCD® Transvene™ System was 98.4% which again was comparable to that reported with the PCD® Epicardial System, 98.7%. Thus the incorporation of a nonthoracotomy lead system had no effect on the efficacy of the PCD® Device in detecting and terminating spontaneous VT/VF episodes.

The reported incidence of complications is comparable between the two systems. The reported incidence of observations was statistically lower in the PCD® Transvene™ System.

Finally, the reported Sudden Cardiac Death survival rates in the two patient groups is statistically the same (PCD® Transvene = 99.5%; PCD® Epicardial = 98.9%). However, there is statistical improvement in the overall survival in the PCD® Transvene™ System patient population. There was a significant improvement in overall survival in the patients

receiving a PCD® Transvene™ System. The Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD® Transvene™ System was 93.3%.

This is significantly improved as compared to the overall one year actuarial survival for the PCD® Epicardial System (88.6%) [p = 0.004]. This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD® Transvene™ System having a 0.7% perioperative mortality versus the a perioperative mortality of 5.3% in the PCD® Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

Comparison of the clinical performance and survival outcome of the PCD® Transvene™ System versus both the PCD® Epicardial and Ventak-P Epicardial Systems indicates that the PCD® Transvene™ Systems performs similarly while providing important patient benefit. The PCD® Transvene™ System eliminates the need for a thoracotomy for the implantation of defibrillation lead systems. This directly improves the overall patient survival by decreasing the perioperative patient morbidity and mortality when compared to the PCD® Epicardial System and Ventak-P Epicardial System. This is added benefit however is not gained at the expense the PCD® Transvene™ System efficacy in treating spontaneous VT/VF episodes when compared to the PCD® Epicardial System.

3. **An update of the PMA clinical study population must be provided. The update must include the data as presented in the PMA application, and must include the clinical experience in the use of the new anchoring sleeves, which are aimed at decreasing the incidence of dislodgement, and a summary of clinical experience (spontaneous treatment efficacy of ventricular tachycardia (VT) and ventricular fibrillation (VF), observations and complications, number of patient deaths and overall survival) of the patients followed for a year or more.**

RESPONSE:

A. The update of the PMA clinical study population is attached. This population consists of 757 patients entered into the Clinical Trial as of 6-24-92 and followed through 2-1-93 with a mean implant duration of 11.7 months.

B. Clinical Experience of Patients with Two Anchoring Sleeves

Analysis has been completed on 234 patients implanted with the Transvene system using leads that are packaged with two anchoring sleeves. **(NOTE: These 234 patients were enrolled in the Clinical Trial after 6-24-92 and are not included in the 757 patient population).** Table 3-1 contains a data summary for the 234 patients. This group of patients has similar characteristics to the 757 patient population in most areas with a slightly higher percentage of patients with VT reported as the primary indication for implant than the 757 group of patients (60.7% vs 49.8%).

PCD® Transvene™ System Data Summary of Patients with Two Anchoring Sleeves	
Number of Patients	234
Number, % Male Number, % Female	192 82.1% 42 17.9%
Mean Age	60.8 yrs
Primary Indication: SCD VT SCD/VT	 75 32.1% 142 60.7% 17 7.2%
Coronary Artery Disease	180 76.9%
Mean Ejection Fraction	33.1% (N=212)

Table 3-1: PCD® System Data Summary for Patients with Two Anchoring Sleeves

Of these 234 patients, 186 have completed their 1 month follow-up and 49 have completed their 3 month follow-up. There has been one lead dislodgement in this group of patients.

Since the introduction of the dual anchoring sleeve the incidence of lead dislodgement has been dramatically reduced.

C. Clinical Experience of Patients Followed For Greater Than or Equal To One Year

Table 3-3 provides a data summary on the patients followed for a year or more. This table includes patient characteristics, defibrillation pathway configuration, mean LED and DFT, spontaneous VT and VF experience and efficacy. The characteristics of this subset of patients are similar to the original 757 patient population. Patients followed for a year or more had a slightly lower percentage of patients having a history of coronary artery disease (69.2% vs 74.1%) and a slightly higher mean ejection fraction (38% vs 35.6%). The differences are small and are not suspected to have an impact on implant duration or survival. Note that since by definition all patients have been followed for at least one year, the overall survival rate and the sudden cardiac survival rate is 100% at one year.

PCD™ Transvene™ System Data Summary	
	Patients with 12 months of Follow-up
Number of Patients	393

Spontaneous VF: Number of Patients Number of Episodes % Success	 176 1105 98.6% (1090/1105)

Table 3-3: PCD™ System Data Summary - Transvene™ Patients with 12 month Follow-up - 2/1/93

201

There have been a total of 7 patient deaths reported in this subset of patients. The deaths occurred greater than 12 months from the date of implant. Table 3-4 summarizes how these patient deaths have been classified.

PCD™ Transvene™ System Summary of Death Classifications in Patients followed for a Year or more	
Classifications	**Number of Deaths**
Sudden Cardiac	0
Non-Sudden Cardiac	4
Noncardiac	3
TOTAL	7

Table 3-4: PCD™ Transvene™ System - Summary of Death Classifications - 2/1/93

Complications and Observations in the patients followed for 1 year or more

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, of the 393 patients with implant durations of greater than or equal to one year, there have been a total of 89 complications reported in 76 patients and 122

observations reported in 99 patients in the PCD™ Transvene™ System patient population. Thus, 19.3% (76/393) of the patients had a clinical event reported which was categorized as a complication vs 19.4% (147/757) in the overall population and 25.2% (99/393) of the patients had a clinical event reported which was categorized as an observation vs 23.8% (180/757) in the overall population.

Table 3-5 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System Reported Complications/Observations in Patients followed for 1 Year or more: By Category		
Category	**Complications**	**Observations**
	Num (% of Pts)	Num (% of Pts)
Increased Defibrillation Requirements	3 (0.8%)	2 (0.5%)
Inappropriate VF Therapy Delivery	-	10 (2.5%)

Total	**89**	**122**

Table 3-5: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table 3-6 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD® Transvene System Reported Complications/Observations in Patients followed ≥1 Year Lead Dislodgements <30 days and >30 days N=393			
Complications		Observations	
<30 days	>30 days	<30 days	>30 days
27 (6.9%)	29 (7.4%)	0 (0)	6 (1.5%)

Table 3-6: PCD Transvene System: Lead Dislodgements occurring <30/>30 days in patients followed for greater than or equal to one year as of 2/1/93

There have been a total of 29 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT or VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 29 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

In summary, this group represents the majority of the overall population and characteristics of the 393 patients with implant durations of greater than or equal to one year were similar to the overall population.

4. **Please provide a clear description of how you identified the "patient who did not meet the implant criteria." Please discuss your implant criteria and how implant testing attempted to satisfy protocol requirements.**

RESPONSE:

For purposes of the PCD® Transvene™ and Epicardial Systems, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less.

"Patients who did not meet implant criteria" were defined as:

- Patients who had less than 3 successful VF terminations at 18 Joules or less;
- Patients in whom the lowest energy of success was greater than 18 Joules;
- Patients in whom either 1 or 2 successful VF terminations with the final lead configuration were obtained at 18 Joules or less; and,
- Patients in whom ventricular tachycardia or ventricular flutter was induced at the time of implant.

The PCD® Transvene™ and Epicardial Systems were evaluated through successive inductions and treatment of ventricular tachyarrhythmias according to study protocol. The protocol asked for a minimum of 3 inductions of VF in order to demonstrate reliable defibrillation efficacy at 18 Joules. If the first lead system evaluated successfully defibrillated the patient three consecutive times at 18 Joules or less, the implant criteria would have been satisfied and the implant could be completed. Additional inductions were required if the first lead system was not efficacious at 18 Joules. Performing additional inductions to obtain a defibrillation threshold was **not** a protocol requirement. The attached figure represents the recommended Defibrillation Efficacy Protocol used in lead evaluation testing for the PCD® Transvene™ and Epicardial Systems.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) Patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) Patients with severe pulmonary disease who cannot tolerate prolonged anesthesia or an open chest procedure;

(3) Patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality post a thoracotomy procedure;

(4) Patients who may eventually require open chest procedures of treatment of their coronary artery disease or cardiac transplant.

For these patients, the PCD® Transvene™ System is the only therapy available. The PCD® Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, options for future therapy remain available; e.g. CABG is associated with decreased morbidity and mortality if there has been no prior open chest procedure.

The investigators felt that for these patients a 10 Joule safety margin between the lowest energy of success (24J) and the maximum output (34J) of the PCD® Device provided adequate defibrillation efficacy evaluation. The investigators used this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup, et al. The Implanted Defibrillator: Relation of Defibrillating Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology, 1985; 6:1315-1321. The investigators felt that for these patients the risk associated with not meeting the recommended implant criteria was outweighed by the benefit of not having to undergo an epicardial system implant with a thoracotomy approach and its associated morbidity and mortality.

To determine whether a patient can be defibrillated reliably with a particular lead system, VF must be induced and successfully terminated at least 3 times in 4 attempts with a stored output energy of 18 Joules or less. The following protocol should be followed in assessing defibrillation efficacy:

Defibrillation Efficacy Protocol
(b)(4)

(b)(4)

Lead system testing will be accomplished using an External Cardioverter/Defibrillator (ECVD), Model 2394 or Model 5355.

NOTE: The following precautions should be observed when initiating and treating episodes of ventricular tachyarrhythmias with the Model 2394 External Cardioverter/ Defibrillator:

5. Of the 214 patients who did not meet the implant criteria and yet were implanted with the device, 170 patients had successful defibrillation with 24 Joules (J). Please provide an update of the clinical experience on these patients, as described in item 3 above. Also, please discuss how your proposed labeling will address this protocol deviation. Will implant criteria be changed?

RESPONSE:

Table 5-1 provides the patient characteristics for 170 patients who did not meet the implant criteria but had successful defibrillation at 24 joules and received the PCD™ Transvene™ System.

PCD™ Transvene™ System Patients Meeting Implant Criteria vs 170 Patients with Successful Defibrillation at 24J		
Patient Characteristics		
Number of Patients	170	543
Mean Follow-Up	9.6 months	12.3 months
Male*	151 (88.8%)	422 (77.7%)
Female	19 (11.2%)	121 (22.3%)
Mean Age	59.8 yrs	59.4 yrs
Indication*		
SCD	63 (37.1%)	209 (38.5%)
VT	77 (45.3%)	78 (51.2%)
SCD/VT	30 (17.6%)	56 (10.3%)
Cardiovascular History		
CAD	137 (77.7%)	396 (72.9%) 173
Cardiomyopathy	58 (34.1%)	(31.9%)
Mean EF*	32.7%	36.3%
NYHA Class		
I	45 (27.6%)	164 (30.9%)
II	90 (55.2%)	278 (52.4%)
III	24 (14.7%)	82 (15.4%)
IV	4 (2.5%)	7 (1.3%)

* Statistically Significant ($p \leq 0.05$)

Table 5-1: PCD™ Transvene™ System: Patients Meeting Implant Criteria N = 170 Patient Characteristics - 2/1/93

There was a statistically significant difference in the number of males ($p=0.002$), the number of patients with the primary indication of VT ($p=0.032$), and the mean EF ($p=0.007$) between the groups above however these differences are not clinically significant.

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table 5-2. There were no statistical or clinically significant differences in outcome as observed below.

PCD™ Transvene™ System Patients Not Meeting Implant Criteria 170 Patients with Successful Defibrillation at 24J		
Implant Data		
Number of Patients	170	543
Spontaneous VT Episode Efficacy	98.5%	98.7%
Spontaneous VF Episode Efficacy	99.4%	98.7%
Number of Patient Deaths	11	37
Perioperative Mortality	0.6%	0.7%
One Year Survival		
Sudden Cardiac	99.4%	99.5%
Non-Sudden Cardiac	98.6%	95.8%
All Cardiac	98.0%	95.4%
Noncardiac	96.3%	98.5%
Overall	93.8%	93.2%

Table 5-2: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria N = 170 - Clinical Outcome - 2/1/93

Complications and Observations: Patients Not Meeting Implant Criteria N = 170

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Of the 170 patients with successful defibrillation at 24 Joules, as of February 1, 1993, there have been a total of 41 complications reported in 33 patients and 34 observations reported in 31 patients in the PCD™ Transvene™ System patient population. Thus, 19.4% (33/170) of the patients had a clinical event reported which was categorized as a complication and 18.2% (31/170) of the patients had a clinical event reported which was categorized as an observation. The percent of patients with complications reported in the overall population of 757 patients was 19.4% (147/757), the same percentage as in this subgroup of 170. There were 23.8% (180/757) of the patients in the overall population with reported observations, a slightly higher percentage than in this subgroup of 170 patients. Table 5-3 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with any of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

Table 5-3: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table 5-4 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days in the 170 patients.

PCD® Transvene System Reported Complications/Observations Lead Dislodgements <30 days and >30 days Patients Not Meeting Implant Criteria 170 Patients with Successful Defibrillation at 24J			
Complications		Observations	
Num (% of Pts)		Num (% of Pts)	
<30 days	>30 days	<30 days	>30 days
9 (5.3%)	14 (8.2%)	1 (0.6)	2 (1.2%)

Table 5-4: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 14 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In the overall patients population of 757, lead dislodgement was reported in 6.5% of the patients implanted for >30 days which is slightly lower than in this subset of patients, 8.2%, which are included in the analysis of the overall population. In all 14 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

In summary, there are no clinically significant differences in the characteristics and/or most importantly in outcome of the 170 patients

that did not meet implant criteria but were successfully defibrillated with 24 joules and those meeting implant criteria. Based on these data, the recommended defibrillation efficacy implant requirements will be revised to the following:

Two consecutive successful defibrillations with the final lead configuration with a stored output energy of 24 Joules or less; or

Three successful defibrillations in four attempts with the final configuration at a stored output energy of 24 Joules or less.

6. **There were 20 patients among the 214 who did not meet the implant criteria and were implanted without the 10 J safety margin. An update of the spontaneous episode experience in the treatment of VT and VF in these patients and the overall survival must be provided.**

RESPONSE:

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The mean ejection fraction of this group was 26.9%, indicating a more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting the recommended defibrillation implant criteria.

Of these 20 patients, VT or VF has been induced at chronic follow-up visits in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD® Transvene™ System was documented.

The overall spontaneous VT episode efficacy for the patient group was 98.9%. While the overall spontaneous VF episode efficacy for the patient group was 96.0%. Examination of the spontaneous VF episodes indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

There have been no patients in this patient population who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, both of which were classified as non-sudden cardiac secondary to end stage heart failure. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may be due to the lower mean ejection fraction and poorer cardiac status of this group.

The clinical outcome (which is summarized in the Table 4-1) of these twenty patients was not adversely affected by not meeting the recommended defibrillation implant criteria since there were no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

PCD® Transvene™ System Patients Not Meeting Implant Criteria Due to Patient Condition	
Number of Patients	20
Mean EF	26.9%
# Patients with Induced VT/VF	16 (80%)
Spontaneous VT Episode Efficacy	98.9%
Spontaneous VF Episode Efficacy	96.0%
One Year Sudden Cardiac Death Survival	100%
One Year Overall Survival	85.5%

Table 4-1: PCD® Transvene™ System: Patients Not Meeting Implant Criteria Due to Poor Patient Condition

7. **Table IK-4, page 151, compares the patients meeting the implant criteria to those who did not meet the criteria. However, many of the percentages were presented without numerical support. Please provide the appropriate numbers.**

RESPONSE:

The spontaneous VT and VF episode efficacy and perioperative mortality presented in table IK-4 are percentages, but the survival calculations are probabilities. The survival probabilities are calculated using a life-table survival analysis. For verification of survival probabilities, the data necessary to do calculations is available upon request. The following table is IK-4 with a June 24, 1992 data cutoff, providing you the additional numerical support for percentages where appropriate.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	Meeting Criteria	Not Meeting Criteria
Number of Patients	543	214
Number of Successful VT Episodes Number of VT Episodes Spontaneous VT Episode Efficacy	3619 3657 99.0%	1743 1773 98.4%
Number of Successful VF Episodes Number of VF Episodes Spontaneous VF Episode Efficacy	708 715 99.0%	258 260 99.2%
Number of Patient Deaths	18	4
Perioperative Mortality	4 0.7%	1 0.5%

Table IK-4: PCD® Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 6/24/92

8. **Please provide an update on the patients who are implanted with the Transvene™ System and were not counted in the PMA population. The update must include a summary of the clinical experience as reference in item 3 above.**

RESPONSE:

Overview of Clinical Experience for Transvene Population of 1330 Patients

This response covers a total of 1335 implants in 1330 patients of the PCD™ Device with the Transvene™ Defibrillation Lead System. The patients included in this report includes the 757 patients described in the original PMA application and an additional 573 patients that have been implanted in the U.S. from 6/25/92 to 2/1/93. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990.

The mean implant duration for this patient population is 8.0 months and ranges from implant to 37.4 months. The cumulative implant duration is 10,653.7 months.

The patient population (N=1330) enrolled in the clinical trial was predominately male (81.6%) with a mean age of 60.4 years. In half of the patients (54.5%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 34.7% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 10.8%. Coronary artery disease was the primary heart disease in 76.2% of the patient population with a mean reported ejection fraction of 34.3% Table 8-1 provides a data summary on these patients. Although there is a slightly higher percentage of patients with the primary indication of VT, 54.5% vs 49.8% (PMA patient population), there are no substantial differences or trends noted from the original PMA population.

PCD™ Transvene™ System Data Summary of Updated Population N = 1330	
Number of Patients	1330
Device Months Follow-up	10,653.7 mo
Mean Follow-up Time	8.0 mo
Maximum Follow-up Time	37.4 mo
Number, % Male Number, % Female	1085 81.6% 245 18.4%
Mean Age	60.4 yrs
Primary Indication: SCD VT SCD/VT	 462 34.7% 725 54.5% 145 10.8%
Coronary Artery Disease	1014 73.4%
Mean Ejection Fraction	1194 34.3%
Defibrillation Pathway: Sequential Simultaneous Single	 980 73.4% 341 25.5% 14 1.1%
Mean LED	16.4J (N = 1236)
Mean DFT	15.4J (N = 496)
Spontaneous VT: Number of Patients Number of Episodes % Success	 424 11577 98.1%
Spontaneous VF: Number of Patients Number of Episodes % Success	 427 2453 98.6%
One Year SCD Survival	99.3%
Overall Survival	93.0%

Table 8-1: PCD™ Transvene System: Data Summary - Updated Pts. (1330) - 2/1/93

Complications and Observations

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Of the 1330 patients, as of February 1, 1993, there have been a total of 225 complications reported in 195 patients and 275 observations reported in 228 patients in the PCD™ Transvene™ System patient population. Thus, 14.7% (195/1330) of the patients had a clinical event which was categorized as a complication and 17.1% (228/1330) of the patients had a clinical event which was categorized as an observation.

Table 8-2 summarizes the reported PCD® Transvene™ System complications and observations by category. In almost all categories, the percentage of patients in which a complication or observation was reported has decreased compared to the original PMA patient population of 757. The percentage of patients with lead dislodgements reported has substantially decreased from 12% with a complication to 8.8% and 1.6% with an observation to 0.9%. No new categories of complications or observations were reported. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System Reported Complications/Observations By Category N = 1330		
Category	**Complications**	**Observations**
	Num (% of Pts)	**Num (% of Pts)**
Increased Defibrillation Requirements	14 (1.1%)	8 (0.7%)
Inappropriate VF Therapy Delivery	-	17 (1.3%)
Inappropriate VT Therapy Delivery	-	68 (5.1%)
Loss of Capture	6 (0.5%)	16 (1.2%)
Oversensing	1 (0.1%)	83 (6.2%)
Undersensing	-	-
Skin Erosion	5 (0.4%)	1 (0.1%)
Pocket Infection	30 (2.3%)	12 (0.9%)
Seroma	10 (0.8%)	20 (1.5%)
Hematoma	12 (0.9%)	23 (1.7%)
Pneumothorax	2 (0.2%)	1 (0.1%)
Pacemaker Syndrome	-	2 (0.2%)
Perforation	7 (0.5%)	-
Subclavian Vein Thrombosis	1 (0.1%)	6 (0.5%)
Lead Fracture	9 (0.7%)	-
Subcutaneous Patch Crinkling	7 (0.5%)	5 (0.4%)
Early Device Explant	4 (0.3%)	-
Total Lead Dislodgement (n = 1330)	117 (8.8%)	12 (0.9%)
Total	**225**	**275**

Table 8-2: PCD Transvene System: Reported Complications/ Observations (n = 1330) - 2/1/93

Table 8-3 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days. As noted earlier, the percentage of patients in which a complication or observation regarding lead dislodgement was reported has decreased from the original PMA patient population of 757.

PCD® Transvene System Reported Complications/Observations Lead Dislodgements <30 and >30 days (N=1330)				
Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=1314	19 (1.4%)	13 (1.0%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 387	19 (4.9%)	11 (2.8%)	2 (0.5%)	2 (0.5%)
SVC Lead Dislodgement n=989	16 (1.9%)	36 (3.6%)	1 (0.1%)	6 (0.6%)
Total Dislodgement n=1330	57 (4.3%)	60 (4.5%)	3 (0.2%)	9 (0.7%)

Table 8-3: PCD Transvene System: Lead Dislodgements <30/>30 days (n=1330) - 2/1/93

There have been a total of 60 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 60 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD™ Transvene™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD™ System component, or as a result of a device induced arrhythmia, or an interaction between a PCD™ System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD™ System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD™ Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether

the PCD™ System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 68 patient deaths reported in the PCD™ Transvene™ System patient population. Table 8-4 summarizes how these patient deaths have been classified.

PCD™ Transvene™ System Summary of Death Classifications (n = 1330)	
Classifications	**Number of Deaths**
Sudden Cardiac	10
Non-Sudden Cardiac	37
Noncardiac	21
TOTAL	68

Table 8-4: PCD™ Transvene™ System - Summary of Death Classifications (n = 1330) - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD™ Transvene™ System.

Actuarial survival analysis on the PCD™ Transvene™ System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD™ Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD™ Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table 8-5. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.8% (10/1330) which is considerably less than the perioperative mortality for the PCD™ System with Epicardial leads (5.3% - 39/742).

PCD™ Transvene™ System One Year Actuarial Survival	
Sudden Cardiac Death	99.3%
Non-Sudden Cardiac	96.3%
All Cardiac	95.6%
Noncardiac	98.1%
Perioperative	0.8%
Overall	93.0%

Table 8-5: PCD™ Transvene™ System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD™ Transvene™ System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate the total patient group (n = 1330) is 99.3%. This is a marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

In conclusion, the data above for the 1330 patients implanted and followed through 2-1-93 is similar to the 757 PMA patient population as expected. Although lead dislodgement is not an unexpected complication and patients are routinely evaluated during follow-up procedures at follow-up visits, in order to minimize the incidence of lead dislodgement, the dual anchoring sleeve has been introduced and the incidence of lead dislodgement has drastically decreased. The one year actuarial survival results continue to be stable, above 99% for SCD and efficacy rates continue at greater than 98%.

9. **Based on your study protocol, please differentiate between defibrillation threshold (DFT) testing and lowest energy to defibrillate (LED) testing. Based on the individual patient report forms of the 757 patients, how many patients underwent what is described as DFT testing and how many had LED testing? Samples of the patient report forms showing the scheme of testing which was categorized as DFT and LED testing must be provided. Please discuss how the DFT and LED data were reported and presented in the PMA application.**

RESPONSE:

The study protocol asks the investigator to determine the efficacy of the implanted lead system with the external test device prior to connecting the leads to the implantable PCD® device. The minimum amount of testing required to demonstrate lead system efficacy is 3 of 4 successful defibrillations at 18 Joules. The protocol asks that investigators go beyond this minimal level and perform testing using a step down procedure. Investigators attempt defibrillation at energy levels lower than 18 Joules in order to establish a defibrillation threshold. In order to make defibrillation testing uniform among the investigators, the protocol asks that testing be done using a common step down protocol. This protocol is as follows:

(b)(4)

(b)(4)

All investigators were asked to perform this step down testing, but the investigator was allowed to stop the step down testing, or waive it completely, if, in the investigators opinion, the patient could not tolerate

additional VF inductions. Since testing did not always follow this step down protocol, two terms were developed to accurately report defibrillation efficacy, Lowest Energy of Defibrillation (LED) and Defibrillation Threshold (DFT). They are defined as follows:

Lowest Energy of Defibrillation (LED):
LED is defined as the lowest programmed energy that successfully defibrillated the heart with the implanted lead system.

Defibrillation Threshold (DFT):
DFT is defined as the lowest programmed energy which successfully defibrillated the heart provided there is a failure at an energy below the lowest success or a success at $\leq$ 5J.

Based on these definitions all patients with a DFT also have an LED but not every patient with an LED has a DFT.

Several examples of the type of data used in this analysis is presented below. The first example shows successful completion of the step-down protocol with the first lead system tested. By having a success at 5 Joules this patient has both a DFT and LED of 5 Joules. This example also shows the various codes used in this section of the data forms.

5. Lead Evaluation Log **DFT and LED = 5 Joules**

Lead System Number	Episode Number	Therapy Number	Induced Rhythm	Therapy Data*	Post Therapy Rhythm	
(b)(4)						

(b)(4)

The next example shows a failure at 5 Joules. This patient, therefore, has a DFT and LED of 10 Joules.

5. Lead Evaluation Log **DFT and LED = 10 Joules**

Lead System Number	Episode Number	Therapy Number	Induced Rhythm	Therapy Data*	Post Therapy Rhythm	
(b)(4)						

(b)(4)

The next example is one where the investigator decided to stop lead evaluation before reaching an energy low enough to demonstrate failure to defibrillate. The implant criteria was met since there was three successes at 18 Joules or less. Since a failure was never demonstrated, we are unable to calculate a DFT, only an LED. The LED in this example is 10 Joules.

5. Lead Evaluation Log **LED = 10 Joules**

Lead System Number	Episode Number	Therapy Number	Induced Rhythm	Therapy Data*	Post Therapy Rhythm	
(b)(4)						

(b)(4)

Typically, more than one lead system is evaluated. The lead systems are described on the previous page of the "Lead System Evaluation Data Form" and identified by number. Every induction and therapy delivered into the lead system is recorded on the "Lead Evaluation Log". This is an example of a difficult patient that required two modifications to the lead system before an efficacious system was found. This patient had an LED of 18 Joules and no DFT. Since defibrillation testing was not performed at an energy less than 18 Joules, a failure level was not established.

Maximum	34
Minimum	0.6
RV-CS-SVC: N	37
Mean	15.2
Std. Dev.	4.9
Maximum	34
Minimum	10

Table VID-8: PCD™ Transvene™ System - Lowest Energy of Defibrillation - 6/24/92

Seven-hundred-three (703) patients had at least one successful defibrillation with the lead system implanted during lead system testing. During the remaining 59 implant procedures (762-703=59) the patient either could not be induced into VF during implant lead testing, only V-Flutter or VT, or testing of the final lead system was waived due to patient condition.

A subset of patients were evaluated with the step-down protocol and either had a defibrillation failure at an energy below 18 Joules or was successful at 5 Joules. A defibrillation threshold (DFT) was calculated in this group of patients. This calculation was performed by Medtronic's statisticians from the information recorded on the study data forms. DFT is defined as the lowest programmed energy which successfully defibrillated the heart provided there is a failure at an energy below the lowest success or a success at $\leq$ 5J. There was no requirement to find the lowest DFT possible in a particular patient.

DFT's were obtained during 316 of the 762 implant procedures presented in this report. Table VID-9 on page 215 of the PMA clinical report contains the DFT's obtained during implant testing.

PCD™ Transvene™ System
Defibrillation Threshold (DFT)

(b)(4)

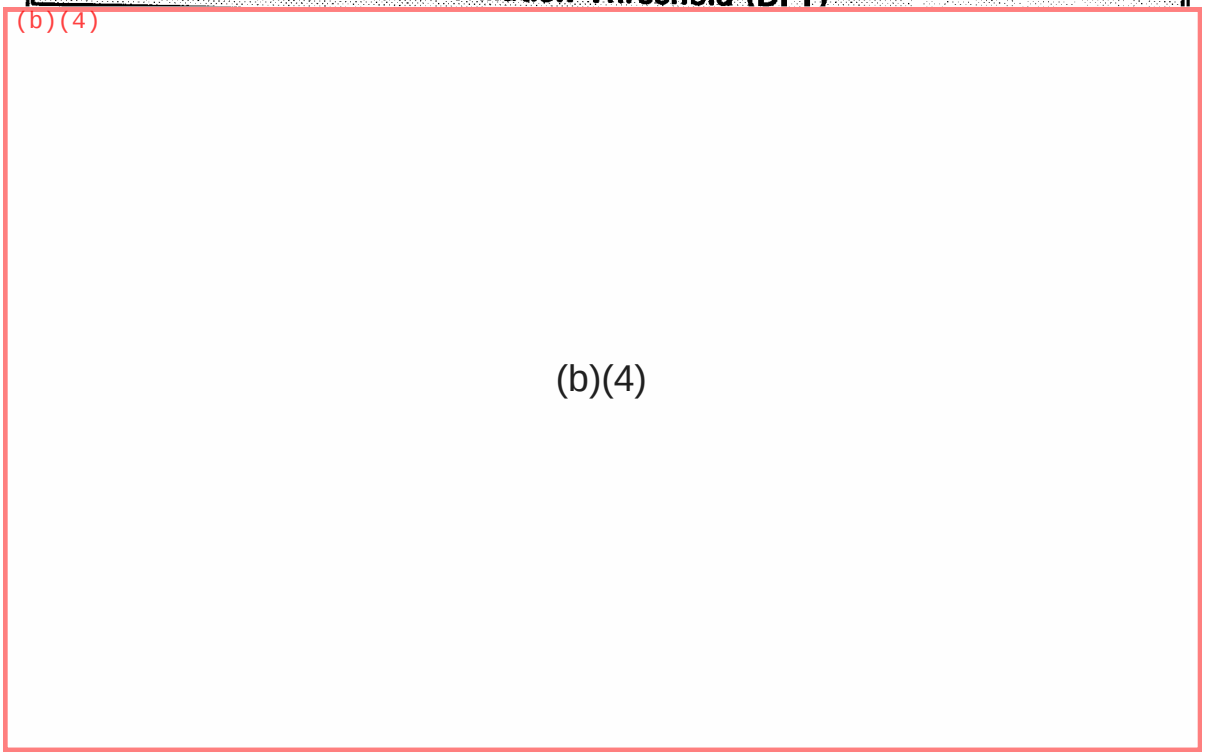

Table VID-9: PCD™ Transvene™ System - Defibrillation Threshold - 6/24/92

In summary the Lowest Energy of Defibrillation (LED) is defined as the lowest programmed energy that successfully defibrillated the patient with the implanted lead system. Defibrillation Threshold (DFT) is defined as the lowest programmed energy which successfully defibrillated the heart provided there is a failure at an energy below the lowest success or a success at $\leq$ 5J. An LED was determined during 703 of the 762 implant procedures included in the September 18, 1992 clinical update. In 316 of these implant procedures we were also able to calculate a DFT. Three-hundred-eighty-seven (387) (703-316=387) implant procedures had only an LED determined, since a failure level was never established.

10. **There is a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. How do you account for this difference? Was the DFT as reported and discussed for all lead configurations obtained using an identical or similar scheme? Please discuss. You must document that there were no significant differences between the scheme for performing DFT and LED testing between the Transvene™ and PCD® Epicardial patient populations, if that is the case.**

RESPONSE:

There was a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. Since there were no differences in the patient population implanted with any of the 3 lead configurations, this may be a configuration that results in lower DFTs than the other configurations. In theory, this may be due to better defibrillation current distribution throughout the myocardium. There is no intent to show that a lower DFT results in a better patient outcome. The premise of the PCD® Epicardial and Transvene™ studies was to demonstrate that if a patient was evaluated at implant and shown to meet implant criteria, that they would be reliably defibrillated over time, and therefore, have a high probability of survival from SCD regardless of which lead system or defibrillation pathway was chosen. We have shown that freedom from SCD at one year is at least equivalent to that afforded by the commercially available AICD for patients who meet the implant criteria regardless of lead system. As was described in Deficiency Response No. 5. Our data demonstrates that there is no difference in outcome between patients who met our 18J implant criteria (3/4 at $\leq$ 18J) or those with a 10J safety margin (at least one success at 24J). The DFT as reported for all Transvene™ and all Epicardial Systems was obtained using the same testing scheme. Please see Deficiency Response Number 9 for a thorough discussion of DFT and LED testing.

As previously discussed in the response to Deficiency #4, implanted defibrillation lead systems were evaluated through successive inductions and treatment of ventricular tachyarrhythmias according to study protocol. The protocol asked for a minimum of 3 inductions of VF in order to demonstrate defibrillation efficacy. The attached table represents the recommended Defibrillation Efficacy Protocol that was used to evaluate **all** lead configurations.

The recommended implant criteria and Defibrillation Efficacy Protocol was **identical** for both the PCD® Transvene™ and Epicardial Systems. References from the investigational plan (provided in IDE submissions for both systems) for the PCD® Transvene™ and Epicardial Systems are attached.

To determine whether a patient can be defibrillated reliably with a particular lead system, VF must be induced and successfully terminated at least 3 times in 4 attempts with a stored output energy of 18 Joules or less. The following protocol should be followed in assessing defibrillation efficacy:

Defibrillation Efficacy Protocol
(b)(4)

(b)(4)

Lead system testing will be accomplished using an External Cardioverter/Defibrillator (ECVD), Model 2394 or Model 5355.

NOTE: The following precautions should be observed when initiating and treating episodes of ventricular tachyarrhythmias with the Model 2394 External Cardioverter/ Defibrillator:

11. Please elaborate on how the comparison of DFTs obtained from the PCD® Epicardial Lead study and the Transvene™ study can be considered as a valid comparison in that the majority of the patients (574 (75.3 percent)) in the Transvene™ study were programmed with the sequential pathway and 178 (23.4 percent) were programmed via the simultaneous pathway. The majority of the patients (496 (65.2 percent)) in the PCD® Epicardial study were programmed with the single pathway. Based on your PCD® Epicardial study, please discuss the DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways.

RESPONSE:

The premise of the PCD® Epicardial and Transvene™ studies was to demonstrate that if a patient was evaluated at implant and shown to meet implant criteria, that they would be reliably defibrillated over time, and therefore, have a high probability of survival from SCD regardless of which lead system or defibrillation pathway was chosen. The Epicardial System is a valid comparison since the same PCD® was used in both systems, the same indications were used, the same implant criteria, the same protocol and data requirements and the studies were performed concurrently at the same centers. There is no other system that is currently market released that is a better, or more applicable control. We have shown for both studies that freedom from SCD at one year is at least equivalent to that afforded by the commercially available AICD for patients who meet the implant criteria regardless of lead system. All of the transvenous defibrillation systems that are available are currently under investigation and as such, limited or no data exists with which to compare our performance. A discussion of DFTs or energy requirements obtained with the use of the single defibrillation pathway versus the sequential and simultaneous pathways is found in the PCD® Epicardial IDE G870102. In Section VII, Page 25 of the Clinical Summary report, it was shown that the DFTs were similar. A copy of that page is provided here for your convenience. The two patch (single pathway) DFT mean was 10.5J. The three patch (sequential/simultaneous) DFT mean was 8.8J. There was no difference in the outcome of patients with either of the systems.

Table VII-7 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. As noted previously, the implant criteria for the PCD™ Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. As the DFT and LED indicate, VF was reliably terminated at an energy below the maximum output (34 Joules) of the PCD Device.

PCD Epicardial System Defibrillation Efficacy by Lead System		
Implant Frequency	**LED**	**DFT**
All Lead Systems	11.9J	9.8J
2 Patch System	12.5J	10.5J
3 Patch System	10.6J	8.8J

Table VII-7: PCD Epicardial System Defibrillation Efficacy by Lead System - 5/14/92

Of the 742 patients screened for a PCD Epicardial System, 92 patients (12.4%) received the system despite not meeting the recommended defibrillation implant criteria. The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, demonstrated adequate defibrillation efficacy for implantation of the PCD Epicardial System.

A safety margin of at least 10 Joules between the successful defibrillation energy (24 J or less) and the maximum output of the PCD Device (34 Joules) was provided in 90% of the patients. The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321.

It is important to note that there was no statistical difference in overall spontaneous VT/VF episode efficacy and one year sudden cardiac death survival in patients who did not meet the recommended defibrillation implant criteria versus those patients who did meet the recommended implant criteria.

12. Please discuss the time between detection and delivery of therapy of the Transvene™ System versus the PCD® Epicardial System.

RESPONSE:

The time between the start of detection and delivery of therapy is dependent on the programmable VT/VF detection and therapy parameters and **not** on the implanted defibrillation lead system.

A representative VT episode duration can be determined by using the most frequently programmed parameters for VT detection and therapy during the clinical trial. For both the PCD® Transvene™ and Epicardial System the most frequent VT detection and therapy parameters were as follows:

(b)(4)

(b)(4)

For both the PCD® Transvene™ and Epicardial System, the majority (90%) of spontaneous VT episodes were terminated with VT Therapy #1. Using the above listed parameters a VT episode would last 8.4 seconds in patient receiving one sequence of antitachycardia pacing and 25.2 seconds in a patient requiring all three sequences for termination of the VT episode. Note, that after each delivery of a pacing sequence the PCD® Device needs to redetect ventricular tachycardia. If VT Therapy #2 (cardioversion) was required for termination of the episode, the episode duration would be 32.6 seconds.

A representative VF episode duration can be determined by using the most frequently programmed parameters for VF detection and therapy during the clinical trial. For both the PCD® Transvene™ and Epicardial System the most frequent VF detection and therapy parameters were as follows:

(b)(4)

(b)(4)

For both the PCD® Transvene™ and Epicardial System, the majority (90%) of spontaneous VF episodes were terminated with VF Therapy #1. Using the above listed parameters a VF episode would last 11.8 seconds in patient requiring VF Therapy #1 for successful reversion. If VF Therapy #2 was required for termination of the episode, the VF episode duration for both the PCD® Transvene™ and Epicardial System would be 20.6 seconds.

Since both the PCD® Transvene™ and Epicardial System patients were programmed to similar VT/VF detection and therapy parameters as well as the majority of spontaneous VT/VF episodes being terminated with Therapy #1, there is no difference in the time between start of detection and delivery of therapy for the two systems.

13. On page 125 of the application, please explain and/or discuss what is meant by "a 2:1 VF sensing margin", how it is determined, and if the patients met the criteria.

RESPONSE:

As previously described in the PCD® Transvene™ System PMA application as well as responses to deficiencies on the PCD® Epicardial System (PMA P900061, Submission dated 10/30/91), analysis of appropriate sensing and detection of VF is performed at the time of implant as well as during the course of follow-up. The goal of this testing is to ensure appropriate VF sensing and detection on an acute and chronic basis.

During defibrillation testing, the Model (b)(4) is programmed to a sensitivity value of (b)(4) which is (b)(4) times the nominal sensitivity setting (b)(4) of the Model (b)(4) Device. During VF inductions, the VF electrogram and corresponding Marker Channels which are available from the Model (b)(4) and (b)(4) are monitored and the majority of the VF signals (b)(4) should have an amplitude equal to or greater than (b)(4)

For the sensitivity parameter, the programming recommendations recommend a programmed value of (b)(4) Using the described testing, this would provide a (b)(4) sensing margin. In other words, appropriate sensing of VF was documented at a value (b)(4) times **less** sensitive than the programmed value and would provide a (b)(4) step safety margin when the PCD® Device is programmed to (b)(4) If the PCD® Device was programmed to a sensitivity value of (b)(4) the described testing would provide a 2:1 VF sensing margin. In other words, appropriate VF sensing was documented at a value (b)(4) times **less** sensitive than the programmed value and would provide a (b)(4) step safety margin when the PCD® Device is programmed to (b)(4) In both of these cases, implant testing and sensitivity value programming allows for changes in the VF electrogram amplitude without impacting appropriate VF sensing and detection.

All of the patients who received the PCD® Transvene™ System met the 2:1 VF sensing margin. At the last known follow-up, 76.6% of the patients were programmed to (b)(4) sensitivity (b)(4) VF sensing margin) and 22.3% were programmed to (b)(4) (b)(4) VF sensing margin). In addition, there have been no reports of undersensing during induced episodes of VF as well as no reported patient deaths due to lack of detection of a spontaneous VF episode.
This clinical experience indicates that the recommended VF sensing implant criteria has provided safe and effective evaluation of VF sensing at implant and ensured chronic appropriate VF sensing.

14. **Of the 329 patients who were followed for 6 months, 130 patients had spontaneous episodes. What was the average number of VT and VF episodes per patient? Of the patients followed for a year, how many had spontaneous episodes of VT and VF and what was the mean number of episodes of VT and VF and what was the mean number of episodes per patient in this group?**

RESPONSE:

Using the June 24, 1992 data cutoff there were 329 patients followed for 6 months or longer. Of the 329 patients, 130 patients had a spontaneous VT episode with a mean of 28.9 (3752/130) episodes per patient and 120 patients had a spontaneous VF episode with a mean of 5.6 (667/120) episodes per patient. A total of 179 patients had either spontaneous VT or VF episodes with a mean of 24.7 (4419/179) episodes per patient.

Of the 115 patients followed for 12 months or longer, 60 patients had a spontaneous VT episode with a mean of 29.5 (1770/60) episodes per patient and 37 patients had a spontaneous VF episode with a mean of 6.7 (248/37) episodes per patient. A total of 67 patients had either spontaneous VT or VF episodes with a mean of 30.1 (2018/67) spontaneous episodes per patient.

15. **On page 130, Table IF-4, you report that there were 5,362 episodes of VT successfully terminated. On page 131, paragraph 2, you state that 25 patients experienced 45 (0.8 percent) episodes of sinus tachycardia or atrial fibrillation. Are these patients included in the success or failure category? Nine hundred and sixty-four episodes of VF were reported, however, 75 episodes were not actual VF. You must clarify how the successful and ineffective therapies and failures are discerned and categorized. Please prepare a table which includes a category of ineffective therapies with actual patient numbers and percentages. In addition, what assurance is there that an episode of supraventricular tachycardia or atrial fibrillation is not misinterpreted as VT or VF by the physician and considered a successful therapy?**

RESPONSE:

For purposes of this clinical trial, spontaneous VT and VF episodes were defined as those episodes that **satisfied the programmed** VT and VF detection criteria. Specifically, all programmed VT and VF detection criteria must be fulfilled to detect an episode. Successful termination of the episode was defined as satisfying the VT/VF episode termination criteria. All spontaneous VT and VF episodes detected and treated by the PCD® Device are used in determining therapy efficacy. An ineffective episode is defined as VT or VF episode detected by the PCD® Device in which all four programmed therapies failed to successfully terminate the episode. Spontaneous episode efficacy is determined by the following ratio: **Number of TOTAL Episodes Successfully Terminated by PCD® Device/Number of TOTAL Episodes Detected by the PCD® Device.** The attached PCD® Device telemetry printouts provide examples of how spontaneous episode efficacy is determined.

For those episodes where all four programmed VT/VF therapies failed to terminate the episode, the clinical follow-up data form was reviewed for investigator's comments on the episode. The investigator reviewed the patient's symptoms at the time of the episode as well as the stored episode information provided by the PCD® Device and indicates on the clinical dataform whether the ineffective therapy was due to a nonventricular tachyarrhythmia such as sinus tachycardia or atrial fibrillation. If there is no such indication on the clinical dataform, it is assumed that the ineffective therapy was for a spontaneous VT or VF episode. It should be noted that for all current ICD Systems, the delivery of inappropriate therapy for atrial fibrillation or sinus tachycardia is a known risk of the therapy.

The Table 15-1 summarizes the spontaneous VT/VF episode experience on 757 patients with a cutoff date of February 1, 1993. The discussion that follows provides additional data on these episodes.

PCD® Transvene™ System Spontaneous VT and VF Episode Experience		
Spontaneous VT Experience		
Category	**# Episodes**	**# Patients**
Overall Experience	10,027	316
Successfully Terminated Experience	9864/10,027 (98.4%)	256

Ineffective Episode Due to VF	5/1982 (0.25%)	4

Table 15-1: PCD® Transvene™ System Spontaneous Episode Experience - 2/1/93

Spontaneous VT Episode Experience

To date, 10,027 spontaneous episodes of VT have been detected by the PCD® Device in 316 patients. Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Sixty patients experienced 163 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed therapies. Sixteen (16) patients experienced 33 episodes of atrial fibrillation with a rapid ventricular response that was not "successfully treated" by the PCD® Device. Twenty-three (23)

patients experienced 62 episodes of sinus tachycardia that was not "successfully treated" by the PCD® Device. It should be noted, that the possibility of inappropriate VT therapy delivery due the detection of atrial fibrillation with rapid ventricular response or sinus tachycardia that meets the programmed VT detection criteria is a known risk for all current ICD Systems.

And finally, twenty-one patients experienced 68 episodes of spontaneous VT in which the programmed VT therapies were ineffective in terminating a spontaneous episode. No patient deaths occurred as a result of ineffective VT therapy. Reprogramming and pharmacologic intervention resolved these events. The table provided at the end of this response summarizes this experience.

Spontaneous VF Episode Experience

To date, 1982 spontaneous episode of VF have been detected by the PCD® device in 317 patients. Most (89.1%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 98.4% were successfully treated with one of the four programmable VF therapies.

Sixteen (16) patients experienced 31 episodes in which the PCD® Device was ineffective in terminating a spontaneous VF episode of VF despite delivery of all four programmed VF therapies. Four (4) patients experienced 11 episodes of atrial fibrillation with a rapid ventricular response that was not "successfully treated" by the PCD® Device. Four (4) patients experienced 7 episodes of sinus tachycardia that was not "successfully treated" by the PCD® Device. One patient experienced 4 episodes of both atrial fibrillation and sinus tachycardia that was not "successfully treated" by the PCD® Device. It should be noted, that the possibility of inappropriate VT therapy delivery due the detection of atrial fibrillation with rapid ventricular response or sinus tachycardia that meets the programmed VT detection criteria is a known risk for all current ICD Systems.

In addition, there were three (3) patients who experienced ineffective therapy for a spontaneous VF episode due to lead performance or secondary to a terminal event. One patient experienced one episode of ineffective VF therapy due to lead dislodgement, a second patient experienced one episode of ineffective VF therapy due lead fracture which generated "noise" which was classified by the PCD® Device as "VF" and the third patient experienced two episodes of ineffective therapy at the time of his monitored death.

And finally, four patients experienced 5 episodes of spontaneous VF in which the programmed VF therapies were ineffective in terminating a

spontaneous VF episode. In three patients, these events were resolved with reprogramming or pharmacologic intervention and as of the last known follow-up these patients remain alive and have had no further ineffective VF therapies.

The last of the four patients experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on monitor the patient developed VF and the PCD® Device appropriately detected and terminated the episode. However, the patient developed EMD and upon admission to the ER was pronounced dead on arrival.

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of either VT or VF was 98.4%. Table 15-2 provides as summary of spontaneous episode efficacy.

PCD® Transvene™ System Spontaneous VT/VF Episode Efficacy	
Spontaneous VT Episodes	
Number of Episodes	10,027
% Overall Efficacy	98.4% (9864/10,027)
% Unsuccessful Due to VT	0.7% (68/10,027)
% Unsuccessful Due to Non VT Arrhythmias	0.9% (95/10,027)
Spontaneous VF Episodes	
Number of Episodes	1982
% Overall Efficacy	98.4% (1951/1982)
% Unsuccessful Due to VF	0.3% (5/1982)
% Unsuccessful Due to Non VF Arrhythmias	1.3% (26/1982)

Table 15-2: PCD® Transvene™ System Spontaneous VT/VF Episode Efficacy

The physicians who are investigators in our study are all highly trained and are qualified by their education and experience to evaluate ICD performance. These physicians are the experts and leaders in their field and, as such, their interpretation of the data is considered the state of the art. Also, as the PCD is not designed nor intended to treat atrial arrhythmias, it is unlikely that the ventricular arrhythmia therapy from the PCD would terminate a ventricular arrhythmia. If an atrial arrhythmia was misinterpreted as a ventricular arrhythmia, the PCD therapy would likely be ineffective and this would, therefore, lower the reported percent success for PCD® therapies.

16. **Table IM-6, page 173 must be modified to include a column on inappropriate therapy or therapies delivered as the device was programmed so that the percentages add up to 100 percent.**

RESPONSE:

Table IM-6 has been modified to include rows for episodes that were unsuccessfully terminated but classified as Atrial Fibrillation or Sinus Tachycardia. Unsuccessful termination of an episode was defined as episodes in which the PCD® Device was ineffective in terminating a spontaneous episode despite delivery of all four programmed therapies.

PCD® Transvene™ System Performance Comparison		
Spontaneous VT Episodes		
	PCD® Transvene™ System	**PCD® Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	5,430	13,706
% Overall Efficacy	5,362/5,430 98.7%	13,449/13,706 98.1%
% Unsuccessful Termination (VT)	27/5,430 0.4%	116/13,706 0.9%
% Unsuccessful Termination (AF,ST)	45/5,430 0.9%	141/13,706 1.0%
Spontaneous VF Episodes		
	PCD® Transvene System	**PCD® Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	973	1,694
% Overall Efficacy	964/973 99.1%	1,671/1,694 98.6%
% Unsuccessful Termination (VT)	1/973 0.1%	9/1,694 0.5%
% Unsuccessful Termination (AF,ST)	8/923 0.8%	14/1,694 0.9%

Table IM-6: PCD® Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 6/24/92

Thirty patients out of 757 in the Transvene™ population experienced 68 (68/5430 = 1.3%) episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Twenty five patients experienced 45 (0.9%) episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

Seventy nine patients out of 742 in the Epicardial population experienced 257 (257/13,706 = 1.9%) episodes in which the PCD® was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Of the ineffective episodes, 141 episodes (1.0%) were due to sinus tachycardia or atrial fibrillation with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

Five patients in the Transvene™ population experienced 9 episodes (9/973 = 0.9%) in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Four patients had eight reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems. It should be noted that the PCD® Device performance was appropriate based on the programmed detection parameters.

Thirteen patients in the Epicardial population experienced 23 episodes (23/1,694 = 1.4%) in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Fourteen of the ineffective episodes (0.9%) were due either to atrial fibrillation with a rapid ventricular response that had been detected as VF, sinus tachycardia or the device not being disabled at the time of explant allowing the PCD® Device to sense external noise as VF. The episodes due to atrial fibrillation and sinus tachycardia were resolved with either modification of antiarrhythmic drug therapy or programmed parameters. It should be noted that the PCD® Device performance was appropriate based on the programmed detection parameters.

17. **On page 162, Table IL-2 lists a category "Fail to Cardiovert/Defibrillate" as 0.8 percent. Please clarify. If a patient survives an episode of an inappropriate therapy, is it categorized as a success? Please discuss. The tables must include percentages with the representative numerical support.**

RESPONSE:

Table IL-2 references a side by side comparison of complication/ observation rates observed in the PCD® Transvene™ System and the AICD Epicardial System. The table is provided here for reference and the PCD® Transvene™ System reflects an update on the clinical experience with the 757 patients with a new cutoff date of 2/1/93. The incidence of "Fail to Cardiovert/Defibrillate" was 0.8% and is now 1.2% due to the increase in mean follow-up time from 5.6 months to 10.8 months.

PCD® Transvene™ System
Comparison of Complication/Observation Rates
PCD® versus AICD

Category	PCD%	AICD%
Fail to Cardiovert/Defibrillate	1.2% (9 pts)	4.1% (7 pts)
Inappropriate/Problematic VT/VF Therapy Delivery	9.6% (73 pts)	20% (55 pts)
Pocket Infection	2.9% (22 pts)	2.2% (6 pts)
Erosion	0.7% (5 pts)	0.7% (2 pts)

The AICD Epicardial System clinical experience data is from Winkle, et al. Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6);135-161. This article was selected because it provides a detailed clinical complication experience on large patient population, 270 patients.

As described in the PCD® Transvene™ System PMA Application clinical experience report, Section X, Comparison to AICD System, the instances of failure to cardiovert and/or defibrillate in the PCD® Transvene™ System patient population were associated with increased defibrillation requirements during induced VF episodes, none of which resulted in patient death. The failures to cardiovert/defibrillate reported in Winkle et al, article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds due to changing patient conditions.

For purposes of this PCD® Transvene™ System clinical trial, spontaneous VT and VF episodes were defined as those episodes that **satisfied the programmed** VT and VF detection criteria. This includes all tachyarrhythmia episodes (i.e, VT, VF and supraventricular tachycardia) that meet the programmed detection criteria. It should be noted for all current ICD Systems, the possible delivery of inappropriate therapy for atrial fibrillation or sinus tachycardia is known risk of the therapy. There have been no patient deaths due to the delivery of inappropriate VT or VF therapy in the PCD® Transvene™ System population. Using the stored episode information available in the PCD® Device and evaluation of the patient's symptoms at the time of the episode, the physician can attempt to discern whether the therapy was delivered for spontaneous VT/VF episode or a nonventricular arrhythmia such as atrial fibrillation or sinus tachycardia.

18. There were 38 inactive patients reported in Table IH-1, however, 34 patients were reported to be no longer active. Please clarify.

RESPONSE:

The text accompanying Table IH-1: Inactive Patients, page 136 of the clinical summary provided in the September 18, 1992 amendment, contained an error. The text preceding the table should state "there are a total of 38 patients who had received a PCD system and are no longer active in the study as of 6/24/92." Note that the information in the table was correct.

As of 2/1/93 there are a total of 82 patients who had received a PCD system and are no longer active in the study. The distribution of these patients is presented below and also appears in the updated clinical summary report under "Inactive Patients."

Transvene Inactive Patients

Reason for inactivity	# of Patients
Patient deaths	51
Infection (explant)	22
Heart transplant	9
Total	82

19. Please discuss how the 1 year sudden cardiac death survival, as reported in Table IF-2, page 128, was calculated. The numbers and an explantation of patient classification must be included. Was every patient included who had a prior cardiac arrest regardless of the arrhythmia.

RESPONSE:

Sudden cardiac death is defined as a death that occurs within one hour of onset of symptoms or where the death is unwitnessed. The sudden cardiac death survival probability shown in Table IF-2 is calculated using a life-table survival analysis procedure. (b)(4) (b)(4)

(b)(4)

(b)(4)

Presentation of the number of patients does not allow calculation of the survival probability. Therefore, a dataset will be available upon request if you desire to verify the survival probability.

The sudden cardiac death survival probability estimates the likelihood that a patient enrolled in the study will survive to one year without dying a sudden cardiac death. All patients in the Transvene™ clinical study are included in the analysis regardless of the indication (VT,SCD or SCD/VT), arrhythmia (VT or VF), or prior cardiac arrest status.

20. On page 177, the number of patients must be provided so that the percentages and calculated p-values can be confirmed.

RESPONSE:

The percentages in Table IM-10 page 177 are calculated using the life-table survival estimate procedure.

PCD® Transvene™ System
Comparison of Actuarial Survival
PCD® Transvene™ System versus PCD® Epicardial System

One Year Survival	PCD® Transvene™ System	PCD® Epicardial System	(b)(4)
Number of Patients	757	742	
Sudden Cardiac	99.8%	98.7%	
Non-Sudden Cardiac	96.8%	95.7%	(b)(4)
All Cardiac	96.6%	94.4%	
Noncardiac*	99.4%	97.3%	
Overall*	95.3%	87.2%	

• (b)(4) (b)(4)

Table IM-10: Comparison of Actuarial Survival: PCD® Transvene™ System versus PCD Epicardial System - 6/24/92

The life-table procedure estimates the probability of survival for intervals. All patients for each population enter the model for estimation and are censored at their last known follow-up or counted as an event at time of death. The calculations were estimated using the commercial statistical software package (b)(4) Therefore, providing a number of patients would not aid in verification of percentages and p-values. For verification of percentages and p-values datasets are available upon request.

21. Table IV-C, page 649 of the original submission shows a comparison of patient variables for the three lead systems and provides p-values for the variables tested, but the hypothesis was not clearly stated. Please state the hypothesis and discuss the p-values obtained when reporting by primary indication, and the chi-square test of the data set and how it was computed.

RESPONSE:

For Table IV-C, page 649 of the original submission the null hypothesis was: the patient characteristics are equivalent for the three lead configurations; RV/SVC/SQ, RV/CS/SQ, and RV/CS/SVC.

PCD® Transvene™ System
RV/SVC/SQ vs RV/CS/SQ vs RV/CS/SVC

CATEGORY	RV/SVC/SQ	RV/CS/SQ	RV/CS/SVC	(b)(4)
Mean Age	57.9	60.7	56.3	
Number, % Male Number, % Female	170 82.9% 35 17.1%	71 83.5% 14 16.5%	19 70.4% 8 29.6%	
Mean Ejection Fraction	37.4%	35.5%	35.8%	
Primary Indication: SCD VT SCD & VT	 79 38.5% 92 44.9% 34 16.6%	 31 36.5% 41 48.2% 13 15.3%	 10 37.0% 12 44.5% 5 18.5%	
NYHA Classification: I/II III/IV	 163 81.1% 38 18.9%	 74 87.1% 11 12.9%	 23 85.2% 4 14.8%

Cardiomyopathy	27 13.2%	14 16.5%	4 14.8%	

(b)(4)

Table IVC: Summary of Variables Tested on Lead Configurations - 11/27/92

(b)(4)

(b)(4)

differences between the observed and expected frequencies (b)(4) Users's Guide: Statistics, (b)(4) (b)(4)

There were no statistically significant differences at a (b)(4) significance level in patient characteristics between the lead configurations. Therefore, we accept the null hypothesis that the patient populations are equivalent.

22. For purposes of justification of data pooling and data analysis of Table IV-C, please discuss why the multiple statistical significant difference was not adjusted at a 0.05 significance level using a more widely accepted procedure such as the Hochberg procedure (Dunnett and Tarnhoue: A Step-up Multiple Test Procedure, Journal of the American Statistical Association, March, 1992, Vol 87: pp. 162-170).

RESPONSE:

The Hochberg procedure was not used to adjust for multiple inference in table IV-C of the original submission because the Dunnett and Tarnhoue article was not published and not known by us until the same month that the original submission was submitted, March 1992. Also procedures that adjust for multiple inference are used to adjust the p-value below 0.05 to correct for a type I error (rejecting the hypothesis of no difference between the populations when the hypothesis should be accepted). As shown in table IV-C below, none of the comparisons are significant at a 0.05 significance level so there is no reason to adjust the significance level below 0.05 to eliminate type I errors.

PCD® Transvene™ System RV/SVC/SQ vs RV/CS/SQ vs RV/CS/SVC				(b)(4)
CATEGORY	RV/SVC/SQ	RV/CS/SQ	RV/CS/SVC

Cardiomyopathy	27 13.2%	14 16.5%	4 14.8%	

Table IV-C: Summary of Variables Tested on Lead Configurations - 11/27/92

23. You claim that confidence interval analysis was performed to compare the overall mortality of the PCD® and AICD™ populations. What was the confidence interval?

RESPONSE:

The survival probability at one year for the Transvene™ population was 95.3%. From the analysis run, using the commercially available statistical software package (b)(4) the survival standard error was also calculated. The confidence interval was calculated by taking the survival probability (b)(4) survival standard error). The survival standard error was (b)(4) therefore the confidence interval for Transvene™ survival at 1 year is (b)(4) The overall survival probability reported for the Ventak-P was 90.8%. We do not have the data necessary to calculate the confidence interval around 90.8% for the Ventak-P. This probability is outside the lower range of the confidence interval for the Transvene™ survival probability at one year, therefore by using the best available information we conclude that there is a statistically significant difference between the survival probabilities.

24. Please clarify and/or discuss the following regarding Table XB-1, page 378, Volume 2:

a. the total number of patients in the Ventak P population (292) versus those reported by primary indication (291); and

RESPONSE:

b. a chi-square test of primary indication, using the (b)(4) computer software, yields a p-value of nearly 0. This is statistically significant, indicating the PCD® and Ventak P populations are significantly different.

RESPONSE:

As noted in the PCD® Transvene™ System PMA Application, for purposes of comparison the Ventak-P Epicardial System described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 was used. Therefore only that data which was presented in this summary is available via the Freedom of Information Act. The primary indication for one patient was not available in the Ventak P Epicardial System summary.

Analysis performed by Medtronic indicated that there was a statistical a difference in the category of patient indication between the two patient population groups. There were more patients that had Sudden Cardiac Death as their primary indication in the PCD® Transvene™ System population than the AICD Epicardial System population (b)(4)

Cox regression analysis was performed to see what effect gender, primary indication and system implanted (PCD® Transvene™ or PCD® Epicardial) had on survival outcome.

This analysis showed that for overall survival at one year the system implanted had an influence on the probability of survival but gender and primary indication had no influence.

Thus, since there is no impact on survival outcome based on primary indication, the PCD® Transvene™ System and AICD Epicardial System can be compared. There was a statistical difference (Confidence Interval Analysis) in one year overall survival between the PCD® Transvene™ (95.6%) and AICD Epicardial System (90.8%). This difference is due to the implanted defibrillation lead system.

25. **Please discuss the incidence of inappropriate therapies reported as observations in the Transvene™ study. It appears as if there has only been a slight improvement over the PCD® Epicardial study as it relates to programming and patient management (drug therapy). Please discuss the experience of both studies and how the labeling supports effective programming of the device parameters and the use of the Onset and Stability algorithms. How many patients in the Transvene™ study have the Onset and Stability algorithms programmed ON? At what interval during the study were the majority of patients programmed with the algorithms? Your experience in the treatment of induced and spontaneous episodes with use of the algorithms must be discussed.**

RESPONSE:

a. Inappropriate Therapies

Inappropriate therapy delivery is defined as the delivery of either VT or VF therapy for reasons other than a spontaneous VT or VF episode. This includes atrial fibrillation with a rapid ventricular response or sinus tachycardia that overlaps with the programmed detection criteria. Delivery of therapy for rhythms other than VT and VF is a known risk of ICD therapy which is clearly discussed in the device labeling.

Physicians initially program the PCD® based on the known cardiac arrhythmias and tend to program the device toward greatest sensitivity for VT and VF detection. When patients go home and recover from the implant procedure they will generally become more active and may experience increases in their sinus rate. If these increased sinus rates overlap the programmed VT detection rate criteria, the patient may experience an inappropriate VT therapy. Similarly atrial arrhythmias may develop as the patient's heart disease progresses. The philosophy behind Medtronic's labeling recommendations and the practice of PCD® investigators is to accept some overdetection of non-VT/VF rather than risk underdetection of a life threatening tachycardia. If the patient experiences inappropriate therapies due to either ventricular response to atrial fib/flutter or sinus tachycardia, the investigator will evaluate both device programming and other medical/surgical therapeutic options. Because of these patient management practices the incidence of inappropriate therapy delivery will never be zero. Physicians will likely always wait until inappropriate therapy delivery occurs before programming supplementary detection criteria.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD® clinical experience than the published experience with the AICD (Winkle, et al. Long-Term Outcome With the Automatic Implantable Cardioverter-Defibrillator; JACC, May, 1989; 13(6); 135-161.). Table XII F-2 on page 253 Transvene™ clinical update dated 9/18/92 shows 10.6% (N=742) of patients with the PCD® epicardial system and 8.2% (N=757) of patients with the Transvene™ system experienced inappropriate VT or VF therapies. The Winkle article reports a 20% rate of delivery of inappropriate therapies. The reduction in inappropriate therapies can be attributed to the incorporation of independently programmable detection algorithms for VT and VF.

The circumstances reported in the Winkle, et al article were nonsustained VT, recurrent stable VT, sinus tachycardia, atrial fibrillation with rapid ventricular response and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD Device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

The slight reduction of inappropriate therapies between the epicardial and the Transvene™ systems is likely due to the difference in the incidence of atrial fibrillation between the two systems. Atrial fibrillation, with a risk of inappropriate shocks and the potential need for concomitant antiarrhythmic drug therapy, is a recognized medical event in patients receiving an ICD System utilizing an epicardial defibrillation lead system. The occurrence of atrial fibrillation in these patients may be related to the thoracotomy procedure required for implant, manipulation of the atrium during the implant procedure or the positioning of the epicardial patch leads near or on the atrium resulting in irritation and induction of atrial fibrillation. The incidence of inappropriate therapy for atrial fibrillation in the PCD Epicardial System was 6.1% while that for that the PCD Transvene System was 4.9%. An decreased incidence of inappropriate therapy results in a decreased potential risk for acceleration on non VT/VF rhythms as well as increased patient acceptance of ICD therapy. Though the introduction of a transvenous lead system has not totally removed the risk of inappropriate therapy for atrial fibrillation, from this clinical experience it appears that the incidence has been decreased.

The Transvene™ clinical update dated September 18, 1992 reported forty nine patients with inappropriate VT therapy which

were all classified as observations and discussed this experience in detail. Inappropriate VT therapy was delivered for atrial fibrillation with a rapid ventricular response in 28 patients and due to sinus tachycardia in 21 patients. This observation was resolved by reprogramming of the VT detection parameters in 21 patients, with modification of drug therapy in 26 patients and no action was required in one patient. One patient with atrial fibrillation underwent successful AV Node ablation. Post this procedure, appropriate PCD Device function was documented.

In two patients in whom inappropriate VT therapy was delivered for sinus tachycardia, the ONSET algorithm was enabled to improve discrimination between VT and sinus tachycardia. The use of this algorithm resulted in no further delivery of inappropriate therapy for sinus tachycardia.

In three patients in whom inappropriate VT therapy was delivered for atrial fibrillation, the STABILITY algorithm was enabled to improve discrimination between VT and atrial fibrillation. The use of this algorithm resulted in no further delivery of inappropriate therapy for atrial fibrillation.

The Transvene™ clinical update also reported thirteen patients who experienced an episode of inappropriate VF therapy, all of which were classified as observations. In nine cases, inappropriate VF therapy was delivered for atrial fibrillation that had a rapid ventricular response that met the programmed VF detection criteria. In two cases, inappropriate VF therapy was delivered secondary to sinus tachycardia that was detected as ventricular fibrillation. Modification of the programmed VF detection criteria or the patient's antiarrhythmic drug therapy corrected these two clinical observations.

One patient received inappropriate VF therapy secondary to the sensing of T waves during sinus rhythm with the PCD device programmed to a sensitivity of (b)(4) This was resolved with reprogramming of the sensitivity to (b)(4) Appropriate VF sensing was documented at this programmed setting.

The final patient received inappropriate VF therapy secondary to nonsustained ventricular tachycardia. In the PCD Device, once "VF" is detected the device is committed to the delivery of defibrillation therapy. This observation was resolved by reprogramming of the FDI and VF NID.

b. Labeling

The PCD® technical manual contains specific recommendations for programming both VT and VF detection. For VT detection, specific statements are made for programming the Tachycardia Detection Interval (TDI), the Number of Intervals to Detect (VT NID), as well as the Onset and Stability Criteria. For VF detection recommendations are made for Sensitivity, Fibrillation Detection Interval (FDI) and Number of Intervals to Detect (VF NID).

The recommendations specify initial programming recommendations for each parameter as well as appropriate warnings for potential programming problems.

The programming recommendations for the Onset Criterion in the PCD® technical manual are:

> Onset Criterion is indicated if inappropriate detection of sinus tachycardia resulting in inappropriate VT therapy delivery has occurred. Treadmill testing, beginning at 81% Onset, is suggested to evaluate the appropriate function of this algorithm.
>
> This algorithm was used safely in 8.5% of 434 patients in the clinical study. Its use has demonstrated its safety and effectiveness.
>
> If the Onset Criterion is ON and is not met at the beginning of a spontaneous ventricular tachycardia, the VT episode could remain "undetected", such as with an exercise-induced VT. If VT Detection uses the Onset Criterion and detection is enabled after the start of a VT, the VT may not be detected.
>
> A low programmed onset percentage value will increase the specificity of the Onset Criterion to detect the targeted tachycardia, but will also decrease the sensitivity of the overall VT detection algorithm.

The programming recommendations for the Stability Criterion in the PCD® technical manual are:

> Stability Criterion is indicated if atrial fibrillation or atrial flutter with a rapid ventricular response has caused inappropriate detection and therapy delivery. A stability value of 60ms is suggested initially.
>
> This algorithm was used safely in 17.9% of 434 patients in the clinical study. Its use has demonstrated its safety and effectiveness.
>
> Decreasing the programmed interval stability value increases the specificity of the Interval Stability Criterion to detect the targeted stable tachycardia, but may also decrease the sensitivity of the detection algorithm.

The labeling directed at programming these two algorithms is necessary and appropriate in that it clearly states that while specificity for VT detection is enhanced, sensitivity for VT detection is reduced. For this reason the recommendations clearly state that these supplementary detection criteria should be used after the need for this increase in specificity has been clearly demonstrated, that is, inappropriate therapies form either sinus tachycardia or atrial fib/flutter have occurred.

The values recommended for initial programming of both of these features was made through analysis of the clinical data base. In both cases the values chosen were the most widely used values.

c. Transvene™ Experience

As of February 1, 1993 thirty-three (33) of the 757 Transvene™ patients in the clinical report had the Onset Criterion enabled and 55 patients had the Stability Criterion enabled. Eleven of these patients had both the Onset and the Stability Criteria programmed ON. The most widely used programmed value for the Onset Criterion was 81% (54.5% of patients with Onset programmed ON). The most widely used programmed value for the Stability Criterion was (b)(4) (45.4% of patients with Stability programmed ON).

Table 25c-1 shows a distribution of the time from implant to the first programming of the Onset and the Stability Criteria. Almost half (48.5% 16/33) of the patients with the Onset Criterion programmed ON did so within the first 30 days following implant. The greatest time from implant to the first programming of the Onset Criterion is 345 days. More than half (63.6% 35/55) of the patients with the Stability Criterion programmed ON did so within the first 30 days. Like the Onset Criterion many patients had the Stability Criterion programmed on for the first time very late in the follow-up period, the greatest being 622 days.

PCD® Transvene™ System Time to Program Onset and Stability Criterions ON		
Days Post Implant	**Onset Criterion (# of Patients Programmed ON)**	**Stability Criterion (# of Patients Programmed ON)**
0 - 10 days	13	29
10 - 30 days	3	6
30 - 100 days	7	9
101 - 200 days	3	3
201 - 300 days	4	4
301 - 400 days	3	1
401+ days	0	3
Total	33	55

Table 25c-1: Time to Program Onset and Stability Criterions ON

While most of the patients requiring these supplementary detection algorithms do so relatively early following implant, some patients require this feature much later. This is an example of the dynamic nature of patient's underlying heart disease and the need to have these programmable features available for use long after implant, as the patient's cardiac condition changes.

At the time of programming either of these supplementary VT detection criteria ON, many patients had arrhythmias induced to assure appropriate detection of VT/VF. Table 25c-2 shows the number of episodes of VT and VF induced during the follow-up evaluation where the criterion was programmed ON. Fifty percent (11/22) of the patients with the Onset Criterion only programmed ON were induced into a tachyarrhythmia at the follow-up evaluation where the programming occurred. Over half (61.3% 27/44) of the patients with the Stability Criterion only programmed ON and 72.7% (8/11) of those patients with both supplementary criteria programmed ON were induced at the follow-up where the programming occurred. In all cases the PCD® system performed appropriately.

PCD® Transvene™ System Induced Episodes When Onset or Stability Were Programmed ON			
	VT	V-Flutter	VF
Onset Only ON (11 of 22 Patients)	18 Episodes 10 Patients	-- --	14 Episodes 8 Patients
Stability Only ON (27 of 44 Patients)	78 Episodes 19 Patients	4 Episodes 2 Patients	41 Episodes 21 Patients
Both ON (6 of 11 Patients)	31 Episodes 6 Patients	-- --	18 Episodes 5 Patients

Table 25c-2: Induced Episodes When Onset or Stability Were Programmed ON

Table 25c-3 shows the spontaneous episode experience in the patients with these two detection criteria programmed ON. Three-hundred-nine (309) episodes occurred in 30 of the patients with the Stability Criterion programmed ON. Two-hundred-ninety-three (293) were successfully terminated by the PCD® Transvene™ system. The remaining episodes were due to ventricular response to atrial fib/flutter that met the programmed Stability Criterion value. Twelve (12) of the "Failed" episodes were in one patient who was hospitalized for titration of medical therapies. Eleven patients with the Onset Criterion experienced 493 VT episodes which were terminated with an efficacy of 99.2%. Ventricular fibrillation was terminated 100% of the time in this patient group.

PCD® Transvene™ System Spontaneous Episodes When Onset or Stability Were Programmed ON		
	VT	VF
Stability Criterion Only # Patients # Episodes Efficacy	 30 309 94.8%	 18 125 100.0%
Onset Criterion Only # Patients # Episodes Efficacy	 11 493 99.2%	 7 17 100.0%
Both Criteria # Patients # Episodes Efficacy	 10 364 97.0%	 4 39 100.0%

Table 25c-3: Spontaneous Episodes When Onset or Stability Were Programmed ON

d. Conclusion

The Onset and the Stability Criteria for VT detection are the same algorithms that were demonstrated to be safe and effective with the market released PCD® Epicardial System. They remain a useful tool in a subset of patients requiring discrimination between ventricular tachycardia and the rapid ventricular response to atrial fib/flutter or sinus tachycardia in the PCD® Transvene™ System.

26. Please discuss the "device related" complications reported for the Transvene™ and the PCD® Epicardial System.

RESPONSE:

As described in the PCD® Transvene™ System PMA Application, "Device Related" complications includes patients in whom the device was explanted for reasons other than patient death, infection or transplant.

In the case of the PCD® Transvene™ System, these patients were discussed in detail in the Clinical Experience Report, Section XII, Complications and Observations and detailed information on each patient was provided in Volume 3, Clinical Appendices, Appendix C. There were four patients (0.5%) in whom the PCD® Device was explanted due to reasons other than death, infection or heart transplant. Reasons for explant included, **(1)** lower than expected battery voltage for time in service due to leakage at the input to one of the integrated circuits (1 unit), **(2)** failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode (1 unit); **(3)** Power on Reset (POR) condition that was not related to the delivery of external defibrillation or cautery (1 unit); and, **(4)** inappropriate delivery of VF therapy during a manual capacitor charge time (1 unit). In all cases, the devices were safely replaced with no adverse patient consequences. The attached information from the PCD® Transvene™ System Application provides a summary of these patients.

In the case of the PCD® Epicardial System, there were seven patients (0.9%) in whom the PCD® Device was explanted due to reasons other than death, infection or heart transplant. The reason for explant for all seven devices was lower than expected battery voltage for time in service. The identified causes for low battery voltage were (1) failure in an integrated circuit which increases the current drain and results in reduced battery longevity (3 units); (2) leakage at the input of one of the integrated circuits where voltage measurement is taken (1 unit); and (3) leakage at tantalum capacitors (3 units). Information on these identified causes for low battery voltage have been previously provided the agency. In all cases, the devices were safely replaced with no adverse patient consequences.

Early Device Explant

There were four patients in whom the PCD Device was explanted due to reasons other than death, infection or heart transplant. In all cases these medical events were classified as complications.

In the first patient the PCD Device was explanted for lower than expected battery voltage measurement for time in service. Analysis indicated the decreased battery voltage measurement was due to leakage at the input to one of the integrated circuits. This lead to a voltage drop across a resistor where the voltage measurement was taken. Analysis indicated the battery to be performing to specifications and the leakage to be a random event.

The second patient received inappropriate VF therapy during reformation of the device capacitors. Analysis of the explanted unit indicated that arcing occurred between the conductors in the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to the excessive voltage applied.

Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this was determined to be a random component failure.

In the third patient, during the pre-hospital discharge electrophysiology study, VT was induced and cardioversion therapy failed to appropriately synchronize and deliver therapy for this induced episode. The PCD Device was explanted and the patient received a second device without difficulties. Analysis of the explanted PCD Device indicated a random device failure in the microprocessor and low power hybrid. The manufacturing process was modified to incorporate a screening process to identify any further devices which may exhibit this behavior.

In the final patient, the PCD Device exhibited a Power On Reset (POR) condition that could not be related to use of electrocautery or external defibrillation. The device was explanted and returned to Medtronic for analysis. Final results on the analysis are not available at the time of this submission but will be submitted to the FDA when they are available.

27. Please describe in detail the complications reported in the patients followed for a year.

RESPONSE:

Complications and Observations in the patients followed for 1 year or more

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, of the 393 patients with implant durations of greater than or equal to one year, there have been a total of 89 complications reported in 76 patients and 122 observations reported in 99 patients in the PCD™ Transvene™ System patient population. Thus, 19.3% (76/393) of the patients had a clinical event which was categorized as a complication and 25.2% (99/393) of the patients had a clinical event which was categorized as an observation. These percentages are consistent with the percentages of patients with complications, 19.4% (147/157) and observations 23.8% (180/757) in the original PMA patient population.

Table 27-1 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System Reported Complications/Observations in Patients followed for 1 Year or more : By Category (n=393)		
Category	**Complications**	**Observations**
	Num (% of Pts)	Num (% of Pts)
Increased Defibrillation Requirements	3 (0.8%)	2 (0.5%)
Inappropriate VF Therapy Delivery	-	10 (2.5%)
Inappropriate VT Therapy Delivery	-	40 (10.2%)
Loss of Capture	2 (0.5%)	6 (1.5%)
Oversensing	-	29 (7.4%)
Undersensing	-	-
Skin Erosion	2 (0.5%)	1 (0.3%)
Pocket Infection	5 (1.3%)	7 (1.8%)
Seroma	1 (0.3%)	9 (2.3%)
Hematoma	1 (0.3%)	7 (1.8%)
Pneumothorax	2 (0.5%)	1 (0.3%)
Pacemaker Syndrome	-	1 (0.3%)
Perforation	1 (0.3%)	-
Subclavian Vein Thrombosis	-	1 (0.3%)
Lead Fracture	6 (1.5%)	-
Subcutaneous Patch Crinkling	5 (1.3%)	3 (0.8%)
Early Device Explant	3 (0.8%)	-
Total Lead Dislodgement	56 (14.2%)	6 (1.5%)
Total	**89**	**122**

Table 27-1: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table 27-2 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD® Transvene System Reported Complications/Observations in Patients followed ≥1 Year Lead Dislodgements <30 days and >30 days (N=393)			
Complications		Observations	
Num (% of Pts)		Num (% of Pts)	
<30 days	>30 days	<30 days	>30 days
27 (6.9%)	29 (7.4%)	0 (0)	6 (1.5%)

Table 27-2: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 29 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 29 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

28. **There was a substantial increase in the number of infections reported in the Transvene™ study. Even though you discussed why there was an increase, based on your experience, how will your labeling address the procedures for reduction in the number if infections? Please validate these procedures.**

RESPONSE:

In the current update of our database, we report in Table IM-7 (a copy is attached for your convenience) that there is a 2.9% incidence of infection leading to explant of the PCD® in the 757 Transvene™ patients and 2.3% for the 742 Epicardial patients. These two rates are not substantially different nor are they different from the 2.4% rate reported in the Ventak-P Summary of Safety and Effectiveness Data, PMA Application P890061, May 2, 1991. Therefore, it is our assertion that there is not a substantial increase in infections and the current labeling is appropriate.

29. A discussion of your experience in the use of the different entry sites for the placement of the Transvene™ leads, and how your labeling assists in the selection of an entry site, must be provided.

RESPONSE:

Transvene leads are placed via several approaches; either through the subclavian, cephalic or jugular veins. The specific site is determined by the implanting physician. Analysis of Transvene data shows that the left subclavian vein is the most frequently used entry site regardless of the type of lead or intended lead location, i.e., RV or CS/SVC lead. A presentation of entry sites is presented below. The total number of RV lead entry sites is greater than the total number of patients included in this report because of patients with multiple lead evaluation sessions. This information was also presented in the clinical experience report provided in the September 1992 PMA amendment.

PCD™ Transvene™ System Venous Entry Site			
	RV Leads Model 6884/6966/SP2100	CS/SVC Leads Model 6881/6963	All Transvene™ Leads
Left Subclavian	483	583	1066
Right Subclavian	40	47	87
Left Cephalic	213	180	393
Right Cephalic	8	7	15
Left Internal Jugular	7	9	16
Right Internal Jugular	11	9	20
Other	5	4	9
Total	767	839	2097

Venous Entry Site - 6/24/92

There have been two reports of fractures of the Model 6884 right ventricular lead associated with clamping of the lead body between the clavicle and first rib. Both of these leads were placed via a right subclavian approach. These patients are discussed in detail in the complications section of the clinical summary. There were no reports of ineffective therapy for a spontaneous VT/VF episode due to a right ventricular lead fracture.

Technical manuals for both the Model 6966 RV lead and Model 6963 CS/SVC lead provide a detailed discussion of selection of a lead entry site. This is addressed under, "Suggested Implantation Procedure" in each of the technical manuals. Copies of the applicable pages of the technical manual for each lead are provided following this response. Note that this information was also provided in the original Transvene PMA application dated March 31, 1992.

POTENTIAL COMPLICATIONS

The potential complications related to the use of transvenous leads include, but are not limited to, the following patient-related conditions that can occur during and following lead insertion: fibrillation or other arrhythmias, conduction disturbances, loss of contractility, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, infection, and tissue necrosis.

Other potential complications related to the lead include, but are not limited to, the following: lead dislodgement, lead conductor fracture, and insulation failure.

ENSURING PRODUCT INTEGRITY

Carefully inspect the package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the package has been compromised prior to the product expiration date, place the contents in a gas-permeable bag and resterilize it with ethylene oxide as described below.

CAUTION: Use ethylene oxide only.

The process should not exceed temperatures of 55° C (125° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

General Instructions

The implantation procedure generally includes using a stylet guide, stylets, and vein lifter; selecting an insertion site; positioning the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; and connecting the lead to the pulse generator.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition. The techniques for selecting an insertion site, using a stylet guide or a stylet, positioning a lead, and anchoring a lead,

150

described below suggest one or two possible versions, while more may exist.

Opening the Package

While lifting the lead out of the package, make sure that the anchoring sleeve does not slide off the distal end of the lead.

Using the Stylet Guide and Stylets

The lead is packaged with the stylet guide attached to the connector pin and a stylet already inserted. If the stylet guide has been removed, replace it by gently pushing it as far as possible onto the connector pin (Figure 1).

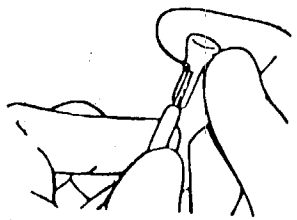

Figure 1. Stylet guide attachment.

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness for different lead and stylet flexibility. Each stylet knob is etched with the stylet diameter and length.

If a stylet is not already in the lead, insert a stylet through the stylet guide and into the lead body. If a slight curve is needed for the stylet, refer to instructions in the section titled "Positioning a Lead in the Coronary Sinus or Superior Vena Cava."

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increase the chance that blood may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

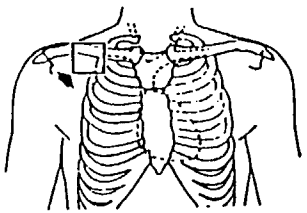
Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein. In general, a left venous entry site will aid in maneuvering the lead into the coronary sinus orifice.

121

CAUTION: If insertion is done via a subclavian approach, the lead should be positined far laterally to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead may eventually cause the conductor to fracture, may cause damage to the insulation, or may cause other damage to the lead. This may result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion./defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, may also precipitate pinching andf subsequent fracture of the lead. If significant resistance is encountered during a subclavian stick implant procedure, do not force the lead by adjusting patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. In such cases it is recommended that an alternate venous entry site be used.

Use fluoroscopy to facilitate accurate lead placement.



Using a Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 2). During insertion of the lead into the vein, make sure the anchoring sleeve does not slide off the distal end of the lead.

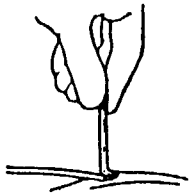


Figure 2. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Lead in the Coronary Sinus or Superior Vena Cava

For added control in maneuvering the lead tip, the distal end of the lead may be slightly curved by inserting a gently curved stylet as shown in Figure 3. A possible angle of curvature is illustrated in Figures 4 and 5.

ENSURING PRODUCT INTEGRITY

Carefully inspect the package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the package has been compromised prior to the product expiration date, place the contents in a gas-permeable package and resterilize it with ethylene oxide as described below.

CAUTION: Use ethylene oxide only.

The process should not exceed temperatures of 55° C (125° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

The implantation procedure generally includes checking the mechanical functioning of the lead electrode before it is inserted; using a stylet guide, stylets, and vein lifter; selecting an insertion site; positioning the lead; securing the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; and connecting the lead to the pulse generator.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition. As described below, the techniques for selecting an insertion site, using a stylet guide or a stylet, positioning a lead, and anchoring a lead suggest one or two possible versions, while more may exist.

Verifying the Mechanical Functioning of the Helix Electrode

Before implantation, verify the mechanical functioning of the electrode, as described below.

1. Within the sterile field, remove the lead and the accompanying stylets from the sterile packaging. The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin that accepts the stylet controls the helix mechanism.

2. To attach the fixation tool, first remove the stylet guide. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).

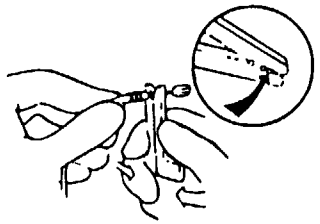

Figure 2. Attachment of the fixation tool to the connector pin.

3. Rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

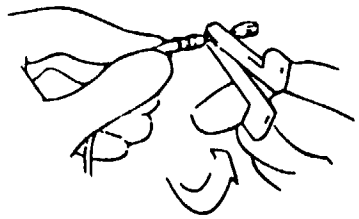

Figure 3. Rotating the fixation tool.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions may damage the lead.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the lead and its conductor coil to unwind.
5. After allowing the lead and its conductor coil to unwind, reattach the fixation tool and turn it counterclockwise until the helix tip is retracted in the sheath.

125

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin with the stylet in it controls the helix mechanism. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 4).

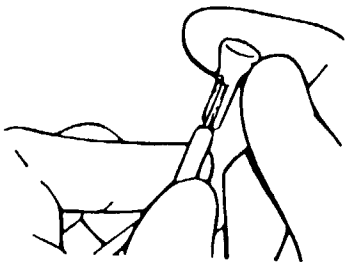

Figure 4. Stylet guide attachment.

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness to accommodate a physician's preference for lead and stylet flexibility.

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increase the chance that blood may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

After the stylet is inserted, gently remove the stylet guide so that it rests alongside the stylet knob.

Selecting an Insertion Site

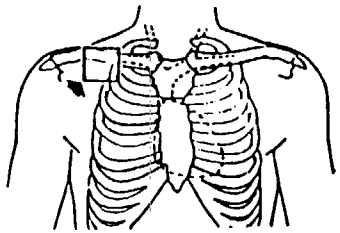
The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein.

CAUTION: If insertion is done via a subclavian approach, the lead should be positioned far laterally to avoid clamping the lead body between the clavicle and the first rib. Clamping the lead may eventually cause the conductor to fractur, may cause damage to the insulation, or may cause other damage to the lead. This may result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, may also precipitate pinching and subsequent fracture of the lead. If significant resis-

126

tance is encountered during a subclavian stick implant procedure, do not force the lead by adjucting patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. In such cases it is recommended that an alternate venous entry site be used.

Use fluoroscopy to facilitate accurate lead placement.



Using the Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 5).

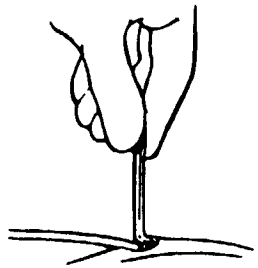


Figure 5. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Ventricular Lead

Advance the lead into the right atrium. For added control in maneuvering the lead tip through the tricuspid valve, the distal end of the lead may be slightly curved by inserting a gently curved stylet (Figure 6). After the lead tip is passed into the ventricle, the curved stylet may be replaced with a straight stylet. Then the lead tip may be advanced to the right ventricular apex while taking care to avoid perforation of the ventricular wall.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 6).

127

30. Of the 22 deaths, 15 systems were explanted and returned for analysis. The results of the analyses (PCD® and Transvene™ leads) must be provided. What did device interrogation reveal? How many of the 41 Transvene™ lead systems which were explanted were returned and analyzed? How long were the leads implanted? A description of the protocol for analysis and the results of the analyses on all leads and devices must be provided. The PMA application must document how your study has addressed the need for the return and analysis of all Transvene™ leads and the PCD®.

RESPONSE:

In the 762 implants in 757 patients, a total of 41 units (5.4%) were explanted secondary to patient deaths, infection, heart transplant, low battery voltage measurement and PCD® Device performance issues. This information was provided in the PCD® Transvene™ System PMA Application, Clinical Experience Report, Section IX, System Performance. For convenience, Table 30-1 provides an overview of the units explanted, and returned to Medtronic for analysis and reason for explant.

PCD® Transvene™ System Reasons for PCD® Device Explant	
Reason	**All Models**
Number of Implants	762
Patient Death	15
Infection	17
Cardiac Transplant	5
Low Battery Voltage Measurement	1
PCD® Device Performance Issues	3
Total	41

Table 30-1: Reasons for PCD® Device Explant

There were 22 reported patient deaths and 15 devices were explanted and returned to Medtronic for analysis. In the remaining 7 deaths, either the family refused to allow the PCD® Transvene™ System to be explanted or the patient expired and was buried prior to notification of the primary investigator.

Of the fifteen devices which were explanted due to patient death, ten (10) have been analyzed and found to be performing within normal specifications. The remaining five (5) PCD® Devices are pending final analysis, however, none of the deaths were classified as being PCD® Transvene™ System related, and initial analysis has not indicated that these devices were performing outside normal specifications. Results of analysis performed on the 41 explanted devices is presented in Table 30-2.

PCD® Transvene™ System Final Analysis on Explanted PCD® Devices (N = 762)	
Within Normal Specifications	20
Hermetic Leakage at IC	1
Random Component Failure	2
Shorted on Pulse 2 Output	1
Analysis Pending	17
Total	41

Table 30-2: Final Analysis on Explanted PCD® Devices

Of the 41 devices explanted, final analysis on 19 units indicated that the devices were functioning within normal specifications. Final analysis is not available on 17 units which have been explanted. The reason for explant in these units includes patient death (5), infection (10) and cardiac transplant (2). It should be noted that none of these devices were explanted secondary to concern over the function of the implanted PCD® Transvene™ System.

Four PCD® Devices were explanted for the following device performance issues:

- explanted due to a Power On Reset (POR) condition that was not related to the delivery of external defibrillation or cautery (N = 1);
- explanted for lower than expected battery voltage for time in service (N = 1);
- explanted secondary to failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode (N = 1); and
- explanted post inappropriate delivery of VF therapy during a manual capacitor charge time (N = 1).

Of the 41 lead systems previously discussed, 21 lead systems, or portions of systems, were returned. Of those 21 only one 6966 lead was damaged, specifically, the helix. The remaining leads were found to be within specification.

The investigational plan requests that if the PCD® Transvene™ System is explanted during the course for any reason (i.e., patient death, infection, cardiac transplant or PCD® Device performance issues) that the PCD® device be returned to Medtronic for analysis. In addition, the patient informed consent also indicates that the patient allows permission of explant of the PCD® Transvene™ System at the possible time of his/her death.

The PCD® Transvene™ System clinical dataform specifically requests information on whether the system has been explanted and justification for not explanting the system.

A description of the protocol for PCD device and Transvene lead analysis is presented below.

M.4 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD™ Transvene™ System and the PCD™ Epicardial System. The PCD™ Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with 742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD™ System. In the PCD™ Transvene™ System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD™ Epicardial System, 14.2% of the patients experienced a clinical complication and 32.9% of the patients experienced a clinical observation.

Table IM-7 and IM-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD™ Transvene System
PCD™ Transvene System versus PCD™ Epicardial System Reported Complications

Reported Complications	PCD™ Transvene™ System (N = 757)	PCD™ Epicardial System (N = 742)
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	9.5%	2.8%
Device Related	0.5%	0.9%

Table IM-7: Reported Complications: PCD™ Transvene™ System versus PCD™ Epicardial System - 2/1/93

31. Please discuss the circumstances surrounding the death of the patient who died (b)(4) months post implant. What did interrogation of the device reveal?

RESPONSE:

The circumstances of this patient death (Patient ID (b)(4) were provided in PMA Amendment (9/18/92), Volume 3 page 543-545. A copy of the patient death summary is provided here for convenience.

In summary, the patient had been admitted for worsening symptoms of congestive heart failure, renal decompensation and increased frequency of spontaneous VT and VF episodes. In addition the patient had digitalis toxicity. The patient's condition worsened and the family members elected not to use heroic measures in the treatment of the patient. The patient eventually expired secondary to progressive cardiac failure due to left ventricular pump dysfunction. The patient death was classified as non-sudden cardiac and not related to the PCD® Transvene™ System. Final interrogation of the PCD® Device, at the time of explant, indicated normal battery voltage and charge time and the patient had experienced no new episodes of VT or VF since the last follow-up visit. The PCD® Device was explanted and analysis found the device to be performing within specifications.

32. Of the perioperative deaths, how many devices were programmed OFF? Please discuss the circumstances surrounding each death. The number of perioperative deaths must be reported in a table and be identified as sudden cardiac, non-sudden cardiac or non-cardiac. Were there other deaths when the device was programmed OFF? 118

RESPONSE:

As of February 1, 1993, there have been a total of 51 reported patients deaths in the 757 patients who received a PCD® Transvene™ System. There have been five (5) reported perioperative patient deaths with a resultant perioperative mortality of 0.7%. The patient death in which the PCD® Device was programmed OFF (Patient ID (b)(6) was classified as non-sudden cardiac and was not related to a ventricular tachyarrhythmia episode. Table 32-1 summarizes these perioperative patient deaths.

PCD® Transvene™ System Perioperative Patient Deaths	
Death Classification	**Number of Patients**
Sudden Cardiac	2
Non-Sudden Cardiac	2
Noncardiac	1
TOTAL	5 (0.7%)
PCD® Device OFF	1

Table 32-1: PCD® Transvene™ System Perioperative Death Classifications

The circumstances of these patient deaths were provided in PMA Amendment (9/18/92), Volume 3 page 503-580. A copy of the patient death summaries is provided here for convenience.

In the total patient death group of 51 patients, there were seven (7) deaths were the device was programmed OFF. In none of these cases did the primary investigator indicate that the patient death was related to the implanted PCD® Transvene™ System. There was one sudden cardiac death in which the PCD® Device was programmed OFF. One month post implant of the PCD® Transvene™ System, this patient experienced fourteen (14) episodes of VF which were all successfully terminated by the PCD® Device. The patient was admitted for evaluation and during this hospitalization requested that the PCD® Device be programmed OFF. Approximately 30 minutes later the patient experienced an episode of ventricular tachycardia and expired. The death classifications for those patient deaths where the PCD® Device was programmed OFF are provided in Table 32-2.

Mean LED	16.0 (n=702)	15.2 (n=105)
Mean DFT	14.8 (n=316)	13.8 (n=62)
Spontaneous VT: Number of Patients Number of Episodes % Success	 226 5430 98.7%	 60 1770 98.9%
Spontaneous VF: Number of Patients Number of Episodes % Success	 198 973 99.1%	 37 248 98.8%
One Year Overall Survival One Year SCD Survival	95.3% 99.8%	100.0% 100.0%
Patients with complications	138 18.2%	24 20.9%

The patients population (n=115) with 12 months or more of follow-up is predominantly male (79.1%) with a mean age of 57.0 years. In the majority of patients (48.7%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. The treatment efficacy for this patient population was 98.9% for spontaneous VT episodes, and 98.8% for VF episodes, which is equivalent to the overall patient population with 98.7% and 99.1% respectively. Overall and sudden cardiac death one year survival for this patient population is 100.0% since all patients have been followed for one year or greater. In the patients followed for 12 months or more there has been one death which is classified as non-sudden cardiac. This death occurred 684 days (22.5 months) post implant. Twenty-four (20.9%) of the patients followed for 12 months had a complication.

Based on the data above, the PCD™ has performed safely and reliably for patients followed for 12 months or greater.

18

34. Please provide an engineering drawing of each Transvene™ lead model which identifies the segments of the lead and a description of the tests that each segment and the full lead body underwent. 136

RESPONSE:

35. Since flex testing exerts a considerable amount of stress on the lead, and is essential to life testing, why was it considered that (b)(4) cycles at a bend radius of (b)(4) inch per lead model over a (b)(4) month period would be sufficient? Describe how the full lead and different segments were flexed. Did you do a finite element stress analysis to validate the flex testing stress?

RESPONSE:

Flex testing is considered an important factor in assessing lead flex life longevity. The Medtronic flex standard minimum requirement is a (b)(4) (b)(4) of (b)(4) cycles at a (b)(4) inch radius. This flex standard was applied to the design of the (b)(4) Lead System Test sequence. Initially each lead was inspected and tested for DC resistance. In the (b)(4) test protocol, each lead went through the following sequence of tests (b)(4)

(b)(4)

(b)(4)

At the end of the Lead System Testing, each lead was visually reinspected, had the DC resistance measured and intermittency tested. In conclusion, all the leads met all test requirements without failure and therefore demonstrate an acceptable assurance of safety and reliability in lead design.

Each lead had a section marked to identify were to flex the lead body. This was done to assure that each lead had the same section of the lead body flexed for each of (b)(4) test cycles. By assuring the same location, each lead body was subjected to a total of (b)(4) cycles of flexing. The marked section was in the same region identified as "Lead Body" in the answer to question 34 for each lead Model. The Lead Body flex test set-up is illustrated below:

FLEX TEST FIXTURE

(b)(4)

(b)(4)

Each lead was flexed at the rate of (b)(4) cycles (b)(4) over a radius of (b)(4) inch at (b)(4) until reaching the required number of cycles per the Lead System Testing protocol.

The Model 6999, a unipolar, subcutaneous patch, was subjected to a flex test of the (b)(4) that could be a result of patient body motion. The patch flex set-up is illustrated below:

36. In light of the failure of your platinum sputtered polyurethane bradycardia pacing leads, and since the Transvene™ lead Model 6966 is also a platinum sputtered polyurethane lead, please provide documentation regarding the failure mechanism of the pacing leads and all relevant information pertaining to these cases. How can we be assured that the failure may be restricted to the bradycardia pacing leads? Based on your testing to date regarding the pacing leads and the testing of the Model 6966 lead, discuss the potential and the probability of failure of the Model 6966 lead. A side by side comparison of the Model 6966 and the 4,000 series bradycardia pacing leads must be provided. The comparison must include material, design, dimensions, function, tests performed and a schematic drawing.

RESPONSE:

Background on Brady Pacing Lead Experiences

Medtronic utilizes two systems to monitor performance of its brady pacing leads. The analysis of returned product is used to identify lead failure mechanisms. However, it cannot be used to estimate clinical performance since all leads/lead segments are not explanted or returned. Clinical performance is monitored through our (b)(4) (b)(4) a multi-center study currently involving eleven representative U.S. Clinical centers and over (b)(4) leads. Lead performance in the (b)(4) is presented as actuarial survival from clinical complications resulting in lead explants or abandonment. Specific complication criteria have been established (reference Medtronic Product Performance Report, February 1993, in Appendix C). Since all leads are not explanted it is not always possible to relate a clinical complication to a specific failure mechanism and not all complications are associated with lead failure.

The primary failure mechanisms for brady pacing leads are conductor fracture and insulation failure. Conductor fractures are primarily associated with the widely accepted "Subclavian Stick" implant procedure using percutaneous lead introducers. Leads implanted by this procedure can be clamped and crushed between the first rib and clavicle, leading to fracture of the conductor, and sometimes, insulation failures as well. Bipolar leads are more susceptible to this failure mechanism than unipolar leads because of their larger lead body diameter. Crush fractures tend to occur primarily during the first two years post implant.

For leads with polyurethane insulation, the primary insulation failure mechanisms are Environmental Stress Cracking (ESC) and Metal Ion

Oxidation (MIO); both tend to occur starting about 2 years post implant. Bipolar leads tend to be more susceptible to insulation failure than unipolar leads.

ESC is associated with stress on the lead either induced during manufacture or via implant procedure. Newer generation Medtronic leads have greater ESC resistance due to improvements in design, manufacturing processes and materials.

MIO is an oxidative degradation of polyurethane insulation. The reaction is catalyzed by metal ions released by the corrosion of the conductor coils. To reduce the potential for MIO, newer Medtronic lead designs have applied a sputtered coating of platinum to the conductor coils. Also, (b)(4) polyurethane tends to be more resistant to MIO than (b)(4) Medtronic has used an accelerated oxidation environment, (b)(4) to evaluate MIO and potential factors that can minimize its occurrence.

A table depicting the frequency of these failure mechanisms (conductor fractures, MIO and ESC) for brady leads, Models 4004/M and 4058/M, follows this response. As shown, conductor fracture due to crush is the predominate failure mode. See table, Failure Mechanisms, following this response.

The Model 4004/M is a bipolar lead incorporating (b)(4) polyurethane and platinum coating. As of February 28, 1993, survival probability of the Models 4004/4004M is (b)(4) months (reference the February 1993 Product Performance Report in Appendix C). Crush fracture is the primary source of lead failures to date, with rates comparable to that of earlier bipolar lead designs.

Over the past several months Medtronic and FDA have had numerous discussions about the occurrences of failure associated with MIO in the Model 4004/M lead. As of February 28, 1993, Returned Product Analyses has identified (b)(4) failures out of approximately (b)(4) leads implanted (b)(4) MIO failures in previous lead designs tend to predominate (b)(4) areas: proximally in the pacemaker pocket, medially in the clavicular region, and distally near the ring electrode. With Models 4004/M, platinum sputter coating appears to reduce the occurrence of MIO proximally and medially. The majority of the MIO failures (b)(4) occurred distally. Distal failure occurs between the ring electrode and the AV valve and appear to be related to flexing of the lead associated with ventricular contractions.

Initial (b)(4) testing was conducted under static conditions and gave no indication of this failure mechanism. Currently testing is underway to develop a dynamic (b)(4) test to study factors affecting this

failure mechanism and potential corrective actions. To date, we have been able to induce failures and are conducting experiments to understand contributing factors.

In order to illustrate the similarities and differences between the brady and tachy leads, a side-by-side comparison of the Model 6966 to the 4,000 series brady leads is presented in a table following this response. Note that only bipolar, polyurethane, brady leads from the 4,000 series are presented (includes Models 4016A, 4058/M, 4024, 4004/M and 4012/4082). This is due to their similarity of design characteristics to the 6966, and also because these brady leads are being, or were, widely used in the field, and therefore present with comprehensive data from the (b)(4) (b)(4) and Medtronic's returned product analysis. Tests performed to qualify the brady leads were the same as those used for the tachy leads (except for high voltage system and crush testing). All tests are consistent with Medtronic standards and requirements for implantable cardiac leads (reference response to #34). Drawings of these brady leads are also presented following the comparative tables.

Some common features to all the leads in the table are the (b)(4) conductor coil, coaxial coil design, polyurethane insulation (b)(4) and/or (b)(4) and platinum alloy electrode material. Like the 6966 lead, the Models 4016A, 4058/M and 4024 also have platinum coating on the conductor coil and (b)(4) as the inner insulation. Individual lead differences include the electrode fixation mechanisms, i.e., screw-in helix versus tines and the (b)(4) versus (b)(4) insulation usage. Using (b)(4) insulation provides more stiffness, and greater resistance to insulation failure, whereas (b)(4) provides for greater ease of handling.

As presented in the lead comparison table, the brady lead most similar to the 6966 lead is the 4016A. Both have (b)(4) polyurethane as the inner(most) insulation, (b)(4) for the middle/outer insulations, distal screw-in fixation mechanisms, similar French (introduction) sizes and virtually identical insulation dimensions. Only the coil dimensions vary slightly. Note that the 4058/M lead is also very similar to the 4016A; the only substantive change is the introduction size, (b)(4) Model 4016A and 4058/M leads have shown excellent clinical performance; for the 4016A actuarial survival is 98.2% at three years (b)(4) implants) and for the 4058/M actuarial survival is 99.7% at three years (b)(4) implants), reference the CLS and returned product analysis as presented in the Medtronic Product Performance Report, Appendix C.

As previously presented, the 6966 lead has a larger body diameter than the brady leads. This is to be expected given the tripolar coaxial design of the lead. Given the larger French size of the 6966, it is more susceptible to crush between the clavicle and rib than the smaller French

leads. Lead fracture due to crush in this area is, however, a recognized failure mechanism for all transvenous leads implanted via subclavian insertion, (brady or tachy leads). This is vigorously addressed in product labeling (lead technical manuals) and includes appropriate cautions about the use of the procedure.

Also, the larger diameter of the 6966 lead body and presence of a defibrillation coil electrode proximal to the distal pace/sense ring of the 6966 lead imparts more stiffness to it than the brady leads. Hence, there is less lead body movement below the valve when the 6966 is implanted in the right ventricle as compared to a brady lead. This was clearly evident in the videotape comparing the in-vivo flexing of both a brady and tachy lead (presented in FDA/Medtronic meeting of February 18, 1993). Decreased flexing of the 6966 lead below the valve is our basis for expecting flex-related MIO will not be a significant failure mechanism of the 6966 lead.

Analysis of Transvene Model 6966 Lead and Clinical Presentation

The Model 6966 tripolar tachy lead is comparatively less flexible than brady leads. Therefore, distal MIO as evident in a very small percent (b)(4) of brady 4004/4004M leads is not necessarily indicative of a similar occurrence in the 6966 lead. A videotape illustrating the clinical flex performance differences between brady and tachy leads was presented during the FDA/Medtronic meeting on February 18.

Analysis of the Model 6966 lead, as it relates to the potential for MIO, indicates that it would be more likely to occur on the middle versus the outer or innermost insulations. Lead failure due to MIO typically is found on the inner insulation on returned bipolar brady leads. Therefore, this failure mechanism is not expected to significantly affect the (b)(4) outer insulation of the 6966 lead. Should MIO occur on the outer insulation of the 6966 lead, the net effect would be an increased defibrillation electrode surface area. This would not be expected to significantly affect system performance. Additionally, the more resistant properties of (b)(4) (to MIO), of the 6966 innermost insulation, are expected to further reduce the potential for MIO (99.7% survival Model 4058/M at three years, see Product Performance Report, Appendix C).

For the Model 6966 lead, should the middle (b)(4) insulation fail, it would likely present initially as an intermittent short (as is more typical with brady leads) and can progress over time if not identified and treated, to a hard (direct) short. These could manifest initially as oversensing, and ultimately as integrated bipolar sensing, respectively (intermittent versus hard short). In the case of a hard short of the middle insulation, specifically, shorting the pacing tip to the common

defibrillation electrode, an integrated bipolar sensing system is created. In this type of system, sensing occurs between the unipolar pacing tip and the common defibrillation electrode (versus standard bipolar sensing between the pace/sense tip and the ring electrodes). This type of sensing system is identical to the (b)(4) (b)(4) currently in clinical trials, and also to Medtronic's historic Transvene RV lead, the Model SP2100 lead. These type of integrated systems have been shown to be clinically acceptable. Note that fifteen Model SP2100 leads were implanted at the start of the Transvene clinical study. There have been no observations or reported problems related to the SP2100 lead performance. (Data from the SP2100 lead have been incorporated in the clinical experience analysis reported in this PMA application.)

Intermittent sensing could result in oversensing, if the detection criteria are also met, and this could result in delivery of inappropriate, i.e., not needed, therapies. This can be considered a "safe failure" given the system would "err" by oversensing (versus undersensing) and the patient could receive an unnecessary therapy. Also, patients are instructed to report therapies to their physicians; this facilitates identification of any inappropriate therapy.

Recently, a Model 6884[1] lead was explanted after 27 months when the patient received a heart transplant. The lead was fully functional at explant, however, returned product analysis has indicated the presence of some MIO in the clavicular region. Transvene leads, like brady leads, are implanted by subclavian insertion and are susceptible to being crushed between the clavicle and first rib. As indicated above, with brady leads this can result in conductor fractures, insulation failures or both. Analysis of the specific Model 6884 lead is ongoing and a more detailed report will be provided in approximately 30 days.

It should be noted that MIO is only one potential failure mechanism of implantable leads. As discussed, others include fracture due to crush in the area of subclavian insertion, environmental stress cracking due to stresses the in-vivo environment may impart to the lead and lead dislodgement.

---

[1] The Model 6884 lead is the earlier version of the Model 6966 lead and differs only in the connector pin configuration; the 6884 has a (b)(4) high voltage connector pin and the 6966 has a (b)(4) high voltage connector pin. Otherwise the leads are the same.

Transvene Clinical Assessment Experience

Given over 2000 worldwide Transvene patients implanted to date, ranging from zero to forty months implant duration, there have been no reports of undersensing, insulation failures, or oversensing that could not be managed via reprogramming. Furthermore, the benefits of Transvene implantation are dramatically apparent from the perspective of perioperative mortality, 0.7 percent for Transvene versus 5.3 percent for epicardial implants. Transvene survival from SCD is 99.5 percent and overall survival is 93.3 percent at one year. Additionally, Transvene implants, on average, require 8 days in hospital versus 11 days for an epicardial system; a significant cost savings. In summary, the benefits of the Transvene system performance clearly surpass the potential for MIO, or other potential failure mechanisms, in the 6966 lead.

Conclusions

Although Medtronic cannot assure that MIO or other lead failure mechanisms will not occur in the Model 6966 lead, the actual benefits of the Transvene system, as previously discussed, would appear to exceed the potential risk due to MIO. Analysis shows that the potential for MIO to occur in the 6966 lead would result in a "safe failure." Note that preclinical and animal testing cannot completely simulate the long-term implant environment, thereby eliminating all potential for lead failures in-vivo. This was recognized by Congress in implementing the Postmarket surveillance provision in the Safe Medical Device Act of 1990. It is clear that postmarket surveillance mechanisms, e.g., returned product analysis and chronic lead monitoring, are more appropriate mechanisms for evaluating and managing potential failure mechanisms of implantable cardiac leads.

Summary of Safety and Effectiveness (March 26, 1993)

A. Indications For Use

The Medtronic PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System with Nonthoracotomy Cardioversion and Defibrillation Electrodes (hereafter referred to as the PCD Transvene System) is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias. Indications for use include:

- Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
- Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.
- Patients undergoing replacement of a previously implanted implantable cardioverter defibrillator.

The patients who meet the above patient selection criteria should have also undergone a complete cardiological evaluation that includes electrophysiological testing. Electrophysiologic evaluation and testing of the safety and efficacy of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the PCD Transvene System.

The PCD Transvene System components, except for the defibrillation lead system, are identical to the PCD Epicardial System which was unanimously recommended for approval by the FDA Advisory Panel on February 3, 1992 and FDA approved on February 11, 1993.

Market approval **is not** being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems. In addition, market approval **is not** being sought for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

B. Description of the Transvene Lead/PCD System

The Medtronic Tachyarrhythmia Control System consists of two fundamental configurations: (1) the implantable configuration and (2) the external configuration. Both configurations use the Transvene lead system. See Figure III B-1

The implantable configuration is composed of a Pacer-Cardioverter-Defibrillator (PCD) device, implantable leads, and a programmer. The PCD device is an implantable, multiprogrammable, automatic tachyarrhythmia control device.

The external configuration is composed of an External Tachyarrhythmia Control Device (ETCD), a patient cable, implantable leads, and a programmer. The ETCD is an externally-operated, multiprogrammable, tachyarrhythmia control device.

Intended Uses - Transvene Leads

Model 6963 Lead

The Medtronic Transvene Model 6963 Unipolar, Coronary Sinus or Superior Vena Cava, Transvenous Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use in the coronary sinus or superior vena cava and is designed to be used with an implantable tachyarrhythmia control device along with at least one other lead, such as the Model 6966 Tripolar, Right Ventricular, Transvenous Lead.

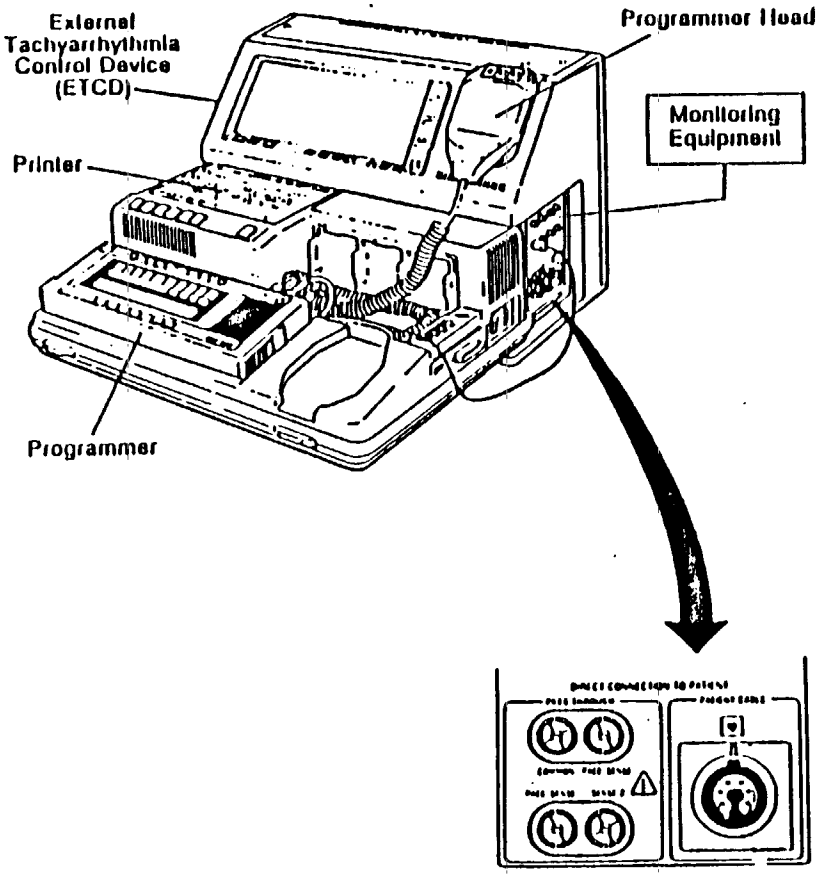
The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

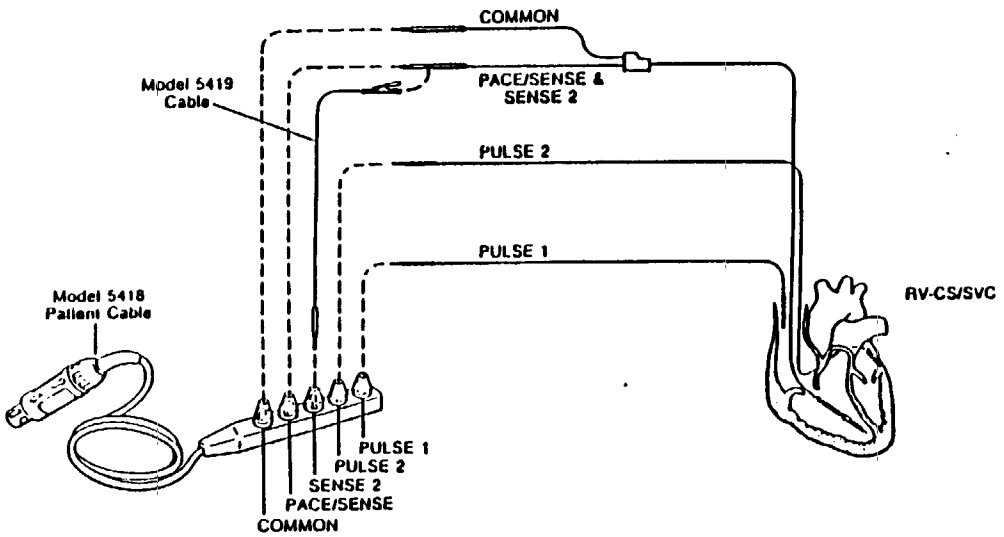
Model 6966 Lead

The Medtronic Transvene Model 6966 Tripolar, Endocardial, Screw-In Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation pulses in the ventricle. The lead has application where implantable tachyarrhythmia control systems are indicated.

The Model 6966 lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool.

Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be potential a problem.





Connections to Model 5418 Patient Cable for
Typical Simultaneous or Sequential Pathway (RV-CS/SVC).

FIGURE III B-1

MEDTRONIC CONFIDENTIAL

2027

The three electrodes of this lead are the coil, ring, and helix:

The defibrillating **coil electrode** is most proximal to the pulse generator and connects electrically to the connector pin of the unipolar leg of the bifurcation. This unipolar leg will not accept a stylet.

The **ring electrode** is proximal to the helix and connects electrically to the connector ring of the bipolar leg of the bifurcation.

The **helix tip electrode** is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector pin with a special fixation tool. The helix electrode connects electrically to the connector PIN of the bipolar leg of the bifurcation. This bipolar leg is the only one that will accept a stylet.

The helix tip electrode and the ring electrode may be used for bipolar pacing and sensing; the coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Model 6999 Lead

The Medtronic Model 6999 Unipolar, Subcutaneous, Oval, Patch Lead features an electrode for the delivery of cardioversion and defibrillation therapies. It is intended for long-term use and is designed to be used with an implantable tachyarrhythmia control device along with at least one complementary defibrillating electrode and a pacing/sensing lead; a third defibrillating electrode may also be used.

The lead has application for patients in whom implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

Intended Uses - PCD Device

The Model 7217B PCD device is intended for use in patients who are at high risk of sudden death due to ventricular tachyarrhythmia.

Current medical research indicates that such patients should:

- have survived at least one episode of a cardiac arrest, presumably due to a ventricular tachyarrhythmia as evidenced by resuscitation using a transthoracic defibrillator. The ventricular tachyarrhythmia should not be caused by an acute myocardial infarction; or

- in the absence of a prior cardiac arrest, have recurrent, sustained ventricular tachycardia that occur spontaneously or can be induced, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically.

Extensive electrophysiologic evaluation and testing of the proposed pacing, cardioversion, or defibrillation therapies are recommended during and after the implantation of the Model 7217B PCD device. Before permanently programming the PCD device to the automatic detection and delivery of the VT and/or VF therapies, the patient should have demonstrated a satisfactory response to the proposed therapy.

Intended Uses - ETCD

The Model 5355 External Tachyarrhythmia Control Device is intended for use in conjunction with an antitachycardia/defibrillation lead system during diagnostic studies for implanting the Model 7217B PCD device.

Indications for use of the ETCD include:

- Patients experiencing recurrent episodes of ventricular tachyarrhythmia,

- Patients who survived a cardiac arrest due to a ventricular tachyarrhythmia and are at risk for repeated episodes,

- Patients who are undergoing an assessment of the efficacy of antitachycardia pacing, cardioversion, or defibrillation therapies in anticipation of an implantable cardioverter-defibrillator.

Components of the System

A list of components used in the system is given below. It is separated into a listing of those components for which market approval is sought and those components that are now commercially available. Market approval is not being sought for use of the PCD Device with other manufacturers transvenous defibrillation lead systems or for the use of the PCD Transvene lead system with other manufacturers implantable cardioverter defibrillators.

Seeking Approval:

Transvene Leads
- Model 6963
- Model 6966
- Model 6999

Pacer-Cardioverter-Defibrillator (PCD) Device
- Model 7217B

External Tachyarrhythmia Control Device (ETCD)
- Model 5355 ETCD
- Model 5418 Patient Cable
- Model 5419 Patient Cable
- Model 5414 Test Load
- Model 5417 EGM Cable

Programmer Software Cartridge
- Model 9788 - Memory Module for 7217B PCD Device and 5355 ETCD Devices

Lead Accessories
- Model 6701 Lead End Cap

Commercially Available:

Programmers Model 9710 and accessories

Printers Model 9751/9712

Components Used in the Implantable Configuration

The implantable configuration is composed of a PCD Device, lead system, and a 9710 Programmer with applicable software cartridge. The implantable device is a Model 7217B PCD Device. The PCD device requires an appropriate lead system consisting of up to three cardioversion/defibrillation electrodes. See Figure III B-2. The Transvene leads used with the Model 7217B PCD Device are the Models 6963, 6966, and 6999.

The Model 9710 Programmer is commercially available. Two printers are also commercially available. When higher printing speeds are desired, it is recommended that the programmer be used with the faster printer, the Model 9751. If slower printing speeds are acceptable, as may be the case in some follow-up situations, the Model 9710 Programmer can be used with the battery-powered Model 9712 Printer.

Components used in the External Configuration

The external tachyarrhythmia control system is composed of the Model 5355 ETCD, a Model 5418 Patient Cable, a Model 5419 cable, lead system, and a Model 9710 Programmer with applicable software cartridge, see Figures IV-A-3, 4. The ETCD uses replaceable batteries as its power source. The Model 5418 Patient Cable and Model 5419 Cable are designed to connect the Transvene leads to the ETCD. Like the implantable system, the ETCD uses the same Transvene leads (Models 6963, 6966, and 6999).

Figure IV-A-3

MEDTRONIC CONFIDENTIAL

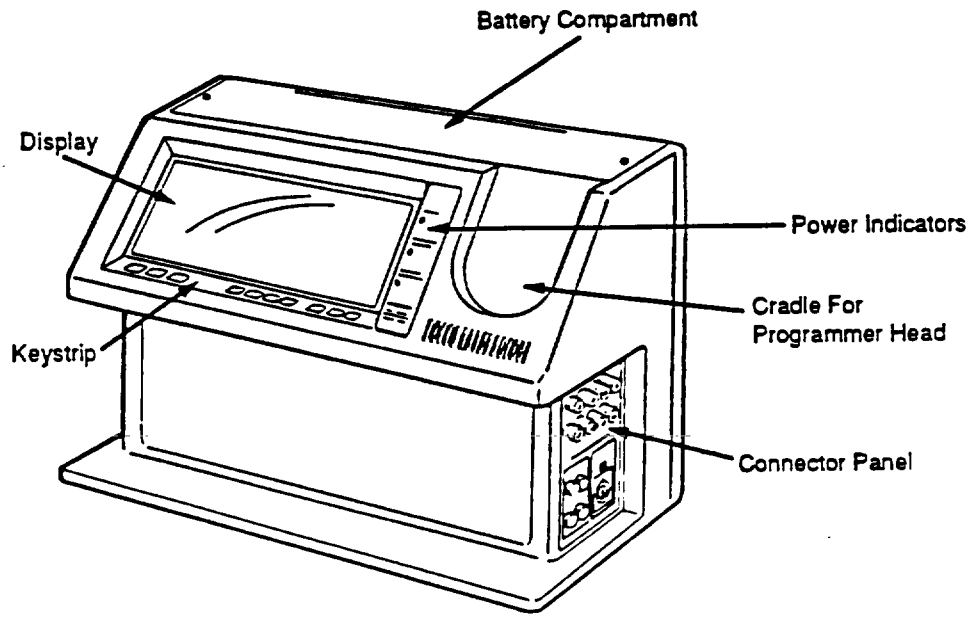

Figure IV-A-4. Model 5355 External Tachyarrhythmia Control Device

Purpose of the System

PCD System Configuration

The PCD Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or a progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation. The PCD Device also has bradycardia pacing capability. The Transvene leads allow the PCD device to deliver these therapies to the heart.

ETCD System Configuration

The ETCD is an external tachyarrhythmia control device designed to deliver overdrive pacing, cardioversion, defibrillation, and bradycardia therapies in the same fashion as the PCD device. The ETCD can be programmed to automatically deliver overdrive pacing therapy upon detection of VT. When used as a component of a system that includes the appropriate Medtronic programmer and applicable software cartridge, the ETCD can deliver manually-initiated VT pacing, cardioversion, and defibrillation therapies. The ETCD allows the assessment of the Transvene lead system characteristics and aids in the assessment of lead system pacing and sensing characteristics.

Overview of System Features

General

The PCD device is designed to automatically detect episodes of VT or VF and, upon detection, deliver the appropriate programmed pacing, cardioversion, or defibrillation therapies. The device has two independently programmable detection and therapy procedures, one for VT and a second for VF.

When used as a component of a system that includes the appropriate Medtronic programmer and dedicated software, the ETCD is designed to deliver manually initiated cardioversion and defibrillation therapies. The ETCD is also designed to detect episodes of VT and VF. It can automatically deliver VT overdrive therapies (burst and ramp) upon detection of a VT.

VT Detection and Therapy

Both the PCD device and ETCD use a VT detection algorithm which can use up to three separately programmable criteria as it monitors the cardiac cycle length to identify the presence of a tachycardia. Upon detection, the devices deliver their first programmed VT therapy. If the VT episode persists and is again detected, up to three additional independently programmable VT therapies may be delivered to restore the patient's normal cardiac rhythm. This progression of four VT therapies can be tailored to each patient's need. For the PCD device the therapies may be selected from two methods of overdrive pacing (burst and ramp) and synchronized cardioversion.

For the ETCD the same overdrive pacing therapies can be automatically delivered, with cardioversion therapy being available as a manual therapy.

VF Detection and Therapy

The VF Detection algorithm monitors the cardiac cycle length to identify a VF episode. Upon detection, the PCD device provides a programmable high energy defibrillation pulse for VF therapy. Up to a maximum of four VF therapies may be delivered for ongoing detected VF episodes. Each defibrillation therapy consists of one (single pulse) or two (simultaneous or sequential) high voltage pulses designed to restore the normal cardiac rhythm.

For the ETCD, each cardioversion or defibrillation therapy, which must be initiated manually via the programmer, also consists of one high-voltage pulse or two (simultaneous or sequential) high-voltage pulses in the same fashion as the PCD devices.

Bradycardia Therapy

For both the ETCD and PCD devices, bradycardia pacing is delivered in the VVI mode. Asynchronous, (VOO), pacing is not available, and is avoided even with magnet application since this type of pacing has increased potential to initiate ventricular arrhythmias in patients receiving this system.

Lead Systems

The PCD Device and the ETCD perform pacing, sensing, cardioversion, and defibrillation through multiple electrodes in the lead system. Listed below are the electrodes and their function:

- The PACE/SENSE electrodes are incorporated in the right ventricular defibrillation lead. These electrodes function as the sensing circuit and deliver pacing pulses. The PACE/SENSE electrodes are used for sensing in conjunction with the SENSE2 electrode.
- The COMMON electrode is an electrode coil that serves as the cathode for cardioversion, defibrillation, and pacing.
- The PULSE2 electrode is an electrode coil that serves as the anode for cardioversion and defibrillation.
- The PULSE1 electrode is an optional electrode coil that serves as an additional anode for sequential and simultaneous cardioversion and defibrillation.

Cardioversion and defibrillation current pathways are between the PULSE2 and COMMON electrode coils and, if the additional lead is implanted, between the PULSE1 and COMMON electrode coils.

Other Capabilities

The physician may use the ETCD or the PCD devices to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the appropriate software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia.

The PCD device will provide the physician with information, via the Programmer, about its present programmed status and data on its operation accumulated between office visits. This information may be printed and retained in the patient's file.

The PCD Device and ETCD can also transmit an electrogram to the programmer. The electrogram is the electrical signal sensed on the leads.

A programmer-generated set of symbols, termed Marker Channel™, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

In addition, the ETCD provides a display of measurements and other information related to delivered cardioversion and defibrillation pulses.

99

With this information and other features, the ETCD can be used to assess the suitability of the lead system and its placement for individual patients.

PCD Battery Longevity Expectations

The longevity of the Model 7217B PCD Device depends upon several factors, including programmed bradycardia pacing parameters, the percentage of paced to sensed events, the pacing load, and on the frequency of high voltage capacitor charging. The longevity projections found in Table IV-A-1 apply under the following conditions:

- 65 ppm pacing rate,
- 5.4 V pacing pulse amplitude,
- 0.49 ms pacing pulse width, and
- 500 ohm pacing lead.

Projected Longevity[1]
Table IV-A-1

Pacing/Sensing	34 Joule Charging Frequency	Average Longevity Model 7217B
100% Sensing	Quarterly	5.0 years
15% Pacing	Monthly	4.2 years
100% Pacing	Monthly	3.4 years

The longevity of the device decreases with the following:

- An increase in pacing rate,
- An increase in pacing amplitude,
- A decrease in pacing impedance,
- An increase in pacing pulse width,
- An increase in the percentage of bradycardia paced to sensed events, or
- An increase in the charging frequency.

Each 34 Joule charging cycle will typically decrease the longevity of the device by approximately six days.

---

[1] These preliminary longevity projections are based upon accelerated battery data and device modeling. They include an estimate of five months between time of manufacture of a PCD device and its implant. If a device was stored for the full twelve-month shelf life, the average longevity would be reduced an estimated 4.3 to 5.9 months, depending on device use. With the stated condition, 100% pacing and monthly 34 Joule charging cycles, the minimum longevity of the device will be 2.5 years (7217B). Average refers to the projected mean longevity of the modeled run of PCD devices at the stated conditions. Minimum longevity means that virtually all (i.e., 99.9%) of all modeled production run of PCD devices will attain the value given.

C. Alternative Practices and Procedures

The use of implantable defibrillators in patients with drug refractory ventricular tachycardia/ fibrillation (VT/VF) and in survivors of sudden cardiac death has reduced the arrhythmic mortality in these patients. Other treatments available to treat ventricular tachyarrhythmias include antiarrhythmic drug therapy, ventricular tachycardia surgery, transthoracic defibrillation and other market released implantable defibrillators with epicardial defibrillation lead systems.

D. Marketing History

All of the Medtronic Transvene Tachyarrhythmia Control System device components which have been implanted in the U.S. to date have been part of the IDE clinical study and have followed the FDA approved investigational protocol. In November 1991, the Medtronic PCD Transvene System, and respective components described in this submission, were market released in Europe. In March 1991, the Medtronic PCD Epicardial System, and respective components, were market released in Europe. And in February 1993, the FDA approved the Medtronic PCD Epicardial System.

E. Adverse Effects

Potential adverse effects which may be associated with the use of the PCD Device include but are not limited to: failure to detect ventricular tachycardia or ventricular fibrillation; failure to terminate ventricular tachycardia or ventricular fibrillation; delivery of pacing or shock therapy when no ventricular tachyarrhythmia is present, which would precipitate an episode of ventricular tachycardia or ventricular fibrillation; acceleration of a ventricular arrhythmia; failure to capture after a shock delivery; discomfort or pain during or following the delivery of electrical shock; or infection.

The following additional, potential adverse effects associated with all pacemaker systems include loss of normal pacemaker function due to battery failure or other component failure, inability to program a pacemaker pulse generator because of programmer failure, infection, erosion, undesired muscle or nerve stimulation, and inadequate sensing or pacing. Any demand pulse generator can be affected by magnetic, electrical and electromagnetic signals of sufficient strength or with characteristics which mimic cardiac function. Possible effects of electrical interference on pulse generator operation include reversion to asynchronous pacing, inhibition of output pulses and rapid synchronous pacing. Certain environmental sources can couple sufficient energy into a cardiac pacing system to damage the pulse generator or cardiac tissue adjacent to the electrodes.

Failure of the pulse generator system to function properly may result in the patient experiencing the symptoms for which the pulse generator was originally indicated.

The potential complications related to the use of the PCD Transvene Lead System include, but are not limited to, the following patient-related conditions: fibrillation, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax and hemothorax. Other potential complications related to the lead system include, but are not limited to, the following: lead dislodgement, lead conductor fracture, and insulation failure.

The above referenced information is provided in the labelling of the PCD Transvene System.

F. Summary of Studies

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6966, Model 6963 and Model 6999 Transvene Leads, Model 7217B PCD, Model 5355 ETCD, and Model 9788 Memory Module.

The animal studies were performed to evaluate acute and chronic performance PCD Transvene System and to validate that the PCD and ETCD System are safe for human use.

Finally, human clinical trials were performed to evaluate the safety and effectiveness of the PCD Transvene System in treating patients with life-threatening ventricular arrhythmias.

All of the studies have demonstrated that the PCD Transvene System functions safely and is appropriate for human use.

The following summaries are provided in this section.

1. Model 6966, Model 6963 and Model 6999 Nonclinical Testing

2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod Model 7217B PCD Nonclinical Testing

3. Animal Testing

4. Clinical Study of the PCD Transvene System

1. Model 6966, Model 6963 and Model 6999 Defibrillation Leads: Summary of Nonclinical Testing

To validate the performance of the Medtronic Tachyarrhythmia Control System nonclinical laboratory (bench) testing, animal studies and human clinical trials were performed. All of the nonclinical bench and animal testing demonstrated that the devices are safe and performed according to design intent.

The nonclinical laboratory (bench) testing provides information relative to the Model 6963 CS/SVC lead, Model 6966 RV lead, Model 6999 SQ patch lead, and related system components.

a. Electrical Testing

Electrical D.C. resistance testing was performed to ensure proper functioning of the Model 6963, 6966 and 6999 leads.

Seventeen Model 6963, thirty-five Model 6966 and eighteen Model 6999 leads were submitted for testing. Electrical resistance was measured utilizing a milliammeter under ambient room conditions. All samples measured were within the individual design specifications.

b. Environmental Analysis Testing

The purpose of the testing was to subject the lead to temperature extremes to determine the lead's resistance to the thermal stresses when transported from extremes of climate.

Thermal Shock

Fifteen Model 6963 and thirty-five Model 6966 leads were subjected to five cycles from -45°C to 70°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute. Thirty-five Model 6999 leads were subjected to five cycles from -40°C to 66°C with a soak time of thirty minutes at each temperature extreme with a transfer time of one minute.

After the thermal shock testing was completed visual inspection and electrical resistance measurements were performed. There were no visual defects and the electrical D.C. resistance of all the samples met the design specification.

c. Mechanical Testing

The purpose of the mechanical testing was to determine the mechanical integrity of the leads to ensure that the devices are safe, reliable, and suitable for their intended use and conform to design specifications. The leads and/or assemblies were subjected to the following:

- flex testing
- composite pull strength testing
- crimp/weld pull strength testing
- insertion/withdrawal force testing
- A.C. impedance/leakage testing

Flex Testing

The flex testing consisted of mounting the insulated conductor coils and uninsulated electrode coils of the Models 6963, 6966 and 6999 in a lead flex test fixture. The insulated conductor coils and uninsulated electrode coils were flexed under ambient room conditions at a specified radius. Eleven samples were used in each test. Samples exceeded specifications and therefore are considered to be satisfactory for their intended use.

Lead Joint Tensile Strengths

Pull testing of the various lead joints is conducted to ensure that the integrity of the joint meets the design specification and is, therefore, adequate for its intended application. The testing conducted consists of a composite pull test which evaluates the overall pull strength of the lead and crimp pull testing that evaluates the crimped connections of the leads to assure specification conformance.

Composite Pull Strength

Leads were boiled in Ringer's solution or soaked in normal saline and pull tested, while wet (the lead is usually cut in half to facilitate fixturing limitations) utilizing a tensile testing machine. The samples were pulled until failure at a rate of five inches per minute. The initial failures were then analyzed statistically for the confidence level in meeting the specification for the composite lead which is 1.0 lb. minimum.

Model 6963 data demonstrates that with a 95% confidence at least 97% (distal) and 99.9% (proximal) of the leads will meet or exceed the specification.

Model 6966 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Model 6999 data demonstrate that with a 99% confidence at least 99.9% of the leads will meet or exceed the specification.

Therefore, Models 6963, 6966 and 6999 leads, with respect to composite pull strength, are adequate for their intended use.

Crimp/Weld Pull Strengths

Crimp and weld pull strength tests were conducted to evaluate the strength of the connections to ensure that they meet the design specification and are, therefore, adequate for their intended application. The connections tested are:

- Distal crimp sleeve to conductor coil crimp (6963)
- Double crimp core to conductor coil crimp (6963)
- Electrode coil to double crimp core weld (6963)
- Electrode coil to distal crimp sleeve weld (6963)
- Tip crimp sleeve to conductor coil crimp (6963)
- Connector pin to conductor coil crimp (6963 and 6999)
- Helix electrode to inner conductor coil crimp (6966)
- Electrode ring to middle conductor coil crimp (6966)
- Transition sleeve to electrode coil weld (6966)
- Transition sleeve to outer conductor coil crimp (6966)
- Fixed connector pin to outer conductor coil crimp (6966)
- Connector ring to middle conductor coil crimp (6966)
- Rotating connector pin to inner conductor coil crimp (6966)
- Manifold crimp sleeve to conductor coil crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4) crimp (6999)
- Manifold crimp sleeve to electrode coil (b)(4) crimp (6999)

Subassemblies were submitted for testing and pull tested by using a tensile testing machine. The samples were pulled until failure at a rate of four inches per minute.

Pull strength testing consisted of a minimum of 15 subassemblies of each crimp connection and a minimum of

7 subassemblies of each weld connection All samples tested exceeded the individual specification. The test results indicated that with a 95% confidence, at least 95% of the leads will have crimp and weld strengths that exceed the specification.

Therefore, the Model 6963, 6966 and 6999 leads, with respect to crimp and weld connection pull strengths, are adequate for their intended use.

Insertion/Withdrawal Forces

Insertion/withdrawal forces are measured to ensure compatibility with the implantable device without causing damage to the lead. Twenty five each of the lead Models 6963, 6966 and 6999 were tested with the Model 7217B PCD Device connector modules. There were no physical changes and all measurements met the design specification.

A.C Impedance/Leakage Testing

Fluid leakage tests are conducted on the lead assemblies/implantable device connector to determine leakage. Ten of each lead model Models 6963, 6966 and 6999 were tested with the Model 7217B connector modules. A.C. impedance was measured from the PCD device case to the lead connections while immersed in fluid. All samples met the design specification.

d. Biocompatibility Testing

The materials used in the Models 6963, 6966 and 6999 that are directly exposed to body tissue are:

- Polyurethane
- Silicone rubber (methylvinylpolysiloxane)
- Silicone rubber/titanium dioxide
- Platinum/Iridium

These materials have been shown to be biocompatible through many years of use in Medtronic permanent implantable endocardial/myocardial permanent pacing leads. In addition to extensive implant experience with these materials, standard biocompatibility tests have been performed to verify the biocompatibility of the above-listed materials. Testing has demonstrated that all materials are nonhemolytic, nonpyrogenic, nontoxic, nonmutagenic and

biocompatible. Therefore, the materials passed the tests and are considered suitable for human implant. The materials used in the Models 6963, 6966 and 6999 are identical to those used in other commercially available Medtronic pacing leads.

e. Lead System (Life) Testing

In addition to the aforementioned tests, the Transvene leads were subjected to system, or life, testing. Further testing also evaluated the leads with respect to crush resistance. Testing included subjecting the leads to soaking, flexing and high-voltage pulsing. A separate test evaluated crush performance. The purpose of these tests was to subject the leads to severe conditions and assess the overall integrity of the system.

D.C. resistance values and intermittance data measured before and after being subjected to soaking, multiple flexing and high voltage pulsing, as well as crushing, demonstrated the non-thoracotomy leads satisfied requirements and are therefore acceptable for their intended use.

2. Non-clinical Testing of the Related Components of the Transvene Lead system: Models 7217B PCD, Model 5355 ETCD and Model 9788 MemoryMod

Non-clinical testing of these components was provided Volume 4 of the original PMA application (P900061) dated September 27, 1990, Volume 3 of the amendment dated March 8, 1991, and Volume 2 of the amendment dated August 30, 1991. A summary of the test results for each of the components is provided.

Model 7217B PCD: Summary of Nonclinical Testing

Testing of the Model 7217B pulse generators and the peripheral devices that comprise the system, i.e., the Pacing System Analyzers, the Model 9710 Programmer utilizing the Model 9788 MemoryMod and the Model 9751 Printer have been tested and found to be acceptable. All aspects of system interaction and operation are in accordance with the Model 7217B PCD Device and Model 9788 technical manuals and system specifications. Therefore, the Medtronic Tachyarrhythmia Control System, in its entirety, is acceptable for its intended use.

Model 9788 Memory Module: Summary of Nonclinical Testing

The Medtronic Model 9788 MemoryMod Cartridge was designed for insertion into the commercially available Model 9710 Programmer. When inserted, it becomes an integral part of the non-invasive programming system for the implantable PCD devices to establish pacing, ventricular tachycardia (VT) detection and therapy, ventricular fibrillation (VF) detection and therapy, and electrophysiological study (EPS) capabilities of an implanted pacemaker/ cardioverter/defibrillator (PCD). Both the Model 7217B PCD device and the Model 5355 ETCD are programmed with the Model 9788 MemoryMod cartridge when used with the Model 9710 Programmer.

Testing of the Model 9788 MemoryMod cartridge has demonstrated conformance to specification requirements. Therefore, the Model 9788 MemoryMod is acceptable for its intended use with the Model 7217B PCD Devices and the Model 5355 ETCD Device.

Model 5355 ETCD: Summary of Nonclinical Testing

Testing of the Model 5355 ETCD and respective accessories has shown conformance to specification requirements. Therefore, the Model 5355 ETCD Device/accessories are acceptable for their intended use.

3. Animal Testing

The information presented in this section is an accumulation of several studies, some of which FDA has previously reviewed in IDE submissions (G870102). These studies demonstrate the safety of the Transvene lead Models 6963, 6966 and 6999.

A variety of non-thoracotomy leads were evaluated in a series of four canine studies. Descriptions of the leads, as well as the study number(s) (1, 2, 3 or 4) in which they were evaluated, are presented below.

Description: Non-thoracotomy Leads

CORONARY SINUS/SUPERIOR VENA CAVA LEADS

Model 6963, evaluated in Study No. 4, is a silicone, unipolar, coronary sinus or superior vena cava lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies.

Model 6881, evaluated in Study Nos. 2, 3 and 4 is functionally equivalent to the Model 6963 except the 6881 has a 3.2 mm connector.

Model 10285, evaluated in Study No. 1, is the temporary version of the Model 6963/6881.

RIGHT VENTRICULAR LEADS

Model 6966, evaluated in Study No. 4, is a polyurethane, tripolar, extendable/retractable, screw-in lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies. Additionally, the 6966 has a 3.2 mm connector for pacing and sensing.

Model 6884, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6966 except the 6884 has a 3.2 mm connector in place of the 6.5 mm connector for the cardioversion-defibrillation electrode.

Model 10284, evaluated in Study No. 1, is the temporary version of the Model 6966/6884.

SUBCUTANEOUS PATCH LEADS

Model 6999, evaluated in Study No. 4, is a silicone, unipolar, oval, subcutaneous patch with a 6.5 mm connector and platinum alloy electrode coils that are partially embedded in the silicone patch for delivery of cardioversion and defibrillation therapies. Additionally, the patch is embedded with (b)(4) (b)(4)

Model 6895, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6999 except the 6895 has a 3.2 mm connector and is covered with (b)(4) (b)(4)

Model 10317, evaluated in Study No. 3, is functionally equivalent to the 6895 except it is embedded on the outer edge with (b)(4) (b)(4)

Although model numbers differ, all leads in each of the three groups are functionally equivalent. The various model numbers reflect an evolution of temporary to transvenous lead development, as well as minor changes, such as the connector pin modification from 3.2 mm to 6.5 mm.

Additional devices were used to evaluate the non-thoracotomy lead studies in canines. These are described below.

External Devices for Implant Support

Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD provides the same detection capabilities as the implantable Model 7217B PCD Device. Therapies are identical except that the maximum output energy is 40 joules (J) and automatic defibrillation and cardioversion are not available in the Model 5355. The Model 5355 ETCD provides measurement and display of output waveform parameters and ETCD status, an isolated electrogram signal, and passthrough connections of pacing and sensing electrodes to external instrumentation.

Model 2394 External Cardioverter/Defibrillator (ECVD)

The Model 2394 ECVD instrument can deliver: (1) a single stimulation pulse on one output channel, or (2) a pair of pulses, delivered individually on the two different output channels. Monophasic and biphasic pulses are provided, output capacitance can be varied between 10 and 150 microFarads (mf) depending on which external capacitor modules are used, and pulse width

can be specified as a fixed duration (0.1-19.9 ms) or "tilt" (10-90%). Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Model 2376 External Cardioverter/Defibrillator (ECVD)

The output stimulation parameters of the Model 2376 are very similar to those of the Model 2394 except for the following modifications:

- All pulses are monophasic, truncated, exponential waveforms.
- Output capacitance is fixed at 50 microFarads and pulse width is determined by a fixed pulse duration only.
- Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Study Methods

All canine studies were conducted according to the 1966 and 1970 Animal Welfare Acts, 1985 NIH Laboratory Animal Use and Care Guidelines and GLP regulations. Adult mongrel canines were used for all studies. The dogs weighed 20 kg or more.

Specific details of each study are presented in the following "Animal Studies/Results" section.

Each study is briefly described below. Both acute and chronic studies were performed to assess the toxicity of the non-thoracotomy lead system as well as its stability over time.

Study #1: Acute Toxicity Testing of Non-thoracotomy Leads

The objective of this study was to quantify the amount and nature of shock-induced damage to the myocardial tissue resulting from multiple, high energy defibrillation shocks delivered through transvenous defibrillation leads and a subcutaneous patch. This information has previously been submitted to the agency in the Non-Thoracotomy IDE, reference Document Control Number G870102/S23; FDA Approved October 4, 1990. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results of these studies revealed only minimal shock-induced necrosis (<0.1-0.5 percent by weight), which did not result in functional impairment of the cardiac tissue. Therefore, the use of the Model 6963, 6966 and 6999 leads did not result in significant myocardial damage in canines and could be safely implanted in humans.

Study #2: Model 6881, 6884 and 6895 Chronic Lead Evaluation

The objective of this study was to evaluate the suitability of the lead system for human clinical use. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Study results demonstrate that the performance of the non-thoracotomy lead system when used with the PCD and ETCD devices is in conformance with system design and expected operation.

One canine in this study has presented with two mastocytomas; a common type of skin tumor in middle-aged canines. This observation is not related to the PCD system, nor is it relevant to the clinical application of the PCD system. The tumors were excised and the animal remains in good health.

Study #3: Model 6881, 6884 and 6895 Chronic Lead Defibrillation Study

This study is an evaluation of the chronic stability of the non-thoracotomy lead system via the monitoring of defibrillation and pacing thresholds. In addition, histopathological examinations have been performed to assess the amount and nature of shock-induced damage to the myocardial tissue resulting from defibrillation shocks. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results demonstrate stable pacing, sensing and defibrillation thresholds over time. Additionally, histopathology analysis shows no cardiac tissue damage due to delivery of defibrillation shocks.

Study #4: Model 6963, 6966 and 6999 Chronic Lead Defibrillation Study

This study is an ongoing evaluation of the non-thoracotomy lead system to assess chronic defibrillation threshold stability, pacing thresholds, intracardiac sensing capabilities and tissue damage. Results indicate the lead system performs as intended; DFTs and pacing thresholds have remained stable throughout the study (60 weeks) and intracardiac sensing is appropriate. Additionally, pathology data, to date, indicates minimal localized trauma to the cardiac tissue (<0.05 percent by weight).

Conclusion

All of these canine studies have demonstrated that the non-thoracotomy lead system, which includes the Model 6963 CS/SVC lead, 6966 RV lead and 6999 SQ patch lead, functions safely and is therefore appropriate for human use.

4. Summary of Clinical Experience

A. Introduction

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device (Medtronic Model 7217B with Epicardial Cardioversion/Defibrillation Leads) incorporates multiprogrammability, multiple detection and therapeutic options for the treatment of ventricular tachycardia and fibrillation. The current system, while providing lifesaving treatment of ventricular arrhythmias, requires a significant surgical procedure (thoracotomy, median sternotomy, etc.) for the placement of the epicardial lead system. The need to reduce the surgical mortality and morbidity associated with epicardial cardioversion/defibrillation lead systems has lead to the development of the PCD® Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene™ Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of **February 1, 1993.**

The PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, with the addition of Transvene™ leads.

The data analysis is organized in functional rather than chronological categories in order to present a complete picture of each of the PCD® Device's various functions. The sections included in this summary are:

- Indicated Patient Population/Therapeutic Options
- PCD Therapy Applications
- Indicated Patient Population
- Study Objectives and Protocol Summary
- Overview of Clinical Experience
  - Implant Data
  - Spontaneous VT/VF Episode Experience

Overall Success Rate
- Complications and Observations
- Inactive Patients
- Patient Deaths
- Clinical Experience by Primary Indication
- Patients not Meeting Implant Criteria
- Comparison to AICD Clinical Experience
- Comparison to PCD® Epicardial Clinical Experience
- PCD® Transvene™ System Performance

This summary provides an overview of the clinical experience which verifies that the PCD® Transvene™ System is safe and effective in the indicated patient population.

B. Indicated Patient Population

B.1 Patient Population

The PCD® Transvene™ System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD® Device.

Results provided in this application will support Medtronic's request for market release of the PCD® System for use in the following patient population:

- Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

- Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Malignant ventricular tachyarrhythmias remain a major unsolved problem in the management and prevention of coronary artery disease. It is estimated that 450,000 people experience sudden cardiac death annually, and 80%-90% of these events are caused by ventricular fibrillation. (Gillum RF. Sudden coronary death in the United States. Circulation 1989; 79:756-765.)

Survivors of out-of-hospital cardiac arrest not associated with acute myocardial infarction are at risk for recurrent cardiac arrest as reported by Wilber, et al.(Wilber, et al. Out-of-Hospital Cardiac Arrest - Use of Electrophysiologic Testing in the Prediction of Long-Term Outcome. NEJM 1988; Vol.318:19-24.). In this study group of 166 survivors of out-of-hospital cardiac arrest, ventricular arrhythmias were inducible in 131 patients (79%) and were suppressed by antiarrhythmic drug therapy or surgery (or both) in 91 patients (72%). During a median follow-up of 21 months, cardiac arrest recurred in 29 patients: 11 in whom inducible arrhythmias had been suppressed, 12 in whom inducible arrhythmias persisted and 6 in whom arrhythmias could not be induced at initial electrophysiologic study.

C. PCD® Transvene System Therapy Applications

The PCD® System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias and/or recurrent ventricular tachycardia.

For this patient population, the primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular arrhythmias. The use of the PCD® Transvene™ system allows for the application of identical therapies as an epicardial system without requiring an open chest procedure for implantation of the lead system. This less invasive surgical approach allows the system to be applied in patients who may not be able to undergo an open chest procedure. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD® pulse generator.

The PCD® System allows the titration of therapies for patients with ventricular tachycardia while providing critical defibrillation backup. Multiple detection algorithms are designed to allow the device to distinguish ventricular tachycardia from sinus tachycardia and atrial fibrillation. In addition, independent detection algorithms for VT and VF allow the delivery of different types of therapy for each of these two arrhythmias. The incorporation of antitachycardia pacing algorithms allows the use of pacing for the termination of well tolerated ventricular tachycardia. These algorithms, which are rate adaptive, can adapt

to changes in the ventricular tachycardia and successfully terminate the episode. Defibrillation therapy is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The incorporation of multiple cardioversion and defibrillation pathways (SINGLE, SEQUENTIAL and SIMULTANEOUS) allows the physician to provide an adequate cardioversion/defibrillation efficacy safety margin for all patients. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia.

Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters, and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

D. Study Objectives and Protocol Summary

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD® System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD® system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD® system, pace/sense, detection and therapy functions in both the acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population. The analysis will also provide data demonstrating the safety and effectiveness of the Model 5355 ETCD.

This summary presents safety and efficacy evaluation performed on 757 patients, 657 of which have implant durations equal to or greater than six months.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD® System:

Pre-implant Patient Assessment
Lead System Testing at Implant
Implantable Pulse Generator Testing at Implant
Pre-hospital Discharge Testing
Follow-up Evaluation 1 and 3 months post implant then at 3 month intervals

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD® System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD® System with Transvene™ Leads is included in this report.

E. Overview of Clinical Experience

This report covers a total of 762 implants in 757 patients of the PCD® Device with the Transvene™ Defibrillation Lead System. A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table E-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD® Transvene™ System
Implant Distribution

	Total	U.S.	Int'l
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table E-1: PCD® Transvene™ System - Implant Distributions - 2/1/93

The mean documented implant duration for this patient population is 11.7 months and ranged from implant to 37.4 months. The cumulative implant duration is 8894.8 months. There are 657 patients with implant durations equal to or greater than six months. Table E-2 provides the distribution of follow-up quantity of patients by data form type.

PCD® Transvene™ System
Follow-Up Quantity
by Data Form Type

(b)(4)

(b)(4)

Table E-2: PCD® Transvene™ System - Follow-Up Quantity - 2/1/93

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary

indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table E-3 provides a data summary on these patients. Also included is the data summary of the patients with 6 months and 12 months of follow-up.

Table IF-2: PCD® System Data Summary - All Transvene™ Patients versus Transvene™ Patients with 6 mo Follow-up - 2/1/93

a1

E.1 Implant Data

Implants of the PCD® Device may use two or three Transvene™ leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

Table E-4 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD® Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD® Transvene™ System **Mean LED and DFT Values**				
Lead System	**Implant Frequency**	**Mean LED**	**Implant Frequency**	**Mean DFT**
All Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table E-4: PCD® Transvene™ System - LED and DFT Values - 2/1/93

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD® Device.

E.2 Spontaneous VT and VF Episode Experience

A total of 458 patients (60.5%) have experienced a spontaneous ventricular tachyarrhythmia episode that has been detected and treated by the PCD® Device. A total of 141 patients experrienced VT only, 142 patients (18.8%) experienced VF only and 175 patients (23.1%) experienced both an episode of VT and VF.

There have been a total of 12,009 episodes of spontaneous VT or VF as detected by the PCD®. The overall PCD® Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD® is presented in Table E-5.

PCD® Transvene™ System
Success Rate in Terminating Spontaneous VT/VF Episodes

	Number of Episodes Successful	Total Number of Episodes	Efficacy Rate
VT	9864	10,027	98.4%
VF	1951	1982	98.4%
Total	11,815	12,009	98.4%

Table E-5: PCD® Transvene™ System - Success Rate for Spontaneous VT/VF Episodes - 2/1/93

E.2.1 Spontaneous VT

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 10,027 spontaneous episodes of VT have been detected by the PCD® Device in 316 patients. The mean number of episodes per patient with VT was 31.7 and ranged from 1 - 531 episodes.

Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Of the 9864 successfully terminated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® Transvene™ System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Sixty patients experienced 163 (1.6%) episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirty-nine patients experienced 95 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 68 episodes occurred in 21 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy**. Reprogramming and pharmacologic intervention resolved these events.

E.2.2 Spontaneous VT Episode Experience By Primary Indication

The primary indications for implant of the PCD Transvene System were sudden cardiac death (**SCD**), recurrent sustained ventricular tachycardia (**VT**) and sudden cardiac death associated with recurrent sustained ventricular tachycardia (**SCD/VT**). Spontaneous VT episode efficacy by primary indication is provided in Table E-6. The overall efficacy for spontaneous VT episodes is greater than 98% for each of the patient groups. There is no difference in therapy efficacy among the patient's indications. Table E-6 contains the spontaneous VT episode therapeutic efficacy.

PCD® Transvene™ System
Spontaneous VT Episode Therapeutic Efficacy
By Primary Indication

Indication	# Episodes Successful	# Total Episodes	% Success
SCD	1148	1157	99.2%
VT	7450	7591	98.1%
SCD/VT	1266	1279	99.0%
Total	9864	10027	98.4%

Table E-6: PCD® Transvene™ System - Spontaneous VT Episode Efficacy by Primary Indication -2/1/93

E.2.3 Spontaneous VT Episode Experience By Therapy Type

The PCD® Device incorporates three programmable VT therapy types, RAMP, BURST and CARDIOVERSION, for the treatment of recurrent ventricular tachycardia. Spontaneous VT episode efficacy by programmed therapy type is provided in Table E-7.

PCD® Transvene™ System Spontaneous VT Episode Efficacy By Programmed Therapy Type			
VT Therapy Type	**# Success**	**# Attempts**	**% Efficacy**
Ramp	4903	5374	91.2%
Burst	4266	4738	90.0%
Cardioversion	695	818	85.0%

Table E-7: Spontaneous VT Episode Efficacy by Therapy Type - 2/1/93

E.2.4 Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 2491 spontaneous episodes of VF have been detected by the PCD® Device in 317 patients. The mean number of episodes per patient was 7.9 and ranged from 1 - 262 episodes. A review of the chart per investigator for this patient that experienced the 77 episodes of VF revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (91.3%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 99.1% were successfully treated with one of the four programmable VF therapies.

Sixteen patients experienced 31 episodes (1.3%) in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Nine patients had 22 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Four patients experienced 5 ineffective episodes that were detected as VF by the PCD® System. One of these patients (b)(6) required external defibrillation to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Another patient (b)(6) had an episode recorded as ineffective on the event counters but presented in sinus rhythm. Subsequent evaluation demonstrated appropriate PCD® function. Another of these patients (b)(6) had two spontaneous episodes of VT that were detected as VF by the PCD® while in the hospital for progressive CHF. These episodes required external cardioversion. The patient requested the PCD® be turned OFF. Patients was alive at the last known follow-up. The last of these four patients (b)(6) experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on a monitor the patient developed VF. The PCD® delivered the programmed therapy which terminated the episode but the patients developed EMD, arrived at the ER comatose and died.

Four patients (one patient (b)(6) experienced 2 episodes due to AF but is described below again) experienced 4 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. One patient (b)(6) experienced an episode where all four therapies

failed secondary to RV lead fracture. The patient had Twiddlers Syndrome. Reoperation was required. It appears that the inappropriate therapy was not due to VT/VF but due to noise. Another patient ((b)(6) had a surgical procedure (CABG) where the CS lead dislodged post surgery. The episode that was detected was due to the lead dislodgment. The third patient (b)(6) had incessent episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The fourth patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

E.2.5 Spontaneous VF Episode Experience By Primary Indication

The primary indications for implant of the PCD® Transvene™ System were sudden cardiac death (**SCD**), recurrent sustained ventricular tachycardia (**VT**) and sudden cardiac death associated with recurrent sustained ventricular tachycardia (**SCD/VT**). Spontaneous VF episode efficacy by primary indication is provided in Table E-8. There is no difference in therapy efficacy among the patient's indications. The overall efficacy for spontaneous VF episodes is greater than 98% for each of the patient groups.

PCD® Transvene™ System
Spontaneous VF Episode Therapeutic Efficacy
By Primary Indication

Indication	# Episodes Successful	# Total Episodes	% Success
SCD	665	686	96.9%
VT	908	916	99.1%
SCD/VT	378	380	99.5%
TOTAL	1951	1982	98.4%

Table E-8: PCD® Transvene™ System - Spontaneous VF Episode Efficacy by Primary Indication -2/1/93

E.2.6 Spontaneous VF Episode Experience By Therapy Type

The PCD® Device incorporates three programmable defibrillation pathways, SEQUENTIAL, SINGLE and SIMULTANEOUS, for the treatment of ventricular fibrillation. Spontaneous VF episode efficacy by programmed defibrillation pathway is provided in Table E-9.

PCD Transvene™ System
Spontaneous VF Episode Efficacy
By Programmed Therapy Type

VF Therapy Type	# Success	# Attempts	% Efficacy
Sequential	1525	1549	98.5%
Simultaneous	426	433	98.4%

Table E-9: PCD® Transvene™ System - Spontaneous VF Episode Efficacy by Therapy Type - 2/1/93

E.3 Overall Success Rate

Of the 757 patients who received a PCD® Transvene™ System, 597 patients (78.9% - 597/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. The performance of the PCD® Transvene™ System therapies have been thoroughly evaluated and been shown to be effective in detecting and terminating episodes of ventricular tachyarrhythmia.

There have been no reports of a patient death due to the PCD® Transvene™ System not detecting a spontaneous episode of VT or VF.

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of either VT or VF was 98.4% with a VT success rate of 98.4% and VF success rate of 98.4%. The incidence of unsuccessful termination of an apparent "true" episode of ventricular tachycardia despite delivery of all four therapies was 0.7% (68/10027).

The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite delivery of all four therapies was 0.3% (5/1982).

The evaluation of spontaneous episode experience indicates that the PCD® Transvene™ System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

F. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, there have been a total of 176 complications identified in 147 patients and 214 observations identified in 180 patients in the PCD® Transvene™ System patient population. Thus, 19.4% (147/757) of the patients have experienced a clinical event which was defined as a complication and 23.8% (180/757) of the patients have experienced a clinical event which was defined as an observation. Table F-1 summarizes how these events were reported with U.S versus International.

PCD® Transvene™ System Reported Complications/Observations U.S versus International		
	# of Complications	# of Observations
U.S.	104	93
International	72	121
Total	176	214

Table IG-1: PCD® Transvene™ System Complications/Observations U.S. versus International - 2/1/93

Table IG-2 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System Reported Complications/Observations By Category		
Category	**Complications**	**Observations**
	Num (% of Pts)	Num (% of Pts)
Increased Defibrillation Requirements	9 (1.2%)	8 (1.1%)
Inappropriate VF Therapy Delivery	-	14 (1.8%)
Inappropriate VT Therapy Delivery	-	59 (7.8%)

Total Lead Dislodgement (n = 757)	91 (12.0%)	12 (1.6%)
Total	**176**	**214**

Table IG-2: PCD® Transvene™ System: Reported Complications and Observations - 2/1/93

Table IG-3 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD® Transvene System
Reported Complications/Observations
Lead Dislodgements <30 days and >30 days

Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=741	14 (1.9%)	10 (1.3%)	0 (0%)	1 (0.1%)
CS Lead Dislodgement n= 261	12 (4.6%)	10 (3.8%)	2 (0.8%)	2 (0.8%)
SVC Lead Dislodgement n=535	16 (3.0%)	29 (5.4%)	1 (0.2%)	6 (1.1%)
Total Lead Dislodgement n=757	42 (5.6%)	49 (6.5%)	3 (0.4%)	9 (1.2%)

Table IG-3: PCD Transvene System: Lead Dislodgements <30 days and >30 days - 2/1/93

There have been a total of 49 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 48 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent pervenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

G. Inactive Patients

There are a total of 82 patients who had received a PCD® System and are no longer active in the study as of 2/1/93. Table G-1 shows the distribution of inactive patients by reason for no longer being active in the PCD® Transvene™ System clinical study.

PCD® Transvene™ System Inactive Patients	
Inactive Patients	**All Patients**
Patient Deaths	51
Infection (Explant)	22
Heart Transplant	9
Total	82

Table G-1: PCD® Transvene™ System - Inactive Patients - 2/1/93

H. Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD® Transvene™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac: Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.

Cardiac: Deaths that occurred where the primary cause of death was determined to be cardiac in nature.

Non-Sudden: Deaths that occur greater than one hour after the onset of symptoms.

Sudden: Deaths that occur within one hour of the onset

of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**

Perioperative: Deaths that occur within thirty days of implant.

System Related: A death which results from a malfunction (operation not according to design specification) of a PCD® System component, or as a result of a device induced arrhythmia, or an interaction between a PCD® System component and the patient.

Procedure Related: A death which occurs as a result of a procedure required to implant, follow or test a PCD® System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD® Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD® System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 51 patient deaths reported in the PCD® Transvene™ System patient population. Table H-1 summarizes how these patient deaths have been classified.

PCD® Transvene™ System
Summary of Death Classifications
(n = 757)

Classifications	Number of Deaths
Sudden Cardiac	5
Non-Sudden Cardiac	30
Noncardiac	16
Total	51

Table H-1: PCD® Transvene™ System - Summary of Death Classifications - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD® Transvene™ System.

Actuarial survival analysis on the PCD® Transvene™ System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD® Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD® Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table H-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD® System with Epicardial leads (5.3% - 39/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD® Transvene™ System (n = 757) and all patients that were screened for a PCD® Transvene™ System (n = 854) regardless of implant outcome.

PCD® Transvene™ System One Year Actuarial Survival		
	Received PCD® Transvene™ System	**Screened for a PCD® Transvene™ System**
Sudden Cardiac Death	99.5%	99.4%
Non-Sudden Cardiac	96.2%	96.6%
All Cardiac	95.8%	96.1%
Noncardiac	98.1%	98.3%
Perioperative	0.7%	1.6%
Overall	93.3%	92.9%

Table H-2: PCD® Transvene™ System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD® Transvene™ System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.5% in the patient group that received a Transvene™ System and 99.4% in those who were screened for a Transvene™ System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

I. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD® Transvene™ System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD® Transvene™ System in these three groups are summarized in Table I-1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 98.4%, in the VT patient group 98.3%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD® Transvene™ System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 98.6%

This analysis indicates that the PCD® Transvene™ System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

Table I-1: PCD® Transvene™ System Data Summary by Primary Indication - 2/1/93

J. Patients Not Meeting Implant Criteria

J.1 Overview

The PCD® Transvene™ System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD® Transvene™ System decreases the potential perioperative and long term mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who can not tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality following a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, a transvenous ICD System is the only therapy available. The PCD® Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, more options for future therapy remain available; e.g. CABG is associated with increased morbidity and mortality if there has been prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In an

epicardial lead system, the lead system has a larger electrode surface area theoretically decreasing defibrillation requirements.

The smaller electrode surface areas of the PCD® Transvene™ System defibrillation leads might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that 70% of patients evaluated may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not required.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

A total of 854 patients had an evaluation of a PCD® Transvene™ System and are divided into the following groups - (1) Patients who received a PCD® Transvene™ System; and (2) Patients screened for a PCD® Transvene™ System and received a PCD® Epicardial System. Figure 1 provides an overview of the outcome of these patients.

PCD® Transvene™ SYSTEM IMPLANT EVALUATION

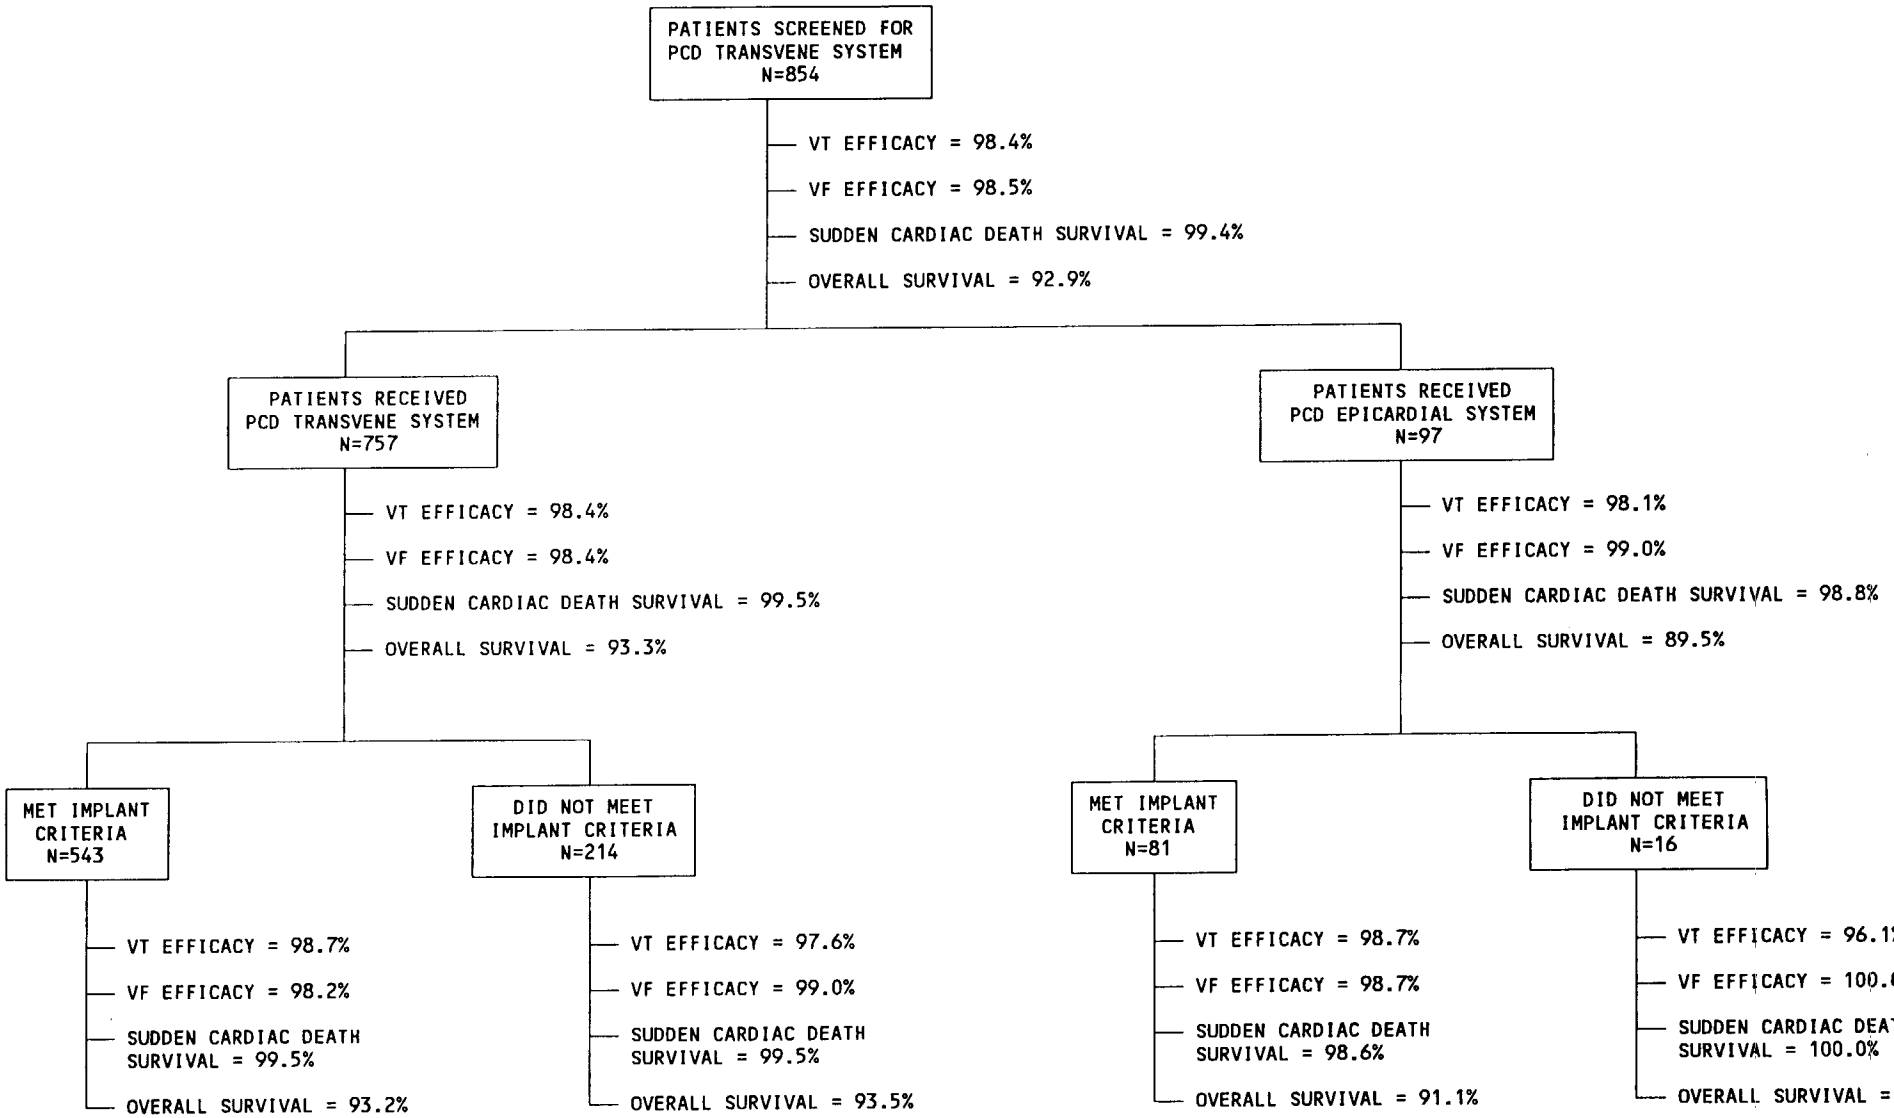

Figure 1: Patients Screened for a Transvene™ System

MEDTRONIC CONFIDENTIAL 236

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD® Transvene™ System ultimately received the system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD® Transvene™ System. It should be noted that 97.4% of the patients (737/757) received the PCD® Transvene™ System with at least a 10 Joule defibrillation safety margin between the lowest energy of success (24J) and the maximum output (34J) of the PCD® Device.

The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup P., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321. Finally, and perhaps most importantly, the investigators also felt that for these patients the risk associated with not meeting the recommended implant criteria was outweighed by the risk of not implanting an ICD or implanting an epicardial system.

There were twenty patients (2.6%), who received a PCD® Transvene™ System, whose cardiovascular condition precluded further completion of the PCD® Transvene™ System and adequate definition of a defibrillation safety margin. In all cases, the physician felt that the benefit of the PCD® Transvene™ System outweighed the risk of further inductions or the risk of a thoracotomy and elected not to evaluate or implant a PCD® Epicardial System.

J.2 Patients Receiving PCD® Transvene™ System & Did Not Meet Implant Criteria

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration at an output energy of 18 Joules or less. Of the 757 patients who **received** a PCD® Transvene™ System, 214 patients (28.3%) did not meet the recommended defibrillation implant criteria and yet still received the PCD® Transvene™ System. The physicians justification for implanting the PCD® Transvene™ System despite not meeting the recommended defibrillation implant criteria are presented in Table J-1.

PCD® Transvene™ System
Reasons for Not Meeting Implant Criteria
Physician Justification

Reason	Number of Patients
Success at $\leq$ 24 Joules	170
Difficult/Unable to Induce VF	24
Patient Condition	20
Total	214

Table J-1: PCD® Transvene™ System: Physician Justification for Not Meeting Implant Criteria - 2/1/93

Further analysis of the patient who did not meet the recommended implant criteria indicates however, that 91% (194/214) had a 10 Joule safety margin between the lowest energy of successful defibrillation and the maximum output of the PCD Device (34J). Therefore, of the 757 patients who received a PCD® Transvene™ System, 97.4% (737/757) had at least a 10 Joule defibrillation safety with the implanted lead configuration.

There were 20 patients (2.6%) in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The

implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules and or equal to 34 Joules (**N = 11**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3**).

Table J-2 provides a comparison of patient characteristics between patients who met the PCD® Transvene™ System implant criteria and those patients who did not meet the implant criteria but still received the PCD® Transvene™ System.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Patient Characteristics		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Follow-Up	12.3 months	10.1 months
Male*	422 (77.7%)	188 (87.9%)

IV	7 (1.3%)	92.0%)
Number ON Drugs at Implant	223 (41.1%)	97 (45.3%)
Number ON Amiodarone	78 (14.4%)	38 (17.8%)

* Statistically Significant ($p \leq 0.05$)

Table J-2: PCD® Transvene™ System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 2/1/93

Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with

coronary disease with concomitant life threatening ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD® Transvene™ System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD® Transvene™ System.

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table J-3.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Spontaneous VT Episode Efficacy	98.7%	97.6%
Spontaneous VF Episode Efficacy	98.7%	99.0%
Number of Patient Deaths	37	14
Perioperative Mortality	0.7%	0.5%
One Year Survival		
Sudden Cardiac	99.5%	99.5%
Non-Sudden Cardiac	95.8%	97.2%
All Cardiac	95.4%	96.7%
Noncardiac	98.5%	97.1%
Overall	93.2%	93.5%

Table J-3: PCD® Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 2/1/93

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD® Device therapies failed to terminate the episode.

Five patients experienced 7 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Three patients had 5 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Two patients experienced 2 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. The first patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The second patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

Eighteen patients experienced 68 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Nine patients experienced 44 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 24 episodes occurred in 8 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (10.1 vs 12.3 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Finally, the survival of patients receiving a PCD® Transvene™ System without meeting implant criteria (N = 214) was compared to patients receiving a PCD® Epicardial System without meeting implant criteria (N = 92). This comparison is provided in Table J-4.

PCD® Transvene™ System Patients Not Meeting Implant Criteria Survival Analysis versus PCD® Epicardial System Patients Not Meeting Implant Criteria Survival Analysis		
	PCD® Transvene System Not Meeting Implant Criteria	PCD® Epicardial System Not Meeting Implant Criteria
Number of Patients	214/757 (28.5%)	92/742 (12.4%)
Number of Deaths	14	17
Sudden Cardiac	99.5%	98.6%
Non-Sudden Cardiac	97.2%	98.8%
Noncardiac	97.1%	97.3%
Overall*	93.5%	87.6%

* Statistically Significant ($p \leq 0.05$)

Table J-4: PCD® Transvene™ System: Patients Not Meeting Implant Criteria - PCD Transvene System vs PCD® Epicardial System - 2/1/93

Though the PCD® Transvene™ System had a higher incidence of patients not meeting implant criteria (28.5%) compared to the PCD® Epicardial System (12.4%), there was no statistical difference in the sudden cardiac death patient survival. However, the overall survival of patients not meeting implant criteria with the Transvene™ System was significantly better ($p = 0.037$) when compared to the PCD® Epicardial System patients not meeting implant criteria, 93.5% and 87.6%, respectively.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate demonstration of device effectiveness and justified the implant of the PCD Transvene System. Finally, there have been no patients deaths secondary to unsuccessful termination of a spontaneous VT or VF episode in this patient population.

J.3 Description of Patients Not Meeting Implant Criteria

As noted previously, the patients not meeting implant criteria (N=214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules [79.4% of the patients]; (2) Difficult to induce VF [11.2% of the patients]; and (3) Implant procedure terminated due to poor patient condition [9.4% of the patients]. These patient groups are reviewed in the following discussion.

Lowest Energy of Defibrillation < 24 Joules

There were 170 patients in whom the PCD® Transvene™ System was implanted with a defibrillation safety margin of at least 10 Joules. Table J-5 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD® Transvene™ System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD® Transvene™ System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System (141 patients or 82.9% had only VF induced). In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4%% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, however, is limited to an average of 9.7 months.

PCD® Transvene™ System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation:	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7
Overall Spontaneous VF Episode Efficacy	99.4%
One Year Survival:	
Sudden Cardiac	99.4%
Overall	93.8%

Table J-5: PCD® Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at $\leq$ 24 Joules Clinical Experience - 2/1/93

Difficult to Induce VF

There were 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of the these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least

three episodes of VF were not induced at the time of implant, 13 patients (54.2%) have experienced a spontaneous VF episode and 21 patients (87.5%) have had VT or VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD® Transvene™ System.

There has been one reported patient death (b)(6) in the patient group with a resultant one year sudden cardiac death and overall actuarial survival of 100%.

Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these 20 patients, VT or VF has been induced at a chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD® Transvene™ System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, further reviewed indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus, there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

K. Comparison to AICD System Experience

K.1 Overview

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD® Transvene™ System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD® Transvene™ System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD® Transvene™ System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

K.2 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD® Transvene™ System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table K-1.

There were no differences between the two patient groups.

PCD® Transvene™ System Comparison of Patient Characteristics PCD® versus AICD		
	PCD®	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males % Females	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: SCD VT SCD/VT	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table K-1: Comparison of Patient Characteristics, PCD® versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD® Transvene™ System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD® Transvene™ population than in the AICD population ($p = 0.001$).

K.3 Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD® Transvene™ System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD® device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead

system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD® Transvene™ System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD® Transvene™ System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD® device provides information on the total number of VT and VF episodes detected by the PCD® device and the total number of VT and VF episodes successfully treated by the PCD® device as well as the number of VT/VF episodes where the PCD® device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD® device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD® Transvene™ System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD® Transvene™ System detection criteria.

A total of 10,027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD® device

episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

Table K-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD® Transvene™ System includes **both complications and observations.** In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD® Transvene™ System
Comparison of Complication/Observation Rates
PCD® versus AICD

Category	PCD®%	AICD%
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table K-2: Comparison of Complication/Observation Rates: PCD® Transvene™ System vs AICD Epicardial System - 2/1/93

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD® Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD® Transvene™ System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD® Transvene™ System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD® device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 3.2% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD® Transvene™ System offers clinical advantages in reducing the need for a thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing.

K.4 Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD® Transvene™ System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 51 deaths (6.7%) were reported in the PCD® Transvene™ System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD® Transvene™ System population had a lower perioperative mortality, 0.7% vs 2.7% ($p = 0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD® Transvene™ System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be

160

228

nonfunctional and awaiting replacement. For purposes of this comparison, 7 patient deaths were **censored** in the PCD® Transvene™ System patient population because the devices were deactivated at the time of patient death.

This PCD® Transvene™ System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD® Transvene™ System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD® Transvene™ System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD® System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD® Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

L. Comparison to PCD® Epicardial System Clinical Results

The PCD® Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD® Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD® Transvene™ System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD® Epicardial System and PCD® Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD® device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD® Transvene™ System clinical experience to the reported PCD® Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

L.1 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the PCD® Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table L-1 contains the characteristics of the 757 patients receiving the PCD® Transvene™ System versus the

characteristics of the 742 patients who received the PCD® Epicardial System as of 1/5/93.

PCD® Transvene™ System
Comparison of Patient Characteristics

	PCD® Transvene™ System	PCD® Epicardial System
Number of Patients	757	742
Mean Follow-Up Time	11.7 months	16.3 months
% Males* % Females	610 80.6% 147 19.4%	637 85.8% 105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication*: SCD VT SCD/VT	 281 37.1% 377 49.8% 99 13.2%	 214 28.8% 405 54.6% 123 16.6%
Cardiovascular History: Coronary Artery Disease Cardiomyopathy	 561 74.1% 238 13.1%	 569 76.7% 222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* (b)(4) (b)(4)

Table L-1: Comparison of Patient Characteristics, PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34.0% for the PCD® Epicardial patient group.

Analysis indicated that the PCD® Transvene™ System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females (b)(4) (b)(4) It is not expected that these differences will result in a different clinical outcome in the PCD® Transvene™ System patient population as compared to the PCD® Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD® Transvene™ System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups (b)(4) (b)(4) The PCD® Transvene™ System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD® Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD® Transvene™ System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but were non-inducible during electrophysiologic testing so that drug testing was not feasible.

L.2 Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD® Transvene™ System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table L-2 provides a comparison of the efficacy of the PCD® Transvene™ and PCD® Epicardial System in treating spontaneous episodes of VT and VF.

PCD® Transvene™ System Performance Comparison of Spontaneous VT/VF Efficacy PCD® Transvene™ vs Epicardial		
Spontaneous VT Episodes		
	PCD® Transvene™ System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	10,027	20,061
% Overall Efficacy	98.4%	98.3%
% Unsuccessful Termination	0.7%	1.0%
Spontaneous VF Episodes		
	PCD® Transvene System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	1092	2636
% Overall Efficacy	98.4%	98.7%
% Unsuccessful Termination	0.3%	0.5%

Table L-2: PCD® Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of VT or VF is 98.5%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD® Epicardial System which was 98.4%. Therefore, the PCD® Transvene™ System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

L.3 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD® Transvene™ System and the PCD® Epicardial System. The PCD® Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with

742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD® System. In the PCD® Transvene™ System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD® Epicardial System, 12.8% of the patients experienced a clinical complication and 25.7% of the patients experienced a clinical observation.

Table L-3 provides a comparison of the reported complications and the incidence in the two patient populations.

PCD® Transvene System
PCD® Transvene System versus PCD® Epicardial System
Reported Complications

Reported Complications	PCD® Transvene™ System (N=757)	PCD® Epicardial System (N=742)
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	2.8%
Device Related	0.5%	0.9%

Table L-3: Reported Complications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

L.4 Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD® Transvene™ and Epicardial System was performed.

Table L-4 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD® Transvene™ System patient population was 11.7 months while for the PCD® Epicardial System it was 16.3 months.

PCD® Transvene™ System
Death Classifications
PCD® Transvene™ System versus PCD® Epicardial System

Death Classification	PCD® Transvene™ System (N = 757)	PCD® Epicardial System (N = 742)
Sudden Cardiac	5	24
Non-Sudden Cardiac	30	54
All Cardiac	35	78
Noncardiac	16	34
Total	51	112

Table L-4: Death Classifications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Table L-5 provides a comparison of actuarial survival rates between the PCD® Transvene™ and PCD® Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths

which occur in the first thirty days post implant of the PCD® System.

PCD® Transvene™ System
Comparison of Actuarial Survival
PCD® Transvene™ System versus PCD® Epicardial System

One Year Survival	PCD® Transvene™ System	PCD® Epicardial® System
Number of Patients	757	742
Sudden Cardiac	99.5%	98.9%
Non-Sudden Cardiac	96.2%	96.7%
All Cardiac	95.8%	95.7%
Noncardiac	98.1%	98.0%
Overall*	93.3%	88.6%

(b)(4)

(b)(4)

(b)(4)

*

Table L-5: Comparison of Actuarial Survival: PCD® Transvene™ System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD® Transvene System®. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD® Transvene™ System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD® Epicardial System (88.6%) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD® Transvene™ System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD® Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

M. PCD® System Performance

M.1 PCD® Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection, therapy performance, and analysis of explanted devices were evaluated to assess the performance of the PCD® Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD® Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD® Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD® Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 58 devices explanted. Reasons for explant were patient death (23), infection (22), cardiac transplant (9), low battery voltage (1) and PCD Device performance issues (3). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits and this affected the battery indicator circuit only and did not affect the critical functions of the device. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other three devices indicated that two were due to random component failure and one due to shorting on Pulse 2 output. Thus, arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily

applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

Based on the clinical data collected, the PCD® Device has performed safely and reliably in the indicated patient population.

M.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of conductor coil fracture is 0.5% (4/757).

Based on the clinical data collected, the Transvene™ leads have performed safely and reliably.

N. Summary

The overall clinical experience with the PCD® Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD® Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD® Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD® Transvene™ System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD® Transvene™ System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD® Transvene™ System.

PCD® Transvene™ System Performance

- The PCD® Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

O. Clinical Experience Summary Conclusions

The PCD® Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The PCD® Transvene™ System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the perioperative and overall patient mortality as compared to the PCD® Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of 7.6 days as opposed to a mean of 10.6 days (b)(4) (b)(4) for the PCD® Epicardial System.

Medtronic asserts and the PCD® Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

H

Summary of Clinical Experience

A. Introduction

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device (Medtronic Model 7217B with Epicardial Cardioversion/Defibrillation Leads) incorporates multiprogrammability, multiple detection and therapeutic options for the treatment of ventricular tachycardia and fibrillation. The current system, while providing lifesaving treatment of ventricular arrhythmias, requires a significant surgical procedure (thoracotomy, median sternotomy, etc.) for the placement of the epicardial lead system. The need to reduce the surgical mortality and morbidity associated with epicardial cardioversion/defibrillation lead systems has lead to the development of the PCD® Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene™ Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of **February 1, 1993.**

The PCD® Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, with the addition of Transvene™ leads.

The data analysis is organized in functional rather than chronological categories in order to present a complete picture of each of the PCD® Device's various functions. The sections included in this summary are:

- Name, Intended Use of System
- Tachyarrhythmia Control System Features
- Indicated Patient Population
- Study Objectives and Protocol Summary
- Overview of Clinical Experience
  - Implant Data
  - Spontaneous VT/VF Episode Experience

Overall Success Rate
- Complications and Observations
- Inactive Patients
- Patient Deaths
- Clinical Experience by Primary Indication
- Patients not Meeting Implant Criteria
- Comparison to AICD Clinical Experience
- Comparison to PCD® Epicardial Clinical Experience
- PCD® Transvene™ System Performance

This summary provides an overview of the clinical experience which verifies that the PCD® Transvene™ System is safe and effective in the indicated patient population.

B. Name and Intended Use of the System

The Pacer-Cardioverter-Defibrillator (PCD®) device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD® Device is used in conjunction with appropriate lead systems for the treatment of patients with ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The PCD® Device also provides backup pacing in the VVI mode and noninvasive electrophysiologic (EP) study capabilities.

The PCD® Device is programmed with the market released Medtronic programmer and a unique MemoryMod™ Cartridge. The PCD® Device incorporates a two-way telemetry system which receives operational instructions from the programmer and transmits status, electrogram and event information back to the programmer for display and/or printout.

The External Tachyarrhythmia Control Device (ETCD) is an external, multiprogrammable, tachyarrhythmia control device. Its operation is similar to the PCD® Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it displays measurements of cardioversion and defibrillation therapy parameters. The ETCD is used for making defibrillation threshold measurements during the PCD® Device implantation procedure.

Components

The Medtronic PCD® Transvene™ System, which is represented in Figures 1A and 1B, for which market release approval is being requested, consists of the following components:

Implanted Device and Related Programming System
Pacer-Cardioverter-Defibrillator (PCD®) Device
Model 7217B

Programmer
Model 9710 programmer and related accessories (currently market released), plus
Model 9788 MemoryMod™ Software Cartridge
Lead System
Electrode Leads:
Model 6966
Model 6963
Model 6999

Implant Measurements System
Model 5355 ETCD™ External Tachyarrhythmia Control Device
Model 5418 Patient Cable
Model 5414 Test Load
Model 5417 EGM Cable
Model 5419 Jumper Cable

The physical characteristics of the Model 7217B are summarized in Table IB-1:

PCD® Model 7217B **Physical Characteristics**	
Feature	**Model 7217B**
Volume	113 cc
Weight	198 grams
Connector Module	Four connector ports
Power Source	Wilson Greatbatch Model 8830 Lithium Silver Vanadium Oxide
Sensing Configuration	Standard Bipolar
Pacing Configuration	Integrated Bipolar

Table IB-1: Features: Model 7217B - 2/1/93

The Model 7217B PCD® Device uses the pace/sense leads for sensing, thus providing **standard bipolar** sensing. Pacing is delivered in the integrated bipolar configuration.

C. Tachyarrhythmia Control System Features

C.1 PCD® Device

The PCD® Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation.

The main features of the PCD® Device include the detection and treatment of recurrent ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The device has two independently programmable detection and therapy algorithms, one for VT and a second for VF. A series of up to four tiered therapies can be delivered after detection of VT and a separately programmed series of up to four therapies after the detection of VF. If a therapy does not convert the arrhythmia, the next programmed therapy is delivered.

Other features of the device include VVI back-up pacing, flexible programming, noninvasive electrophysiology study capabilities, and information reports.

VT Detection and Therapy

The VT detection algorithm includes up to three separately programmable criteria to identify the presence of a tachycardia.

The PCD® Device employs a feature that automatically adjusts signal detection sensitivity to assure proper detection while minimizing sensing of T-waves following intrinsic cardiac events. This function, **Auto-Adjusting Sensitivity**, is active during any sensing period, including VT and VF detection. It allows use of sensitive settings required for VF detection without oversensing during normal sinus rhythm.

The device utilizes interval length as the primary VT detection criterion; it also provides two additional detection

criteria to add specificity in detecting pathological VT. The two programmable parameters of the Interval Criterion are:

- **Tachycardia Detection Interval (TDI):** Intervals shorter than this value (and longer than FDI are classified as VT intervals.

- **Number of Intervals to Detect (VT NID):** This parameter determines how many consecutive VT intervals must be sensed for therapy to be delivered.

The two additional criteria are:

- **Onset Criterion:** Used to determine when the rate of change in cycle length is sufficiently abrupt to qualify as the onset of paroxysmal VT and not sinus tachycardia.

- **Stability Criterion:** Used to determine when the intervals vary sufficiently on a beat to beat basis to differentiate VT from a rapid ventricular response due to atrial fibrillation.

After a VT episode has fulfilled the programmed detection criteria, the system treats the arrhythmia by delivering one of the three types of VT therapies: Burst, Ramp, or Cardioversion Therapy. Therapy delivery is highly programmable and is "tiered" to allow progression through different therapies selected by the physician to match a patient's particular clinical needs. Up to four separate therapies may be programmed in any combination of the three types to treat each arrhythmia episode. The three therapies are detailed below:

Burst Therapy treats the VT episode by pacing the heart with a "burst" of pulses at a rate greater than that of the VT episode but adapted to the VT rate. The rate adaptive pulse intervals are a programmed percentage of actual tachycardia cycle length. If a pacing sequence is ineffective and the episode is redetected, the pulse interval of the next sequence can be decremented further resulting in a higher pacing rate.

Ramp Therapy decrements each pulse interval within a single sequence of multiple pulses with the first pulse to pulse interval adapted to the VT cycle length. Each subsequent pulse interval in the Ramp sequence is shortened from the preceding interval by a programmed value. If the pacing sequence is ineffective and the VT is redected, Ramp Therapy adds an additional stimulus in each subsequent sequence.

Cardioversion Therapy: delivers synchronized, high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

VF Detection and Therapy

In order to ensure appropriate sensing and detection of VF, the device uses a probabilistic detection algorithm that allows for missed detections due to variations in ventricular depolarization amplitudes and intervals during VF.

Similar to the VT detection algorithm, the PCD® Device detects VF by monitoring the cardiac cycle length and comparing it to the programmed VF detection criteria, which is called the VF Interval Criterion.

The two programmable parameters of this criterion are:

- **Fibrillation Detection Interval (FDI):** Intervals equal to or shorter than this value are classified as VF intervals.
- **Number of Intervals to Detect (VF NID):** This parameter determines how many VF intervals must be sensed for therapy to be delivered.

After a VF episode has fulfilled the programmed detection

criteria, the system treats the arrhythmia by delivering up to four defibrillation therapies.

Defibrillation Therapy delivers high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

Bradycardia Therapy

The PCD® Device delivers bradycardia pacing in the VVI mode.

Other Capabilities

The PCD® Device can be used to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the Model 9788 MemoryMod™ software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia episode.

The PCD® Device will provide the physician with information, via the Programmer about its present programmed status and data on its operation. This information may be printed and retained in the patient's file.

A programmer-generated set of symbols, termed Marker Channel, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

Figure 2 provides an ECG example of an induced episode of VT detected and terminated by antitachycardia pacing and Figure 3 shows an induced episode of VF detected and terminated by a defibrillation therapy delivered by the PCD® Device.

C.2 Transvene™ Lead Systems

The PCD® Transvene™ System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three leads may be used to deliver cardioversion and defibrillation pulses. These configurations are based on a tri-polar, Right Ventricular (RV) lead (Model 6966), and either a Coronary Sinus (CS)/Superior Vena Cava (SVC) lead (Model 6963) or a Subcutaneous (SQ) lead (Model 6999) or all three of these leads (e.g. RV/CS/SQ, RV/SVC/SQ or RV/SQ, RV/SVC). The Model 6963 lead can be placed in either the Coronary Sinus/Great Cardiac vein or the Superior Vena Cava (SVC).

A system using two leads delivers cardioversion and defibrillation pulses between two electrodes. A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE1 and PULSE2) to the COMMON defibrillation electrode.

In these systems, the retractable, helical tip and ring of the RV lead are used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

To detect VT/VF, the PCD® device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD® device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD® confirms termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

1) At implant by evaluating the pacing and sensing thresholds and the defibrillation efficacy in treating

induced VF;

2) Chronically by evaluating (1) the defibrillation efficacy in terminating induced episodes of VT or VF; (2) the efficacy of VT and VF therapies in treating spontaneous episodes; (3) the evaluation of pace/sense characteristics of the implanted lead system and (4) the incidence of lead complications or observations such as dislodgement or fracture.

C.3 Model 9788 MemoryMod™ Software Cartridge and 9710 Programmer

Programming and interrogation of the PCD® Device is performed using the Model 9788 MemoryMod™ software cartridge in conjunction with the Model 9710 programmer. The use of the programmer allows the modification of VT and VF detection, therapy, and bradycardia support therapy parameters. It allows the physician the ability to review and record programmed device settings, perform noninvasive EP procedures and deliver emergency therapy and review other non-programmable information including charge time, battery voltage and event recording. In addition, it allows the user to evaluate the battery status of the PCD® Device as well as determine if the device has delivered therapy for spontaneous episodes of VT and VF.

C.4 Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD is intended for use in conjunction with an antitachycardia/defibrillation lead system to evaluate VT and VF sensing and therapy efficacy for terminating ventricular tachycardia and ventricular fibrillation prior to the implantation of the PCD® system.

Testing the lead system for permanent implantation, including VF sensing and defibrillation efficacy, is done using the Model 5355 ETCD™ or Model 2394 ECVD. The 5355 is an external, multiprogrammable, tachyarrhythmia control device, which can automatically deliver bradycardia and tachycardia pacing therapies and can deliver manually initiated cardioversion or defibrillation therapies. Its operation is similar to the PCD® Device except that

cardioversion and defibrillation therapies are delivered manually. In addition, it measures and displays parameters, e.g., pathway impedance of cardioversion and defibrillation therapies. The Model 2394 ECVD is also an external cardioverter defibrillator. However, its functions are limited to only manual cardioversion and defibrillation. The output pulses are equivalent to the Model 5355 and Model 7217B PCD®. Additionally, the Model 2394 ECVD does not have the capability to deliver either bradycardia or tachycardia pacing therapies.

The Model 5355 ETCD™ is controlled via the Model 9710 programmer and the MemoryMod™ software cartridge, Model 9788. The Model 2394 ECVD is controlled manually.

D. Indicated Patient Population

The PCD® System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD® Device.

Results provided in this application will support Medtronic's request for market release of the PCD® System for use in the following patient population:

> Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
>
> Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

For this patient population the primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD® pulse generator.

The PCD® System allows the titration of therapies for patients

with ventricular tachycardia while providing the critical defibrillation backup. Defibrillation backup is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia. Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

E. Study Objectives and Protocol Summary

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD® System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD® system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD® system, pace/sense, detection and therapy functions in both the acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population. The analysis will also provide data demonstrating the safety and effectiveness of the Model 5355 ETCD.

The objectives of the clinical study were:

* to evaluate the sensitivity and specificity of the PCD® Device with Transvene™ lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms;

* to monitor the efficacy of the PCD® Device with Transvene™ lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (Successful Termination/Number of Detected Episodes with Therapy Delivered). Investigators were free to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely;

27

* to evaluate the performance of the Model 6966, 6963 and 6999 Transvene™ leads;

* to monitor the patient selection criteria and patient management methods required by the PCD® Device and Transvene™ leads.

* to evaluate the safety and effectiveness of the Model 5355 ETCD™ when used during the implant procedure. Specifically, tachyarrhythmia episode induction, detection, termination and ease of use were analyzed.

* to evaluate the safety and performance of the Model 9710 Programmer and the 9788 MemoryMod™ Software Cartridges in programming sensing and therapy parameters and the appropriate delivery of noninvasive electrophysiologic stimulation.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD® System:

Pre-implant Patient Assessment
Lead System Testing at Implant
Implantable Pulse Generator Testing at Implant
Pre-hospital Discharge Testing
Follow-up Evaluation 1 and 3 months post implant then at 3 month intervals

Specific data was collected at each of these points to meet the objectives of the clinical study. This included:

Pre-implant Patient Assessment - extensive pre-implant testing was performed to ensure that the general patient selection criteria were met. This testing included at least an electrophysiologic evaluation, measurement of ejection fraction, and assessment of the patient's New York Heart Association (NYHA) classification of their cardiovascular status. Depending on the patient history, cardiac catheterization and exercise testing were also conducted.

Lead System Testing - implant evaluation was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate, ventricular tachycardia. The Model 5355 ETCD™ or the 2394 External Cardioverter Defibrillator (ECVD) was used for testing.

This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The PCD® Device implant criteria were:

1) successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2) a 2:1 VF sensing safety margin.

Implanted Pulse Generator Testing - this implant evaluation was performed to demonstrate proper detection and termination of ventricular fibrillation by the implanted PCD® System with VF Therapy #1 programmed to 34 Joules in addition to pacing and sensing thresholds.

Pre-hospital Discharge Testing - testing performed at the pre-hospital discharge included proper detection and termination of induced ventricular tachycardia. Final sensing and therapy parameters are programmed at the PHD.

Follow-up Evaluation - regular testing was performed to evaluate the chronic stability of detection and therapy parameters of the PCD® System. This testing included an assessment of the relative stability of the energy required to defibrillate a patient and efficacy and acceleration rate assessment of the VT therapies. The number of spontaneous VT/VF episodes treated by the PCD® Device were evaluated. Complication rates and patient mortality data were also evaluated.

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD® System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

Clinical data presented in this summary includes experience with the Model 7216A and 7217B PCD® Devices with the Model 6966, 6963 and 6999 Transvene™ Leads. This report presents the clinical evaluation of the safety and efficacy of the PCD® Device with Transvene™ Leads implanted in 757 patients of which 657 have implant durations equal to or greater than six months.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD® System with Transvene™ Leads is included in this report.

F. Overview of Clinical Experience

This report covers a total of 762 implants in 757 patients of the PCD® Device with the Transvene™ Defibrillation Lead System. A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table IF-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD® Transvene™ System Implant Distribution			
	Total	**U.S.**	**Int'l**
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table IF-1: PCD® Transvene™ System - Implant Distributions - 2/1/93

The mean documented implant duration for this patient population is 11.7 months and ranged from implant to 37.4 months. The cumulative implant duration is 8894.8 months. There are 657 patients with implant durations equal to or greater than 6 months and 393 patients with implant durations equal to or greater than 1 year.

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table IF-2 provides a data summary on these patients. Also included is the data summary of the patients with 6 months and 12 months of follow-up.

PCD® Transvene™ System Data Summary			
	All Patients (3 Electrode Systems)	Patients with **6** months of Follow-up	Patients with **12** months of Follow-up
Number of Patients	757	657	393
Device Months Follow-up	8894.8	8602.6	6454.6
Mean Follow-up Time	11.7 mo	13.0 mo	16.3 mo
Maximum Follow-up Time	37.4 mo	37.4 mo	37.4 mo
Number, % Male **Number, % Female**	610 80.6% 147 19.4%	527 80.2% 130 19.8%	310 78.9% 83 21.1%

Table IF-2: PCD® System Data Summary - All Transvene™ Patients versus Transvene™ Patients with 6 mo Follow-up - 2/1/93

F.1 Implant Data

Implants of the PCD® Device may use two or three Transvene™ leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

Two terms were developed to accurately report defibrillation efficacy, Lowest Energy of Defibrillation (LED) and Defibrillation Threshold (DFT). They are defined as follows:

> Lowest Energy of Defibrillation (LED): The lowest programmed energy that successfully defibrillated the patient with the implanted lead system.
>
> Defibrillation Threshold (DFT): The lowest programmed energy which successfully defibrillated the heart provided there is a failure at an energy below the lowest success or a success at less than or equal to 5J.

Table IF-3 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD® Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD® Transvene™ System Mean LED and DFT Values				
Lead System	Implant Frequency	Mean LED	Implant Frequency	Mean DFT
All Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table IF-3: PCD® Transvene™ System - LED and DFT Values - 2/1/93

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD® Device.

F.2 Spontaneous VT and VF Episode Experience

A total of 458 patients (60.5%) have experienced a spontaneous ventricular tachyarrhythmia episode that has been detected and treated by the PCD® Device. A total of 141 (18.6%) experienced VT only, 142 patients (18.8%) experienced VF only and 175 patients (23.1%) experienced both an episode of VT and VF.

There have been a total of 12,009 episodes of spontaneous VT or VF as detected by the PCD®. The overall PCD® Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD® is presented in Table IF-4.

PCD® Transvene™ System Success Rate in Terminating Spontaneous VT/VF Episodes			
	Number of Episodes Successful	Total Number of Episodes	Efficacy Rate
VT	9864	10,027	98.4%
VF	1951	1982	98.4%
Total	11,815	12,009	98.4%

Table IF-4: PCD® Transvene™ System - Success Rate for Spontaneous VT/VF Episodes - 2/1/93

F.2.1 Spontaneous VT

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 10,027 spontaneous episodes of VT have been detected by the PCD® Device in 316 patients. The mean number of episodes per patient with VT was 31.7 and ranged from 1 - 531 episodes.

Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Of the 9864 successfully terminated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® Transvene™ System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Sixty patients experienced 163 (1.6%) episodes in which

the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirty-nine patients experienced 95 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 68 episodes occurred in 21 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

F.2.2 Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 1982 spontaneous episodes of VF have been detected by the PCD® Device in 317 patients. The mean number of episodes per patient was 4.3 and ranged from 1 - 77 episodes. A review of the chart per investigator for this patient that experienced the 77 episodes of VF revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (89.1%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 98.4% were successfully treated with one of the four programmable VF therapies.

Sixteen patients experienced 31 episodes (1.3%) in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Nine patients had 22 reported ineffective VF spontaneous episodes that were due to sinus

tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Four patients experienced 5 ineffective episodes that were detected as VF by the PCD® System. One of these patients (b)(6) required external defibrillation to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Another patient (b)(6) had an episode recorded as ineffective on the event counters but presented in sinus rhythm. Subsequent evaluation demonstrated appropriate PCD® function. Another of these patients (b)(6) had two spontaneous episodes of VT that were detected as VF by the PCD® while in the hospital for progressive CHF. These episodes required external cardioversion. The patient requested the PCD® be turned OFF. Patients was alive at the last known follow-up. The last of these four patients (b)(6) experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on a monitor the patient developed VF. The PCD® delivered the programmed therapy which terminated the episode but the patients developed EMD, arrived at the ER comatose and died.

Four patients (one patient (b)(6) experienced 2 episodes due to AF but is described below again) experienced 4 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. One patient (b)(6) experienced an episode where all four therapies failed secondary to RV lead fracture. The patient had Twiddlers Syndrome. Reoperation was required. It appears that the inappropriate therapy was not due to VT/VF but due to noise. Another patient (b)(6) had a surgical procedure (CABG) where the CS lead dislodged post surgery. The episode that was detected was due to the lead dislodgement. The third patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The fourth patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

F.3 Overall Success Rate

Of the 757 patients who received a PCD® Transvene™ System, 597 patients (78.9% - 597/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. The performance of the PCD® Transvene™ System therapies have been thoroughly evaluated and been shown to be effective in detecting and terminating episodes of ventricular tachyarrhythmia.

There have been no reports of a patient death due to the PCD® Transvene™ System not detecting a spontaneous episode of VT or VF.

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of either VT or VF was 98.4% with a VT success rate of 98.4% and VF success rate of 98.4%. The incidence of unsuccessful termination of an apparent "true" episode of ventricular tachycardia despite delivery of all four therapies was 0.7% (68/10027). The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite delivery of all four therapies was 0.3% (5/1982).

The evaluation of spontaneous episode experience indicates that the PCD® Transvene™ System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

G. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, there have been a total of 176 complications reported in 147 patients and 214 observations reported in 180 patients in the PCD® Transvene™ System patient population. Thus, 19.4% (147/757) of the patients had reported a clinical event which was categorized as a complication and 23.8% (180/757) of the patients had reported a clinical event which was categorized as an observation. Table IG-1 summarizes how these events were reported with U.S versus International.

PCD® Transvene™ System
Reported Complications/Observations
U.S versus International

	# of Complications	# of Observations
U.S.	104	93
International	72	121
Total	176	214

Table IG-1: PCD® Transvene™ System Complications/Observations U.S. versus International - 2/1/93

Table IG-2 summarizes the reported PCD® Transvene™ System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with any of the current ICD devices. These complications and observations are discussed in the PCD® device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD® Transvene System
Reported Complications/Observations
By Category

Category	Complications	Observations
Increased Defibrillation Requirements	9 (1.2%)	8 (1.1%)
Inappropriate VF Therapy Delivery	-	14 (1.8%)
Inappropriate VT Therapy Delivery	-	59 (7.8%)
Loss of Capture	6 (0.8%)	14 (1.8%)
Oversensing	-	54 (7.1%)
Undersensing	-	-

Total	**176**	**214**

Table IG-2: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table IG-3 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD® Transvene System
Reported Complications/Observations
Lead Dislodgements <30 days and >30 days

Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=741	14 (1.9%)	10 (1.3%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 261	12 (4.6%)	10 (3.8%)	2 (0.8%)	2 (0.8%)
SVC Lead Dislodgement n=535	16 (3.0%)	29 (5.4%)	1 (0.2%)	6 (1.1%)
Total Dislodgement n=757	42 (5.6%)	49 (6.5%)	3 (0.4%)	9 (1.2%)

Table IG-3: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 49 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In all 49 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD® Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

H. Inactive Patients

There are a total of 82 patients who had received a PCD® System and are no longer active in the study as of 2/1/93. Table IH-1 shows the distribution of inactive patients by reason for no longer being active in the PCD® Transvene™ System clinical study.

PCD® Transvene™ System Inactive Patients	
Reason for Inactivity	**# of Patients**
Patient Deaths	51
Infection (Explant)	22
Heart Transplant	9
Total	82

Table IH-1: Inactive Patients - 2/1/93

I. Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD® Transvene™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac: Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.

Cardiac: Deaths that occurred where the primary cause of death was determined to be cardiac in nature.

Non-Sudden: Deaths that occur greater than one hour after the onset of symptoms.

Sudden: Deaths that occur within one hour of the onset of symptoms or where the death is

unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed**.

Perioperative: Deaths that occur within thirty days of implant.

System Related: A death which results from a malfunction (operation not according to design specification) of a PCD® System component, or as a result of a device induced arrhythmia, or an interaction between a PCD® System component and the patient.

Procedure Related: A death which occurs as a result of a procedure required to implant, follow or test a PCD® System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD® Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD® System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 51 patient deaths reported in the PCD® Transvene™ System patient population. Table II-1 summarizes how these patient deaths have been classified.

PCD® Transvene™ System
Summary of Death Classifications
(n = 757)

Classifications	Number of Deaths
Sudden Cardiac	5
Non-Sudden Cardiac	30
Noncardiac	16
Total	51

Table II-1: PCD® Transvene™ System - Summary of Death Classifications - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD® Transvene™ System.

Actuarial survival analysis on the PCD® Transvene™ System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD® Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD® Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table II-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD® System with Epicardial leads (5.3% - 39/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD® Transvene™ System (n = 757) and all patients that were screened for a PCD® Transvene™ System (n = 854) regardless of implant outcome.

PCD® Transvene™ System One Year Actuarial Survival		
	Received PCD® Transvene™ System	**Screened for a PCD® Transvene™ System**
Sudden Cardiac Death	99.5%	99.4%
Non-Sudden Cardiac	96.2%	96.6%
All Cardiac	95.8%	96.1%
Noncardiac	98.1%	98.3%
Perioperative	0.7%	1.6%
Overall	93.3%	92.9%

Table II-2: PCD® Transvene™ System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD® Transvene™ System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.5% for those in the patient group that received a Transvene™ System and 99.4% for those who were screened for a Transvene™ System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

J. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD® Transvene™ System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD® Transvene™ System in these three groups are summarized in Table IJ-1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 98.4%, in the VT patient group 98.3%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD® Transvene™ System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 98.6%

This analysis indicates that the PCD® Transvene™ System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

Table IJ-1: PCD® Transvene™ System Data Summary by Primary Indication - 2/1/93

K. Patients Not Meeting Implant Criteria

K.1 Overview

The PCD® Transvene™ System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD® Transvene™ System decreases the potential perioperative and long term mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who can not tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality following a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, a transvenous ICD System is the only therapy available. The PCD® Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, more options for future therapy remain available; e.g. CABG is associated with increased morbidity and mortality if there has been prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In an epicardial lead system, the lead system has a larger

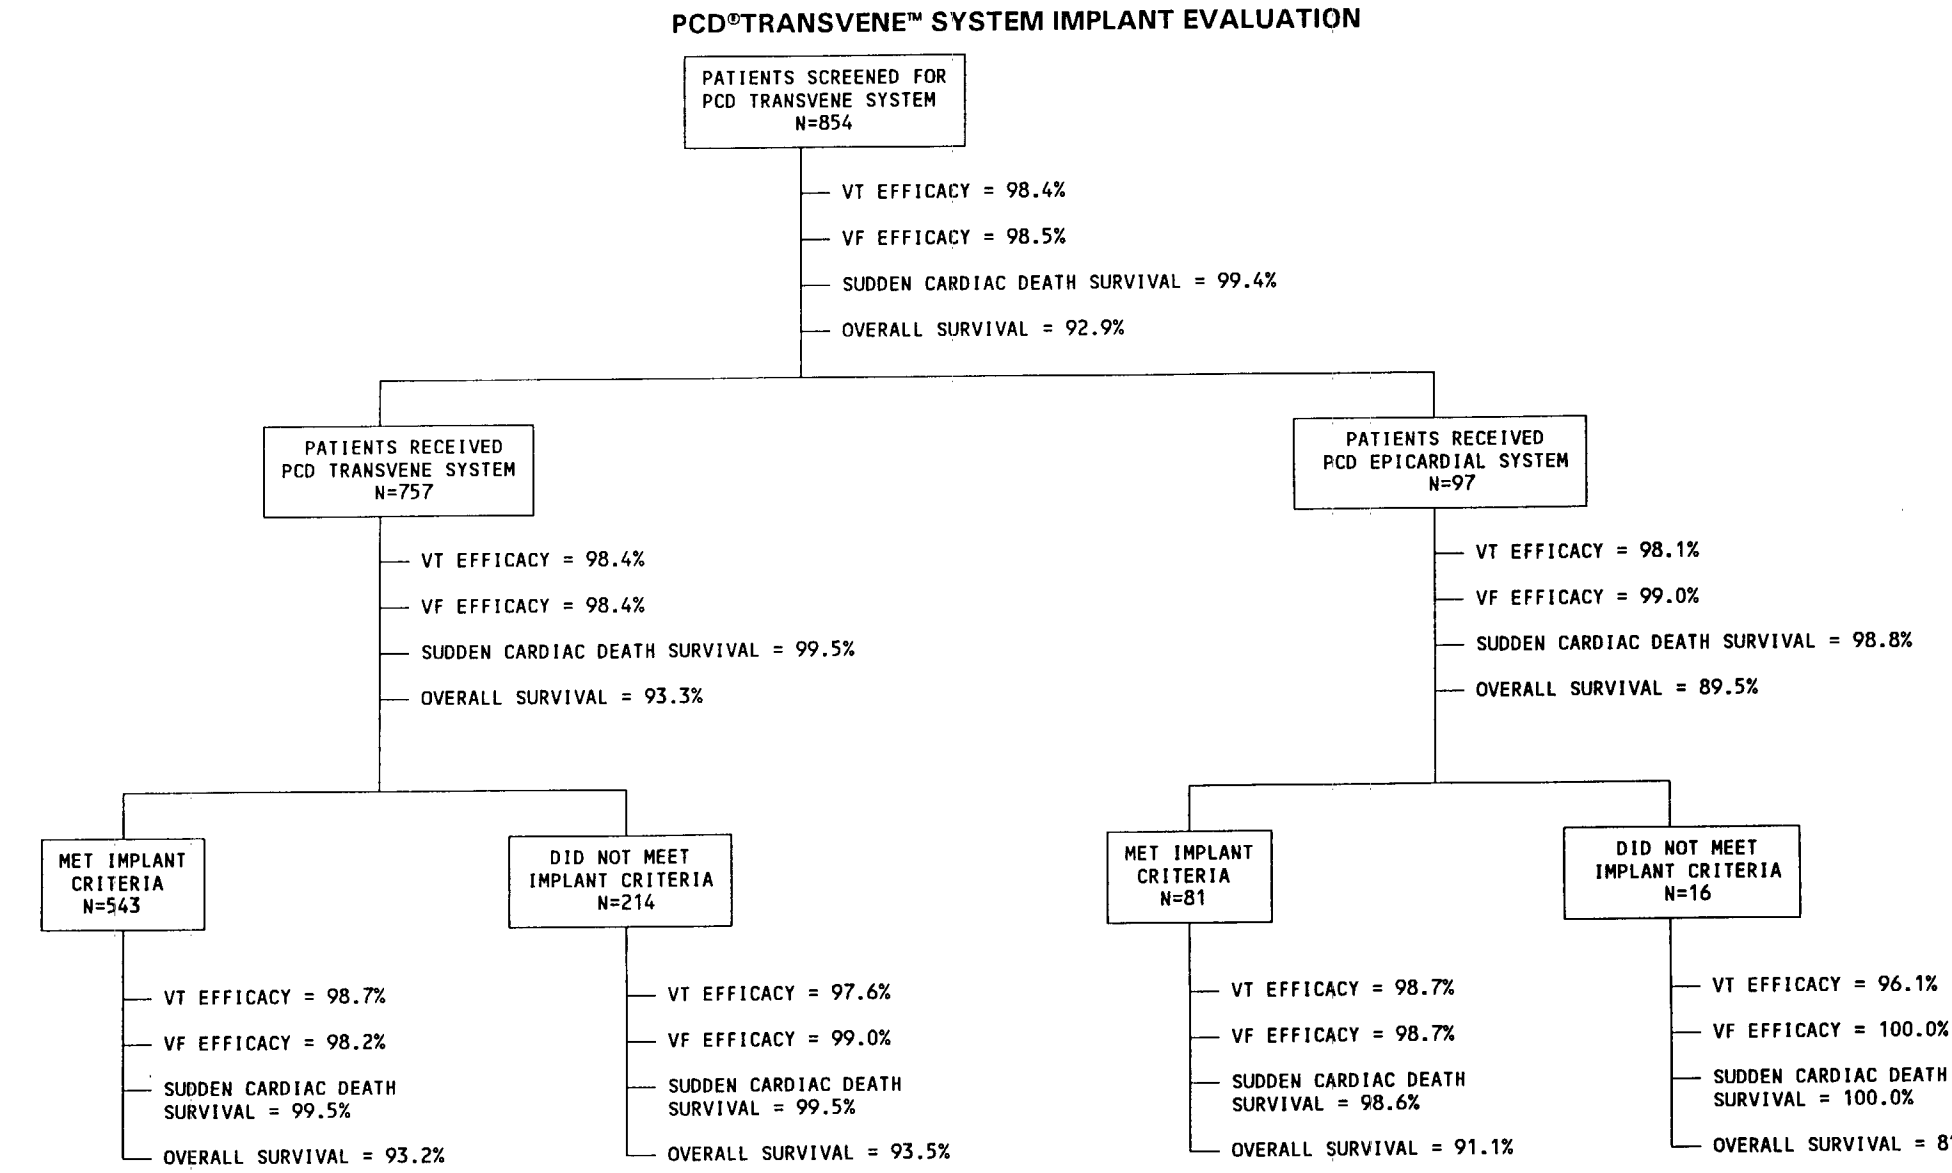
electrode surface area theoretically decreasing defibrillation requirements.

The smaller electrode surface areas of the PCD® Transvene™ System defibrillation leads might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that 70% of patients evaluated may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not required.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

A total of 854 patients had an evaluation of a PCD® Transvene™ System and are divided into the following groups - (1) Patients who received a PCD® Transvene™ System; and (2) Patients screened for a PCD® Transvene™ System and received a PCD® Epicardial System. Figure 1 provides an overview of the outcome of these patients.



igure 1: Patients Screened for a Transvene™ System

MEDTRONIC CONFIDENTIAL

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD® Transvene™ System ultimately received the system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD® Transvene™ System. It should be noted that 97.4% of the patients (737/757) received the PCD® Transvene™ System with at least a 10 Joule defibrillation safety margin between the lowest energy of success (24J) and the maximum output (34J) of the PCD® Device.

The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup P., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321. Finally, and perhaps most importantly, the investigators also felt that for these patients the risk associated with not meeting the recommended implant criteria was outweighed by the risk of not implanting an ICD or implanting an epicardial system.

There were twenty patients (2.6%), who received a PCD® Transvene™ System, whose cardiovascular condition precluded further completion of the PCD® Transvene™ System and adequate definition of a defibrillation safety margin. In all cases, the physician felt that the benefit of the PCD® Transvene™ System outweighed the risk of further inductions or the risk of a thoracotomy and elected not to evaluate or implant a PCD® Epicardial System.

K.2 Patients Receiving PCD® Transvene™ System & Did Not Meet Implant Criteria

For purposes of the PCD® Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration at an output energy of 18 Joules or less. Of the 757 patients who **received** a PCD® Transvene™ System, 214 patients (28.3%) did not meet the recommended defibrillation implant criteria and yet still received the PCD® Transvene™ System. The physicians justification for implanting the PCD® Transvene™ System despite not meeting the recommended defibrillation implant criteria are presented in Table IK-1.

PCD® Transvene™ System
Reasons for Not Meeting Implant Criteria
Physician Justification

Reason	Number of Patients
Success at $\leq$ 24 Joules	170
Difficult/Unable to Induce VF	24
Patient Condition	20
Total	214

Table IK-1: PCD® Transvene™ System: Physician Justification for Not Meeting Implant Criteria - 2/1/93

Further analysis of the patient who did not meet the recommended implant criteria indicates however, that 91% (194/214) had a 10 Joule safety margin between the lowest energy of successful defibrillation and the maximum output of the PCD Device (34J). Therefore, of the 757 patients who received a PCD® Transvene™ System, 97.4% (737/757) had at least a 10 Joule defibrillation safety with the implanted lead configuration.

There were 20 patients (2.6%) in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as

follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules and or equal to 34 Joules (**N = 11**);

- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6**); and

- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3**).

Table IK-2 provides a comparison of patient characteristics between patients who met the PCD® Transvene™ System implant criteria and those patients who did not meet the implant criteria but still received the PCD® Transvene™ System.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Patient Characteristics		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Follow-Up	12.3 months	10.1 months

* Statistically Significant ($p \leq 0.05$)

Table IK-2: PCD® Transvene™ System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 2/1/93

Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with coronary disease with concomitant life threatening

ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD® Transvene™ System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD® Transvene™ System.

Implant data obtained in these two patient groups is presented in Table IK-3. As would be expected the patients not meeting the implant criteria had higher mean DFT and LED values when compared to the patients who did meet the implant criteria. However, the mean DFT (18.8J) and LED (19.5J) values obtained in patients not meeting implant criteria provided at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD® Device (34J) in nearly all (97.4%) of the patients.

Table IK-3: PCD® Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Implant Data - 2/1/93

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table IK-4.

PCD® Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**

Non-Sudden Cardiac	95.8%	97.2%
All Cardiac	95.4%	96.7%
Noncardiac	98.5%	97.1%
Overall	93.2%	93.5%

Table IK-4: PCD® Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 2/1/93

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD® Device therapies failed to terminate the episode.

Five patients experienced 7 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Three patients had 5 reported ineffective VF

spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Two patients experienced 2 episodes in which the PCD® detected the episodes as VF but were actually episodes due to extraordinary circumstances. The first patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The second patient (b)(6) was in hospital and there was an episode of VF detected. However, the device was interrogated before termination of the episode was detected. There was external intervention associated with the terminal event. The device was not interrogated again.

Eighteen patients experienced 68 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Nine patients experienced 44 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD® Device responded appropriately based on the programmed detection parameters.

The remaining 24 episodes occurred in 8 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (10.1 vs 12.3 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Finally, the survival of patients receiving a PCD® Transvene™ System without meeting implant criteria

(N = 214) was compared to patients receiving a PCD® Epicardial System without meeting implant criteria (N = 92). This comparison is provided in Table IK-5.

PCD® Transvene™ System Patients Not Meeting Implant Criteria Survival Analysis versus PCD Epicardial System Patients Not Meeting Implant Criteria Survival Analysis		
	PCD Transvene System Not Meeting Implant Criteria	PCD Epicardial System Not Meeting Implant Criteria
Number of Patients	214/757 (28.5%)	92/742 (12.4%)
Number of Deaths	14	17
Sudden Cardiac	99.5%	98.6%
Non-Sudden Cardiac	97.2%	98.8%
Noncardiac	97.1%	97.3%
Overall*	93.5%	87.6%

* Statistically Significant ($p \leq 0.05$)

Table IK-5: PCD® Transvene™ System: Patients Not Meeting Implant Criteria - PCD Transvene System vs PCD® Epicardial System - 2/1/93

Though the PCD® Transvene™ System had a higher incidence of patients not meeting implant criteria (28.5%) compared to the PCD® Epicardial System (12.4%), there was no statistical difference in the sudden cardiac death patient survival. However, the overall survival of patients not meeting implant criteria with the Transvene™ System was significantly better ($p = 0.037$) when compared to the PCD® Epicardial System patients not meeting implant criteria, 93.5% and 87.6%, respectively.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate demonstration of device effectiveness and justified the implant of the PCD Transvene System. Finally, there have been no patients deaths secondary to unsuccessful termination of a spontaneous VT or VF episode in this patient population.

K.3 Description of Patients Not Meeting Implant Criteria

As noted previously, the patients not meeting implant criteria (N=214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules [79.4% of the patients]; (2) Difficult to induce VF [11.2% of the patients]; and (3) Implant procedure terminated due to poor patient condition [9.4% of the patients]. These patient groups are reviewed in the following discussion.

Lowest Energy of Defibrillation < 24 Joules

There were 170 patients in whom the PCD® Transvene™ System was implanted with a defibrillation safety margin of at least 10 Joules. Table IK-6 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD® Transvene™ System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD® Transvene™ System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System. In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, however, is limited to an average of 9.7 months.

PCD® Transvene™ System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7
Overall Spontaneous VF Episode Efficacy	99.4%
One Year Survival:	
Sudden Cardiac	99.4%
Overall	93.8%

Table IK-6: PCD® Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at $\leq$ 24 Joules Clinical Experience - 2/1/93

Difficult to Induce VF

There were 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of the these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD® Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of

implant, 13 patients (54.2%) have experienced a spontaneous VF episode and 21 patients (87.5%) have had VT or VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD® Transvene™ System.

There has been one reported patient death (b)(6) in this patient group. Since this patient died after one year, the one year sudden cardiac death and overall actuarial survival remains 100%.

Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD® Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these 20 patients, VT or VF has been induced at a

chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD® Transvene™ System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, examination of events indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

Conclusion

In conclusion, 214 patients received the PCD® Transvene™ System despite not meeting the recommended implant criteria. These 214 patients are divided into the following groups:

- successful defibrillation of VF at 24 Joules or less (170/214),
- difficult to induce at least three episodes of VF at implant (24/214), and
- worsening patient condition which prevented further inductions (20/214).

It should be noted that 91 % (194/214) of the patients not meeting the recommended implant criteria had at least one successful termination of induced ventricular tachyarrhythmia (VT, VFlutter or VF) at 24 Joules or less.

L. Comparison to AICD System Experience

L.1 Overview

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD® Transvene™ System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD® Transvene™ System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD® Transvene™ System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

L.2 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD® Transvene™ System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table IL-1. There were no differences between the two patient groups.

PCD® Transvene™ System
Comparison of Patient Characteristics
PCD® versus AICD

	PCD®	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table IL-1: Comparison of Patient Characteristics, PCD® versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD® Transvene™ System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD® Transvene™ population than in the AICD population ($p = 0.001$).

L.3 Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD® Transvene™ System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD® device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead

system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD® Transvene™ System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD® Transvene™ System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD® device provides information on the total number of VT and VF episodes detected by the PCD® device and the total number of VT and VF episodes successfully treated by the PCD® device as well as the number of VT/VF episodes where the PCD® device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD® device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD® Transvene™ System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD® Transvene™ System detection criteria.

A total of 10027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD® device

episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD® device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

Table IL-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD® Transvene™ System includes **both complications and observations.** In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD® Transvene™ System
Comparison of Complication/Observation Rates
PCD® versus AICD

Category	PCD®%	AICD%
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection (explant)	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table IL-2: Comparison of Complication/Observation Rates: PCD® Transvene™ System vs AICD Epicardial System - 2/1/93

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD® Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in

the PCD® Transvene™ System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD® Transvene™ System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD® device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 3.2% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD® Transvene™ System offers clinical advantages in reducing the need for a

thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing.

L.4 Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD® Transvene™ System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 51 deaths (6.7%) were reported in the PCD® Transvene™ System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD® Transvene™ System population had a lower perioperative mortality, 0.7% vs 2.7% ($p = 0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD® Transvene™ System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, seven patient deaths were **censored** in the

PCD® Transvene™ System patient population because the devices were deactivated at the time of patient death.

This PCD® Transvene™ System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD® Transvene™ System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD® Transvene™ System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD® System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD® Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

M. Comparison to PCD® Epicardial System Clinical Results

The PCD® Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD® Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the

type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD® Transvene™ System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD® Epicardial System and PCD® Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD® device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD® Transvene™ System clinical experience to the reported PCD® Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

M.1 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD® Transvene™ System to the PCD® Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table IM-1 contains the characteristics of the 757 patients receiving the PCD® Transvene™ System versus the characteristics of the 742 patients who received the PCD® Epicardial System as of 1/5/93.

PCD® Transvene™ System Comparison of Patient Characteristics		
	PCD® Transvene System	**PCD® Epicardial System**
Number of Patients	757	742
Mean Follow-Up Time	11.7 months	16.3 months
% Males*	610 80.6%	637 85.8%
% Females	147 19.4%	105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication*		
SCD	281 37.1%	214 28.8%
VT	377 49.8%	405 54.6%
SCD/VT	99 13.2%	123 16.6%
Cardiovascular History		
Coronary Artery Disease	561 74.1%	569 76.7%
Cardiomyopathy	238 13.1%	222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* **Statistically Significant**

Table IM-1: Comparison of Patient Characteristics, PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD® Transvene™ System patient group and 34.0% for the PCD® Epicardial patient group.

Analysis indicated that the PCD® Transvene™ System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that these differences will result in a different clinical outcome in the PCD® Transvene™ System patient population as compared to the PCD® Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD® Transvene™ System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested

between the two patient groups ($p = 0.001$). The PCD® Transvene™ System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD® Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD® Transvene™ System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but were non-inducible during electrophysiologic testing so that drug testing was not feasible.

M.2 Implant Data Comparison

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and were:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. At least a 2:1 VF sensing safety margin

Pace/Sense Performance

In both the PCD® Transvene™ and PCD® Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:	$\leq$ 1.5V @ 0.5 ms
R-Wave Amplitude:	$\geq$ 5 mV
Slew Rate:	$\geq$ 0.75 volt/sec
Resistance:	200 - 880 ohms

Table IM-2 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD® Transvene™ and Epicardial Systems. It should be noted

that the pace/sense values presented for the PCD® Epicardial System are for the Model 7217B PCD® Device.

PCD® Transvene™ System Performance Comparison Implant Pace/Sense Parameters		
Parameter	**PCD® Transvene System**	**PCD® Epicardial System**
Pacing Threshold*	0.87 V (0.1-3.6V)	0.98 V (0.2-5.3 V)
R Wave Amplitude*	14.2 mV (1.3-32 mV)	13.5 mV (2.2-37.2 mV)
Slew Rate*	1.66 v/S (0.25-9.8 v/S)	1.38 v/S (0.15-7.2 v/S)
Resistance*	575 ohms (264-1381 ohms)	438 ohms (157-1206)

* Statistically Significant

Table IM-2: PCD® Transvene™ System: Comparison of Implant Pace/Sense Parameters - 2/1/93

The implant pace/sense parameters obtained for the PCD® Transvene™ System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). This is anticipated because endocardial pace/sense parameters are better than epicardial values for bradycardia pacing electrode systems. This difference has no clinical impact on the pacing and sensing performance of the PCD® Transvene™ System.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is presented in Table IM-3. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

PCD® Transvene™ System Performance Comparison Chronic Pace/Sense Parameters		
Parameter	**PCD® Transvene System**	**PCD® Epicardial System**
Electrogram Amplitude	10.0 mV (0.5 - 25 mV)	9.5 mV (0.5 - 40 mV)
Pulse Width Threshold	0.24 ms (0.03-1.59 ms)	0.24 ms (0.03-1.59 ms)

Table IM-3: PCD® Transvene™ System: Comparison of Chronic Pace/Sense Parameters - 2/1/93

The incidence of loss of capture requiring lead system modification in the PCD® Transvene™ System was 0.8% while the incidence in the PCD® Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD® Transvene™ System while the incidence in the PCD® Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense data performance indicates that the performance of the PCD® Transvene™ System is similar to that reported with the PCD® Epicardial System. The PCD® Transvene™ System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table IM-4 provides a comparison of defibrillation thresholds determined at implant for the PCD® Transvene™ and PCD® Epicardial Systems.

PCD® Transvene™ System Performance Comparison Implant Defibrillation Thresholds	
System	**Mean DFT**
PCD® Transvene™ System*	14.8J
PCD® Epicardial System	9.8J

* **Statistically Significant ($p \leq 0.05$)**

Table IM-4: PCD® Transvene™ System: Comparison of Implant DFT - 2/1/93

The PCD® Transvene™ System did have a significantly higher mean implant defibrillation threshold ($p = 0.0001$). It should be noted, that it was expected that the PCD® Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

The programmed defibrillation pathways for the two patient populations is presented in Table IM-5. The implanted PCD® Transvene™ Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD® Transvene™ System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD® Transvene™ System implant criteria. Most of the PCD® Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

PCD® Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD® Transvene System**	**PCD® Epicardial System**
Sequential	574 (75.3%)	251 (33.0%)
Simultaneous	178 (23.4%)	14 (1.8%)
Single	10 (1.3%)	496 (65.2%)

Table IM-5: PCD® Transvene™ System: Comparison of Programmed Defibrillation Pathway - 2/1/93

The differences in the programmed status of the PCD® device in the PCD® Transvene™ System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD® device performed safely and effectively in both patient populations.

M.3 Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD® System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD® Transvene™ System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table IM-6 provides a comparison of the efficacy of the PCD® Transvene™ and PCD® Epicardial System in treating spontaneous episodes of VT and VF.

PCD® Transvene™ System Performance Comparison		
Spontaneous VT Episodes		
	PCD® Transvene™ System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	10,027	20,061
% Overall Efficacy	98.4%	98.3%
% Unsuccessful Termination	0.7%	1.0%
Spontaneous VF Episodes		
	PCD® Transvene System	**PCD® Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Episodes	1982	2636
% Overall Efficacy	98.4%	98.7%
% Unsuccessful Termination	0.3%	0.5%

Table IM-6: PCD® Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD® Transvene™ System in terminating spontaneous episodes of VT or VF is 98.5%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD® Epicardial System which was 98.4%. Therefore, the PCD® Transvene™ System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

M.4 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD® Transvene™ System and the PCD® Epicardial System. The PCD® Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with 742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD® System. In the PCD® Transvene™ System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD® Epicardial System, 14.2% of the patients experienced a clinical complication and 32.9% of the patients experienced a clinical observation.

Table IM-7 and IM-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD® Transvene System
PCD® Transvene System versus PCD® Epicardial System
Reported Complications

Reported Complications	PCD® Transvene™ System (N = 757)	PCD® Epicardial System (N = 742)
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	2.8%
Device Related	0.5%	0.9%

Table IM-7: Reported Complications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

PCD® Transvene™ System PCD® Transvene System versus PCD® Epicardial System Reported Observations		
Reported Observations	**PCD® Transvene™ System (N=757)**	**PCD® Epicardial System (N=742)**
Ineffective Therapy	1.1%	1.1%
Inappropriate Therapy	9.6%	13.6%
Pace/Sense Related	9.0%	14.0%
Infection Related	5.3%	2.5%
Lead Related	2.3%	1.2%
Device Related	-	-

Table IM-8: Reported Observations: PCD® Transvene System versus PCD® Epicardial System - 2/1/93

M.5 Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD® Transvene™ and Epicardial System was performed.

Table IM-9 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD® Transvene™ System patient population was 11.7 months while for the PCD® Epicardial System it was 16.3 months.

PCD® Transvene™ System Death Classifications PCD® Transvene™ System versus PCD® Epicardial System		
Death Classification	**PCD® Transvene™ System (N = 757)**	**PCD® Epicardial System (N = 742)**
Sudden Cardiac	5	24
Non-Sudden Cardiac	30	54
All Cardiac	35	78
Noncardiac	16	34
TOTAL	51	112

Table IM-9: Death Classifications: PCD® Transvene™ System versus PCD® Epicardial System - 2/1/93

Table IM-10 provides a comparison of actuarial survival rates between the PCD® Transvene™ and PCD® Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD® System.

PCD® Transvene™ System Comparison of Actuarial Survival PCD® Transvene™ System versus PCD® Epicardial System			(b)(4)
One Year Survival	**PCD® Transvene™ System**	**PCD® Epicardial System**	
Number of Patients	757	742	
Sudden Cardiac	99.5%	98.9%	
Non-Sudden Cardiac	96.2%	96.7%	(b)(4)
All Cardiac	95.8%	95.7%	
Noncardiac	98.1%	98.0%	
Overall*	93.3%	88.6%	

* (b)(4) (b)(4)

Table IM-10: Comparison of Actuarial Survival: PCD® Transvene™ System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD® Transvene System™. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD® Transvene™ System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD® Epicardial System (88.6%) (b)(4) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD® Transvene™ System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD® Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

N. PCD® System Performance

N.1 PCD® Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection, therapy performance, and analysis of explanted devices were evaluated to assess the performance of the PCD® Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD® Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD® Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD® Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 58 devices explanted. Reasons

81

for explant were patient death (23), infection (22), cardiac transplant (9), low battery voltage (1) and PCD Device performance issues (3). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits and this affected the battery indicator circuit only and did not affect the critical functions of the device. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other three devices indicated that two were due to random component failure and one due to shorting on Pulse 2 output. Thus, arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

Based on the clinical data collected, the PCD® Device has performed safely and reliably in the indicated patient population.

N.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of conductor coil fracture is 0.5% (4/757).

Based on the clinical data collected, the Transvene™ leads

have performed safely and reliably.

O. Summary

The overall clinical experience with the PCD® Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD® Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD® Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD® Transvene™ System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

- The PCD® Transvene™ System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD® Transvene™ System.

PCD® Transvene™ System Performance

- The PCD® Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

P. Clinical Experience Summary Conclusions

The PCD® Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

The PCD® Transvene™ System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the perioperative and overall patient mortality as compared to the PCD® Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of 7.6 days as opposed to a mean of 10.6 days ($p = 0.001$) for the PCD® Epicardial System.

Medtronic asserts and the PCD® Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

I. Summary of Clinical Experience

I. Summary of Clinical Experience

A. Introduction

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT, however, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing. It is necessary to perform a significantly more invasive procedure, a thoracotomy, in order to implant the epicardial leads. Thus, the need to incorporate programmability, multiple detection and therapeutic options, and a less invasive lead system has lead to the development of a tiered therapy device, the PCD™ Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD™ Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene™ Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of June 24, 1992.

The PCD™ Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, with the addition of Transvene™ leads.

The data analysis is organized in functional rather than chronological categories in order to present a complete picture of each of the PCD™ Device's various functions. The sections included in this summary are:

- Name, Intended Use of System
- Tachyarrhythmia Control System Features
- Indicated Patient Population
- Study Objectives and Protocol Summary
- Overview of Clinical Experience
  - Implant Data
  - Spontaneous VT/VF Episode Experience
  - Overall Success Rate
- Complications and Observations
- Inactive Patients

- Patient Deaths
- Clinical Experience by Primary Indication
- Patients not Meeting Implant Criteria
- Comparison to AICD Clinical Experience
- Comparison to PCD™ Epicardial Clinical Experience
- PCD™ Transvene™ System Performance

This summary provides an overview of the clinical experience which verifies that the PCD™ Transvene™ System is safe and effective in the indicated patient population.

B. Name and Intended Use of the System

The Pacer-Cardioverter-Defibrillator (PCD™) device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD™ Device is used in conjunction with appropriate lead systems for the treatment of patients with ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The PCD™ Device also provides backup pacing in the VVI mode and noninvasive electrophysiologic (EP) study capabilities.

The PCD™ Device is programmed with the market released Medtronic programmer and a unique MemoryMod™ Cartridge. The PCD™ Device incorporates a two-way telemetry system which receives operational instructions from the programmer and transmits status, electrogram and event information back to the programmer for display and/or printout.

The External Tachyarrhythmia Control Device (ETCD) is an external, multiprogrammable, tachyarrhythmia control device. Its operation is similar to the PCD™ Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it displays measurements of cardioversion and defibrillation therapy parameters. The ETCD is used for making defibrillation threshold measurements during the PCD™ Device implantation procedure.

Components

The Medtronic PCD™ Transvene™ System, which is represented in Figures 1A and 1B, for which market release approval is being requested, consists of the following components:

<u>Implanted Device and Related Programming System</u>
Pacer-Cardioverter-Defibrillator (PCD™) Device
Model 7217B

Programmer
Model 9710 programmer and related accessories (currently market released), plus
Model 9788 MemoryMod™ Software Cartridge
Lead System
Electrode Leads:
Model 6966
Model 6963
Model 6999

Implant Measurements System
Model 5355 ETCD™ External Tachyarrhythmia Control Device
Model 5418 Patient Cable
Model 5414 Test Load
Model 5417 EGM Cable
Model 5419 Jumper Cable

The physical characteristics of the Model 7217B are summarized in Table IB-1:

PCD™ Model 7217B Physical Characteristics	
Feature	**Model 7217B**
Volume	113 cc
Weight	198 grams
Connector Module	Four connector ports
Power Source	Wilson Greatbatch Model 8830 Lithium Silver Vanadium Oxide
Sensing Configuration	Standard Bipolar
Pacing Configuration	Integrated Bipolar

Table IB-1: Features: Model 7217B - 6/24/92

The Model 7217B PCD™ Device uses the pace/sense leads for sensing, thus providing **standard bipolar** sensing. Pacing is delivered in the integrated bipolar configuration.

C. Tachyarrhythmia Control System Features

C.1 PCD™ Device

The PCD™ Device is an implantable device designed to detect episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF), and upon detection, automatically deliver the appropriate therapy or progression of therapies programmed by the physician for each patient. The available therapy types that can be programmed are overdrive pacing, cardioversion, and defibrillation.

The main features of the PCD™ Device include the detection and treatment of recurrent ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The device has two independently programmable detection and therapy algorithms, one for VT and a second for VF. A series of up to four tiered therapies can be delivered after detection of VT and a separately programmed series of up to four therapies after the detection of VF. If a therapy does not convert the arrhythmia, the next programmed therapy is delivered.

Other features of the device include VVI back-up pacing, flexible programming, noninvasive electrophysiology study capabilities, and information reports.

VT Detection and Therapy

The VT detection algorithm includes up to three separately programmable criteria to identify the presence of a tachycardia.

The PCD™ Device employs a feature that automatically adjusts signal detection sensitivity to assure proper detection while minimizing sensing of T-waves following intrinsic cardiac events. This function, **Auto-Adjusting Sensitivity**, is active during any sensing period, including VT and VF detection. It allows use of sensitive settings required for VF detection without oversensing during normal sinus rhythm.

The device utilizes interval length as the primary VT detection criterion; it also provides two additional detection

criteria to add specificity in detecting pathological VT. The two programmable parameters of the Interval Criterion are:

- **Tachycardia Detection Interval (TDI):** Intervals shorter than this value (and longer than FDI are classified as VT intervals.

- **Number of Intervals to Detect (VT NID):** This parameter determines how many consecutive VT intervals must be sensed for therapy to be delivered.

The two additional criteria are:

- **Onset Criterion:** Used to determine when the rate of change in cycle length is sufficiently abrupt to qualify as the onset of paroxysmal VT and not sinus tachycardia.

- **Stability Criterion:** Used to determine when the intervals vary sufficiently on a beat to beat basis to differentiate VT from a rapid ventricular response due to atrial fibrillation.

After a VT episode has fulfilled the programmed detection criteria, the system treats the arrhythmia by delivering one of the three types of VT therapies: Burst, Ramp, or Cardioversion Therapy. Therapy delivery is highly programmable and is "tiered" to allow progression through different therapies selected by the physician to match a patient's particular clinical needs. Up to four separate therapies may be programmed in any combination of the three types to treat each arrhythmia episode. The three therapies are detailed below:

Burst Therapy treats the VT episode by pacing the heart with a "burst" of pulses at a rate greater than that of the VT episode but adapted to the VT rate. The rate adaptive pulse intervals are a programmed percentage of actual tachycardia cycle length. If a pacing sequence is ineffective and the episode is redetected, the pulse interval of the next sequence can be decremented further resulting in a higher pacing rate.

Ramp Therapy decrements each pulse interval within a single sequence of multiple pulses with the first pulse to pulse interval adapted to the VT cycle length. Each subsequent pulse interval in the Ramp sequence is shortened from the preceding interval by a programmed value. If the pacing sequence is ineffective and the VT is redected, Ramp Therapy adds an additional stimulus in each subsequent sequence.

Cardioversion Therapy: delivers synchronized, high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

VF Detection and Therapy

In order to ensure appropriate sensing and detection of VF, the device uses a probabilistic detection algorithm that allows for missed detections due to variations in ventricular depolarization amplitudes and intervals during VF.

Similar to the VT detection algorithm, the PCD™ Device detects VF by monitoring the cardiac cycle length and comparing it to the programmed VF detection criteria, which is called the VF Interval Criterion.

The two programmable parameters of this criterion are:

- **Fibrillation Detection Interval (FDI):** Intervals equal to or shorter than this value are classified as VF intervals.
- **Number of Intervals to Detect (VF NID):** This parameter determines how many VF intervals must be sensed for therapy to be delivered.

After a VF episode has fulfilled the programmed detection

criteria, the system treats the arrhythmia by delivering up to four defibrillation therapies.

Defibrillation Therapy delivers high-energy pulses in one of the following configurations:

- A **single** pulse delivered over one pathway.
- A **simultaneous** pulse delivered over two pathways.
- Two **sequential** pulses separated by a very short interval delivered over two different pathways.

Bradycardia Therapy

The PCD™ Device delivers bradycardia pacing in the VVI mode.

Other Capabilities

The PCD™ Device can be used to conduct noninvasive electrophysiologic studies (EPS) via the programmer with the Model 9788 MemoryMod™ software cartridge. The physician can also manually deliver various therapies via the programmer to manage an induced or spontaneous tachyarrhythmia episode.

The PCD™ Device will provide the physician with information, via the Programmer about its present programmed status and data on its operation. This information may be printed and retained in the patient's file.

A programmer-generated set of symbols, termed Marker Channel, allows real-time visualization of sensing, pacing, detection, and therapy events occurring within the device.

Figure 2 provides an ECG example of an induced episode of VT detected and terminated by antitachycardia pacing and Figure 3 shows an induced episode of VF detected and terminated by a defibrillation therapy delivered by the PCD™ Device.

C.2 Transvene™ Lead Systems

The PCD™ Transvene™ System uses leads which do not require open-chest surgery to implant. Multiple configurations involving either two or three leads may be used to deliver cardioversion and defibrillation pulses. These configurations are based on a tri-polar, Right Ventricular (RV) lead (Model 6966), and either a Coronary Sinus (CS)/Superior Vena Cava (SVC) lead (Model 6963) or a Subcutaneous (SQ) lead (Model 6999) or all three of these leads (e.g. RV/CS/SQ, RV/SVC/SQ or RV/SQ, RV/SVC). The Model 6963 lead can be placed in either the Coronary Sinus/Great Cardiac vein or the Superior Vena Cava (SVC).

A system using two leads delivers cardioversion and defibrillation pulses between two electrodes. A system using three leads delivers cardioversion and defibrillation pulses either simultaneously or sequentially from the anode electrodes (PULSE1 and PULSE2) to the COMMON defibrillation electrode.

In these systems, the retractable, helical tip and ring of the RV lead are used for sensing, thus providing standard, bipolar sensing. The tip electrode is termed PACE/SENSE and the ring electrode is termed SENSE2. Bradycardia pacing takes place between the tip (PACE/SENSE) and the COMMON defibrillation electrode.

To detect VT/VF, the PCD™ device monitors the cardiac cycle length for fulfillment of the programmed VT/VF detection criteria. When the programmed criteria are fulfilled, the PCD™ device detects the VT or VF episode and delivers the first programmed therapy. If this therapy is ineffective and the VT/VF is again detected, the next programmed therapy is delivered. This progression continues until the PCD™ confirms termination or delivers all programmed therapies.

The performance of the Models 6966, 6963, and 6999 are evaluated at the following times:

efficacy in terminating induced episodes of VT or VF; (2) the efficacy of VT and VF therapies in treating spontaneous episodes; (3) the evaluation of pace/sense characteristics of the implanted lead system and (4) the incidence of lead complications or observations such as dislodgement or fracture.

C.3 Model 9788 MemoryMod™ Software Cartridge and 9710 Programmer

Programming and interrogation of the PCD™ Device is performed using the Model 9788 MemoryMod™ software cartridge in conjunction with the Model 9710 programmer. The use of the programmer allows the modification of VT and VF detection, therapy, and bradycardia support therapy parameters. It allows the physician the ability to review and record programmed device settings, perform noninvasive EP procedures and deliver emergency therapy and review other non-programmable information including charge time, battery voltage and event recording. In addition, it allows the user to evaluate the battery status of the PCD™ Device as well as determine if the device has delivered therapy for spontaneous episodes of VT and VF.

C.4 Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD is intended for use in conjunction with an antitachycardia/defibrillation lead system to evaluate VT and VF sensing and therapy efficacy for terminating ventricular tachycardia and ventricular fibrillation prior to the implantation of the PCD™ system.

Testing the lead system for permanent implantation, including VF sensing and defibrillation efficacy, is done using the Model 5355 ETCD™ or Model 2394 ECVD. The 5355 is an external, multiprogrammable, tachyarrhythmia control device, which can automatically deliver bradycardia and tachycardia pacing therapies and can deliver manually initiated cardioversion or defibrillation therapies. Its operation is similar to the PCD™ Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it measures and displays parameters, e.g., pathway impedance of cardioversion and defibrillation therapies. The Model 2394 ECVD is also an external cardioverter defibrillator. However, its functions are limited to only manual cardioversion and defibrillation. The output

pulses are equivalent to the Model 5355 and Model 7217B PCD™. Additionally, the Model 2394 ECVD does not have the capability to deliver either bradycardia or tachycardia pacing therapies.

The Model 5355 ETCD™ is controlled via the Model 9710 programmer and the MemoryMod™ software cartridge, Model 9788. The Model 2394 ECVD is controlled manually.

D. Indicated Patient Population

The PCD™ System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD™ Device.

Results provided in this application will support Medtronic's request for market release of the PCD™ System for use in the following patient population:

> Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or
>
> Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

For this patient population the primary benefits from the use of the PCD™ System center on the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD™ pulse generator.

The PCD™ System allows the titration of therapies for patients with ventricular tachycardia while providing the critical defibrillation backup. Defibrillation backup is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia. Finally, the benefits of programmability of tachyarrhythmia detection and therapy

parameters, VVI parameters and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

E. Study Objectives and Protocol Summary

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD™ System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD™ system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD™ system, pace/sense, detection and therapy functions in both the acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population. The analysis will also provide data demonstrating the safety and effectiveness of the Model 5355 ETCD.

The objectives of the clinical study were:

* to evaluate the sensitivity and specificity of the PCD™ Device with Transvene™ lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms;

* to monitor the efficacy of the PCD™ Device with Transvene™ lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (Successful Termination/Number of Detected Episodes with Therapy Delivered). Investigators were free to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely;

* to evaluate the performance of the Model 6966, 6963 and 6999 Transvene™ leads;

* to monitor the patient selection criteria and patient management methods required by the PCD™ Device and Transvene™ leads.

* to evaluate the safety and effectiveness of the Model 5355 ETCD™ when used during the implant procedure. Specifically, tachyarrhythmia episode induction, detection, termination and ease of use were analyzed.

- to evaluate the safety and performance of the Model 9710 Programmer and the 9788 MemoryMod™ Software Cartridges in programming sensing and therapy parameters and the appropriate delivery of noninvasive electrophysiologic stimulation.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD™ System:

Pre-implant Patient Assessment
Lead System Testing at Implant
Implantable Pulse Generator Testing at Implant
Pre-hospital Discharge Testing
Follow-up Evaluation 1 and 3 months post implant then at 3 month intervals

Specific data was collected at each of these points to meet the objectives of the clinical study. This included:

Pre-implant Patient Assessment - extensive pre-implant testing was performed to ensure that the general patient selection criteria were met. This testing included at least an electrophysiologic evaluation, measurement of ejection fraction, and assessment of the patient's New York Heart Association (NYHA) classification of their cardiovascular status. Depending on the patient history, cardiac catheterization and exercise testing were also conducted.

Lead System Testing - implant evaluation was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate, ventricular tachycardia. The Model 5355 ETCD™ or the 2394 External Cardioverter Defibrillator (ECVD) was used for testing.

This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The PCD™ Device implant criteria were:

1) successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2) a 2:1 VF sensing safety margin.

Implanted Pulse Generator Testing - this implant evaluation was performed to demonstrate proper detection and termination of ventricular fibrillation by the implanted PCD™ System with VF Therapy #1 programmed to 34 Joules in addition to pacing and sensing thresholds.

Pre-hospital Discharge Testing - testing performed at the pre-hospital discharge included proper detection and termination of induced ventricular tachycardia. Final sensing and therapy parameters are programmed at the PHD.

Follow-up Evaluation - regular testing was performed to evaluate the chronic stability of detection and therapy parameters of the PCD™ System. This testing

included an assessment of the relative stability of the energy required to defibrillate a patient and efficacy and acceleration rate assessment of the VT therapies. The number of spontaneous VT/VF episodes treated by the PCD™ Device were evaluated. Complication rates and patient mortality data were also evaluated.

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD™ System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

Clinical data presented in this summary includes experience with the Model 7216A and 7217B PCD™ Devices with the Model 6966, 6963 and 6999 Transvene™ Leads. This report presents the clinical evaluation of the safety and efficacy of the PCD™ Device with Transvene™ Leads implanted in 757 patients of which 329 have implant durations equal to or greater than six months.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD™ System with Transvene™ Leads is included in this report.

F. Overview of Clinical Experience

This report covers a total of 762 implants in 757 patients of the PCD™ Device with the Transvene™ Defibrillation Lead System. A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table IF-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD™ Transvene™ System Implant Distribution			
	Total	U.S.	Int'l
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table IF-1: PCD™ Transvene™ System - Implant Distributions - 6/24/92

The mean documented implant duration for this patient population is 5.6 months and ranged from implant to 28.6 months. The cumulative implant duration is 4246.4 months. There are 329 patients with implant durations equal to or greater than six months.

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table IF-2 provides a data summary on these patients. Also included is the data summary of the patients with 6 months of follow-up.

PCD™ Transvene™ System Data Summary		
	All Patients (3 Electrode Systems)	Patients with 6 months of Follow-up
Number of Patients	757	329
Device Months Follow-up	4246.4	3367.8
Mean Follow-up Time	5.6 mo	10.2 mo
Maximum Follow-up Time	28.6 mo	28.6 mo
Number, % Male **Number, % Female**	610 80.6% 147 19.4%	264 80.2% 65 19.8%
Mean Age	59.4 yrs	58.0 yrs
Primary Indication: **SCD** **VT** **SCD/VT**	 281 37.1% 377 49.8% 99 13.1%	 130 39.5% 152 46.2% 47 14.3%
Coronary Artery Disease	561 74.1%	228 69.3%
Mean Ejection Fraction	688 35.6%	301 38.0%
Defibrillation Pathway: **Sequential** **Simultaneous** **Single**	 574 75.3% 178 23.4% 10 1.3%	 247 74.6% 77 23.3% 7 2.1%
Mean LED	16.0J (N=702)	15.4J (N=306)
Mean DFT	14.8J (N=316)	13.9J (N=155)
Spontaneous VT: **Number of Patients** **Number of Episodes** **% Success**	 226 5430 98.7%	 130 3752 99.0%
Spontaneous VF: **Number of Patients** **Number of Episodes** **% Success**	 198 973 99.1%	 120 667 98.7%
One Year SCD Survival	99.8%	100.0%

Table IF-2: PCD™ System Data Summary - All Transvene™ Patients versus Transvene™ Patients with 6 mo Follow-up - 6/24/92

F.1 Implant Data

Implants of the PCD™ Device may use two or three Transvene™ leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

Table IF-3 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD™ Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

PCD™ Transvene™ System Mean LED and DFT Values				
Lead System	Implant Frequency	Mean LED	Implant Frequency	Mean DFT
All Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table IF-3: PCD™ Transvene™ System - LED and DFT Values - 6/24/92

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD™ Device.

F.2 Spontaneous VT and VF Episode Experience

A total of 311 patients (41.1%) have experienced a spontaneous ventricular tachyarrhythmia episode that has

been detected and treated by the PCD™ Device. One hundred and thirteen patients (14.9%) experienced VT only, 85 patients (11.2%) experienced VF only and 113 patients (14.9%) experienced both an episode of VT and VF.

There have been a total of 6403 episodes of spontaneous VT or VF as detected by the PCD™. The overall PCD™ Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD™ is presented in Table IF-4.

PCD™ Transvene™ System Success Rate in Terminating Spontaneous VT/VF Episodes			
	Number of Episodes Successful	Total Number of Episodes	Efficacy Rate
VT	5362	5430	98.7%
VF	964	973	99.1%
Total	6326	6403	98.8%

Table IF-4: PCD™ Transvene™ System - Success Rate for Spontaneous VT/VF Episodes - 6/24/92

F.2.1 Spontaneous VT

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 5430 spontaneous episodes of VT have been detected by the PCD™ Device in 226 patients. The mean number of episodes per patient with VT was 24 and ranged from 1 - 413 episodes.

Most spontaneous VT episodes (91.0%) were successfully treated with VT Therapy #1 and 98.7% were successfully treated with one of the four programmable VT therapies.

Of the 5362 successfully terminated spontaneous VT episodes, 92.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD™ Transvene™ System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Thirty patients experienced 68 (1.3%) episodes in which the PCD™ Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Twenty five patients experienced 45 (0.8%) episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD™ Device responded appropriately based on the programmed detection parameters.

The remaining 23 episodes occurred in five patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** The patient's antiarrhythmic drug regimen was modified to improve efficacy.

F.2.2 Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 973 spontaneous episodes of VF have been detected by the PCD™ Device in 198 patients. The mean number of episodes per patient was 4.9 and ranged from 1 - 77 episodes. A review of the chart per investigator for this patient that experienced the 77 episodes of VF

revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (87.3%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 99.1% were successfully treated with one of the four programmable VF therapies.

Five patients experienced 9 episodes (0.9%) in which the PCD™ Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Four patients had eight reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems. The other patient (b)(6) required external defibrillation to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. All of these patients have subsequently done well with no more reported ineffective VF therapies.

F.3 Overall Success Rate

Of the 757 patients who received a PCD™ Transvene™ System, 443 patients (58.5% - 443/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. The performance of the PCD™ Transvene™ System therapies have been thoroughly evaluated and been shown to be effective in detecting and terminating episodes of ventricular tachyarrhythmia.

There have been no reports of a patient death due to the PCD™ Transvene™ System not detecting a spontaneous episode of VT or VF.

The overall success rate of the PCD™ Transvene™ System in terminating spontaneous episodes of either VT or VF was 98.8% with a VT success rate of 98.7% and VF success rate of 99.1%. The incidence of unsuccessful termination of an apparent "true" episode of ventricular tachycardia despite delivery of all four therapies was 0.4% (23/5430). The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite delivery of

all four therapies was 0.1% (1/973).

The evaluation of spontaneous episode experience indicates that the PCD™ Transvene™ System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

G. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of June 24, 1992, there have been a total of 138 complications identified in 138 patients and 157 observations identified in 157 patients in the PCD™ Transvene™ System patient population. Thus, 18.2% (138/757) of the patients have experienced a clinical event which was defined as a complication and 20.7% (157/757) of the patients have experienced a clinical event which was defined as an observation. Table IG-1 summarizes how these events were reported with U.S versus International.

PCD™ Transvene™ System Reported Complications/Observations U.S versus International		
	Complications	Observations
	# of Patients	# of Patients
U.S.	77	68
International	61	89
Total	138	157

Table IG-1: PCD™ Transvene™ System Complications/Observations U.S. versus International - 6/24/92

Table IG-2 summarizes the reported PCD™ Transvene™ System complications and observations by category. The category "Ineffective Therapies" included patients in whom increased defibrillation requirements were documented; "Inappropriate Therapies" includes patients in whom VT/VF therapies were delivered for nonpathological rhythms; "Pacing or Pace/Sense Related" includes patients in whom undersensing, oversensing or loss of capture was documented; "Infection Related" includes reports of pocket infection, seroma, and hematoma was documented; and "Device Related" includes patients in whom the device was explanted for reasons other than patient death, infection, or transplant.

The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD™ device and Transvene™ manual. **None of the reported complications or observations have resulted in a patient death.**

PCD™ Transvene™ System Reported Complications/Observations By Category		
Category	**Complications**	**Observations**
Ineffective Therapies	0.8%	0.5%
Inappropriate Therapies	-	8.2%
Pacing or Pace/Sense Related	0.8%	4.1%
Infection Related - Device Explanted	2.0%	-
Infection Related - Device not Explanted	1.5	4.9%
Device Related	0.5%	-

Table IG-2: PCD™ Transvene™System - Complications/Observations - 6/24/92

The "Lead Related" complications/observations include perforation, lead fracture, subcutaneous patch crinkling, and lead dislodgement. Table IG-3 contains a summary of the reported "Lead Related" complications/observations.

PCD™ Transvene™ System Lead Related Complications	
Category	**Complication**
Right Ventricular Perforation	5 (0.7%)
Subclavian Vein Thrombosis	1 (0.1%)
Lead Fracture	4 (0.5%)
Subcutaneous Patch Crinkling	7 (0.9%)
Lead Dislodgement	33 (4.4%)

Table IG-3: PCD™ Transvene™ System - Lead Related Complications - 6/24/92

There have been a total of 33 lead dislodgements reported in 33 patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during

pacing/sensing threshold evaluation during routine follow-up. In all 33 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system.

Lead dislodgements are not specific to the PCD™ Transvene™ System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent pervenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

H. Inactive Patients

There are a total of 34 patients who had received a PCD™ System and are no longer active in the study as of 6/24/92. Table IH-1 shows the distribution of inactive patients by reason for no longer being active in the PCD™ Transvene™ System clinical study.

PCD™ Transvene™ System Inactive Patients	
Inactive Patients	**All Patients**
Patient Deaths	22
Infection (Explant)	11
Heart Transplant	5
Total	38

Table IH-1: Inactive Patients - 6/24/92

I. Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become

an accepted and important clinical tool. An analysis of the sudden cardiac death survival in the PCD™ Transvene™ System patient population was performed.

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD™ System component, or as a result of a device induced arrhythmia, or an interaction between a PCD™ System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD™ System.

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD™ Transvene™ System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD™ System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 22 patient deaths reported in the PCD™ Transvene™ System patient population. Table II-1 summarizes how these patient deaths have been classified.

PCD™ Transvene™ System Summary of Death Classifications (n = 757)	
Classifications	**Number of Deaths**
Sudden Cardiac	3
Non-Sudden Cardiac	15
Noncardiac	4
TOTAL	22

Table II-1: PCD™ Transvene™ System - Summary of Death Classifications - 6/24/92

None of the patient deaths were attributed to a malfunction of the PCD™ Transvene™ System.

Actuarial survival analysis on the PCD™ Transvene™ System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD™ Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD™ Transvene™ System but failed to receive a Transvene™ system are not included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table II-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD™ System with Epicardial leads (4.7% - 35/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD™ Transvene™ System (n = 757) and all patients that were screened for a PCD™ Transvene™

System (n = 854) regardless of implant outcome.

PCD™ Transvene™ System One Year Actuarial Survival		
	Received PCD™ Transvene™ System	Screened for a PCD™ Transvene™ System
Sudden Cardiac Death	99.8%	99.8%
Non-Sudden Cardiac	96.8%	97.1%
All Cardiac	96.6%	97.0%
Noncardiac	99.4%	99.4%
Perioperative	0.7%	1.5%
Overall	95.3%	94.8%

Table II-2: PCD™ Transvene™ System - One Year Actuarial Survival - 6/24/92

The positive impact of the PCD™ Transvene™ System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.8%, both in the patient group that received a Transvene™ System and those who were screened for a Transvene™ System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

J. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD™ Transvene™ System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent

ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD™ Transvene™ System in these three groups are summarized in Table IJ.1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 99.1%, in the VT patient group 98.7%, and in the SCD/VT group 99.0%. Thus, independent of the indication for implant, the PCD™ Transvene™ System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 99.7%

This analysis indicates that the PCD™ Transvene™ System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

PCD™ Transvene™ System Data Summary by Primary Indication

Table IJ-1: PCD™ Transvene™ System Data Summary by Primary Indication - 6/24/92

K. Patients Not Meeting Implant Criteria

K.1 Overview

The PCD™ Transvene™ System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD™ Transvene™ System decreases the potential perioperative and long term mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who can not tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality following a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, a transvenous ICD System is the only therapy available. The PCD™ Transvene™ System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, more options for future therapy remain available; e.g. CABG is associated with increased morbidity and mortality if there has been prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In an epicardial lead system, the lead system has a larger

electrode surface area theoretically decreasing defibrillation requirements.

The smaller electrode surface areas of the PCD™ Transvene™ System defibrillation leads might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that 70% of patients evaluated may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD™ Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not required.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

A total of 854 patients had an evaluation of a PCD™ Transvene™ System and are divided into the following groups - (1) Patients who received a PCD™ Transvene™ System; and (2) Patients screened for a PCD™ Transvene™ System and received a PCD™ Epicardial System. Figure 4 provides an overview of the outcome of these patients.

PCD™ TRANSVENE™ SYSTEM IMPLANT EVALUATION

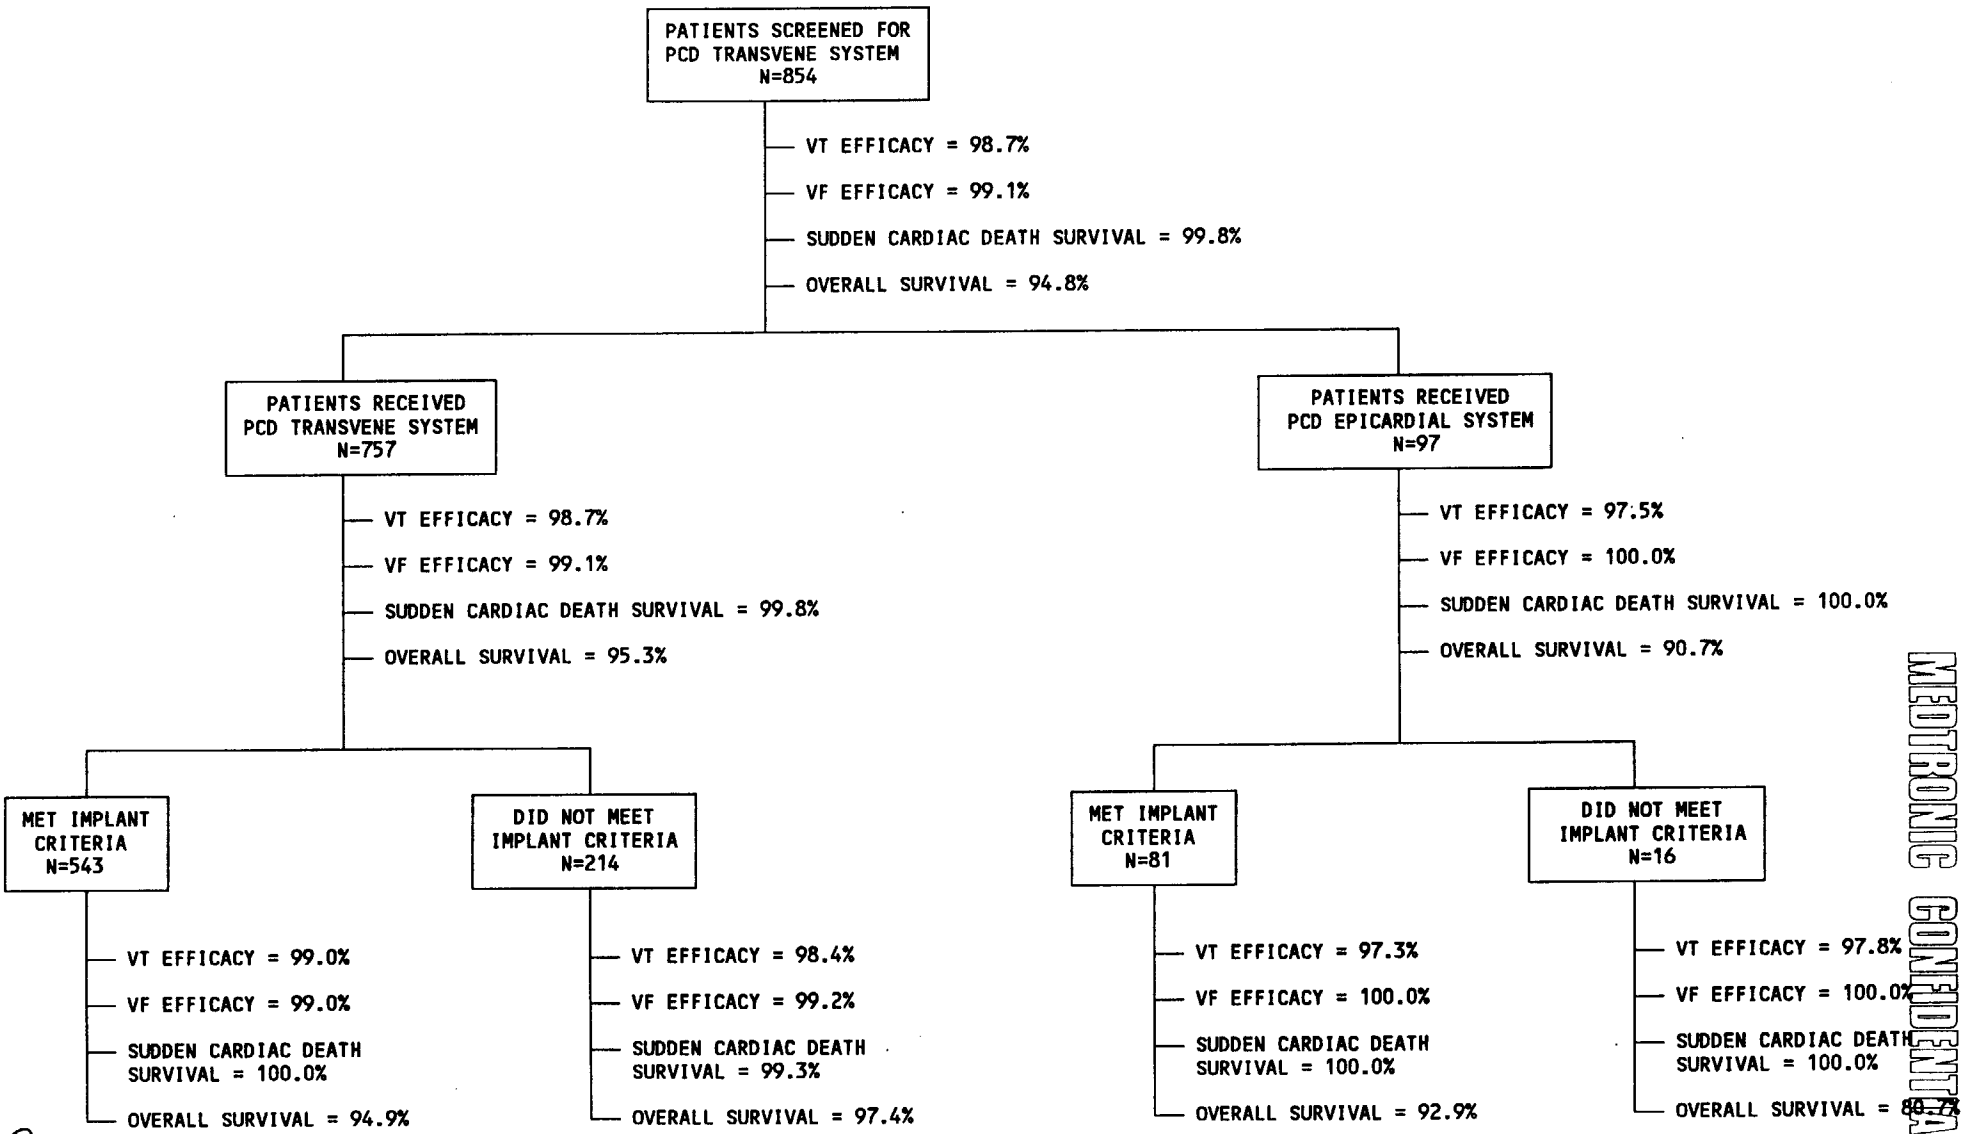

Figure IX.1: Patients Screened for a Transvene™ System

MEDTRONIC CONFIDENTIAL 144

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD™ Transvene™ System ultimately received the system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD™ Transvene™ System. It should be noted that 97.4% of the patients (737/757) received the PCD™ Transvene™ System with at least a 10 Joule defibrillation safety margin between the lowest energy of success (24J) and the maximum output (34J) of the PCD™ Device.

The investigators utilized this 10 Joule safety margin as a benchmark based on the clinical experience discussed in the article, Troup P., et al. The Implanted Defibrillator: Relation of Defibrillating Lead Configuration and Clinical Variables to Defibrillation Threshold. Journal of American College of Cardiology 1985; 6:1315-1321. Finally, and perhaps most importantly, the investigators also felt that for these patients the risk associated with not meeting the recommended implant criteria was outweighed by the risk of not implanting an ICD or implanting an epicardial system.

There were twenty patients (2.6%), who received a PCD™ Transvene™ System, whose cardiovascular condition precluded further completion of the PCD™ Transvene™ System and adequate definition of a defibrillation safety margin. In all cases, the physician felt that the benefit of the PCD™ Transvene™ System outweighed the risk of further inductions or the risk of a thoracotomy and elected not to evaluate or implant a PCD™ Epicardial System.

K.2 Patients Receiving PCD™ Transvene™ System & Did Not Meet Implant Criteria

For purposes of the PCD™ Transvene™ System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration at an output energy of 18 Joules or less. Of the 757 patients who **received** a PCD™ Transvene™ System, 214 patients (28.3%) did not meet the recommended defibrillation implant criteria and yet still received the PCD™ Transvene™ System. The physicians justification for implanting the PCD™ Transvene™ System despite not meeting the recommended defibrillation implant criteria are presented in Table IK-1.

PCD™ Transvene™ System Reasons for Not Meeting Implant Criteria Physician Justification	
Reason	**Number of Patients**
Success at $\leq$ 24 Joules	170
Difficult/Unable to Induce VF	24
Patient Condition	20
TOTAL	214

Table IK-1: PCD™ Transvene™ System: Physician Justification for Not Meeting Implant Criteria - 6/24/92

Further analysis of the patient who did not meet the recommended implant criteria indicates however, that 91% (194/214) had a 10 Joule safety margin between the lowest energy of successful defibrillation and the maximum output of the PCD Device (34J). Therefore, of the 757 patients who received a PCD™ Transvene™ System, 97.4% (737/757) had at least a 10 Joule defibrillation safety with the implanted lead configuration.

There were 20 patients (2.6%) in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD™ Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules and or equal to 34 Joules (**N = 11**);

- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6**); and

- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3**).

Table IK-2 provides a comparison of patient characteristics between patients who met the PCD™ Transvene™ System implant criteria and those patients who did not meet the implant criteria but still received the PCD™ Transvene™ System.

PCD™ Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Patient Characteristics		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Follow-Up	6.2 months	4.0 months
Male*	422 (77.7%)	188 (87.9%)

Number ON Amiodarone	78 (14.4%)	38 (17.8%)

* **Statistically Significant ($p \leq 0.05$)**

Table IK-2: PCD™ Transvene™ System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 6/24/92

Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with

coronary disease with concomitant life threatening ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD™ Transvene™ System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD™ Transvene™ System.

Implant data obtained in these two patient groups is presented in Table IK-3. As would be expected the patients not meeting the implant criteria had higher mean DFT and LED values when compared to the patients who did meet the implant criteria. However, the mean DFT (18.8J) and LED (19.5J) values obtained in patients not meeting implant criteria provided at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD™ Device (34J) in nearly all (97.4%) of the patients.

PCD™ Transvene™ System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria

Perioperative Mortality	0.7%	0.5%
One Year Survival		
Sudden Cardiac	100%	99.3%
Non-Sudden Cardiac	96.4%	98.6%
All Cardiac	96.4%	97.9%
Noncardiac	99.2%	100%
Overall	94.9%	97.4%

Table IK-4: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 6/24/92

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD™ Device therapies failed to terminate the episode.

In one patient (Patient ID (b)(6) all four programmed VF therapies were unsuccessful in terminating a spontaneous episode of VF. However, this was an inappropriate VF therapy delivered due to atrial fibrillation with a rapid ventricular response rather than VF. Reprogramming and modification of the patient's antiarrhythmic drug therapy

corrected the problem. Thus, there were no patients who experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There were eight patients (30 spontaneous VT episodes) where all four programmed VT therapies failed to terminate the episode. In four patients, the ventricular tachycardia was ineffectively terminated and the patient's drug therapy was modified in order to improve the efficacy of the programmed VT therapies. Four patients, three who experienced atrial fibrillation and the other sinus tachycardia, had episodes where all four VT therapies failed to terminate the " spontaneous VT episode". In all cases, the delivery of inappropriate VT therapy was resolved by modification of the patients' drug therapy.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (4.0 vs 6.2 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Finally, the survival of patients receiving a PCD™ Transvene™ System without meeting implant criteria (N=214) was compared to patients receiving a PCD™ Epicardial System without meeting implant criteria (N=92). This comparison is provided in Table IK-5.

PCD Transvene System Patients Not Meeting Implant Criteria Survival Analysis versus PCD Epicardial System Patients Not Meeting Implant Criteria Survival Analysis		
	PCD Transvene System Not Meeting Implant Criteria	PCD Epicardial System Not Meeting Implant Criteria
Number of Patients	214/757 (28.5%)	92/742 (12.4%)
Number of Deaths	4	13
Sudden Cardiac	99.3%	97.9%
Non-Sudden Cardiac	98.6%	100%
Noncardiac	100%	95.2%
Overall*	97.4%	83.8%

* (b)(4) (b)(4)

Table IK-5: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria - PCD Transvene System vs PCD™ Epicardial System - 6/24/92

Though the PCD™ Transvene™ System had a higher incidence of patients not meeting implant criteria (28.5%) compared to the PCD™ Epicardial System (12.4%), there was no statistical difference in the sudden cardiac death patient survival. However, the overall survival of patients not meeting implant criteria with the Transvene™ System was significantly better (b)(4) (b)(4) when compared to the PCD™ Epicardial System patients not meeting implant criteria, 97.4% and 83.3%, respectively.

The investigators felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate demonstration of device effectiveness and justified the implant of the PCD Transvene System. Finally, there have been no patients deaths secondary to unsuccessful termination of a spontaneous VT or VF episode in this patient population.

K.3 Description of Patients Not Meeting Implant Criteria

As noted previously, the patients not meeting implant criteria (N=214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or

less than 24 Joules [79.4% of the patients]; (2) Difficult to induce VF [11.2% of the patients]; and (3) Implant procedure terminated due to poor patient condition [9.4% of the patients]. These patient groups are reviewed in the following discussion.

Lowest Energy of Defibrillation < 24 Joules

There were 170 patients in whom the PCD™ Transvene™ System was implanted with a defibrillation safety margin of at least 10 Joules. Table IK-6 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD™ Transvene™ System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD™ Transvene™ System could be implanted.

Of these patients, 148 (87.1%) have had VF induced at a chronic follow-up visit and in each case, VF was successfully terminated by the PCD Transvene System. In addition, 31 patients (18.2%) have experienced a spontaneous VF episode with an overall efficacy of 100%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 100% and the one year sudden cardiac death actuarial survival was also 99.1%. The duration of follow up, however, is limited to an average of 4 months.

PCD™ Transvene™ System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7
Overall Spontaneous VF Episode Efficacy	100%
One Year Survival	
Sudden Cardiac	99.1%
Overall	97.6%

Table IK-6: PCD™ Transvene™ System: Patients Not Meeting Implant Criteria with 3/4 Successes at $\leq$ 24 Joules Clinical Experience - 6/24/92

Difficult to Induce VF

There were 24 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of the these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD™ Transvene™ System implant criteria because at least three episodes of VF were not induced at the time of

implant, 8 patients (33.3%) have experienced a spontaneous VF episode and 19 patients (79.2%) have had VF induced during a chronic follow-up. In all cases, VF was successfully reverted by the PCD™ Transvene™ System.

There have been no reported patient deaths in the patient group with a resultant one year sudden cardiac death and overall actuarial survival of 100%.

Patient Condition

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD™ Transvene™ System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients is summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these twenty patients, ventricular fibrillation has been

induced at a chronic follow-up visit in 15 patients (75%) and in all cases successful defibrillation with the implanted PCD™ Transvene™ System was documented.

The overall spontaneous VF episode efficacy for this patient group was 92.6% however further reviewed indicated that one patient experienced atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There has been one reported patient death, (Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 93.8%. This lower overall one year survival may due to the lower mean ejection fraction of this patient group.

The clinical outcome in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

Conclusion

In conclusion, 214 patients received the PCD™ Transvene™ System despite not meeting the recommended implant criteria. These 214 patients are divided into the following groups:

- successful defibrillation of VF at 24 Joules or less (170/214),
- difficult to induce at least three episodes of VF at implant (24/214), and
- worsening patient condition which prevented further inductions (20/214).

It should be noted that 91 % (194/214) of the patients not meeting the recommended implant criteria had at least one successful termination of induced ventricular tachyarrhythmia (VT, VFlutter or VF) at 24 Joules or less.

L. Comparison to AICD System Experience

L.1 Overview

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD™ Transvene™ System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD™ Transvene™ System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD™ Transvene™ System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

L.2 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD™ Transvene™ System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD™ Transvene™ System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table IL-1. There were no differences between the two patient groups.

PCD™ Transvene™ System
Comparison of Patient Characteristics
PCD™ versus AICD

	PCD™	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	5.6 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table IL-1: Comparison of Patient Characteristics, PCD™ versus Ventak-P 6/24/92

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD™ Transvene™ System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD™ Transvene™ System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD™ Transvene™ population than in the AICD population ($p = 0.001$).

L.3 Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD™ Transvene™ System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD™ Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD™ device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead

system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD™ Transvene™ System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD™ Transvene™ System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD™ device provides information on the total number of VT and VF episodes detected by the PCD™ device and the total number of VT and VF episodes successfully treated by the PCD™ device as well as the number of VT/VF episodes where the PCD™ device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD™ device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD™ Transvene™ System experience of 757 patients with a mean follow-up of 5.6 months, 311 patients (41%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD™ Transvene™ System detection criteria.

A total of 5430 spontaneous VT and 973 spontaneous VF episodes have been recorded by the PCD™ device episode

counters. Of the 5362 successfully treated spontaneous VT episodes, 92% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD™ device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

Table IL-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD™ Transvene™ System includes **both complications and observations.** In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD™ Transvene™ System
Comparison of Complication/Observation Rates
PCD™ versus AICD

Category	PCD™%	AICD%
Fail to Cardiovert/Defibrillate	0.8%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	8.2%*	20%
Pocket Infection	2.0%	2.2%
Erosion	0.3%	0.7%

* Includes Observations only; there were no Complications in this category.

Table IL-2: Comparison of Complication/Observation Rates: PCD™ Transvene™ System vs AICD Epicardial System - 6/24/92

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD™ Transvene™ System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD™ Transvene™ System patient population were

associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death. In six cases, the implanted system was modified to provide adequate defibrillation efficacy, in four cases the patient's drug therapy was modified and in the final two cases, reprogramming provided for adequate defibrillation efficacy.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD™ Transvene™ System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD™ device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 2.0% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD™ Transvene™ System offers clinical advantages in reducing the need for a thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing.

L.4 Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD™ Transvene™ System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 22 deaths (2.9%) were reported in the PCD™ Transvene™ System patient population. Of the 18 cardiac deaths, 15 were non-sudden cardiac and 3 were sudden cardiac. Four deaths were classified as noncardiac. Five of the 22 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD™ Transvene™ System population had a lower perioperative mortality, 0.7% vs 2.7% ($p = 0.006$).

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD™ Transvene™ System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be

nonfunctional and awaiting replacement. For purposes of this comparison, two patient deaths were **censored** in the PCD™ Transvene™ System patient population because the devices were deactivated at the time of patient death.

This PCD™ Transvene™ System sudden cardiac death survival of 100% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6 %. More importantly, the overall one year actuarial survival for the PCD™ Transvene™ System was 95.6% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD™ Transvene™ System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD™ System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD™ Transvene™ System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

M. Comparison to PCD™ Epicardial System Clinical Results

The PCD™ Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD™ Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD™ Transvene™ System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD™ Epicardial System and PCD™ Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD™ device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD™ Transvene™ System clinical experience to the reported PCD™ Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

M.1 Comparison of Patient Characteristics

In comparing the clinical experience with the PCD™ Transvene™ System to the PCD™ Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table IM-1 contains the characteristics of the 757 patients receiving the PCD™ Transvene™ System versus the

characteristics of the 742 patients who received the PCD™ Epicardial System as of 5/14/92.

PCD™ Transvene™ System Comparison of Patient Characteristics		
	PCD™ Transvene System	PCD™ Epicardial System
Number of Patients	757	742
Mean Follow-Up Time	5.6 months	9.7 months
% Males* % Females	610 80.6% 147 19.4%	637 85.8% 105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication* SCD VT SCD/VT	 281 37.1% 377 49.8% 99 13.2%	 214 28.8% 405 54.6% 123 16.6%
Cardiovascular History Coronary Artery Disease Cardiomyopathy	 561 74.1% 238 13.1%	 569 76.7% 222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* Statistically Significant

Table IM-1: Comparison of Patient Characteristics, PCD™ Transvene™ System versus PCD™ Epicardial System - 6/24/92

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD™ Transvene™ System patient group and 34.0% for the PCD™ Epicardial patient group.

Analysis indicated that the PCD™ Transvene™ System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that these differences will result in a different clinical outcome in the PCD™ Transvene™ System patient population as compared to the PCD™ Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD™ Transvene™ System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups ($p = 0.001$). The PCD™ Transvene™ System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD™ Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD™ Transvene™ System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but were non-inducible during electrophysiologic testing so that drug testing was not feasible.

M.2 Implant Data Comparison

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and were:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. At least a 2:1 VF sensing safety margin

Pace/Sense Performance

In both the PCD™ Transvene™ and PCD™ Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:	$\leq$ 1.5V @ 0.5 ms
R-Wave Amplitude:	$\geq$ 5 mV
Slew Rate:	$\geq$ 0.75 volt/sec
Resistance:	200 - 880 ohms

Table IM-2 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD™ Transvene™ and Epicardial Systems. It should be noted that the pace/sense values presented for the PCD™ Epicardial System are for the Model 7217B PCD™ Device.

PCD™ Transvene™ System Performance Comparison Implant Pace/Sense Parameters		
Parameter	**PCD™ Transvene System**	**PCD™ Epicardial System**
Pacing Threshold*	0.87 V (0.1-3.6V)	0.98 V (0.2-5.3 V)
R Wave Amplitude*	14.2 mV (1.3-32 mV)	13.5 mV (2.2-37.2 mV)
Slew Rate*	1.66 v/S (0.25-9.8 v/S)	1.38 v/S (0.15-7.2 v/S)
Resistance*	575 ohms (264-1381 ohms)	438 ohms (157-1206)

* **Statistically Significant**

Table IM-2: PCD™ Transvene™ System: Comparison of Implant Pace/Sense Parameters - 6/24/92

The implant pace/sense parameters obtained for the PCD™ Transvene™ System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). This is anticipated because endocardial pace/sense parameters are better than epicardial values for bradycardia pacing electrode systems. This difference has no clinical impact on the pacing and sensing performance of the PCD™ Transvene™ System.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is

presented in Table IM-3. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

PCD™ Transvene™ System **Performance Comparison** Chronic Pace/Sense Parameters		
Parameter	**PCD™ Transvene System**	**PCD™ Epicardial System**
Electrogram Amplitude	9.6 mV (0.2 - 25 mV)	9.6 mV (0.5-2.5 mV)
Pulse Width Threshold	0.24 ms (0.03-1.59 ms)	0.28 ms (0.03-1.59 ms)

Table IM-3: PCD™ Transvene™ System: Comparison of Chronic Pace/Sense Parameters - 6/24/92

The incidence of loss of capture requiring lead system modification in the PCD™ Transvene™ System was 0.8% while the incidence in the PCD™ Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD™ Transvene™ System while the incidence in the PCD™ Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense data performance indicates that the performance of the PCD™ Transvene™ System is similar to that reported with the PCD™ Epicardial System. The PCD™ Transvene™ System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a

success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table IM-4 provides a comparison of defibrillation thresholds determined at implant for the PCD™ Transvene™ and PCD™ Epicardial Systems.

PCD™ Transvene™ System **Performance Comparison** Implant Defibrillation Thresholds	
System	**Mean DFT**
PCD™ Transvene™ System*	14.8J
PCD™ Epicardial System	9.8J

* Statistically Significant ($p \leq 0.05$)

Table IM-4: PCD™ Transvene™ System: Comparison of Implant DFT - 6/24/92

The PCD™ Transvene™ System did have a significantly higher mean implant defibrillation threshold ($p = 0.0001$). It should be noted, that it was expected that the PCD™ Transvene™ System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

The programmed defibrillation pathways for the two patient populations is presented in Table IM-5. The implanted PCD™ Transvene™ Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD™ Transvene™ System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD™ Transvene™ System implant criteria. Most of the PCD™ Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

PCD™ Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD™ Transvene System**	**PCD™ Epicardial System**
Sequential	574 (75.3%)	251 (33.0%)
Simultaneous	178 (23.4%)	14 (1.8%)
Single	10 (1.3%)	496 (65.2%)

Table IM-5: PCD™ Transvene™ System: Comparison of Programmed Defibrillation Pathway - 6/24/92

The differences in the programmed status of the PCD™ device in the PCD™ Transvene™ System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD™ device performed safely and effectively in both patient populations.

M.3 Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD™ System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An additional benefit of the PCD™ Transvene™ System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table IM-6 provides a comparison of the efficacy of the PCD™ Transvene™ and PCD™ Epicardial System in treating spontaneous episodes of VT and VF.

PCD™ Transvene™ System Performance Comparison		
Spontaneous VT Episodes		
	PCD™ Transvene™ System	**PCD™ Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	5430	13,706
% Overall Efficacy	98.7%	98.1%
% Unsuccessful Termination	0.4%	1.0%
Spontaneous VF Episodes		
	PCD™ Transvene System	**PCD™ Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	973	1694
% Overall Efficacy	99.1%	98.6%
% Unsuccessful Termination	0.1%	0.5%

Table IM-6: PCD™ Transvene™ System: Comparison of Spontaneous VT/VF Episode Efficacy - 6/24/92

The overall success rate of the PCD™ Transvene™ System in terminating spontaneous episodes of VT or VF is 98.7%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD™ Epicardial System which was 98.2%. Therefore, the PCD™ Transvene™ System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

M.4 Incidence of Complications/Observations

A comparison of the reported complications and observations was made between the PCD™ Transvene™ System and the PCD™ Epicardial System. The PCD™ Epicardial System patient population used for comparison included clinical experience as of May 14, 1992 with 742 patients and a mean implant duration of 9.7 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD™ System. In the PCD™ Transvene™ System patient population, 18.2% of the patients experienced a clinical complication and 20.8% of the patients experienced a clinical observation. In the PCD™ Epicardial System, 12.8% of the patients experienced a clinical complication and 25.7% of the patients experienced a clinical observation.

Table IM-7 and IM-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD™ Transvene System
PCD™ Transvene System versus PCD™ Epicardial System
Reported Complications

Reported Complications	PCD™ Transvene™ System (N = 757)	PCD™ Epicardial System (N = 742)
Increased Defibrillation Requirements	0.8%	0.5%
Inappropriate Therapy	-	1.8%
Pace/Sense Related	0.9%	3.5%
Infection Related - Explant	2.0%	1.9%
Lead Related	6.6%	2.8%
Device Related	0.5%	0.9%

Table IM-7: Reported Complications: PCD™ Transvene™ System versus PCD™ Epicardial System - 6/24/92

PCD™ Transvene™ System PCD™ Transvene System versus PCD™ Epicardial System Reported Observations		
Reported Observations	**PCD™ Transvene™ System (N = 757)**	**PCD™ Epicardial System (N = 742)**
Ineffective Therapy	0.5%	1.1%
Inappropriate Therapy	8.2%	10.6%
Pace/Sense Related	4.1%	10.2%
Infection Related	5.3%	2.2%
Lead Related	2.2%	1.2%
Device Related	-	-

Table IM-8: Reported Observations: PCD™ Transvene System versus PCD™ Epicardial System - 6/24/92

M.5 Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD™ Transvene™ and Epicardial System was performed.

Table IM-9 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD™ Transvene™ System patient population was 5.6 months while for the PCD™ Epicardial System it was 9.7 months.

PCD™ Transvene™ System Death Classifications PCD™ Transvene™ System versus PCD™ Epicardial System		
Death Classification	**PCD™ Transvene™ System (N=757)**	**PCD™ Epicardial System (N=742)**
Sudden Cardiac	3	20
Non-Sudden Cardiac	15	41
All Cardiac	18	61
Noncardiac	4	27
TOTAL	22	88

Table IM-9: Death Classifications: PCD™ Transvene™ System versus PCD™ Epicardial System - 6/24/92

Table IM-10 provides a comparison of actuarial survival rates between the PCD™ Transvene™ and PCD™ Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD™ System.

PCD™ Transvene™ System Comparison of Actuarial Survival PCD™ Transvene™ System versus PCD™ Epicardial System			(b)(4)
One Year Survival	**PCD™ Transvene™ System**	**PCD™ Epicardial™ System**	
Number of Patients	757	742	
Sudden Cardiac	99.8%	98.7%	
Non-Sudden Cardiac	96.8%	95.7%	(b)(4)
All Cardiac	96.6%	94.4%	
Noncardiac*	99.4%	97.3%	
Overall*	95.3%	87.2%	
* (b)(4) (b)(4)			

Table IM-10: Comparison of Actuarial Survival: PCD™ Transvene™ System versus PCD Epicardial System - 6/24/92

There was a significant increase in overall survival in the patients receiving a PCD™ Transvene System™. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD™ Transvene™ System was 95.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD™ Epicardial System (87.2%) (b)(4) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD™ Transvene™ System having a 0.7% perioperative mortality versus the a perioperative mortality of 4.7% in the PCD™ Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

N. PCD™ System Performance

N.1 PCD™ Device

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity, ventricular tachyarrhythmia detection, therapy performance, and

analysis of explanted devices were evaluated to assess the performance of the PCD™ Device.

Extended longevity of implantable cardioverter defibrillators should decrease the number of device replacements a given patient would experience over their lifetime and decrease unnecessary patient morbidity. Thus, the PCD™ Device longevity, which is monitored utilizing battery voltage and charge time obtained via telemetry, was analyzed. The PCD™ Device longevity data collected is consistent with the longevity projections.

The combined experience of induced and spontaneous VT/VF episode experience has shown that the PCD™ Device VT/VF detection and therapies have performed safely and according to design specifications when required to treat induced and spontaneous VT/VF episodes.

There have been a total of 41 devices explanted. Reasons for explant were patient death (15), infection (17), cardiac transplant (5), low battery voltage (1) and PCD Device performance issues (3). The analysis of the device that was explanted due to lower than expected battery voltage indicated that the decreased battery voltage measurement was due to hermetic leakage at the input to one of the integrated circuits and this affected the battery indicator circuit only and did not affect the critical functions of the device. This leads to a voltage drop across a resistor where the voltage measurement is taken. Analysis indicated that the battery was performing to specifications and the hermetic leakage was a random event. Analysis of the other three devices indicated that two were due to random component failure and one due to shorting on Pulse 2 output. Thus, arcing occurred between the conductors inside the hermetically enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this failure was assumed to be a random component failure.

Based on the clinical data collected, the PCD™ Device has performed safely and reliably in the indicated patient population.

N.2 Transvene™ Lead Performance

The Transvene™ Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 4246 months. The reported incidence of conductor coil fracture is 0.5% (4/757).

Based on the clinical data collected, the Transvene™ leads have performed safely and reliably.

O. Summary

The overall clinical experience with the PCD™ Transvene™ System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.8%, 96.8%, 96.6%, and 99.4%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.8% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD™ Device malfunction.

Complications/Observations

- Complications were reported in 18.2% of the patient population and observations were reported in 20.7% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the patients entered into this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (41.1%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD™ Transvene™ System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.7% and the SCD/VT patient group 100.0%.

VT/VF Detection and Therapy Performance

- The PCD™ Transvene™ System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.7%.

- The PCD™ Transvene™ System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 99.1%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD™ Transvene™ System.

PCD™ Transvene™ System Performance

- The PCD™ Transvene™ System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene™ leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

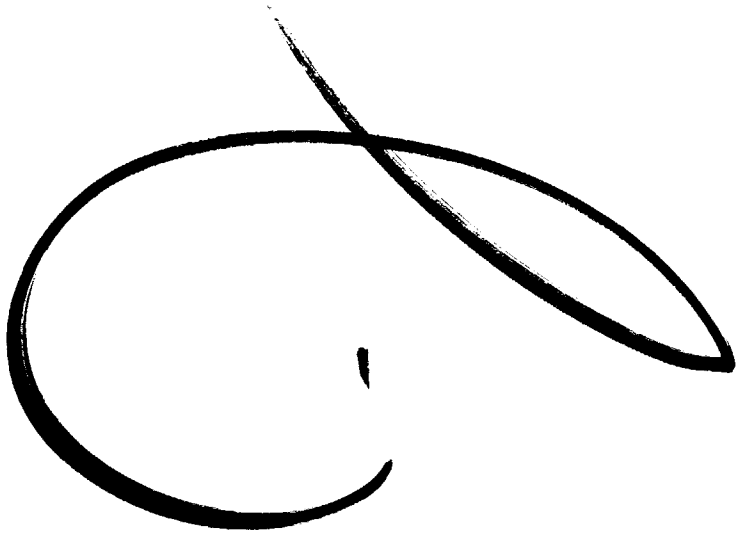
P. Clinical Experience Summary Conclusions

The PCD™ Transvene™ System is a tiered therapy device which combines features of bradycardia pacing support, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. The incorporation of these features has allowed the physician to titrate the ICD therapy to meet specific patient clinical needs, allowed fewer shocks to be delivered for recurrent ventricular tachycardia because of antitachycardia pacing features, allowed fewer cases of inappropriate therapy delivery due to programmable detection and allowed a sudden cardiac death survival rate identical to the Ventak-P Epicardial System.

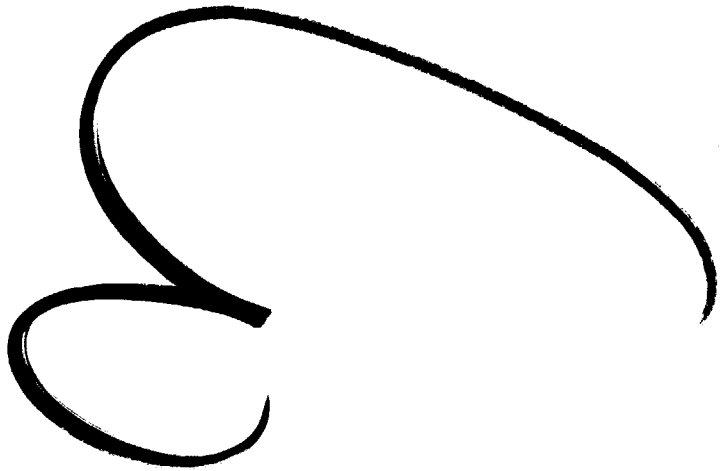
The PCD™ Transvene™ System, due to the elimination of the need for a thoracotomy, has provided a marked improvement in both the perioperative and overall patient mortality as compared to the PCD™ Epicardial System. In addition, due to the decreased perioperative morbidity and mortality, the post implant hospital stay has been decreased to a mean of seven days as opposed to a mean of fourteen days for the PCD™ Epicardial System.

Medtronic asserts and the PCD™ Transvene™ investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene™ Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

II. Center/Implant Distribution



III. Compliance



II. Centers/Implant Distribution

This report involves 800 patients and 805 implant procedures. Five patients had two complete systems implanted due to infection of the first implanted systems. These five reimplants are included in the implant analysis presented in this report since the entire PCD™ system was removed and replaced. Forty-three (43) of these 800 patients received "Non-Standard" systems and are, therefore, analyzed separately (see Section VIIIG). Therefore, 762 implant procedures in 757 patients are included in the following analysis. The following table shows how these 762 implants are distributed between the Models 7216A and 7217B and between U.S. and International investigators.

PCD™ Transvene™ System Implant Distribution						
	Total		U.S.		Int'l	
7217B	744	97.6%	444	99.3%	300	95.2%
7216A	18	2.4%	3	0.7%	15	4.8%

Table II: Implant Distribution - 6/24/92

These 757 patients received their PCD™ Transvene™ Systems in 78 investigative centers in the U.S. and Internationally (35 U.S., 43 Int'l). There were a mean of 9.8 implants per center (min 1, max 60). A complete list of investigative centers, number of implants and date of first implant is provided in Appendix A.

III. Compliance

The study protocol requires that patients be followed at 1 and 3 months post implant and then every three months. Overall compliance at the six month follow-up was 93.7%. For further discussion of follow-up compliance and a definition of follow-up intervals see Appendix B.

Analysis

IV. Justification for Data Pooling

This section will describe the results of the analysis to demonstrate that the data from the U.S. and International investigative centers and the two device model numbers may be pooled. This section will also compare the three lead systems which will be presented throughout the report.

A. Comparison of U.S. and International Patients

Statistical comparisons were made between the two populations age, sex, ejection fraction, primary indication, NYHA, and previous cardiovascular history. Table F1 in Appendix F summarizes the results of statistical analysis.

All study investigators used the same:

a. patient selection criteria,
b. investigational protocol procedures, and
c. indications for implant of PCD™ Transvene™ System.

Of the variables analyzed patient age, ejection fraction, primary indication, NYHA classification, coronary artery disease and cardiomyopathy showed a statistically significant difference between the U.S. and the International patient populations at a 0.05 significance level. The difference in NYHA classification becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix F for multiple inference adjustments. Coronary artery disease, ejection fraction, cardiomyopathy, primary indication and age remain statistically significant after adjusting for multiple inference. The U.S. patient population has a higher percentage of patients with coronary artery disease and cardiomyopathy, lower mean ejection fraction, more patients with VT as their primary indication and a higher mean age. The difference in age may explain the differences in underlying disease and cardiac ejection fraction. These factors that are statistically significant but are not considered to be clinically significant enough to require stratification of the U.S. and International patient populations. The differences may have to do with regional attitudes toward access to health care for the aged. A breakdown of outcome variables for the U.S. and International patient populations will be provided in section VIII-I.

B. Comparison of Model 7216A and Model 7217B

Table F2 in Appendix F summarizes the results of statistical analysis comparing the Model 7216A to Model 7217B. No parameters were found to be statistically significant between the two PCD™ models at a 0.05 significance level.

C. Lead Configurations

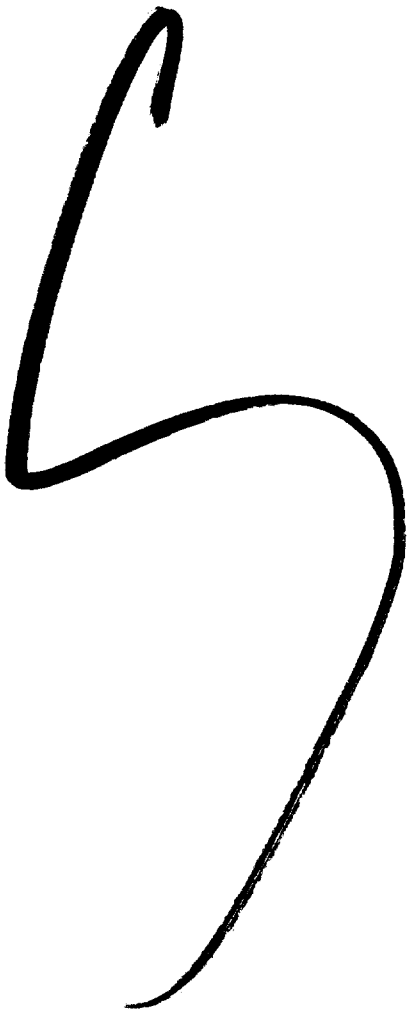
Table F3 in Appendix F shows comparisons of patient variables for the three lead systems. This was done to document that there were no significant differences in patient characteristics between the implanted lead configurations.

Of the variables analyzed in Table F3 sex and cardiomyopathy showed a statistically significant difference between the three lead configurations at a 0.05 significance level. The difference in sex and percentage of patients with cardiomyopathy becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix F for multiple inference adjustments.

D. Statistical Analysis Conclusions

The statistical comparisons between the U.S. and International populations indicated no clinically significant differences therefore the data may be pooled. Analysis of the patients receiving the two PCD™ models indicates no statistically significant differences therefore the data from the two devices may be pooled.

The results from the comparison of lead systems indicated no statistically significant differences in patient demographics, primary indication, or heart disease.



V. Patient Data

A. Primary Indications

The PCD™ Transvene™ System is intended for use in patients who are at risk of sudden death due to ventricular tachyarrhythmias. Patients currently identified as appropriate candidates for a PCD™ system include those who have:

1. survived at least one episode of cardiac arrest (manifested by a loss of consciousness) due to a ventricular tachyarrhythmia that was not caused by an acute myocardial infarction (abbreviated below as SCD for Sudden Cardiac Death); or

2. recurrent, sustained ventricular tachycardia that remains inducible via programmed electrical stimuli or exercise, or occurs spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated chronically by the patient (abbreviated below as VT for Ventricular Tachycardia); or

3. Congenital Long QT Syndrome with recurrent syncope despite full medical therapy (e.g. beta blockers, phenytoin, and/or phenobarbital) (abbreviated below as Long QT). (Request for approval of this indication is being withdrawn since no patient was enrolled in the study with this indication).

Although no patients in the described patient population have been implanted for Long QT Syndrome (b)(4) patients have Long Q-T Syndrome as their underlying heart disease. They have all either had an episode of SCD and/or VT, so their primary indication is reported as SCD or VT rather than Long Q-T. The sponsor continues to believe that Long Q-T Syndrome is an appropriate indication for the PCD™ System and will, therefore, continue to allow investigators to implant for this indication if they are presented with the appropriate patient. However, this indication is not included in the current labeling because it has not yet been thoroughly evaluated.

Patients with ventricular tachyarrhythmias associated with reversible causes such as ischemia (patients without diseased myocardium, positive thallium scan, and severe coronary artery

disease), drug intoxication, arrhythmogenic drug response, electrolyte imbalances, hypoxia, or other causes of transient arrhythmias, e.g., electrocution, WERE NOT considered as potential candidates for the PCD™ System.

The table below summarizes the primary indications for receiving the PCD™ Transvene™ System.

PCD™ Transvene™ System Primary Indication		
SCD	281	37.1%
VT	377	49.8%
SCD & VT	99	13.1%
Total	757	100.0%

Table V-1: Primary Indication - 6/24/92

Key: SCD - Sudden Cardiac Death survivor, without recurrent sustained VT

VT - Ventricular Tachycardia (recurrent, sustained), without an episode of sudden cardiac death

SCD & VT- Patients having had both sudden cardiac death and recurrent, sustained, ventricular tachycardia

The distribution of primary indication differs from the patient population receiving the commercially available AICD as reported in the 1988 PACE article (Thomas, et al, Implantable Defibrillation: Eight years Clinical Experience. PACE. 1988; 11(11): 2053-8)) with respect to the percent of the population with sustained ventricular tachycardia without having experienced an episode of sudden cardiac death. The article cited reported 31.5% (N = 3610) of their patients with VT and no episodes of SCD while the patient population receiving the PCD™ had 49.8% (N = 757) (Chi square $P < 0.001$). This difference is expected because of the antitachycardia pacing feature of the PCD™. The use of pacing therapies for ventricular tachycardia enhances patient acceptance over higher energy cardioversion pulses and extends the longevity of the PCD™ pulse generator.

B. Patient Demographics

(b)(4)

PCD™ Transvene™ System Patient Demographics
Patient Sex:
(b)(4)

Table V-2: Patient Demographics - 6/24/92

(b)(4)

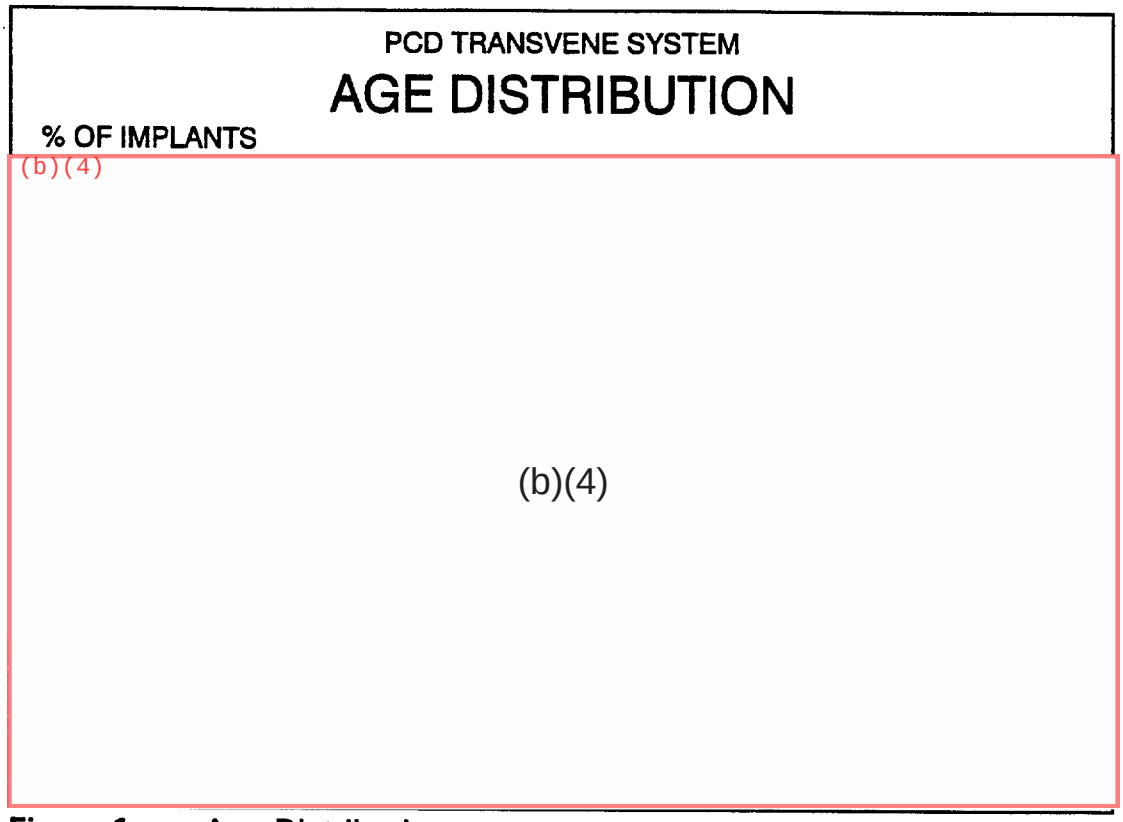


Figure 1: Age Distribution

C. Primary Cardiovascular Disease

The primary heart disease of the patients involved in the PCD™ Transvene™ clinical study is presented in Table V-3. Primary heart disease differs from primary indications for receiving the PCD™ system. The primary heart disease is generally the underlying cause of the patient's arrhythmia. The arrhythmia resulting from the underlying heart disease is the reason the patients receive the PCD™, not the underlying disease itself.

As expected, the majority (561 or 74.1) of the patient population had coronary artery disease as their primary heart disease, either alone or in combination with other conditions.

(b)(4)

(b)(4)

F. Conclusions - Implant Data

Five-hundred-forty-three (543) of the 854 patients evaluated for a Transvene™ system met the implant criteria. Seven-hundred-fifty-seven (757) received a Transvene™ system or 88.6% of the patients evaluated. Seven-hundred-thirteen (713) patients or 94.2% of the 757 patients receiving the Transvene™ system had an LED $\leq$ 24 Joules.

C. Induced and Spontaneous VT Episode Experience

The primary benefits from the use of the PCD™ System are the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD™ pulse generator. The PCD™ System allows the titration of therapies for patients with ventricular tachycardia while providing critical defibrillation backup.

The purpose of this section is to describe VT detection and therapy. Information and experience obtained from both induced and spontaneous episodes of VT will demonstrate the safe and effective operation of the PCD™ for detection and treatment of ventricular tachycardias.

The criteria for detecting episodes of ventricular tachycardia are independent of the detection criteria for ventricular fibrillation. Up to four independently programmable ventricular tachycardia (VT) therapies may be chosen and automatically delivered from among two overdrive pacing modes; burst and ramp, and synchronous cardioversion.

Cardioversion pulses can be delivered by three methods:

- Single Pulse - a single pulse is delivered between two electrodes with a single current pathway.

- Simultaneous Pulse - two pulses are delivered simultaneously via two current pathways of three electrodes. Two of the electrodes act as the anodes (positive) while the third acts as a common (negative) cathode for both pulses.

- Sequential Pulse - two pulses are delivered in a sequential fashion (one pulse is delivered, followed by a short delay, and then the second pulse is delivered) over two different pathways, between three electrodes. Again, two of the electrodes act as the anodes while the third acts as the common electrode for both pulses.

The clinical study was designed to evaluate the operation, safety, and effectiveness of the PCD™ System components in detecting

and treating episodes of ventricular tachycardia and ventricular fibrillation.

The objectives of the clinical study that are addressed in this section are:

- to evaluate the ability of the PCD™ Device to properly detect episodes of VT and to evaluate the ability of the system to appropriately discriminate between VT/VF;

- to determine the efficacy of the PCD™ Device with Transvene™ lead systems in treating VT.

Ventricular tachycardia is detected by the PCD™ using two primary detection parameters, tachycardia detection interval (TDI) and number of intervals to detect (VT NID). In addition, two optional parameters, the "Onset Criteria" and the "Interval Stability Criteria", may be utilized in special situations. The "Onset Criteria" is designed to differentiate between sinus tachycardia and ventricular tachycardia. The "Stability Criteria" is designed to differentiate between ventricular tachycardia and atrial arrhythmias with a rapid ventricular response.

1. Tachycardia Detection Interval (TDI)

   The programmable tachycardia detection interval (TDI) allows the physician to choose the range of intervals between the programmed TDI and the fibrillation detection interval (FDI) that are detected as VT. If the VT detection criteria are all fulfilled, the rhythm will be treated by one of the three (3) programmable VT therapy types; Ramp, Burst or Cardioversion. Intervals longer than or equal to the programmed TDI but shorter than the minimum programmed pacing rate are considered as normal sensed events. Sensed intervals shorter than the FDI are applied towards the VF detection criteria.

   Table VIIC-1 shows the distribution of the last known programmed tachycardia detection interval (TDI) for those patients with VT detection programmed ON at last known follow-up. Note that this excludes patients that died (22), those patients that had their device explanted (14), and patients with VT detection programmed OFF (219). Patients with VF only as their primary indication often have

VT detection programmed OFF if they do not have a VT to treat. The most common TDI's programmed are between

4. Stability and Onset Criterion

An implantable cardioverter defibrillator such as the PCD™ Device attempts to distinguish clinical ventricular tachyarrhythmias from both sinus and other non-ventricular tachyarrhythmias such as rapid atrial fibrillation or flutter. The Stability algorithm is intended to prevent inappropriate VT detection when rapid ventricular contractions with irregular intervals caused by atrial fibrillation would otherwise fulfill the Interval Criterion. The Onset algorithm is intended to avoid inappropriate VT detection during an episode of sinus tachycardia with gradually increasing rates.

Prior to implant of the PCD™ system, the patient undergoes a complete evaluation of his arrhythmia status. This usually includes a cardiovascular history, electrophysiology study, holter monitoring, and exercise testing. Through this testing the investigator can determine if the patient is likely to have a non-ventricular arrhythmia that could be inappropriately detected as ventricular tachycardia and result in the delivery of a anti-tachycardia pacing therapy or cardioversion.

The physician has several clinical options when dealing with such patients prior to the use of the Onset or Stability algorithms. In the case of patients whose maximum sinus rate overlaps with the VT rate the physician can program the Tachycardia Detection Interval (TDI) to ensure that only VT is detected and treated by the PCD™ Device. In addition, the physician may elect to place the patient on beta blocker therapy to lower the patient's maximum sinus rate during exercise. If the patients maximum sinus rate continues to overlap the VT rate, the use of the Onset algorithm may be the best method of avoiding inappropriate VT detection. In patients with rapid ventricular responses to atrial fibrillation the physician can elect to treat the atrial fibrillation with antiarrhythmic therapy. If there is still a problem with inappropriate detection and therapy delivery, the use of the Stability algorithm may be warranted.

5. Programming Conclusions

Reprogrammings tend to occur early in the follow-up period indicating that parameter values selected as a result of early evaluation remain appropriate for the reported implant duration in this patient population. The programming ranges available in the PCD™ system are appropriate.

(b)(4)

(b)(4)

(b)(4)

(b)(4)

6. Conclusion

Clinical experience indicates that the current labelling provides appropriate recommendations for the implant of bradycardia pacemakers, including dual chamber devices, with the PCD Transvene System. In addition, implant and follow-up data on these patients indicates that a bipolar bradycardia pacemaker can be safely implanted in conjunction with the PCD Transvene System.

C. Patients Not Meeting Implant Criteria

1. Section Overview

The PCD Transvene System offers a simpler and safer implantation technique for an implantable cardioverter defibrillator system. In addition, the PCD Transvene System decreases the potential perioperative and long term mortality associated with current epicardial system implantation approaches.

There is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. Because of the surgical risks and postsurgical complications associated with the implant of an epicardial lead system, implantation in the following patient groups may not be desirable or possible:

(1) patients in whom there is no indication for concomitant cardiovascular surgery at the time of ICD implant;

(2) patients with severe pulmonary disease who can not tolerate prolonged anesthesia or an open chest procedure;

(3) patients with severe congestive heart failure (ejection fraction < 40%) who are at increased risk for perioperative mortality post a thoracotomy procedure;

(4) patients who may eventually require open chest procedures for treatment of their coronary artery disease or cardiac transplant.

For these patients, the PCD Transvene System is the only therapy available. The PCD Transvene System simplifies and greatly reduces the risk associated with lead introduction, making therapy available to these patient groups. Because there is no need to open the chest of these patients, options for future therapy remain available; e.g. CABG is associated with decreased morbidity and mortality if there has been no prior open chest surgery.

However, it is expected that nonthoracotomy lead systems will have higher mean implant defibrillation thresholds as compared to traditional epicardial lead systems. In an epicardial lead system, the lead system has a larger electrode surface area which would theoretically decrease defibrillation requirements.

The smaller electrode surface areas of the PCD Transvene System defibrillation leads might reduce the proportion of patients in whom the implant criteria could be met. Not meeting the implant criteria may reduce the chronic effectiveness of the lead system. Recent studies indicated that only 70% of patients evaluated may be candidates for a nonthoracotomy defibrillation lead system (Wilber, D, et al. Clinical Advances in Nonepicardial Implantable Defibrillator Lead Systems. The Journal of Invasive Cardiology. Vol.3, No.6,November/December 1991).

For purposes of the PCD Transvene System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less. The determination of a defibrillation threshold was not necessary.

A defibrillation threshold (**DFT**) was defined as the energy at the lowest successful defibrillation attempt, provided the patient had a failure below the lowest success or a success at $\leq$ 5J. The lowest energy of defibrillation (**LED**) was defined as the lowest programmed energy that successfully defibrillated the patient. In both cases, conversion of ventricular tachycardia or ventricular flutter to sinus rhythm was **not** included in the determination of the DFT or LED.

IX. System Performance

A. PCD Device

1. Overview

Devices implanted for the treatment of recurrent ventricular tachyarrhythmias should perform safely and reliably in the indicated patient population. Device longevity and explant analysis were evaluated to assess the PCD device performance.

There have been a total of 41 (5.4%) devices explanted due to patient death, pocket infection, cardiac transplant or low battery voltage measurement and PCD Device performance issues.

There have been no patient deaths related to PCD malfunction. Based on the data presented in this section, the PCD device has performed safely and reliably in the indicated patient population.

2. Introduction

The data from a total of 762 implants in 757 patients of the PCD Transvene Systems been accumulated as of June 24, 1992. These implants have been followed for a mean of 5.6 months with a range of 0 -28.6 months. The cumulative implant duration for the total patient population is 4246.4 months.

Table IX A-1 shows the number of implants, device months experience and incidence of early device explant for reasons other than patient death, infection or cardiac transplant.

PCD™ Transvene™ System PCD Performance	
	All Implants
Data Cutoff	6/24/92
Number of Implants	762
Mean Follow-Up Months	5.6 months
Device Months of Implantation	4246.4 months
Early Device Explant	0.5%

Table IX A-1: Overview of PCD Transvene System Performance - 6/24/92

There were four devices explanted for reasons other than death, infection or transplant. These devices are discussed in detail in Section 4., Explanted Device Analysis.

As part of both the clinical protocol and required device follow-up, device battery performance was evaluated via telemetered battery voltage and charge time data.

There have been no reported patient deaths secondary to a malfunction of the PCD device or implanted Transvene lead system.

The clinical performance of the PCD System, as reported in the following sections, demonstrates that the Model 7217B PCD device when implanted with the Transvene System performed safely in the indicated patient population.

3. Explanted Unit Analysis

In the 762 implants, a total of 41 units (5.4%) were explanted secondary to patient deaths, infection, heart transplant, low battery voltage measurement and PCD Device performance issues. Table IX A-2 provides an overview of the units explanted, and returned to Medtronic for analysis and reason for explant.

PCD™ Transvene™ System Reasons for PCD Device Explant	
Reason	**All Models**
Number of Implants	762
Patient Death	15
Infection	17
Cardiac Transplant	5
Low Battery Voltage Measurement	1
PCD Device Performance Issues	3
Total	41

Table IX A-2: Reasons for PCD Device Explant - 6/24/92

The investigational plan requests that if the patient expires during the course of the clinical study that the PCD device be explanted and returned to Medtronic for analysis. There were 22 reported patient deaths and 15 devices were explanted and returned to Medtronic for analysis. In the remaining 7 deaths, the patients expired and were buried before the devices could be explanted.

Results of analysis performed on the 41 explanted devices is presented in Table IX A-3.

PCD™ Transvene™ System Final Analysis on Explanted PCD Devices (N = 762)	
Within Normal Specifications	16
Hermetic Leakage at IC	1
Random Component Failure	2
Shorted on Pulse 2 Output	1
Analysis Pending	21
Total	41

Table IX A-3: Final Analysis on Explanted PCD Devices - 6/24/92

Of the 41 devices explanted, final analysis on 16 units indicated that the devices were functioning within normal specifications. Final analysis is not available on 21 units which have been explanted. The reason for explant in these units includes patient death (6), infection (13) and cardiac transplant (2). It should be noted that none of these devices were explanted secondary to concern over the function of the implanted PCD Transvene System.

Four PCD Devices were explanted for the following device performance issues:

- explanted due to a Power On Reset (POR) condition that was not related to the delivery of external defibrillation or cautery (N = 1);
- explanted for lower than expected battery voltage for time in service (N = 1);
- explanted secondary to failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode (N = 1); and
- explanted post inappropriate delivery of VF therapy during a manual capacitor charge time (N = 1).

These devices are discussed in detail in the discussion that follows.

4. Summary

a. Data on a total of 762 PCD Transvene System implants with a mean implant duration of 5.6 months and a cumulative implant duration of 4246.4 months is reported.

b. PCD device battery performance has been effectively monitored utilizing battery voltage obtained via telemetry and charge time and the data obtained supports the longevity projections.

c. There have been a total of 41 (5.4%) units explanted during the duration of the study as of June 24, 1992. The majority of these units were explanted due to patient death, pocket infection or cardiac transplant. One device was explanted secondary to lower than expected battery voltage for time in service. Three devices were explanted secondary to PCD Device performance issues.

d. The identified reason for low battery voltage in the PCD Transvene System experience was due to hermetic leakage at the input to one the integrated circuits which lead to a voltage drop across a resistor where the voltage measurement is taken. The actual battery voltage was normal in this device.

5. Conclusion

The PCD device longevity has been appropriately monitored via battery voltage and charge time. There have been no patient deaths related to PCD malfunction. Based on the data presented in this section, the PCD device when implanted with the Transvene System has performed safely and reliably in the indicated patient population.

X. Comparison to AICD Epicardial System Clinical Experience

A. Overview

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT. However, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing due to the pain associated with cardioversion shock therapy. The need to incorporate programmability, multiple detection and therapeutic options and a desire to avoid thoracic surgery has lead to the development of tiered therapy devices such as the PCD Transvene System.

These tiered therapy devices combine features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. Tiered therapy devices should provide enhanced clinical benefit as measured by complication rates and avoidance of cardioversion shocks. The one year actuarial survival rates should be comparable between the PCD Transvene System and the AICD Epicardial System.

The current AICD Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD Transvene System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD Transvene System will have complications and observations that are specific to the lead system, the overall performance should be equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD Transvene System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

B. Comparison of Patient Characteristics

In comparing the clinical experience with the PCD Transvene System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The patient characteristics of the patients receiving the PCD Transvene System were compared to the patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table X B-1. There were no differences between the two patient groups.

PCD™ Transvene™ System
Comparison of Patient Characteristics
PCD versus AICD

	PCD	Ventak-P
Number of Patients	757	292
Mean Follow-Up Time	5.6 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table X B-1: Comparison of Patient Characteristics, PCD versus Ventak-P 6/24/92

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD Transvene System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as their primary indication in the PCD Transvene population than in the AICD population ($p = 0.001$).

C. Comparison of Clinical Performance

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

Implant Defibrillation Thresholds

For the purposes of the PCD Transvene System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional system, The increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The

recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead system while the other utilized a transvenous defibrillation lead system.

This data indicate that the PCD Transvene System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD Transvene System patient population was evaluated by utilizing the stored episode information provided in both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD device provides information on the total number of VT and VF episodes detected by the PCD device and the total number of VT and VF episodes successfully treated by the PCD device as well as the number of VT/VF episodes where the PCD device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. This data assists the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD Transvene System experience of 757 patients with a mean follow-up of 5.6 months, 311 patients (41%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode.

A total of 5430 spontaneous VT and 973 spontaneous VF episodes have been recorded by the PCD device episode counters. Of the 5362 successfully treated spontaneous VT episodes, 92% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

Incidence of Complications

For purposes of the PCD System clinical study relevant medical events were classified as either **clinical complications** or **clinical observations**. The classification was based on the following definitions:

Complication: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

Observation: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Table X C-1 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD Transvene System includes **both** complications and observations. In the following table, the complications are reported for the categories of Fail to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD™ Transvene™ System Comparison of Complication/Observation Rates PCD versus AICD		
Category	**PCD%**	**AICD%**
Fail to Cardiovert/Defibrillate	0.8%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	8.2%*	20%
Pocket Infection	2.0%	2.2%
Erosion	0.3%	0.7%

* Includes Observations only; there were no Complications in this category.

Table X C-1: Comparison of Complication/Observation Rates: PCD Transvene System vs AICD Epicardial System - 6/24/92

The incidence of failure to cardiovert and/or defibrillate was lower in PCD Transvene System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD Transvene System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death. In six cases, the implanted system was modified to provide adequate defibrillation efficacy, in four cases the patient's drug therapy was modified and in the final two cases, reprogramming provided for adequate defibrillation efficacy.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD Transvene System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The circumstances reported in Winkle, et al were nonsustained VT, VT, sinus tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 2.0% which was comparable to Winkle's article.

Thus, the incidence of complications and observations was similar to that of the AICD Epicardial System in the categories of ineffective VT/VF therapies, infection requiring explant and erosion. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD Transvene System offers the potential clinical advantages in removing the need for a thoracotomy for implantation and the associated morbidity.

D. Comparison of One Year Actuarial Survival

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD Transvene System, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

A total of 22 deaths (2.9%) were reported in the PCD Transvene System patient population. Of the 18 cardiac deaths, 15 were non-sudden cardiac and 3 were sudden cardiac. Four deaths were classified as noncardiac. Five of the 22 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden

cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD Transvene System population had a lower perioperative mortality, 0.7% vs 2.7% (b)(4)

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD Transvene System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, two patient deaths were **censored** in the PCD Transvene System patient population because the devices were deactivated at the time of patient death.

This PCD Transvene System sudden cardiac death survival of 100% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6 %. More importantly, the overall one year actuarial survival for the PCD Transvene System was 95.6% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD Transvene System patient population. [Note: Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality.]

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD Transvene System is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD Transvene System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

E. Summary

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The Ventak-P Epicardial System provides only one type of therapy for the treatment of both recurrent VT and VF. The PCD Transvene System incorporates tiered therapy which combines features of bradycardia support pacing, antitachycardia pacing,low energy cardioversion as well as defibrillation therapy to allow titration of therapy to patient specific ventricular tachyarrhythmias.

In addition, the PCD Transvene System eliminates the need for a thoracotomy for implantation thus increasing the number of patients who may be considered for the therapy and improving both perioperative and overall one year survival.

A comparison of Ventak-P Epicardial System clinical experience and PCD Transvene System clinical experience indicates that the devices are being used in patients with similar cardiovascular disease history.

The mean DFT value at implant of the PCD Transvene System falls well below the maximum output (34J) of the PCD device and is comparable to that reported with the Ventak-P Epicardial System.

The percentage of patients receiving therapy from the PCD Transvene System is comparable to that reported in the Ventak-P Epicardial System experience. However, greater than 90% of the VT episodes are treated by antitachycardia pacing in the PCD Transvene System experience versus cardioversion shocks in the Ventak-P Epicardial System experience. This reduction in shocks is a clinical benefit to the patients.

The reported incidence of most complications is comparable between the two systems. The incorporation of programmable VT/VF detection has decreased the delivery of inappropriate therapy for sinus tachycardia and/or atrial fibrillation with a rapid ventricular response. The incorporation of programmable VT/VF detection and therapy algorithms has not resulted in an increase in reported complications.

The reported Sudden Cardiac Death survival rates in the two patient groups is comparable (PCD Transvene System - 100%; Ventak-P System - 98.6%). This indicates that the programmable features within the PCD Transvene System have improved the types of therapy available for the treatment of recurrent VT and VF without adversely affecting sudden cardiac death survival.

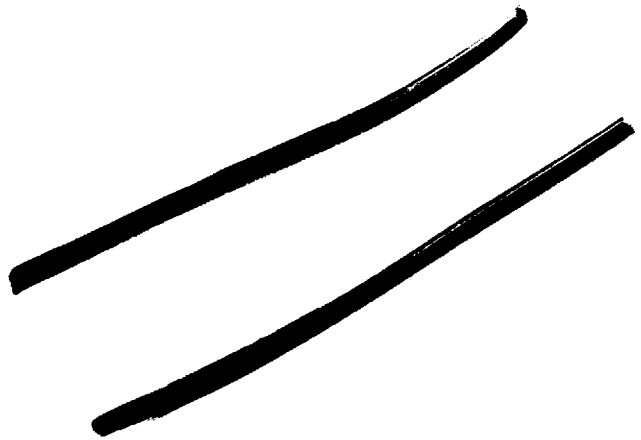
More importantly, the overall one year actuarial survival for the PCD Transvene System was 95.6% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD Transvene System patient population.

F. Conclusion

The PCD Transvene System incorporates additional detection and therapy features as compared to currently market released system and has been used in a comparable patient population. In that patient population the PCD Transvene System has allowed for fewer shocks to be delivered because of the antitachycardia pacing features, fewer cases of inappropriate therapy delivery due to programmable detection and a identical sudden cardiac death survival rate.

In addition, the elimination of a thoracotomy for implant in the PCD Transvene System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

XI. Comparison to PCD
Epi. Clinical Results



XI. Comparison to PCD Epicardial System Clinical Experience

A. Overview

The PCD Epicardial System, is a tiered therapy device that, combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD Transvene System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches. One measure of the positive impact of the PCD Transvene System is hospital stay post implant. There was a statistically significant ($p = 0.001$) improvement for patients receiving a PCD Transvene System (mean hospital stay - 7.2 days) versus patients receiving a PCD Epicardial System (mean hospital stay - 10.3 days).

The PCD Epicardial System and PCD Transvene System are identical except for the implanted defibrillation lead system. Thus the performance of the PCD device, and associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the lead system implanted may impact clinical outcome.

This section provides a comparison of the PCD Transvene System clinical experience to the reported PCD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type

of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

B. Comparison of Patient Characteristics

In comparing the clinical experience with the PCD Transvene System to the PCD Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD Transvene System were compared to the characteristics of the 742 patients who received the PCD Epicardial System as of 5/14/92.

PCD™ Transvene™ System
Comparison of Patient Characteristics

	PCD Transvene System	PCD Epicardial System
Number of Patients	757	742
Mean Follow-Up Time	5.6 months	9.7 months
% Males* % Females	610 80.6% 147 19.4%	637 85.8% 105 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication* SCD VT SCD/VT	 281 37.1% 377 49.8% 99 13.2%	 214 28.8% 405 54.6% 123 16.6%
Cardiovascular History Coronary Artery Disease Cardiomyopathy	 561 74.1% 238 13.1%	 569 76.7% 222 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* Statistically Significant

Table XI B-1: PCD Transvene System Comparison to PCD Epicardial System - 6/24/92

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34.0% for the PCD Epicardial patient group.

Analysis indicated that the PCD Transvene System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that this difference will result in a different clinical outcome in the PCD Transvene System patient population as compared to the PCD Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD Transvene System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups ($p = 0.001$). The PCD Transvene System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the distribution of indication for implant between the two patient groups. The PCD Transvene System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients have a higher probability of having experienced a sudden cardiac death episode but being non-inducible during electrophysiologic testing thus drug testing is not feasible.

C. Implant Data Comparison

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and were:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. A 2:1 VF sensing safety margin

Pace/Sense Performance

In both the PCD Transvene and PCD Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:	$\leq$ 1.5V @ 0.5 ms
R-Wave Amplitude:	$\geq$ 5 mV
Slew Rate:	$\geq$ 0.75 volt/sec
Resistance:	200 - 880 ohms

Table XI C-1 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD Transvene and Epicardial Systems. It should be noted that the pace/sense values presented for the PCD Epicardial System are for the Model 7217B PCD Device.

PCD™ Transvene™ System
Performance Comparison
Implant Pace/Sense Parameters

Parameter	PCD Transvene System	PCD Epicardial System
Pacing Threshold*	0.87 V (0.1-3.6V)	0.98 V (0.2-5.3 V)
R Wave Amplitude*	14.2 mV (1.3-32 mV)	13.5 mV (2.2-37.2 mV)
Slew Rate*	1.66 v/S (0.25-9.8 v/S)	1.38 v/S (0.15-7.2 v/S)
Resistance*	575 ohms (264-1381 ohms)	438 ohms (157-1206)

* Statistically Significant

Table XI C-1: PCD Transvene System: Comparison of Implant Pace/Sense Parameters - 6/24/92

The implant pace/sense parameters obtained for the PCD Transvene System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). However, this difference had no clinical impact on the pacing and sensing performance of the PCD Transvene System.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is presented in Table XI C-2. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

PCD™ Transvene™ System Performance Comparison Chronic Pace/Sense Parameters		
Parameter	**PCD Transvene System**	**PCD Epicardial System**
Electrogram Amplitude	9.6 mV (0.2 - 25 mV)	9.6 mV (0.5-2.5 mV)
Pulse Width Threshold	0.24 ms (0.03-1.59 ms)	0.28 ms (0.03-1.59 ms)

Table XI C-2: PCD Transvene System: Comparison of Chronic Pace/Sense Parameters - 6/24/92

The incidence loss of capture due requiring lead system modification in the PCD Transvene System was 0.8% while the incidence in the PCD Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD Transvene System while the incidence in the PCD Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense performance indicates that the performance of the PCD Transvene System is similar to that reported with the PCD Epicardial System. The PCD Transvene System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of

evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table XI C-3 provides a comparison of defibrillation thresholds determined at implant for the PCD Transvene and PCD Epicardial Systems.

PCD™ Transvene™ System
Performance Comparison
Implant Defibrillation Thresholds

System	Mean DFT
PCD Transvene System*	14.8J
PCD Epicardial System	9.8J

* Statistically Significant

Table XI C-3: PCD Transvene System: Comparison of Implant DFT - 6/24/92

The PCD Transvene System did have a statistically significantly higher mean implant defibrillation threshold ($p = 0.0001$). It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a traditional epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. With the PCD Transvene System an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

As indicated previously, the defibrillation implant criteria for both systems was 3/4 successful terminations of VF at 18 Joules or less. In the PCD Epicardial System, 12.4% (92/742) of the

patients received the system without meeting the defined implant criteria. In the PCD Transvene System, 28.3% (214/757) of the patients received the system without meeting the defined implant criteria.

Though the incidence of not meeting implant criteria was higher in the PCD Transvene System ($p = 0.001$) it was clinically justified. The reasons for not meeting implant criteria included deteriorating patient condition, failure to induce VF or 3/4 successes at less than 24 Joules. The investigator's felt in every case that the testing performed at the time of implant, though it did not meet the recommended implant criteria, did provide an adequate defibrillation safety margin when programming VF Therapy #1. The investigator's also felt that these patients medical condition precluded a PCD Epicardial System with a thoracotomy approach. The advantage of not performing a thoracotomy to implant the PCD Epicardial System outweighed the risk of not meeting the recommended implant defibrillation criteria.

The long term clinical efficacy of the two systems was evaluated by the incidence of clinical cases of failure to successfully defibrillate a spontaneous episode of VF despite delivery of all four programmed therapies. In addition, the incidence of modification of the implanted lead system in order to improve defibrillation efficacy in the two systems was evaluated.

In the PCD Transvene System, there were a total of 973 spontaneous episodes of VF detected by the PCD Device in 198 patients. The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite the delivery of all four therapies was 0.1% (1/973).

In the PCD Epicardial System, there were a total of 1694 spontaneous episodes of VF detected by the PCD Device in 258 patients. The incidence of unsuccessful termination of an apparent "true" episode of ventricular fibrillation despite the delivery of all four therapies was 0.5% (9/1694).

The incidence of increased defibrillation requirements requiring modification of the implanted defibrillation lead system was similar in the two systems. The reported incidence in the PCD Transvene System was 0.8% while in the PCD Epicardial System the incidence was 0.6%.

This comparison of implant and chronic defibrillation performance indicates that the performance of the PCD Transvene System is similar to that reported with the PCD Epicardial System. The PCD Transvene System provides appropriate acute and chronic safety margins for defibrillation therapy and has not required an increased need for modification of the lead system to maintain defibrillation efficacy when compared to the PCD Epicardial System. Finally, the PCD Transvene System has effectively treated spontaneous episodes of VF without an increase in the incidence of ineffective therapies.

D. Programmed Parameter Status

In comparing the programmed status of PCD Transvene and PCD Epicardial System patients, three areas of difference were identified -number of patients with VF detection/therapy only enabled, range of VF Therapy #1 defibrillation energies and programmed defibrillation pathways. The use of the remaining PCD Device parameters was similar in the two patient groups.

Table XI D-1 provides the PCD Device programmed status for the two patient populations. There was a higher percentage of patients with VF Detection/Therapy only programmed ON in the PCD Transvene System patient population (29.0%) as compared to the PCD Epicardial System (20.1%). This difference is reflective of the indication for implant in the two patient groups. The PCD Transvene System patient population had a higher incidence of patients who were sudden cardiac death survivors without recurrent VT (37.1%) versus the PCD Epicardial System (28.8%).

There was also a difference in the number of inactive patients in the two patient groups. "Inactive Patients" includes patients no longer active in the study due to patient death, explant due to infection or explant due to heart transplant. The PCD Epicardial System had 105 patients (14.2%) who were no longer active in the study while the PCD Transvene System had 38 patients (5.0%).
This difference was due to a greater number of patient deaths in the PCD Epicardial System, 88, compared to a total of 22 patient deaths in the PCD Transvene System patient population.

PCD™ Transvene™ System Performance Comparison PCD Device Programmed Status		
Programmed Status	**PCD Transvene System**	**PCD Epicardial System**
VT/VF Detection/Therapy ON	516 (68.2%)	529 (71.5%)
VF Detection/Therapy Only ON	219 (29.0%)	149 (20.1%)
VVI Only*	21 (2.8%)	62 (8.4%)
TOTAL	757	742

* VVI Only reflects patients who are have not undergone the pre-hospital discharge EPS

Table XI D-1: PCD Transvene System: Comparison of PCD Device Programmed Status - 6/24/92

Table XI D-2 provides the distribution of programmed VF Therapy #1 energies for the two patient groups. This difference in programmed VF Therapy #1 defibrillation energies is related to the implant defibrillation thresholds obtained in the two groups. The mean implant DFT for the PCD Transvene System was 9.8J and ranged from 0.6 to 30.0 J Joules. The recommendation for VF Therapy #1 is to program the stored energy to 34 Joules, twice the implant DFT or 18 Joules, whichever is greater. The physicians followed these recommendations and the range values used reflects this. The mean implant DFT for the PCD Epicardial System was 9.8J and ranged from 0.4 to 26.0 Joules. This difference in the mean DFT and range of DFT's allowed the use of lower energy values when following the programming recommendations for VF Therapy #1.

PCD™ Transvene™ System Performance Comparison Programmed VF Therapy #1 Energy Last Known Follow-Up Visit		
VF Therapy #1 Energy Range	**PCD Transvene System**	**PCD Epicardial System**
≤ 5 J	30 (4.0%)	80 (10.8%)
6-10 J	3 (0.4%)	33 (4.5%)
11-18J	81 (10.7%)	121 (16.4%)
20-30J	21 (2.8%)	16 (2.2%)
34J	621 (82.1%)	490 (66.2%)

Table XI D-2: PCD Transvene System: Comparison of Programmed VF Therapy #1 Energy - 6/24/92

The programmed defibrillation pathways for the two patient populations is presented in Table XI D-3. The implanted PCD Transvene Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD Transvene System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD Transvene System implant criteria. The majority of the PCD Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

PCD Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD Transvene System**	**PCD Epicardial System**
Sequential	574 (75.3%)	251 (33.0%)
Simultaneous	178 (23.4%)	14 (1.8%)
Single	10 (1.3%)	496 (65.2%)

Table XI D-3: PCD Transvene System: Comparison of Programmed Defibrillation Pathway - 6/24/92

The differences in the programmed status of the PCD device in the PCD Transvene System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD device performed safely and effectively in both patient populations.

E. Spontaneous VT/VF Episodes Efficacy Comparison

The primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular tachyarrhythmias. The additional benefit of the PCD Transvene System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table XI E-1 provides a comparison of the efficacy of the PCD Transvene and PCD Epicardial System in treating spontaneous episodes of VT and VF.

PCD Transvene System Performance Comparison		
Spontaneous VT Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	5430	13,706
% Overall Efficacy	98.7%	98.1%
% Unsuccessful Termination	0.4%	1.0%
Spontaneous VF Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	5.6 months	9.7 months
Number of Episodes	973	1694
% Overall Efficacy	99.1%	98.6%
% Unsuccessful Termination	0.1%	0.5%

Table XI E-1: PCD Transvene System: Comparison of Spontaneous VT/VF Episode Efficacy - 6/24/92

The overall success rate of the PCD Transvene System in terminating spontaneous episodes of VT or VF is 98.8%. In addition, there have been no reported patient deaths due to ineffective termination of a spontaneous VT/VF episode. This success rate compares very favorably with the overall success rate of the PCD Epicardial System of 98.2%. Therefore, the PCD Transvene System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

F. Incidence of Complications/Observations

For purposes of the PCD System clinical study relevant medical events were classified as either **clinical complications** or **clinical observations**. The classification was based on the following definitions:

Complication: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

Observation: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

A comparison of the reported complications and observations was made between the PCD Transvene System and the PCD Epicardial System. The PCD Epicardial System patient population used for comparison included clinical experience as of May 14, 1992 with 742 patients and a mean implant duration of 9.7 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD System. In the PCD Transvene System patient population, 18.2% of the patients experienced a clinical complication and 20.8% of the patients experienced a clinical observation. In the PCD Epicardial System, 12.8% of the patients experienced a clinical complication and 25.7% of the patients experienced a clinical observation.

Table XI F-1 and F-2 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD Transvene System versus PCD Epicardial System Reported Complications		
Reported Complications	**PCD Transvene System (N=767)**	**PCD Epicardial System (N=742)**
Increased Defibrillation Requirements	0.8%	0.5%
Inappropriate Therapy	-	1.8%
Pace/Sense Related	0.9%	3.5%
Infection Related - Explant	2.0%	1.9%
Lead Related	6.6%	2.8%
Device Related	0.5%	0.9%

Table XI F-1: Reported Complications: PCD Transvene System versus PCD Epicardial System - 6/24/92

PCD Transvene System versus PCD Epicardial System Reported Observations		
Reported Observations	**PCD Transvene System (N=767)**	**PCD Epicardial System (N=742)**
Ineffective Therapy	0.5%	1.1%
Inappropriate Therapy	8.2%	10.6%
Pace/Sense Related	4.1%	10.2%
Infection Related	5.3%	2.2%
Lead Related	2.2%	1.2%
Device Related	-	-

Table XI F-2: Reported Observations: PCD Transvene System versus PCD Epicardial System - 6/24/92

The PCD Epicardial System requires a thoracotomy for implantation because of the need to insert two or more epicardial patch leads. This exposes the patient to increased surgical risk and potentially limits the type of patient who may be considered for implant of the system. The requirement of thoracotomy contributes significantly to patient morbidity and mortality, patient discomfort, and prolonged hospitalization. Clinically significant complications associated with epicardial implants include atrial fibrillation with additional risk of inappropriate therapy, potential erosion of native coronary arteries or bypass grafts by the epicardial patches and requirement for repeated thoracotomy in seriously ill patients if an infection develops. The PCD Transvene System offers a less invasive, simpler and safer implantation technique and should decrease the incidence of complications and observations associated with epicardial system implants.

Further analysis was performed to evaluate if the incidence of specific complications and observations was different between the two patient populations.

The incidence of inappropriate therapy delivery in the two patient groups was evaluated. Inappropriate therapy delivery is defined as the delivery of either VT or VF therapy for reasons other than spontaneous VT or VF episode. This includes atrial fibrillation with a rapid ventricular response or sinus tachycardia that overlaps with the programmed detection criteria. In addition, inappropriate therapy may be delivered due to oversensing due to hardware issues such as a loose set screw. Specifically a comparison was made between the incidence of atrial fibrillation resulting in inappropriate therapy between the two patient groups and this data is presented in Table XI F-3.

Atrial fibrillation, with a risk of inappropriate shocks and the potential need for concomitant antiarrhythmic drug therapy, is a recognized medical event in patients receiving an ICD System utilizing an epicardial defibrillation lead system. The occurrence of atrial fibrillation in these patients may be related to the thoracotomy procedure required for implant, manipulation of the atrium during the implant procedure or the positioning of the epicardial patch leads near or on the atrium resulting in irritation and induction of atrial fibrillation. The incidence of inappropriate therapy for atrial fibrillation in the PCD Epicardial System was 6.1% while that for that the PCD Transvene System was 4.9%. An decreased incidence of inappropriate therapy results in a

decreased potential risk for acceleration on non VT/VF rhythms as well as increased patient acceptance of ICD therapy. Though the introduction of a transvenous lead system has not totally removed the risk of inappropriate therapy for atrial fibrillation, from this clinical experience it appears that the incidence has been decreased.

PCD Transvene System versus PCD Epicardial System Incidence of Inappropriate Therapy for Atrial Fibrillation				
	PCD Transvene System		PCD Epicardial System	
	Number	Total %	Number	Total %
Inappropriate VF Therapy	9	1.2%	11	1.5%
Inappropriate VT Therapy	28	3.7%	34	4.6%
Overall Incidence	37	4.9%	45	6.1%

Table XII F-3: PCD Transvene System: Incidence of Inappropriate Therapy for Atrial Fibrillation - 6/24/92

The incidence of pocket infection in the two patient groups was also evaluated. In the patient receiving an ICD System with epicardial defibrillation lead systems, if an infection does develop patch explant is usually required resulting in repeated thoracotomy to remove the system.

The incidence of pocket infection that required explant of the PCD System was similar in the two patient groups - **2.0% for the PCD Transvene System versus 1.9% for the PCD Epicardial System.** The incidence of pocket infection that could be successfully treated with antibiotic therapy alone was similar between the PCD Transvene and Epicardial Systems (1.1% versus 2.2%). This similarity in the incidence of pocket infection between the two patient groups is not unexpected. The PCD Transvene System, though it does not required a thoracotomy, can require the evaluation of multiple lead orientations to obtain adequate defibrillation efficacy thus resulting in a prolonged operative procedure.

It should be noted however, that the reported incidence of infection in both patient groups is equivalent to that reported with current market released implantable cardioverter defibrillator system of 2.4% (Ventak-P Summary of Safety and Effectiveness Data, PMA Application Number P890061, May 2, 1991).

The final comparison was made between the incidence of lead dislodgement in the two patient groups. In both systems, the clinical impact of a lead dislodgement is the potential for inappropriate therapy delivery, nondetection of VT/VF or ineffective therapy for an episode of VT/VF. Also in both systems, reoperation is usually required to reestablish a lead system that provides adequate defibrillation efficacy. The incidence of overall lead dislodgement (complications and observations) in the PCD Epicardial System was 0.9% while the overall incidence (complications and observations) in the PCD Transvene System was 5.5%. This difference was not unexpected since in the PCD Epicardial System the patch leads are usually physically sutured either to the epicardium or pericardium resulting in a marked decrease potential for dislodgement.

In the case of the PCD Transvene System, there were typically two and perhaps three transvenous leads implanted. Though the leads are secured by suturing the anchoring sleeve at the venous entry site they are more susceptible to dislodgement due to patient activity, particularly movement of the upper extremities. Though the incidence was higher in the PCD Transvene System, the clinical outcome was identical in the two patient groups - there have been no reported patient deaths secondary to a lead dislodgement in either patient group.

This analysis indicates that the PCD Transvene System offers not only potential clinical advantages in removing the need for a thoracotomy for implantation and the associated morbidity but has not increased morbidity as compared to patients receiving a PCD Epicardial System.

G. Survival Analysis Comparison

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD Transvene and Epicardial System was performed.

Table XI G-1 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD Transvene System patient population was 5.6 months while for the PCD Epicardial System it was 9.7 months.

PCD Transvene System Death Classifications PCD Transvene System versus PCD Epicardial System		
Death Classification	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**
Sudden Cardiac	3	20
Non-Sudden Cardiac	15	41
All Cardiac	18	61
Noncardiac	4	27
TOTAL	22	88

Table XI G-1: Death Classifications: PCD Transvene System versus PCD Epicardial System - 6/24/92

Table XI G-2 provides a comparison of actuarial survival rates between the PCD Transvene and PCD Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD System.

PCD Transvene System Comparison of Actuarial Survival PCD Transvene System versus PCD Epicardial System			(b)(4)
One Year Survival	PCD Transvene System	PCD Epicardial System	
Number of Patients	757	742	
Sudden Cardiac	99.8%	98.7%	
Non-Sudden Cardiac	96.8%	95.7%	(b)(4)
All Cardiac	96.6%	94.4%	
Noncardiac*	99.4%	97.3%	
Overall*	95.3%	87.2%	

* Statistically Significant

Table XI G-2: Comparison of Actuarial Survival: PCD Transvene System versus PCD Epicardial System - 6/24/92

There was a significant increase in overall survival in the patients receiving a PCD Transvene System. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD Transvene System was 95.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD Epicardial System (87.2%) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD Transvene System having a 0.7% perioperative mortality versus the a perioperative mortality of 4.7% in the PCD Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

H. Summary

A comparison of PCD Transvene System clinical experience and PCD Epicardial System clinical experience indicates that the devices are being used in patients with similar cardiovascular disease history.

The mean DFT value at implant of the PCD Transvene System falls well below the maximum output (34J) of the PCD device and are comparable to those obtained with the PCD Epicardial System.

The differences in PCD device programmed status in the two groups is a reflection of the patients receiving the PCD Transvene System and the defibrillation requirements of a nonthoracotomy lead system.

However, despite differences in the programmed status, the PCD device performed safely and effectively in both patient groups.

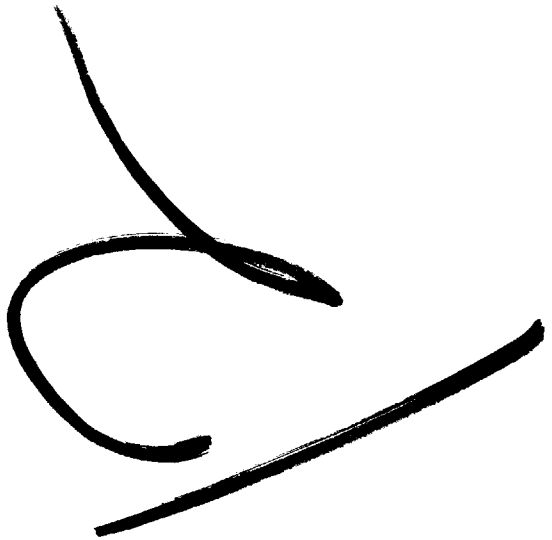
The reported incidence of complications is comparable between the two systems. The reported incidence of observations was statistically lower in the PCD Transvene System.

Finally, the reported Sudden Cardiac Death survival rates in the two patient groups is very similar (PCD Transvene = 99.8%; PCD Epicardial = 98.7%). However, there is statistical improvement in the overall survival in the PCD Transvene System patient population. This is directly related to the decreased perioperative morbidity and mortality associated with the PCD Transvene System.

I. Conclusion

The PCD Transvene System eliminates the need for a thoracotomy for the implantation of defibrillation lead systems. This directly improves the overall patient survival by decreasing the perioperative patient morbidity and mortality when compared to the PCD Epicardial System. This is added benefit however is not gained at the expense the PCD Transvene System efficacy in treating spontaneous VT/VF episodes when compared to the PCD Epicardial System.

observations



XII. Complications and Observations

A. Overview

The introduction of a multiprogrammable implantable cardioverter defibrillator (ICD) devices should assist the physician in resolving the majority of relevant clinical events via modifications in programmed parameters and/or drug therapy rather than via invasive procedures. However, there will continue to be certain relevant clinical events which will require invasive procedures for resolution. The incorporation of these programmable features should not result in an increase in reported clinical complications and/or observations.

The current market released implantable cardioverter defibrillator system requires a surgical thoracotomy for implantation because of the need to insert one or more epicardial patch leads. This exposes the patient to increased surgical risk and potentially limits the type of patient who may be considered for implant of the system. The requirement of surgical thoracotomy contributes significantly to perioperative complications, patient discomfort, and prolonged hospitalization. Clinically significant complications associated with epicardial implants include atrial fibrillation with additional risk of spurious shocks, transient worsening of ventricular arrhythmias, potential erosion of native coronary arteries or bypass grafts by the epicardial patches and requirement for repeated thoracotomy in seriously ill patients if an infection develops. The need for a less invasive, simpler and safer implantation technique is widely recognized. The introduction of a nonthoracotomy lead system should decrease the incidence of complications and observations associated with epicardial system implants.

An analysis of the reported complications and observations was performed and the incidence of these events was compared to that reported with the PCD Epicardial System and that reported in the literature with the market released AICD Epicardial System.

As of June 24, 1992 in the PCD Transvene System patient population, there have been a total of 138 complications identified in 138 patients and 157 observations identified in 157 patients. Thus 18.2% (138/757) of the patients have experienced a clinical event which was defined as a complication and 20.7% (157/757) of the patients have experienced a clinical event which was defined as an observation.

A review of the clinical data that follows indicates that the inclusion of programmable VT/VF detection and therapy parameters into the PCD device has not increased the incidence of reported complications and/or observations. In addition, the PCD Transvene System has performed safely in this patient population with no complications or patient deaths reported due to device malfunction and has not increased the potential risk to the patient.

This section includes the following subsections:

• **Definitions**	Discussion of definitions used to classify each of the complications and observations.
• **Physician Review**	Discussion of purpose of physician review board created to review all reported complications and observations.
• **Event Analysis**	Analysis of reported complications and observations, incidence and resolution.
• **PCD Epicardial System Comparison**	Discussion of PCD Transvene System experience in comparison to the PCD Epicardial System experience
• **AICD Comparison**	Discussion of PCD Transvene System experience in comparison to the published AICD System experience.
• **Event Summary**	For each patient, a detailed summary of the circumstances of the complication and/or observation is provided in Appendix C.

The section concludes with a summary and conclusions which can be drawn from the patient complication/observation clinical experience.

B. Definitions

The complications and observations are divided into various categories as they appear on the Follow-Up Data Form in the Relevant Medical Events section. The events are divided into complications or observations based on the following definitions.

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device

These definitions were used to categorize the reported clinical events for use in calculation of the reported incidence of complications and observations.

C. Physician Review of Complications

All deaths and significant complications have been, and will continue to be, reviewed by a committee comprised of PCD Transvene System investigators and other physicians. Two committees have been formed, one to review North American clinical events and the other for European clinical events. The members of the two committees is provided in Section XII, Patient Deaths. The primary objective of this committee was to determine whether the PCD Transvene System was related to these complications and, if so, what changes may be required to prevent such events in the future.

D. Clinical Complications and Observations Data Summary

This section provides a summary of the reported complications and observations that have occurred worldwide in patients who have been implanted with a PCD Transvene System.

As of June 24, 1992 there have been a total of 138 complications identified in 138 patients and 157 observations identified in 157 patients. Thus 18.2% (138/757) of the patients have experienced a clinical event which was defined as a complication and 20.7% (157/757) of the patients have experienced a clinical event which was defined as a observation.

Table XII D-1 summarizes how these clinical events were classified.

PCD Transvene System Reported Complications/Observations U.S. versus International		
	Complications	**Observations**
U.S.	77 pts	68 pts
International	61 pts	89 pts
Total	138 pts	157 pts

Table XIID-1: PCD Transvene System Complications/Observations U.S. versus International - 6/24/92

E. Clinical Event Analysis

Reported Incidence of Complications and Observations

As of June 24, 1992 there have been a total of 138 complications identified in 138 patients and 157 observations identified in 157 patients. Thus 18.2% (138/757) of the patients have experienced a clinical event which was defined as a complication and 20.8% (157/757) of the patients have experienced a clinical event which was defined as a observation. Table XII E-1 summarizes how these clinical events were classified.

The percentage is the ratio of the number of Complications or Observations in a given category to the total number of patients (n = 757) in the study population **(NOTED AS Tot%)**.

The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and nonthoracotomy leads technical manual.

The reported significant complications have been reviewed by a committee (Clinical Event Review Committee) comprised of PCD investigators and other physicians. The primary objective of this committee was to determine whether the PCD Transvene System was related to these complications and, if so, what changes may be required to prevent such events in the future.

The data in the following sections indicates that the PCD Transvene System has performed safely and effectively in the indicated patient population.

PCD Transvene System Reported Complications/Observations By Category				
Category	Complications		Observations	
	Number	Tot%	Number	Tot%

Table XII E-1: PCD Transvene System: Reported Complications/Observations - 6/24/92

Reported Complications and Observations by Follow-Up Interval

An analysis was done on the patient group to determine the distribution of reported complications and observations over time. As a reference, the mean follow-up for the entire patient group is 5.6 months and ranges from implant to 28.6 months. Table XII E-2 provides an analysis of reported clinical events. For purposes of this table the reported complications and observations have been combined.

PCD Transvene System Reported Complications/Observations By Follow-up Interval							
	Follow-Up Interval						
Category	Implant 1 Month	1-3 Month	3-6 Month	6-9 Month	9-12 Month	12+ Month	Total
Increased Defibrillation Requirements	8	1	1	-	-	-	10
Inappropriate VF Therapy	8	2	1	2	-	-	13
Inappropriate VT Therapy	12	15	8	6	5	3	49
Loss of Capture	10	2	-	-	-	1	13
Oversensing	13	6	2	2	1	-	24
Undersensing	-	-	-	-	-	-	-
Skin Erosion	-	2	1	-	-	-	3
Pocket Infection	4	13	4	2	-	-	23
Seroma	12	2	1	1	-	-	16
Hematoma	16	5	-	-	-	-	21
Pneumothorax	3	-	-	-	-	-	3
Pacemaker Syndrome	-	-	1	1	-	-	2
Right Ventricle Perforation	5	-	-	-	-	-	5
Subclavian Vein Thrombosis	-	2	2	-	-	-	4
Lead Fracture	-	-	2	1	-	1	4
Subcutaneous Patch Crinkling	3	4	3	2	-	-	12
RV Lead Dislodgement	15	7	-	-	-	-	22
CS Lead Dislodgement	17	4	2	-	-	-	23
SVC Lead Dislodgement	15	21	6	2	-	-	44
Early Device Explant	1	3	-	-	-	-	4
Clinical Event Total by Follow-up Interval	142	89	34	19	6	5	295
% Patients Completed Follow-Up	18.9%	14.1%	6.9%	6.0%	3.3%	4.4%	

Table XII E-2: PCD Transvene System Reported Complications and Observations by Follow-Up Interval - 6/24/92

Of the reported complications and observations, 48.1% occurred in the first thirty days post implant of the PCD Transvene System. Of the 631 patients who have completed a one month follow-up, 14.1% have experienced either a complication or observation. The majority of these clinical events were associated with the actual implantation of the system itself such as pocket infection and lead dislodgement.

Complications and observations reported at equal to or greater than six months accounted for 10.2% of the reported relevant medical events. Of the 329 patients who have completed a six month follow-up, 6.0% have experienced either a complication or an observation. The majority of these were observations that were resolved either with reprogramming of the PCD device, modification of drug therapy or required no action by the physician for resolution of the clinical event. It should be noted that the "12+ Month" columns reflects all complications and observations reported in patients with implant durations equal to **and** greater that 12 months.

Thus based on this clinical data, the reported incidence of complication and observations with the PCD Transvene System decreases over the implant duration of the system.

Complication and Observation Summary

A brief discussion of each of the complication/observation categories is provided in the following discussion. The technical manuals include discussion of these reported complications and observations. These discussions can be found in the **Programming Considerations and Warnings and Precautions** sections of the PCD Device technical manual as well as the PCD Transvene System manuals. The technical manuals are provided with this submission.

Increased Defibrillation Requirements

There were ten reported cases of failure to defibrillate, six of which were classified as complications and four which were classified as observations.

In the six cases classified as a complication, the patients received a three lead PCD Transvene System and met the required implant criteria of 3/4 successes at 18J. At the prior to discharge electrophysiology study, VF could not be reliably defibrillated at 18J or 34J. In four patients, the PCD Transvene System was explanted and replaced with a three lead epicardial defibrillation system. In the fifth case a hybrid system was implanted which consisted of a Model 6884 right ventricular lead, for pace/sense functions, and two 6897L epicardial patch leads. And in the final patient, a new PCD Transvene System was identified which provided appropriate defibrillation efficacy. In all three cases effective defibrillation was documented.

In the four cases classified as observations, the ineffective defibrillation was observed during an electrophysiology study. In three cases the patient's antiarrhythmic drug regimen was modified (addition of Sotalol) to improve defibrillation efficacy. In the final case, all four VF Therapies were programmed to 34 Joules. There have been no reports of ineffective defibrillation for spontaneous VF in these patients.

Inappropriate VF Therapy Delivery

This medical event was reported in thirteen patients, all of which were classified as observations. In nine cases, inappropriate VF therapy was delivered for atrial fibrillation that had a rapid ventricular response that met the programmed VF detection

criteria. In two cases, inappropriate VF therapy was delivered secondary to sinus tachycardia that was detected as ventricular fibrillation. Modification of the programmed VF detection criteria or the patient's antiarrhythmic drug therapy corrected these two clinical observations.

One patient received inappropriate VF therapy secondary to the sensing of T waves during sinus rhythm with the PCD device programmed to a sensitivity of 0.3 mV. This was resolved with reprogramming of the sensitivity to 1.2 mV. Appropriate VF sensing was documented at this programmed setting.

The final patient received inappropriate VF therapy secondary to nonsustained ventricular tachycardia. In the PCD Device, once "VF" is detected the device is committed to the delivery of defibrillation therapy. This observation was resolved by reprogramming of the FDI and VF NID.

Inappropriate VT Therapy Delivery

This medical event was reported in forty nine patients and was classified as an observation in all cases. Inappropriate VT therapy was delivered for atrial fibrillation with a rapid ventricular response in 28 patients and due to sinus tachycardia in 21 patients. This observation was resolved by reprogramming of the VT detection parameters in 21 patients, with modification of drug therapy in 26 patients and no action was required in one patient. One patient with atrial fibrillation underwent successful AV Node ablation. Post this procedure, appropriate PCD Device function was documented.

In two patients in whom inappropriate VT therapy was delivered for sinus tachycardia, the ONSET algorithm was enabled to improve discrimination between VT and sinus tachycardia. The use of this algorithm resulted in no further delivery of inappropriate therapy for sinus tachycardia.

In three patients in whom inappropriate VT therapy was delivered for atrial fibrillation, the STABILITY algorithm was enabled to improve discrimination between VT and atrial fibrillation. The use of this algorithm resulted in no further delivery of inappropriate therapy for atrial fibrillation.

Loss of Capture

Loss of capture was reported in thirteen patients. Six cases were classified as a complications and required invasive procedures to resolve the loss of capture. In four cases, repositioning of the RV lead was required and in one case, the investigator elected to implant a new RV lead. In the sixth patient, the loss of capture was secondary to a loose connection at the Model 6884 lead connection to the PCD device header. The pocket was reopened, the set screw was tightened and the problem was resolved.

Seven cases were classified as an observation and in four of the cases could be resolved by programming the PCD device to full output (5.4V/1.59 ms). In the remaining three cases, modification of drug therapy was required to resolve the loss of capture.

Oversensing

This medical event was reported in twenty four patients. Oversensing of post VVI pacing was the cause in 13 patients and sensing of T waves in sinus rhythm was the cause in 11 patients. In all cases, the medical event was classified as an observation.

This sensing of T waves did not result in detection of either VT or VF and was resolved with reprogramming of the refractory period (10 patients), sensitivity (5 patients) or no action was taken (9 patients).

Undersensing

There have been no reports of undersensing in the PCD Transvene System.

Skin Erosion

There have been three cases reported, two which were classified as a complication and the remaining case classified as an observation. In the two cases classified as a complication, a skin erosion was noted at the pocket incision site, the pocket was reopened and the area debrided with resolution of the skin erosion. Antibiotic therapy resolved the case classified as an observation.

Pocket Infection

This medical event was reported in twenty three patients. In 15 of the cases, all of which were classified as complications, the pocket infection resulted in explant of the entire implanted PCD Transvene System. Four of the patients has subsequently had a new PCD Transvene System implanted while the remaining patients still have not had a new system implanted.

In 8 cases classified as an observation, the infection was successfully treated with antibiotic therapy.

An analysis of the implant procedures for these patients was performed. In those patients who developed a pocket infection a mean of 9.5 inductions were performed at implant and a mean of 3.0 lead configurations were evaluated at implant. This compares to those patients who did not develop a pocket infection who had a mean of 7.3 inductions performed at implant and a mean of 2.2 lead configurations evaluated at implant. This data indicates that the patients who developed pocket infection had longer implant procedures that may have placed at increased for the development of a pocket infection.

An analysis was performed to determine if other clinical circumstances in addition to a potentially prolonged implant procedure contributed to the development of pocket infection in these patients.

Three patients had a history of diabetes mellitus, one patient was undergoing renal dialysis and one patient had a history of Crohn's disease being treated with steroid therapy. These concomitant diseases processes could contribute to an increase risk for development of infection.

Two patients had a history of prior pocket infection with a previously implanted ICD System and one patient required multiple lead evaluations prior to the implant of the PCD Transvene System. These clinical histories could contribute to an increase risk for development of infection.

Eight patients developed pocket infections after reoperations required for repositioning of the dislodged lead. In seven cases, eventual explant of the entire PCD Transvene System was required and the final patient was successfully treated with

antibiotic therapy and the pocket infection resolved.

It should be noted that the incidence of patients who developed pocket infection and required explant of the PCD Transvene System was 2.0%. In the PCD Epicardial System, the incidence of patients who required explant of the system due to infection was 1.9%. Thus there is no difference between the two patient groups.

Seroma

This medical event was reported in sixteen patients, 11 of which were classified as observations and 5 classified as a complication.

A seroma developed at the pocket site in ten patients, four were classified as complications and six were classified as an observation. A seroma developed at the SQ patch site in five patients, one which was classified as a complication and four which were classified as an observation. Finally, one patient developed a seroma at both the SQ patch and pocket site. This was classified as an observation.

In the cases classified as a complication, aspiration of the fluid which resolved the seroma. In the cases classified as observation, antibiotic therapy was required in two patients and in nine patients the seroma resolved without treatment.

Hematoma

This medical event was reported in twenty-one patients, 17 of which were classified as observations and 4 classified as a complication.

A hematoma developed at the pocket site in 11 patients, one was classified as a complication and 10 were classified as an observation. A hematoma developed at the SQ patch site in six patients, one which was classified as a complication and five which were classified as an observation. In four patients, a hematoma developed at both the SQ patch and pocket site. Two of these cases were classified as complications and two as observations.

In the cases classified as a complication, aspiration of the fluid which resolved the hematoma. In the cases classified as

observation, antibiotic therapy was required in three patients and in 14 patients the hematoma resolved without treatment.

Pneumothorax

This medical event was reported in three patients. In the two patients, in whom this medical event was classified as a complication, a PCD Transvene System was implanted via a left subclavian approach and the patient developed a pneumothorax in the immediate perioperative period. A chest tube was inserted for resolution of the pneumothorax and the patients recovered without further complications.

The patient, in whom this medical event was classified as a observation, also had a PCD Transvene System implanted via a left subclavian approach. This patient also developed a pneumothorax in the immediate perioperative period. In this case, the pneumothorax resolved without intervention.

Pacemaker Syndrome

There were two reports of pacemaker syndrome which were classified as observations. The patients experienced symptoms of pacemaker syndrome with VVI bradycardia support pacing. The VVI standby rate was reprogrammed to a lower rate to allow for the patient's intrinsic heart rate to predominate which resolved the patient's symptoms.

Right Ventricle Perforation

This medical event was reported in five patients and was classified as a complication in all cases. In four cases, the right ventricular perforation was noted at the time of implant of the PCD Transvene System. In the final case, the right ventricular perforation occurring after a repositioning of the RV lead one month post implant.

One patient who experienced a right ventricular perforation ultimately expired in the perioperative period. This patient received a PCD Transvene System that consisted of a coronary sinus lead, right ventricular lead and subcutaneous patch. The right ventricular lead (Model 6884) was positioned easily with two attempts necessary to screw the helix into the myocardium. Only one lead configuration was tested and a total of six inductions

were performed. This patient's medical history was significant for chronic obstructive pulmonary disease that was being treated with steroid therapy.

The lead system was connected to the PCD Device and one final VF induction was performed. This episode was neither sensed or converted by the two 34 Joule shocks delivered manually from the PCD Device. Several external defibrillation and prolonged resuscitative measures were required to restore sinus rhythm. After this episode it was determined that the pacing thresholds had increased to greater than 10 Volts and there was no identifiable ventricular electrogram from the RV lead. The investigator felt at this time that this suggested either RV lead dislodgement or perforation, lead malfunction or device malfunction. However, due to the patient's poor pulmonary status the procedure was terminated without performing any further evaluations. The PCD Device VT/VF detection and therapies were deactivated for the immediate post-operative period. The investigator noted that the plan was to reevaluate the lead system post-operatively once the patient's status had stabilized.

The patient's recovery was uneventful over the next 48 hours with no significant chest pains or cardiac rubs on physical exam. ECG documentation indicated asynchronous pacing with non capture. The patient developed severe chest pain, dyspnea and profound hypotension. Despite intubation and administration of fluids and pressors he developed electromechanical dissociation followed by episodes of asystole and ventricular tachycardia/fibrillation. The diagnosis of cardiac tamponade was made but due to the patient's pulmonary disease pericardiectomy and repair of the myocardial perforation was not performed. The patient expired after prolonged resuscitative measures.

An autopsy identified a perforation of the right ventricle by the RV lead, accompanied by hemopericardium and presumed cardiac tamponade. No other potential causes of death could be identified.

The investigator classified this patient death as cardiac, non-sudden and related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and felt that the death was related to the specific implant procedure and not the PCD Transvene System.

In three of the remaining cases, the right ventricular perforation was diagnosised at the time of implant. Two of the patients ultimately required a thoracotomy for repair of the perforation and received PCD Epicardial Systems. In the third patient, the physician repositioned the RV lead with resolution of symptoms and the patient received a PCD Transvene System.

In all three of the cases, multiple repositioning of the RV lead was required (>5) in order obtain acceptable pacing thresholds due to poor lead/tissue interface.

In the final case, the right ventricular perforation occurred after a repositioning of the RV lead one month post implant. This patient was screened for a PCD Transvene System however did not meet the implant criteria and received a PCD Epicardial System. The RV lead was left in place for pace/sense function. Two weeks post implant, RV lead dislodgement was detected and reoperation was required for repositioning. Approximately one month post implant of the PCD Epicardial System, the patient presented with symptoms of shortness of breath and chest pain. Reoperation was required to repair the perforation and the pace/sense lead system was modified to an epicardial system.

Subclavian Vein Thrombosis

There have been four reports of subclavian vein thrombosis in the PCD Transvene System patient population.

In three cases this medical event was classified as an observation. Two patients were treated with thrombolytic therapy with resolution of the symptoms while the remaining patient required no therapy.

In one patient, initial thrombolytic therapy did not resolve the subclavian thrombosis and the physician elected to explant the PCD Transvene System. However, post explant of the system the subclavian vein thrombosis did not resolve. The patient ultimately received a PCD Epicardial System.

Lead Fractures

There have been four reports of right ventricular lead fractures, all of which were classified as complications. There were no reports of ineffective therapy for a spontaneous VT/VF episode due to the

right ventricular lead fracture. In this report, there have been a total of 757 right ventricular leads implanted. Thus the incidence of lead fracture in the right ventricular leads implanted is 0.5%.

In three patients, the right ventricular lead fracture was documented based on an increase in pacing thresholds. In the fourth patient, the diagnosis was based on the delivery of inappropriate VF therapy delivery. In all cases, the fracture was confirmed via chest x-ray. All of the systems were implanted via a subclavian approach and, for resolution, required reoperation, removal of the lead and implantation of new right ventricular lead. Analysis of the leads indicates that the conductor coil fracture was due to crushing of the lead body between the first rib and clavicle. These patients have experienced no further complications.

The Model 6966 technical manual recommends that the lead be inserted by venotomy through routes including the right or left cephalic vein or the external or internal jugular vein. The following "Caution" is provided if insertion is done via a subclavian approach:

If insertion is done via a subclavian approach, the lead should be positioned far laterally to avoid clamping the lead body between the clavicle and first rib. Clamping the lead may eventually cause the conductor to fracture, may cause damage to the insulation, or may cause other damage to the lead. This may result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, may also precipitate pinching and subsequent fracture of the lead. If significant resistance is encountered during a subclavian stick implant procedure, do not force the lead by adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. In such cases it is recommended that an alternate venous entry site be used.

The PCD Transvene System technical manuals discuss potential complications of use of the lead system one of which is potential conductor coil fracture. The possible effects of conductor fracture discussed in the technical manual include intermittent or continuous loss of defibrillation, cardioversion therapy, sensing or tachycardia therapy. It is recommended that if such a loss occurs, sensing thresholds and x-rays should be checked for lead dislodgement or conductor fracture.

Subcutaneous Patch (Model 6895/6999) Crinkling

This medical event was reported in twelve patients and was classified as a complication in 7 patients and as a observation in the remaining 5 patients. In the cases classified as a complication, the subcutaneous patch crinkling occurred in the perioperative period and required modification of the lead system.

In all of these cases, the physician felt that the defibrillation efficacy of the system had been compromised by the crinkling of the subcutaneous patch.

In 5 patients subcutaneous patch crinkling was demonstrated by routine chest x-ray post implant of the PCD Transvene System. Ventricular fibrillation was reinduced and successfully reverted. The investigators elected to make no modifications to the lead system.

Lead Dislodgement

There have been a total of 89 lead dislodgements reported in 87 patients. The **overall incidence** of lead dislodgement in this patient population is 11.7% (89 dislodgements/762 implants with a mean implant duration of 5.6 months). In 10.2% of the reported cases, (77/757), the dislodgement was classified as a **complication** and required reoperation. In 1.6% of the reported cases, (12/757), the dislodgement was classified as an **observation** and the reoperation was not required.

In none of the cases did the lead dislodgement result in ineffective therapy for a spontaneous VT or VF episode or patient death. It is important to note, that the majority (52.8%) of the lead dislodgements occurred in the first thirty days post implant of the PCD Transvene System. Table XII E-3 summarizes the overall incidence of lead dislodgement and those that occurred at implant duration greater than 30 days.

PCD Transvene System Dislodgement Experience		
All Lead Dislodgements		
	Complications	**Observations**
Overall Incidence	10.2% (77/757)	1.6% (12/757)
> 30 Days Incidence	4.4% (33/757)	1.2% (9/757)
Model 6884/6966 Right Ventricular Lead		
	Complications	**Observations**
Overall Incidence	2.8% (21/741)	0.1% (1/741)
> 30 Days	0.8% (6/741)	0.1% (1/741)
Model 6881/6963 Superior Vena Cava Lead		
	Complications	**Observations**
Overall Incidence	6.9% (37/535)	1.3% (7/535)
> 30 Days	4.1% (22/535)	1.1% (6/535)
Model 6881/6963 Coronary Sinus Lead		
	Complications	**Observations**
Overall Incidence	7.3% (19/261)	1.3% (7/261)
> 30 Days	1.9% (5/261)	0.8% (2/261)

Table XII E-3: PCD Transvene System Dislodgement Frequency Overview - 6/24/92

Lead dislodgements were documented by electrophysiologic evaluation (10 cases), chest x-ray obtained during routine follow-up (65 cases), pace/sense threshold evaluation during routine follow-up (13 cases) or due to inappropriate therapy delivery (2 cases). In 77 cases reoperation was required to reposition the lead and evaluate defibrillation system. In the remaining 12 cases, VF inductions were performed to evaluate the efficacy of the implanted lead system and based on the results the physician elected to make no surgical modifications to the system.

Lead dislodgements are not specific to the PCD Transvene System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers

demonstrated a high lead dislodgement rate of at least 20%. (Smyth PND, et al. Permanent pervenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery 1976;72:565-570.) Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads used with the current market release ICD System to be 6.3% (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications and Survival in Patients with Malignant Ventricular Arrhythmias. JACC Vol.11. No.6 June 1988: 1278-86).

The potential clinical impact of lead dislodgement was evaluated in the 87 patients who experienced a lead dislodgement. The evaluation included patient death, infection rate and spontaneous VT/VF episode efficacy. There were no patient deaths due to ineffective termination of spontaneous VT/VF episodes secondary to lead dislodgement reported. Eight patients (10.4%) did develop pocket infections after the reoperation required for repositioning of the dislodged lead.

In seven cases, eventual explant of the entire PCD Transvene System was required and the final patient was successfully treated with antibiotic therapy and the pocket infection resolved.

Spontaneous episode efficacy was also evaluated to determine whether prior to diagnosis of the lead dislodgement the patients were at risk of prolonged episodes of VT/VF. In 47 patients (53%) the lead dislodgement was identified prior to the patient's discharge from the hospital. Therefore more than half of the dislodgements were identified prior to the patient being in an outpatient setting where the risks of a lead dislodgement are greater. None experienced an episode of spontaneous VT/VF prior to the identification of the lead dislodgement.

In the remaining 40 patients, 21 patients experienced spontaneous VT episodes and 24 experienced spontaneous VF episodes prior to diagnosis of the lead dislodgement. The spontaneous VT episode efficacy was 97.9% and the spontaneous VF episode efficacy was 99.3% None of these episodes required Therapy #4 for successful termination. None of patients experienced prolonged episodes of VT/VF where the PCD Transvene System was ineffective in terminating the episode due to the lead dislodgement.

Table XII E-4 provides information on lead dislodgements with the PCD Transvene System and the number which were identified prior to hospital discharge and the number which were identified post hospital discharge.

PCD Transvene System Reported Lead Dislodgement			
Lead Model	**Frequency**	**Prior to Discharge**	**Post Discharge**
RV (6884/6966)	21	14	7
RV (SP2100)	1	1	-
CS (6881/6963)	23	17	6
SVC (6881/6963)	44	15	29
TOTAL	89	47	42

Table XII E-4: PCD Transvene System Lead Dislodgement Frequency - 6/24/92

The frequency of dislodgement of each lead model was determined based on the total number of leads of that type implanted. Table XII E-5 provides the frequency by lead model and position.

PCD Transvene System Frequency of Dislodgement By Lead Model			
Model Number	**# Dislodgements**	**# Implants**	**Overall Frequency**
RV - SP2100	1	16	6.3%
RV - 6884/6966	21	741	2.8%
CS - 6881/6963	23	261	8.8%
SVC - 6881/6963	44	535	8.2%

Table XII E-5: PCD Transvene System Frequency of Dislodgement By Lead Model - 6/24/92

The incidence of lead dislodgement by follow-up interval is provided in Table XII E-6. This data indicates that 52.8% of the lead dislodgements occurred in the first thirty days post implant of the PCD Transvene System while the remaining dislodgements (47.2%) occurred more than 30 days post implant of the PCD Transvene System.

PCD Transvene System Lead Dislodgement By Follow-Up Interval							
Model	≤ 1 Week	1-4 Weeks	1-3 M	3-6 M	6-9 M	9-12 M	12+ M
6884/6966-RV	5	9	7	-	-	-	-
SP2100-RV	-	1	-	-	-	-	-
6881/6963-CS	12	5	4	2	-	-	-
6881/6963-SVC	3	12	21	6	2	-	-
TOTAL	20	27	32	8	2	-	-

Table XII E-6: PCD Transvene System Lead Dislodgement by Follow-Up Interval - 6/24/92

The analysis in Table XII E-6 only reflects the incidence of dislodgement by follow-up interval and does not reflect the number of each lead model that had completed a particular follow-up interval. Table XII E-7 provides this particular analysis.

PCD Transvene System Dislodgement Experience By Completed Follow-Up	
Model 6884/6966 Right Ventricular Lead	
# Patients Completed Three Month Follow-Up	514
Dislodgement Rate in First 3 Months Post Implant	4.1% (21/514)
Model 6881/6963 Coronary Sinus Lead	
# Patients Completed Three Month Follow-Up	196
Dislodgement Rate in First 3 Months Post Implant	10.7% (21/196)
Model 6881/6963 Superior Vena Cava Lead	
# Patients Completed Three Month Follow-Up	349
Dislodgement Rate in First 3 Months Post Implant	10.3% (36/349)

Table XII E-7: PCD Transvene System Dislodgement Experience by Completed Follow-Up - 6/24/92

The dislodgement rate of the Model 6884/6966 right ventricular leads on a per-patient basis was expected to be no greater than 10% in the first three months post-implant. This is based on clinical experience with the Medtronic Model 4016 bradycardia pacing lead which is similar in design to the Model 6884/6966 right ventricular lead. The incidence of dislodgement of the Model 6884/6966 in the first three months post implant was 4.1%.

The dislodgement rate of the Model 6881/6963 lead in the coronary sinus position on a per-patient basis was not expected to be significantly greater than that reported for bradycardia coronary sinus leads - approximately 13%. The incidence of dislodgement of the Model 6881 lead in the coronary sinus lead position in the first three months post implant was 10.7%.

In the case of the Model 6881/6963 lead in the superior vena cava position, was compared to the AICD System experience with spring/patch defibrillation lead systems. As noted earlier. Winkle et al, reported a superior vena cava lead dislodgement rate of 6.3%. The incidence of dislodgement of the Model 6881/6963 lead in the superior vena cava position in the first three months post implant was 10.3%.

The PCD Transvene System technical manuals discuss potential complications of use of the lead system one of which is potential dislodgement of the leads. The possible effects of lead dislodgement discussed in the technical manual include intermittent or continuous loss of defibrillation, cardioversion therapy, sensing or tachycardia therapy. It is recommended that if such a loss occurs, sensing thresholds and x-rays should be checked for lead dislodgement.

In addition, the technical manual provides recommendations on positioning the PCD Transvene Lead System, securing the Model 6884/6966 electrode into the endocardium and use of the anchoring sleeve(s) provided with the lead system.

Early Device Explant

There were four patients in whom the PCD Device was explanted due to reasons other than death, infection or heart transplant. In all cases these medical events were classified as complications.

In the first patient the PCD Device was explanted for lower than expected battery voltage measurement for time in service. Analysis indicated the decreased battery voltage measurement was due to leakage at the input to one of the integrated circuits. This lead to a voltage drop across a resistor where the voltage measurement was taken. Analysis indicated the battery to be performing to specifications and the leakage to be a random event.

The second patient received inappropriate VF therapy during reformation of the device capacitors. Analysis of the explanted unit indicated that arcing occurred between the conductors in the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to the excessive voltage applied.

Since this is the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this was determined to be a random component failure.

In the third patient, during the pre-hospital discharge electrophysiology study, VT was induced and cardioversion therapy failed to appropriately synchronize and deliver therapy for this induced episode. The PCD Device was explanted and the patient received a second device without difficulties. Analysis of the explanted PCD Device indicated a random device failure in the microprocessor and low power hybrid. The manufacturing process was modified to incorporate a screening process to identify any further devices which may exhibit this behavior.

In the final patient, the PCD Device exhibited a Power On Reset (POR) condition that could not be related to use of electrocautery or external defibrillation. The device was explanted and returned to Medtronic for analysis. Final results on the analysis are not available at the time of this submission but will be submitted to the FDA when they are available.

In all three cases, the patients received a second PCD Device without difficulties.

Resolution of Complications and Observations

The incorporation of programmable VT/VF detection and therapy algorithms allows the physician the flexibility to resolve clinical events via reprogramming and/or modification of drug therapy rather than invasive procedures. Certain complications, such as pocket infections, lead dislodgement or fractures, because of their potential negative impact on the patient's outcome will require invasive procedures for resolution. Table XII E-8 provides data on how the reported complications and observations were resolved. "**Reprogram**" indicates that only reprogramming was required, "**Drugs**" indicates that only modification of drug therapy was required and "**Reprogram/Drugs**" indicates that both a modification of programmed parameters and drug therapy was required to resolve the clinical event. "**Invasive**" indicates that a surgical procedure was required to resolved the clinical event and "**No Action**" indicates that the physician elected to not to treat the clinical event.

Table XII E-8: PCD Transvene System Resolution of Complications and Observations by Category - 6/24/92

Clinical Event Analysis Summary

The reported complications and observations in the PCD Transvene System clinical study are recognized clinical events that may occur with **any** of the current ICD devices. The incorporation of programmability in the PCD device has allowed the resolution of 33.1% of the reported observations without the need for invasive procedures. It is interesting to note that in 33.8% of the recognized clinical events, the physician elected to take no action to treat the clinical event.

Appropriate labelling has been incorporated in the PCD device technical manual to address the reported complications and observations.

F. Comparison with PCD Epicardial System Clinical Experience

A comparison of the reported complications and observations was made between the PCD Transvene System and the PCD Epicardial System. The PCD Epicardial System patient population used for comparison includes clinical experience as of May 15, 1992 with 742 patients and a mean implant duration of 9.7 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD System. The reported incidence of complications, 18.2% for the PCD Transvene System and 12.8% for the PCD Epicardial System was similar for the two patient groups. In addition, the reported incidence of observations, 20.7% for the PCD Transvene System and 25.7% for the PCD Epicardial System was similar.

Table XII F-1 and F-2 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD Transvene System versus PCD Epicardial System Reported Complications		
Category	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**
Ineffective Therapies	0.8%	0.5%
Inappropriate Therapies	-	1.8%
Pacing or Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.0%	1.9%
Infection Related - No Explant	1.5%	0.5%
Lead Related	6.6%	2.8%
Device Related	0.5%	0.9%

Table XII F-1: Reported Complications: PCD Transvene System versus PCD Epicardial System - 6/24/92

PCD Transvene System versus PCD Epicardial System Reported Observations		
Category	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**

Infection Related - No Explant	4.9%	2.2%
Lead Related	2.2%	1.2%
Device Related	-	-

Table XII F-2: Reported Observations: PCD Transvene System versus PCD Epicardial System - 6/24/92

The PCD Epicardial System requires a surgical thoracotomy for implantation because of the need to insert two or more epicardial patch leads. This exposes the patient to increased surgical risk and potentially limits the type of patient who may be considered for implant of the system. The requirement of surgical thoracotomy contributes significantly to perioperative complications, patient discomfort, and prolonged hospitalization.

Clinically significant medical events that may be associated with epicardial implants include atrial fibrillation with additional risk of inappropriate therapy, potential erosion of native coronary arteries or bypass grafts by the epicardial patches and requirement for repeated thoracotomy in seriously ill patients if an infection develops. The PCD Transvene System offers a less invasive, simpler and safer implantation technique and should decrease the incidence of complications and observations associated with epicardial system implants.

The overall reported incidence of complications and observations was similar in the two patient groups. Analysis was performed to evaluate if the incidence of specific complications and observations was different between the two patient populations.

The **incidence of inappropriate therapy delivery** in the two patient groups was evaluated. Inappropriate therapy delivery is defined as the delivery of either VT or VF therapy for reasons other than spontaneous VT or VF episode. This includes atrial fibrillation with a rapid ventricular response or sinus tachycardia that overlaps with the programmed detection criteria. In addition, inappropriate therapy may be delivered due to oversensing due to hardware issues such as a loose set screw. Specifically a comparison was made between the incidence of atrial fibrillation resulting in inappropriate therapy between the two patient groups and this data is presented in Table XII F-3.

Atrial fibrillation, with a risk of inappropriate shocks and the potential need for concomitant antiarrhythmic drug therapy, is a recognized medical event in patients receiving an ICD System utilizing an epicardial defibrillation lead system. The occurrence of atrial fibrillation in these patients may be related to the thoracotomy procedure required for implant, manipulation of the atrium during the implant procedure or the positioning of the epicardial patch leads near or on the atrium resulting in irritation and induction of atrial fibrillation. The incidence of inappropriate

therapy for atrial fibrillation in the PCD Epicardial System was 7.8% while that for that the PCD Transvene System was 4.7%. Though this difference was not statistically significant ($p = 0.089$) this difference was clinically important. An decreased incidence of inappropriate therapy results in a decreased potential risk for acceleration on non VT/VF rhythms as well as decreasing patient acceptance of ICD therapy. Though the introduction of a transvenous lead system has not totally removed the risk of inappropriate therapy for atrial fibrillation, from this clinical experience it appears that the there is a trend towards a decreased in the incidence of this observation.

PCD Transvene System versus PCD Epicardial System Incidence of Inappropriate Therapy for Atrial Fibrillation				
	PCD Transvene System		PCD Epicardial System	
	Number	Total %	Number	Total %
Inappropriate VF Therapy	5	1.6%	10	2.3%
Inappropriate VT Therapy	10	3.2%	24	5.5%
Overall Incidence	15	4.7%	34	7.8%

Table XII F-3: PCD Transvene System: Incidence of Inappropriate Therapy for Atrial Fibrillation - 6/24/92

The **incidence of pocket infection** in the two patient groups was also evaluated. In the patient receiving an ICD System with epicardial defibrillation lead systems, if an infection does develop patch explant is usually required resulting in repeated thoracotomy to remove the system. The incidence of pocket infection that required explant of the PCD System was similar in the between the PCD Transvene and Epicardial Systems (2.0% versus 1.9%).

This similarity in the incidence of pocket infection between the two patient groups indicates that even though the PCD Transvene System can require the evaluation of multiple lead orientations to obtain adequate defibrillation efficacy there is not a resultant increase in risk of pocket infection.

The reported incidence of infection in both patient groups is similar to that reported with current market released implantable cardioverter defibrillator system of 2.3% (Nisam et al, ICD Clinical Update: First Decade, Initial 10,000 Patients. PACE, Vol.14, February 1991, Part II, pg 255-262).

The final comparison was made between the incidence of **lead dislodgement** in the two patient groups. In both systems, the clinical impact of a lead dislodgement is the potential for inappropriate therapy delivery, nondetection of VT/VF or ineffective therapy for an episode of VT/VF. Also in both systems, reoperation is usually required to reestablish a lead system that provides adequate defibrillation efficacy. The overall incidence (complications and observations) of lead dislodgement in the PCD Epicardial System was 0.9% while the overall incidence (complications and observations) in the PCD Transvene System was 5.5%.

This difference was not unexpected since in the PCD Epicardial System the patch leads are usually physically sutured either to the epicardium or pericardium resulting in a marked decrease potential for dislodgement. In the case of the PCD Transvene System, there were typically two and perhaps three transvenous leads implanted. Though the leads are secured by suturing the anchoring sleeve at the venous entry site they are more susceptible to dislodgement due to patient activity, particularly movement of the upper extremities. Though the incidence was higher in the PCD Transvene System, the clinical outcome was identical in the two patient groups - there have been no reported patient deaths secondary to a lead dislodgement in either patient group.

This analysis indicates that the PCD Transvene System offers not only potential clinical advantages in removing the need for a thoracotomy for implantation and the associated mortality but has not increased morbidity as compared to patients receiving a PCD Epicardial System.

G. Comparison with AICD Epicardial System Clinical Experience

The Automatic Implantable Cardioverter/Defibrillator produced by Cardiac Pacemakers, Inc. is the only implantable cardioverter defibrillator device to have obtained approval from the U.S. FDA for market release. As such, this system represents the only market released device available for comparison to the PCD Transvene System. There are important differences in the capabilities and operation of these two systems, particularly in the area of antibradycardia and antitachycardia pacing. In addition, the current AICD System is implanted only with defibrillation lead systems requiring a thoracotomy. Nevertheless, a comparison of those aspects that are similar is provided in Table XII G-1.

PCD Transvene System
Comparison of Reported Complications
PCD versus AICD

Category	PCD%	AICD%
Fail to Cardiovert/ Defibrillate	0.8%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery*	8.2%	20%
Pocket Infection	2.0%	2.2%
Erosion	0.3%	0.7%

* Includes complications and observations

Table XII G-1: Comparison of Complication/Observation Rates: PCD Transvene System versus AICD System - 6/24/92

The AICD complications are based on a recent published article (Winkle, et al. Long-Term Outcome With the Automatic Implantable Cardioverter-Defibrillator; JACC, May, 1989; 13(6); 135-161.)

The incidence of failure to cardiovert and/or defibrillate was similar in the two groups. The instances of failure to cardiovert and/or defibrillate in the PCD Transvene System patient population were all associated with increased defibrillation requirements none of which resulted in patient death.

In three cases the implanted lead system was modified to provide adequate defibrillation efficacy, in two cases the patient's drug therapy was modified and in the final case reprogramming provided for adequate defibrillation efficacy.

The instances of failure to cardiovert or defibrillate in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD Transvene System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate therapy included sinus tachycardia being detected as VT/VF and atrial fibrillation with rapid ventricular response being detected as VT/VF.

The circumstances reported in the Winkle, et al article were nonsustained VT, recurrent stable VT, sinus tachycardia, atrial fibrillation with rapid ventricular response and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD Device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

The incidence of pocket infection in the PCD Transvene System (2.0%) is similar to that reported with the AICD Epicardial System (2.2%).

Thus, the incidence of complications and observations was similar to that of the AICD in the categories of ineffective VT/VF therapy, infection and erosion. Clinically significant is that the incidence of inappropriate therapy delivery is lower in the PCD Transvene System than the AICD System.

This analysis indicates that the PCD Transvene System offers not only potential clinical advantages in removing the need for a thoracotomy for implantation and the associated morbidity but does not place the patient at additional risk as compared to patients receiving a AICD System.

H. Summary

1. The overall complication rate, defined as the ratio of the number of patients having at least one complication to the total number of patients, reported in this study was found to be 18.2%. The rate of observations was found to be 20.7%.

2. As compared to PCD Epicardial System clinical experience, the PCD Transvene System offers not only potential clinical advantages in removing the need for a thoracotomy for implantation and the associated morbidity and has not increased the incidence of comparable complications and observations.

3. The incidence of complications and observations was similar to that of the AICD System with no increase in patient morbidity.

4. The PCD Transvene System was safe with no patient deaths due to device malfunction in this patient population.

I. Conclusion

A total of 138 patients (18.2%) of the patients have experienced a relevant medical event which was classified as a complication while 157 patients (20.7%) have experienced a relevant medical event which was classified as an observation.

The incorporation of multiprogrammable features in the PCD device has decreased the incidence of certain reported complications and observations. Therefore, tiered therapy has been safely incorporated into the PCD device while maintaining an acceptable complication rate.

The PCD Transvene System offers not only potential clinical advantages in removing the need for a thoracotomy for implantation and the associated morbidity but maintains the safety of the PCD Epicardial System in terms of the number of patients experiencing a complication or observation.

The complications/observations reported in the PCD Transvene System experience are similar to those reported in the PCD Epicardial System. None of the clinical complications or observations reported to date have required a modification in the indication for implant for the PCD Transvene System or modification in the system labelling. This analysis indicates that the PCD device when implanted with a nonthoracotomy lead system is performing safely.

XIII. Patient Deaths

A. Section Overview

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool.

The current market released implantable cardioverter defibrillator system requires a surgical thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to increased surgical risk and potentially limits the type of patient who may be considered for implant of the system. The requirement of surgical thoracotomy contributes to the morbidity and mortality of these patients. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD Transvene System, would decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

In order to demonstrate the positive impact of the PCD Transvene System on patient survival, analysis of the sudden cardiac death survival in the PCD Transvene System patient population was performed and compared to the reported survival of similar patients treated with PCD Epicardial System, the market released Ventak-P Epicardial System and antiarrhythmic drug therapy.

As of June 24, 1992 there have been a total of **22 patient deaths** reported in this patient population who received a PCD Transvene System consisting of three leads (N=757). The PCD Transvene System sudden cardiac death survival rate in this patient group is 99.8%. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year. **The PCD Transvene System Sudden Cardiac Death survival at one year of 99.8% which is very comparable to that of the PCD Epicardial System, 98.7% and commercially available implantable defibrillator, 98.6%.**

In summary, the incorporation of a nonthoracotomy defibrillation lead system has improved the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial system implant approaches while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

B. Introduction

This section provides a summary of the patient deaths that have occurred worldwide in patients who have been implanted with a PCD device with an nonthoracotomy defibrillation lead system. Patient deaths which occurred prior to June 24, 1992 are included in calculations of patient survival and death rates for total, cardiac, and sudden mortality rates.

This section includes the following subsections:

• **Definitions**	Discussion of definitions used to classify each of the patient deaths
• **Physician Review**	Discussion of purpose of physician review board created to review all patient deaths
• **Death Analysis**	Analysis of patient deaths which includes patient characteristics, discussion of sudden cardiac deaths, perioperative deaths and survival data
• **Actuarial Survival**	One year actuarial survival analysis for patients who received a PCD Transvene System.
• **PCD Comparison**	Discussion of the PCD Transvene System experience in comparison to the PCD Epicardial System experience
• **AICD Comparison**	Discussion of the PCD Transvene System experience in comparison to the AICD Epicardial System experience
• **Death Summaries**	For each patient, a detailed summary of the circumstances of the patient death is provided. These are provided in Appendix D.

The section concludes with a summary and conclusions which can be drawn from the patient death clinical experience.

As of June 24, 1992 there have been a total of **22 patient deaths** reported in this patient population group of 757. Fifteen of the deaths occurred in the United States and the remaining seven deaths occurred in the International patient group.

The Table XIII B-1 summarizes how these patient deaths have been classified:

PCD Transvene System Summary of Death Classifications	
Death Classifications	
Classification	**All Patients (N=757)**
Sudden Cardiac	3
Non-Sudden Cardiac	16
Noncardiac	3
TOTAL	22

Table XIII B-1: Summary of PCD Transvene System Death Classifications - 6/24/92

There have been five perioperative deaths in the total group of 22 patient deaths with a resultant perioperative mortality of 0.7%.

None of the reported patient deaths have been related to the implanted PCD Transvene System.

There have been four patient deaths in the patients who did not meet the PCD Transvene System implant criteria. Two of these deaths have been classified as sudden cardiac however in both cases the investigator did not feel the patient death was related to the implanted PCD Transvene System. The remaining two deaths were classified as non-sudden cardiac and were related to end stage cardiac failure.

Finally, there have been no patient deaths reported secondary to ineffective treatment of a spontaneous VT/VF episode, lead dislodgement or lead fracture.

All of the patient deaths have been reviewed by a Clinical Event Review Committee (CERC) comprised of PCD Transvene System investigators and other physicians.

The primary objective of this committee was to determine whether the PCD Transvene System was related to the deaths and, if so, what changes may be required to prevent such events in the future and to review the classification of the deaths as specified by the primary investigator.

The data included in the following sections indicates that the PCD Transvene System has been safe and effective in reducing the Sudden Cardiac Death rate in the indicated patient population while maintaining a high efficacy rate in terminating spontaneous VT/VF episodes.

C. Definitions

Each patient death was classified by the primary investigator using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was not determined to be cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden deaths were categorized as being **Witnessed** or **Unwitnessed**.
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD System component, or as a result of a device-induced arrhythmia, or an interaction between a PCD System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow, or test a PCD System.

This classification scheme was used to categorize patients for use in the actuarial analysis of survival. These definitions are identical to those in the medical literature discussing the Ventak-P Epicardial System clinical experience.

D. Physician Review of Deaths

All deaths and significant complications have been, and will continue to be, reviewed by a committee comprised of PCD device investigators and other physicians. Two committees have been formed, one to review North American deaths and complications, and the other for European clinical events.

The members of the **North American** committee are:

(b)(4), (b)(6)	
(b)(4), (b)(6)	Electrophysiologist; University of Washington;Seattle
	Electrophysiologist; University of Minnesota; Minneapolis
	Electrophysiologist; Foothills Hospital; Calgary, Alberta, Canada
	Cardiovascular Surgeon; Sacre Coeur Hospital; Montreal, Canada
	Cardiac Pathologist; University of Washington; Seattle

The members of the **European** committee are:

(b)(4), (b)(6)	
(b)(4), (b)(6)	Electrophysiologist, Heidelberg,Germany
	Electrophysiologist, Munster,Germany
	Electrophysiologist, Maastricht, Netherlands
	Electrophysiologist, Bonn,Germany
	Electrophysiologist, Stockholm, Sweden
	Electrophysiologist, Hamburg,Germany

These Clinical Event Review Committees (CERCs) have met to review the deaths that are reported in the following sections. All of the patient deaths have been reviewed by a committee (Clinical Event Review Committee) comprised of PCD investigators and other physicians.

The primary objective of this committee was to determine whether the PCD Transvene System was related to the deaths and, if so, what changes may be required to prevent such events in the future and to review the classification of the deaths as specified by the primary investigator.

Significant comments and modification to death classification by the CERC is provided, when present, in each of the detailed death summaries later in this section. It should be noted that the CERC agreed with the investigator's classification in all cases.

E. Circumstances of Patient Death Analysis

As of June 24, 1992 there have been 757 patients who have received a PCD Transvene System consisting of a three lead system. In this patient group, 22 patient deaths have been reported. Table XIII E-1 provides a summary of the patient characteristics of those patients who have expired.

PCD Transvene System Patient Death Clinical Characteristics	
Clinical Data	All Deaths
Number of Patients	(b)(4)
Mean Age	
Sex Male Female	
Primary Indication SCD VT SCD/VT	
Coronary Artery Disease	
NYHA Class Class I Class II Class III Class IV	
Mean Ejection Fraction Mean Range	
Death Classification Sudden Cardiac Non-Sudden Cardiac Noncardiac	
Perioperative Deaths	
PCD Related	
Spontaneous VT # Episodes # Patients	
Spontaneous VF # Episodes # Patients	

(b)(4)

Table XIIIE-1: PCD Transvene System Patient Death Clinical Characteristics - 6/24/92

In order to evaluate whether the patient death group differed clinically from the alive patient population group a comparison was made between the two groups. There was a statistical difference between the two patients groups in previous history of congestive heart failure, NYHA Classification and mean ejection fraction. The patient death group had a higher incidence of patient's with a previous history of congestive heart failure ($p = 0.030$), more patient's with a NYHA Classification of Class III/IV ($p = 0.001$) and a lower mean ejection fraction ($p = 0.001$).

Patient deaths were further analyzed based on the primary indication for implant of the PCD Transvene System. Table XIIIE-2 provides a further analysis of patient deaths by primary indication for PCD Transvene System implant.

PCD Transvene System Death Classification by Primary Indication			
Classification	**Indication for Implant**		
	SCD (N = 281)	**VT (N = 377)**	**SCD/VT (N = 99)**
Sudden Cardiac	-	3	-
Non-Sudden Cardiac	6	7	3
All Cardiac	6	10	3
Noncardiac	1	2	-
Total Deaths	**7**	**12**	**3**

Table XIIIE-2: PCD Transvene System Death Classification by Primary Indication for Implant - 6/24/92

Those patients whose indication for implant was **sudden cardiac death** accounted for 31.8% of the patient deaths. Those patients whose indication for implant was **recurrent ventricular tachycardia** accounted for 54.6% of the patient deaths. And those patients whose indication for implant was **ventricular tachycardia associated with sudden cardiac death** accounted for 13.6% of the patient deaths. This distribution of indications in the patient deaths reflects the distribution of indications in the patients receiving the PCD Transvene System.

467

There was no difference in patient survival based on what PCD Transvene System lead configuration was implanted (i.e. RV/SVC/SQ, RV/CS/SQ or RV/CS/SVC) or the indication for implant of the PCD Transvene System.

Analysis was done on the distribution of patient deaths over time. As a reference, the mean follow-up for the entire patient data base is 5.6 months with the longest implant duration being 28.6 months.

Perioperative deaths were defined as deaths which occurred within 30 days of implant. Table XIII E-3 provides an analysis of patient deaths by follow-up interval.

PCD Transvene System Patient Deaths by Follow-Up Interval				
	Perioperative	1-3 M	3-6 M	> 6 M
Total by Interval	5	9	3	5

Table XIIIE-3: PCD Transvene System Patient Deaths by Follow-Up Interval - 6/24/92

There were five patient deaths in the perioperative period in patients who received a PCD Transvene System with a resultant perioperative mortality of 0.7%. The death classifications for these patients deaths was sudden cardiac death in two patients, non-sudden cardiac death in two patients and the remaining patient death was classified as noncardiac. This group of patients was predominately male and had a mean age of 67 years. The mean ejection fraction in this patient group was 20% and four of the patients had NYHA Classification of Class III/IV. As a group, these patients did not undergo prolonged implant procedures for the implantation of the PCD Transvene System. From this clinical data, it appears these patients had moderately depressed left ventricular function which would place them at higher risk post any type of surgical procedure.

As a final analysis, the non-sudden cardiac patient deaths were reviewed to determine if any were related to ventricular tachyarrhythmia episodes but the patient death occurred greater than one hour after onset of symptoms. Of the sixteen (16) non-sudden cardiac deaths, two were related to VT/VF episodes and the remaining were related to end stage congestive heart failure.

F. Actuarial Survival

The following represents a summary of the actuarial survival calculations for the PCD Transvene System. Actuarial survival analysis was completed from the perspective of **intention to treat** in those patients who were screened and those who received a PCD Transvene System (N = 757).

Those patients in whom the PCD Device was OFF at the time of death are included in the survival analysis. As a note, in the case of two patient deaths, the PCD Device was OFF at the time of death. One patient death was classified as non-sudden cardiac not related to an episode of VT/VF. The second patient death was classified as sudden cardiac and the patient had requested that the PCD Device be deactivated. The patient death which classified as non-sudden cardiac also occurred during the perioperative period.

Table XIII F-1, F-2 and Figure 1 provide the one year actuarial survival for all types of deaths in the patients who were screened and who received a PCD Transvene System. Note that the actuarial projections do not include perioperative deaths, except in the calculation of one-year survival from death due to all causes (shown in the row labelled **Overall**).

The positive impact of the PCD Transvene System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.8%, both in the patient group that was screened and received a PCD Transvene System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

The PCD Transvene System Sudden Cardiac Death survival at one year is 99.8% which is very similar to that of the PCD Epicardial System, 98.7% and commercially available implantable defibrillator, 98.6%.

PCD Transvene System One Year Actuarial Survival	
	Screened Transvene System (N = 854)
Sudden Cardiac	99.8%
Non-Sudden Cardiac	97.1%
All Cardiac	97.0%
Noncardiac	99.4%
Overall	94.8%

Table XIII F-1: PCD Transvene System Actuarial Survival: Patients Screened - 6/24/92

PCD Transvene System One Year Actuarial Survival	
	Received Transvene System (N = 757)
Sudden Cardiac	99.8%
Non-Sudden Cardiac	96.8%
All Cardiac	96.6%
Noncardiac	99.4%
Overall	95.3%

Table XIII F-2: PCD Transvene System Actuarial Survival: Patients Received - 6/24/92

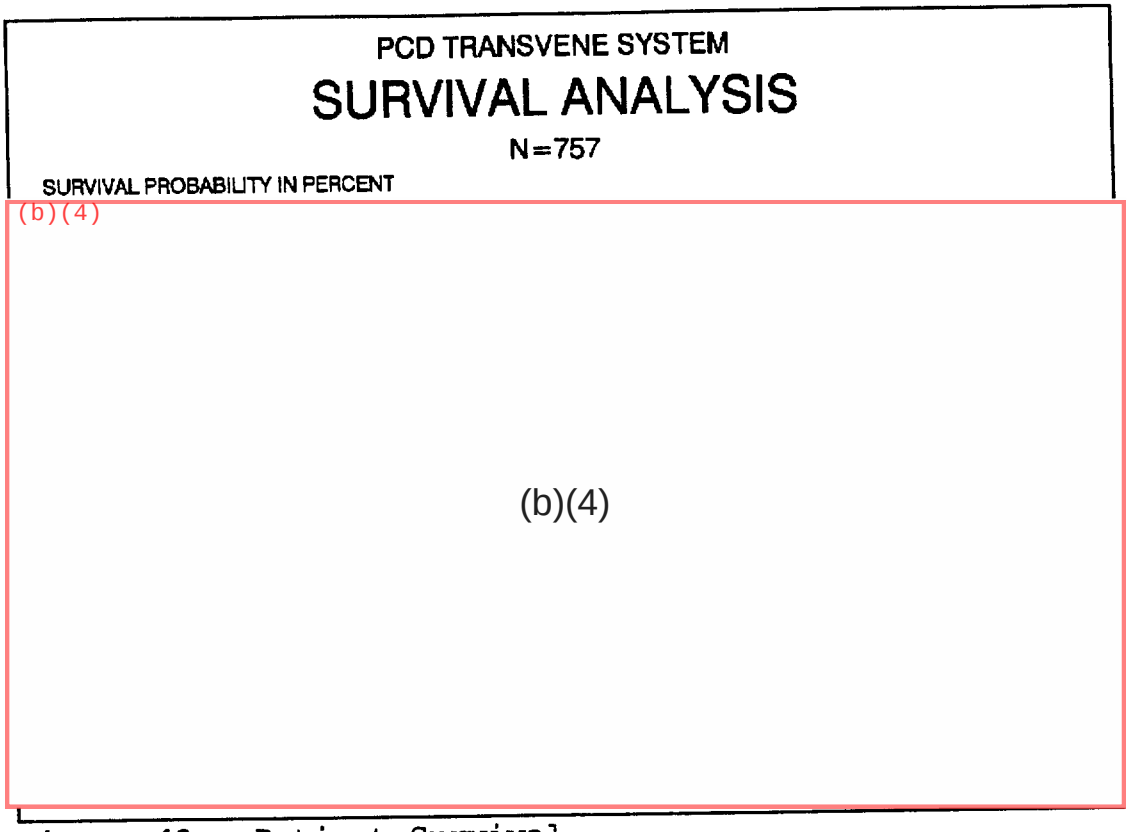

Figure 43: Patient Survival

G. Statistical Analysis For Predictors of Death

Statistical analysis on factors that may be predictive of death was conducted. Specific clinical characteristics of the patients who died were compared to those patients who received a PCD Transvene System and are still alive. Table XIII G-1 shows the factors that were analyzed and their respective P-Values. There was a statistical difference between the two patients groups in previous history of congestive heart failure, NYHA Classification and mean ejection fraction. This statistical difference was not unexpected since patients with more severe underlying cardiovascular disease are at risk for increased mortality. This data **does not** indicate that these patients should be contraindicated for a PCD Transvene System.

PCD Transvene System
Clinical Factors Predictive of Patient Death

VARIABLE	Transvene Deaths	Alive Transvene	Test	P-Value
Primary Indication			(b)(4)	
SCD	7 (31.8%)	274 (37.3%)		
VT	12 (54.6%)	365 (49.7%)		
SCD/VT	3 (13.6%)	96 (13.1%)		
Previous Cardiovascular History				
Coronary Artery Disease	18 (81.8%)	543 (73.9%)		
Myocardial Infarction	13 (59.1%)	503 (68.4%)		
Congestive Heart Failure*	12 (54.6%)	238 (32.4%)		
Cardiomyopathy	7 (31.8%)	231 (31.4%)		
NYHA classification*				
I/II	12 (54.6%)	597 (83.6%)		
III/IV	10 (45.4%)	117 (16.4%)		
Age	65.5 yrs	59.2 yrs		
Ejection Fraction*	24.5% (10-48%)	35.9% (7-88%)		

Table XIII G-1: PCD Transvene System: Analysis on Predictors of Death - 6/24/92

H. Comparison to PCD Epicardial System Clinical Experience

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to perioperative complications, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD Transvene and Epicardial System was performed.

Table XIII H-1 provides a summary of the patient deaths reported in the two patient populations by classification. The PCD Epicardial System data (N = 742) includes patients who received the system as of May 14, 1992.

PCD Transvene System Death Classifications PCD Transvene System versus PCD Epicardial System		
Death Classification	**PCD Transvene System (N = 757)**	**PCD Epicardial System (N = 742)**
Sudden Cardiac	3	20
Non-Sudden Cardiac	16	41
All Cardiac	19	61
Noncardiac	3	27
TOTAL	22	88

Table XIII H-1: Death Classifications: PCD Transvene System versus PCD Epicardial System - 6/24/92

Table XIII H-2 provides a comparison of actuarial survival rates between the PCD Transvene and PCD Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD System.

PCD Transvene System Comparison of Actuarial Survival PCD Transvene System versus PCD Epicardial System			(b)(4)
One Year Survival	PCD Transvene System	PCD Epicardial System	
Number of Patients	757	742	
Sudden Cardiac	99.8%	98.7%	
Non-Sudden Cardiac	96.8%	95.7%	(b)(4)
All Cardiac	96.6%	94.4%	
Noncardiac*	99.4%	97.3%	
Overall*	95.3%	87.2%	

* Statistically Significant

Table XIII H-2: Comparison of Actuarial Survival: PCD Transvene System versus PCD Epicardial System - 6/24/92

Also significant was the increase in overall survival in the patients receiving a PCD Transvene System. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD Transvene System was 95.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD Epicardial System (87.2%) (b)(4) (b)(4)

This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD Transvene System having a 0.7% perioperative mortality versus the a perioperative mortality of 4.7% in the PCD Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for surgical thoracotomy and its associated morbidity and mortality.

I. Comparison to AICD Epicardial System Clinical Experience

The Automatic Implantable Cardioverter Defibrillator (AICD) produced by Cardiac Pacemakers, Inc., is the only such device which has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the AICD produced by CPI and the PCD System produced by Medtronic as well as the implanted defibrillation lead system, there is a natural desire for comparison of the clinical outcome, particularly the impact of these devices on death rate.

Table XIII I-1 provides a comparison of one year actuarial survival rates.

The patient population used for this comparison is the one which is described in Ventak-P Epicardial System Summary of Safety and Effectiveness, dated May 2, 1991, obtained through the freedom of information act.

For purposes of this comparison, only the **overall** actuarial survival rate includes perioperative deaths. All other calculations in both the PCD and Ventak-P group exclude perioperative deaths. Statistical analysis comparing the perioperative patient deaths is not possible since clinical data is not available on the AICD perioperative patient deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P System had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, two patient deaths was **censored** in the PCD Transvene System patient population because the device was deactivated at the time of patient death.

PCD Transvene System Comparison of Actuarial Survival Rate PCD versus AICD		
One Year Survival	**PCD**	**Ventak-P**
Number of Patients	757	292
Sudden Cardiac	100.0%	98.6%
Overall	95.6%	90.8%

Table XIII I-1: Comparison of Actuarial Survival: PCD Transvene System versus AICD Epicardial System - 6/24/92

This comparison indicates that the projected survival from sudden cardiac death of patients receiving a PCD Transvene System is improved to that reported for the Ventak-P Epicardial System.

Thus the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, this comparison indicates that the projected survival from all causes of death **(Overall)** in patients receiving a PCD Transvene System is markedly improved as compared to the Overall one year survival reported for the AICD Epicardial System. This improvement is directly related to the decrease in the perioperative mortality in patients receiving a PCD Transvene System due to elimination of the requirement for a thoracotomy.

J. Summary

1. The projected one year survival for Sudden Cardiac Death, Non-Sudden Cardiac Death, All Cardiac Death and Overall were found to be 99.8%, 96.8%, 96.6%. and 95.3% respectively.

2. The perioperative mortality rate of 0.7% for the PCD Transvene System is significantly lower than that reported for implantable cardioverter defibrillator implants with an epicardial patch lead system.

K. Conclusion

The incorporation of a nonthoracotomy lead system, such as the PCD Transvene System, has decreased the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The positive impact of the PCD Transvene System on patient mortality has been demonstrated by the analysis provided in this section. The sudden cardiac death survival rate for both patients who were screened for and received a PCD Transvene System is 99.8%.

This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year. **The PCD Transvene System Sudden Cardiac Death survival at one year of 99.8% which is very comparable to that of the PCD Epicardial System, 98.7% and commercially available implantable defibrillator, 98.6%.**

Also significant was the increase in overall survival in the patients receiving a PCD Transvene System. The overall one year survival for patients receiving the PCD Transvene System was 95.3%. This is significantly improved (b)(4) as compared to the overall one year actuarial survival for the PCD Epicardial System (87.2%) and the Ventak-P Epicardial System (90.8%).

This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD Transvene System having a 0.7% perioperative mortality versus the a perioperative mortality of 4.7% in the PCD Epicardial System and 2.7% in the Ventak-P Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for surgical thoracotomy and its associated morbidity and mortality.

This improvement in both sudden cardiac death and overall one year survival indicates that the PCD Transvene System has performed safely and effectively in the indicated patient population.

I. Clinical Experience Report

A. System and Study Description

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The current market released device provides defibrillation therapy for VF or hemodynamically unstable VT, however, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing. It is necessary to perform a significantly more invasive procedure, a thoracotomy, in order to implant the epicardial leads. Thus, the need to incorporate programmability, multiple detection and therapeutic options, and a less invasive lead system has lead to the development of a tiered therapy device, the PCD™ Transvene™ System.

This report represents a full report of Medtronic's clinical experience with the Medtronic PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System with Transvene Cardioversion and Defibrillation Electrodes (Reference IDE G870102). The data included in this analysis is all data that was received by Medtronic and entered onto the clinical database as of **February 1, 1993**.

The PCD Model 7217B Multiprogrammable Tachyarrhythmia Control System described in this submission is identical to the system which was recommended for approval by the FDA advisory panel on February 3, 1992, with the addition of Transvene leads and approved by the FDA February 11, 1993.

This summary provides an overview of the clinical experience which verifies that the PCD Transvene System is safe and effective in the indicated patient population.

1. Implanted Devices, Leads, and Pulse Generator

The Pacer-Cardioverter-Defibrillator (PCD) device is an implantable, multiprogrammable, automatic tachyarrhythmia control device. The PCD Device is used in conjunction with appropriate lead systems for the treatment of patients with ventricular tachycardia (VT) and/or ventricular fibrillation (VF). The PCD Device also provides backup pacing in the VVI mode and noninvasive electrophysiologic (EP) study capabilities.

The PCD Device is programmed with the market released Medtronic programmer and a Model 9788 or equivalent MemoryMod™ Cartridge. The PCD Device incorporates a two-way telemetry system which receives operational instructions from the programmer and transmits status, electrogram and event information back to the programmer for display and/or printout.

The External Tachyarrhythmia Control Device (ETCD) is an external, multiprogrammable, tachyarrhythmia control device. Its operation is similar to the PCD Device except that cardioversion and defibrillation therapies are delivered manually. In addition, it displays measurements of cardioversion and defibrillation therapy parameters. The ETCD is used for making defibrillation threshold measurements during the PCD Device implantation procedure.

Components

The Medtronic PCD Transvene System, which is represented in Figures 1A and 1B, for which market release approval is being requested, consists of the following components:

Implanted Device and Related Programming System
Pacer-Cardioverter-Defibrillator (PCD) Device
Model 7217B

Programmer
Model 9710 programmer and related accessories (currently market released), plus
Model 9788 MemoryMod™ Software Cartridge

Lead System
Electrode Leads:
Model 6966
Model 6963
Model 6999
Market Released Medtronic Epicardial Leads

Implant Measurements System
Model 5355 ETCD™ External Tachyarrhythmia Control Device
Model 5418 Patient Cable
Model 5414 Test Load
Model 5417 EGM Cable
Model 5419 Jumper Cable

10

The physical characteristics of the Model 7217B are summarized in Table IA1-1:

PCD Model 7217B Physical Characteristics	
Feature	**Model 7217B**
Volume	(b)(4)
Weight	
Connector Module	
Power Source	(b)(4)
Sensing Configuration	
Pacing Configuration	

Table IA1-1: Features: Model 7217B - 2/1/93

The Model 7217B PCD Device uses the pace/sense leads for sensing, thus providing **standard bipolar** sensing. Pacing is delivered in the integrated bipolar configuration.

2. Study Design and Objectives

The clinical study was designed to evaluate the operation, safety and effectiveness of the PCD System components in detecting and treating episodes of ventricular tachycardia and ventricular fibrillation.

The analysis focuses on data supporting the safety and effectiveness of the PCD system, including the implantable pulse generator and associated transvenous lead system and its therapy in this patient population. The analysis includes the clinical experience with the PCD system, pace/sense, detection and therapy functions in both the acute and chronic implant settings. In addition, data is provided on clinical observations, clinical complications and deaths in this patient population.

The objectives of the clinical study were:

* to evaluate the sensitivity and specificity of the PCD Device with Transvene lead systems to detect episodes of VT and VF, and to evaluate the ability of the system to appropriately discriminate between VT/VF and other potentially nonmalignant rhythms;

* to monitor the efficacy of the PCD Device with Transvene lead systems in treating VT and VF episodes. VT/VF therapy efficacy is determined as the ratio of successful termination of episodes detected to the total number of episodes detected in which one or more therapies were delivered (Successful Termination/Number of Detected Episodes with Therapy Delivered). Investigators were free to choose from any of the available leads and VT/VF therapies that the efficacy was first evaluated acutely;

* to evaluate the performance of the Model 6966, 6963 and 6999 Transvene leads;

* to monitor the patient selection criteria and patient management methods required by the PCD Device and Transvene leads.

Clinical data was collected at the following study points to support the safety and efficacy of the PCD System:

(b)(4)

(b)(4)

Specific data was collected at each of these points to meet the objectives of the clinical study. This included:

Pre-implant Patient Assessment (b)(4) (b)(4)

(b)(4)

(b)(4)

12

Lead System Testing - implant evaluation was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate, ventricular tachycardia. The Market Released Model 5355 ETCD™ or the 2394 External Cardioverter Defibrillator (ECVD) was used for testing.

This testing included (b)(4) The PCD Device implant criteria were:

1) (b)(4)

2)

Implanted Pulse Generator Testing - this implant evaluation was performed to demonstrate proper detection and termination of ventricular fibrillation by the implanted PCD System with VF Therapy #1 programmed to (b)(4) in addition to pacing and sensing thresholds.

Pre-hospital Discharge Testing - testing performed at the pre-hospital discharge included proper detection and termination of induced ventricular tachycardia. Final sensing and therapy parameters are programmed at the PHD.

Follow-up Evaluation - regular testing was performed to evaluate the chronic stability of detection and therapy parameters of the PCD System. This testing included (b)(4)

(b)(4)

Patients were evaluated prior to hospital discharge and/or one (1) month post implant, three months post-implant and then at intervals of every three months. In some cases additional testing was performed at physician discretion to evaluate spontaneous events and/or potential clinical complications.

Medtronic collected all clinical data on the PCD System and its components under the clinical protocol outlined in the Investigational Plan. A common protocol was used on all study patients on a worldwide basis.

B

Clinical data presented in this summary includes experience with the Model 7216A and 7217B PCD Devices with the Model 6966, 6884, 6963, 6881, 6999, and 6895 Transvene Leads (the only difference between the Models 6884/6881/6895 and Models 6966/6963/6999 are the size of the connector pins). This report presents the clinical evaluation of the safety and efficacy of the PCD Device with Transvene Leads implanted in 757 patients of which 657 have implant durations equal to or greater than six months.

International centers were subject to the appropriate requirements (e.g., the Declaration of Helsinki) in order that the data met the statutory requirements of the FDA. All clinical data, U.S. and International, obtained with the PCD System with Transvene Leads is included in this report.

Patient data from U.S. and International patients, Model 7216A and 7217B, and the three implanted lead configurations (RV/CS/SQ, RV/SVC/SQ, and RV/CS/SVC) analyzed in this report were compared with the appropriate statistical tests to justify data pooling. Data analyzed included: age, sex, ejection fraction, primary indication, NYHA classification, and underlying heart disease. No clinically significant differences were found among the patient groups.

Indicated Patient Population

The PCD System is intended to treat patients at risk of sudden cardiac death due to ventricular tachyarrhythmias which have been shown to be reliably terminated, and in the case of VF, terminated at an energy level below the maximum output of the PCD Device.

Results provided in this application will support Medtronic's request for market release of the PCD Transvene System for use in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise,

or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

These are the same indications that were approved for the PCD Epicardial System.

For this patient population the primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular arrhythmias. The use of pacing therapies for the treatment of ventricular tachycardia reduces patient trauma associated with higher energy cardioversion pulses and extends the longevity of the PCD pulse generator.

The PCD System allows the titration of therapies for patients with ventricular tachycardia while providing the critical defibrillation backup. Defibrillation backup is important in the event that an episode of VT accelerates to VF whether spontaneously or as a result of a delivered therapy. The capacity to provide programmable extrastimuli pacing allows noninvasive electrophysiologic studies to be performed. The potential benefits from permanent cardiac pacing provide support for chronic and transient episodes of bradycardia. Finally, the benefits of programmability of tachyarrhythmia detection and therapy parameters, VVI parameters and stored telemetry data on the delivery of therapy may avert the need for reoperation in the event of changing patient conditions or complications.

Study Controls

The clinical experience obtained in the PCD Epicardial System clinical study provides a concurrent control for comparing the clinical performance of the PCD Transvene System. Using the PCD Epicardial System clinical data as a control is appropriate because the patients were being enrolled in the two studies concurrently by the same investigators, and the patient indications, implant criteria, and clinical data requirements were identical for the two patient groups.

The Ventak-P Epicardial System is used as a historical control, since it was the most similar implantable

15

defibrillation system that was market released and had published performance data.

The PCD investigators believe that there is a class of patients who cannot tolerate the thoracotomy required for the utilization of the epicardial patch lead defibrillation lead system and who are at high risk of sudden cardiac death. For these patients, the PCD Transvene System is the only therapy available. Therefore, randomization between the Epicardial and the Transvene lead systems would not be feasible or clinically or ethically appropriate in these patient groups. There was no market released transvenous system available which would make a randomized study design possible.

3. Justification for Data Pooling

This section will describe the results of the analysis to demonstrate that the data from the U.S. and International investigative centers and the two device model numbers may be pooled. This section will also compare the three lead systems which will be presented throughout the report.

a. Comparison of U.S. and International Patients

Statistical comparisons were made between the two populations age, sex, ejection fraction, primary indication, NYHA, and previous cardiovascular history. Table E1 in Appendix E summarizes the results of statistical analysis.

All study investigators used the same:

a. patient selection criteria,
b. investigational protocol procedures, and
c. indications for implant of PCD™ Transvene™ System.

Of the variables analyzed patient age, ejection fraction, primary indication, NYHA classification, coronary artery disease and cardiomyopathy showed a statistically significant difference between the U.S. and the International patient populations at a 0.05

16

significance level. The difference in NYHA classification becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix E for multiple inference adjustments. Coronary artery disease, ejection fraction, cardiomyopathy, primary indication and age remain statistically significant after adjusting for multiple inference. The U.S. patient population has a higher percentage of patients with coronary artery disease and cardiomyopathy, lower mean ejection fraction, more patients with VT as their primary indication and a higher mean age. The difference in age may explain the differences in underlying disease and cardiac ejection fraction. These factors that are statistically significant but are not considered to be clinically significant enough to require stratification of the U.S. and International patient populations. The differences may have to do with regional attitudes toward access to health care for the aged.

b. Comparison of Model 7216A and Model 7217B

Table E2 in Appendix E summarizes the results of statistical analysis comparing the Model 7216A to Model 7217B. No parameters were found to be statistically significant between the two PCD models at a 0.05 significance level.

c. Lead Configurations

Table E3 in Appendix E shows comparisons of patient variables for the three lead systems. This was done to document that there were no significant differences in patient characteristics between the implanted lead configurations.

Of the variables analyzed in Table E3 sex and cardiomyopathy showed a statistically significant difference between the three lead configurations at a 0.05 significance level. The difference in sex and percentage of patients with cardiomyopathy

becomes insignificant when adjusting for multiple inference using the Hochberg procedure (Dunnett and Tamhane, "A Step-Up Multiple Test Procedure," Journal of the American Statistical Association, March 1992, 87:162-170). See Appendix E for multiple inference adjustments.

d. Statistical Analysis Conclusions

The statistical comparisons between the U.S. and International populations indicated no clinically significant differences therefore the data may be pooled. Analysis of the patients receiving the two PCD models indicates no statistically significant differences therefore the data from the two devices may be pooled.

The results from the comparison of lead systems indicated no statistically significant differences in patient demographics, primary indication, or heart disease.Data Pooling/U.S. Demographics

B. Overview of Clinical Experience

This report covers a total of 762 implants of the PCD Device with the Transvene Defibrillation Lead System in 757 patients who received a 3 lead system. There was a total of 97 patients that were screened for Transvene system that did not meet the implant criteria and received a Medtronic Epicardial system and a total of 43 patients that received a non-standard lead system. These patients are described in Section C2, Patients not Meeting Implant Criteria and Section D4, Non-standard Lead Configurations, respectively.

A total of 78 investigative centers participated in the clinical trial with 35 centers in the U.S. and 43 Internationally. The first implant occurred internationally on October 20, 1989, and the first implant in the U.S. occurred on October 16, 1990. Table IB-1 shows the distribution of Model 7216A and Model 7217B patients between U.S. and International investigators.

PCD Transvene System Implant Distribution			
	Total	U.S.	Int'l
7216A	18 (2.4%)	3 (0.7%)	15 (4.8%)
7217B	744 (97.6%)	444 (99.3%)	300 (95.2%)

Table IB-1: PCD Transvene System - Implant Distributions - 2/1/93

The mean documented implant duration for this patient population is 11.7 months and ranged from implant to 37.4 months. The cumulative implant duration is 8894.8 months. There are 657 patients with implant durations equal to or greater than 6 months and 393 patients with implant durations equal to or greater than 1 year.

The patient population enrolled in the clinical trial was predominately male (80.6%) with a mean age of 59.4 years. In half of the patients (49.8%), the primary indication for implant was recurrent, sustained ventricular tachycardia without an episode of sudden cardiac death. Sudden Cardiac Death was the primary indication for 37.1% of the patients and SCD in combination with recurrent, sustained VT was the primary indication in 13.1%. Coronary artery disease was the primary heart disease in 74.1% of the patient population with a mean reported ejection fraction of 35.6% Table IB-2 provides a data summary on these patients. Also included is the data summary of the patients with 6 months and 12 months of follow-up.

PCD Transvene System Data Summary

Table IB-2: PCD System Data Summary - All Transvene Patients versus Transvene Patients with 6 mo Follow-up - 2/1/93

1. Implant Information

Implants of the PCD Device may use two or three Transvene leads. The physician has the flexibility to use whichever lead system best meets the patient's needs.

The venous entry site used for placement of the Transvene leads is determined by the implanting physician. Table IB1-1 shows that the Left Subclavian vein is the most popular venous entry site regardless of type of lead or intended lead location. The total number of RV lead entry sites is greater than the total number of patients included in this report because of patients with multiple lead evaluation sessions (e.g. patients that received a second PCD Transvene system if the initial system was removed due to infection).

PCD Transvene System Venous Entry Site			
	RV Lead Models 6884/6966/SP2100	CS/SVC Lead Models 6881/6963	All Transvene Leads
Left Subclavian	483	583	1066
Right Subclavian	40	47	87
Left Cephalic	213	180	393
Right Cephalic	8	7	15
Left Internal Jugular	7	9	16
Right Internal Jugular	11	9	20
Other	5	4	9
Total	767	839	2097

Table IB1-1: Venous Entry Site - 2/1/93

The location of the subcutaneous patch is presented in Table IB1-2. Location is defined by both anatomical line and intercostal space. The study protocol does not restrict investigators in subcutaneous patch placement. Investigators are free to place it in the most appropriate location for each individual patient.

The most common subcutaneous patch location laterally is the mid axillary line (55.7%). the next most common location is the anterior axillary line (34.3%). The majority of subcutaneous patches are placed between the third and sixth intercostal (53.4%).

The majority of the investigators (92.8%) placed the patch electrode subcutaneously. Fifty-two (52) or 7.2% if investigators placed the patch electrode in a submuscular location.

PCD Transvene System
Location of the Subcutaneous Patch Electrode

Intercostal Space	Mid Clavicular Line	Anterior Axillary Line	Mid Axillary Line	Posterior Axillary Line	Subscapular	Total
1-2	(b)(4)					
3-6						
7-11						
Not Specified						
Total						

(b)(4)

Table IB1-2: Location of the Subcutaneous Patch Electrode - 2/1/93

Table IB1-3 illustrates the lowest energy of defibrillation (LED) and defibrillation threshold (DFT) for the implanted lead systems. The implant criteria for the PCD Device was 3 of 4 episodes of VF successfully terminated at 18 Joules or less with a given lead configuration. Some patients did not have a LED at implant. The LED is only identified if the investigator reported the induced rhythm as VF. Conversion of VT or V Flutter (as defined by the physician) to sinus rhythm was not included in the determination of the LED. In addition, it is not a protocol requirement to obtain a DFT at implant. However, recommendations have been provided to those institutions that prefer to obtain DFT's during the implant procedure.

23

PCD Transvene System Mean LED and DFT Values				
Lead System	Implant Frequency	Mean LED	Implant Frequency	Mean DFT
Total Systems	702	16.0J	316	14.8J
RV-SVC-SQ	455	16.7J	187	15.8J
RV-CS-SQ	210	14.6J	110	12.8J
RV-CS-SVC	37	15.2J	19	16.0J

Table IB1-3: PCD Transvene System - LED and DFT Values - 2/1/93

The mean implant Lowest Energy of Defibrillation (LED) for all lead systems was 16.0J and mean implant Defibrillation threshold (DFT) for all lead systems was 14.8J. As the mean DFT's and LED's indicate, VF was reliably terminated at an energy value below the maximum output (34 Joules) of the PCD Device.

There was a statistically significant difference between the mean DFT obtained with the RV-CS-SQ lead configuration and the mean DFT obtained with the other lead configurations. Since there were no differences in the patient populations implanted with any of the 3 lead configurations, this may be a configuration that results in lower DFTs than the other configurations. In theory, this may be due to better defibrillation current distribution throughout the myocardium. There is no intent to show that a lower DFT results in a better patient outcome. The premise of the PCD Epicardial and Transvene studies was to demonstrate that if a patient was evaluated at implant and shown to meet the implant criteria, that they would be reliably defibrillated over time, and therefore, have a high probability of survival from SCD regardless of which lead system or defibrillation pathway was chosen or the absolute value of the DFT.

Follow-up Data - Quantity

The combined experience from the Model 7216A and the Model 7217B with Transvene lead systems discussed in this analysis is 762 implants in 757 patients followed for a

24

mean of 11.7 months. Maximum follow-up is 37.4 months with 8894.8 total device months of experience. Six-hundred-fifty-seven (657) patients have been followed for at least 6 months and 393 patients have a minimum of one year of follow-up.

Table IB1-4 shows the follow-up time in months for the PCD Transvene System patient population.

PCD Transvene System Follow-up Quantity	
Mean Follow-up	11.7 Months
Std. Dev.	6.5 Months
Maximum	37.4 Months
Minimum	0 Months

Table IB1-4: Follow-up Time - Months (n = 757) - 2/1/93

Compliance

Follow-ups designated as the corresponding scheduled visit and performed between 21 and 59 days post-implant are considered to be 1-month follow-ups; those between 60 and 135 days are considered to be 3-month follow-ups; and those between 136 and 225 days are considered to be 6-month follow-ups; and those between 227 and 317 days are considered to be 9-month follow-ups; and those between 318 and 408 days are considered to be 12-month follow-ups. Follow-ups not designated as a scheduled visit or outside these intervals are counted as interim visits and do not contribute to compliance.

No devices were known to have been implanted by non-investigators, by investigators without IRB approval or equivalent, without patient Informed Consent, or without submission of Implant Data Forms to Medtronic. Implantation of the PCD Epicardial system outside the U.S. was performed in accordance with the "Declaration of Helsinki" or within the laws or regulations of the respective country, whichever accorded greater protection to the patient. Requirements for testing identified in the

Investigational Plan for test procedures were all fulfilled during the investigation. Table IB1-5 contains the follow-up compliance report.

PCD Transvene System Patient Compliance

(b)(4)

Table IB1-5: Follow-up Compliance Report - PCD Transvene System Worldwide Experience - 2/1/93

2. Spontaneous VT and VF Episode Experience

Of the 757 patients who received a PCD Transvene System, 597 patients (78.9% - 597/757) have either experienced a spontaneous VT/VF episode or had VT/VF induced during a post implant electrophysiology study. A total of 458 patients (60.5%) have experienced a spontaneous episode of either VT and/or VF that has been detected and treated by the PCD Device. A total of 141 (18.6%) experienced VT only, 142 patients (18.8%) experienced VF only and 175 patients (23.1%) experienced both an episode of VT and VF.

There have been a total of 12,009 episodes of spontaneous VT or VF as detected by the PCD. The overall PCD Device success rate in terminating spontaneous VT/VF episodes as detected by the PCD is presented in Table IB2-1.

For those episodes where all four programmed VT/VF therapies failed to terminate the episode, the clinical follow-up data form was reviewed for investigator's comments on the episode. The investigator reviewed the patient's symptoms at the time of the episode as well as the stored episode information provided by the PCD Device and indicates on the clinical dataform whether the ineffective therapy was due to a nonventricular tachyarrhythmia such as sinus tachycardia or atrial fibrillation. If there is no such indication on the clinical dataform, it is assumed that the ineffective therapy was for a spontaneous VT or VF episode. It should be noted that for all current ICD Systems, the delivery of inappropriate therapy for atrial fibrillation or sinus tachycardia is a known risk of the therapy.

PCD Transvene System Success Rate for Spontaneous VT/VF Episodes		
	Spontaneous VT Episodes	Spontaneous VF Episodes
Mean Follow-Up	11.7 months	11.7 months
Number of Episodes	10,027	1982
Number of Patients with Episodes	316	317
% Overall Efficacy	9,864/10,027 98.4%	1951/1982 98.4%
% Unsuccessful Termination (VT or VF)	68/10,027 0.7%	5/1982 0.3%
% Unsuccessful Termination (AF,ST, other)	95/10,027 0.9%	26/1982 1.3%

Table IB2-1: PCD Transvene System: Success Rate for Termination of Spontaneous VT/VF Episodes (n = 757) - 2/1/93

a. **Spontaneous VT**

For the purposes of this clinical trial, spontaneous VT was defined as those episodes that satisfied the programmed VT detection criteria. Specifically, all programmed VT detection criteria must be fulfilled to detect a VT episode. Successful termination of the episode was defined as satisfying the VT episode termination criteria.

To date, 10,027 spontaneous episodes of VT have been detected by the PCD Device in 316 patients. The mean number of episodes per patient with VT was 31.7 (316/10,027) and ranged from 1 - 531 episodes.

Most spontaneous VT episodes (90.7%) were successfully treated with VT Therapy #1 and 98.4% were successfully treated with one of the four programmable VT therapies.

Of the 9864 successfully terminated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD Transvene System. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia. This greatly enhances the patient acceptance of ICD therapy since antitachycardia pacing is usually not perceived by the patient.

Sixty patients experienced 163 (1.6%) episodes in which the PCD Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Thirty-nine patients experienced 95 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD Device responded appropriately based on the programmed detection parameters.

38

The remaining 68 episodes occurred in 21 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy**. Reprogramming and pharmacologic intervention resolved these events.

b. Spontaneous VF

For purposes of this clinical trial, VF is defined as those episodes that satisfy the programmed VF detection criteria. Specifically, all programmed VF detection criteria must be fulfilled to detect a VF episode. Successful termination of the episode is defined as satisfying the VF detection criterion for episode termination.

To date, 1982 spontaneous episodes of VF have been detected by the PCD Device in 317 patients. The mean number of episodes per patient was 6.3 and ranged from 1 - 77 episodes. A review of the chart by the investigator for this patient that experienced the 77 episodes of VF revealed that 75 were most likely due to atrial fibrillation. VF detection parameters were modified in this patient.

Most (89.1%) spontaneous VF episodes were successfully treated with VF Therapy #1 and 98.4% were successfully treated with one of the four programmable VF therapies.

Sixteen patients experienced 31 episodes (1.3%) in which the PCD Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Nine patients had 22 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Four patients experienced 5 ineffective episodes that were detected as VF by the PCD® System. One of these patients (b)(6) required external defibrillation

to convert the VF episode. This patient's antiarrhythmic drug regimen was modified to improve defibrillation efficacy. Another patient (b)(6) had an episode recorded as ineffective on the event counters but presented in sinus rhythm. Subsequent evaluation demonstrated appropriate PCD function. Another of these patients (b)(6) had two spontaneous episodes of VT that were detected as VF by the PCD while in the hospital for progressive CHF. These episodes required external cardioversion. The patient requested the PCD be turned OFF. The patient was alive at the last known follow-up. The last of these four patients (b)(6) experienced cardiac arrest at home and was found by the paramedics to be in sinus rhythm. While on a monitor the patient developed VF. The PCD delivered the programmed therapy which terminated the episode but the patient developed EMD, arrived at the ER comatose and died.

Four patients (one patient (b)(6) experienced 2 episodes due to AF but is described below again) experienced 4 episodes in which the PCD detected the episodes as VF but were actually episodes due to extraordinary circumstances. One patient (b)(6) experienced an episode where all four therapies failed secondary to RV lead fracture. The patient had Twiddlers Syndrome. Reoperation was required. It appears that the inappropriate therapy was not due to VT/VF but due to noise. Another patient (b)(6) had a surgical procedure (CABG) where the CS lead dislodged post surgery. The episode that was detected was due to the lead dislodgement. The third patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The fourth patient (b)(6) was in the hospital and there was an episode of VF detected by the PCD and therapy was delivered. However, the device was interrogated before termination of the episode was detected by the PCD. There was external intervention (transthoracic defibrillation) associated with the terminal event. However, the patient ultimately expired. The device was not interrogated again.

30

The evaluation of spontaneous episode experience indicates that the PCD Transvene System's VT and VF detection and therapy functions have performed safely and effectively in the indicated patient population.

3. Summary of Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, there have been a total of 176 complications identified in 147 patients and 212 observations identified in 178 patients in the PCD Transvene System patient population. Thus, 19.4% (147/757) of the patients have experienced a clinical event which was defined as a complication and 23.5% (178/757) of the patients have experienced a clinical event which was defined as an observation.

Table IB3-1 summarizes the reported PCD Transvene System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

PCD Transvene System Reported Complications/Observations By Category		
Category	**Complications**	**Observations**
	Num (% of Pts)	**Num (% of Pts)**

Table IB3-3: PCD Transvene System: Reported Observations Over Time - 2/1/93

Table IB3-4 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days. The ≤30 day period is defined as the acute period. This definition is consistent when compared to endocardial bradycardia lead terminology.

34

PCD Transvene System Reported Complications/Observations Lead Dislodgements <30 days and >30 days				
Category	Complications		Observations	
	Num (% of Pts)		Num (% of Pts)	
	<30 days	>30 days	<30 days	>30 days
RV Lead Dislodgement n=741	14 (1.9%)	10 (1.3%)	0 (0)	1 (0.1%)
CS Lead Dislodgement n= 261	12 (4.6%)	10 (3.8%)	2 (0.8%)	2 (0.8%)
SVC Lead Dislodgement n=535	16 (3.0%)	29 (5.4%)	1 (0.2%)	6 (1.1%)
Total Lead Dislodgement n=757	42 (5.6%)	49 (6.5%)	3 (0.4%)	9 (1.2%)

Table IB3-4: PCD Transvene System: Lead Dislodgements <30/>30 days - 2/1/93

There have been a total of 58 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT of VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In 49 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system and in 9 cases repositioning of the lead was not required..

Lead dislodgements are not specific to the PCD Transvene System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

In an attempt to reduce the rate of lead dislodgement, modifications were made to the lead anchoring sleeve and a second sleeve was added to the lead. The sleeve was modified to increase the grip pressure on the lead body and two sleeves were provided on each lead at the time of manufacture. Analysis has been completed on 439 patients implanted with the Transvene system using leads that are packaged with two anchoring sleeves. **(NOTE: These 439 patients were enrolled in the Clinical Trial after 6-24-92 and are <u>not</u> included in the 757 patient population).** Table IB3-5 contains a data summary for the 439 patients. This group of patients has similar characteristics to the 757 patient population in most areas with a slightly higher percentage of patients with VT reported as the primary indication for implant than the 757 group of patients (61.1% vs 49.8%).

PCD Transvene System Data Summary of Patients with Two Anchoring Sleeves	
Number of Patients	439
Number, % Male Number, % Female	354 80.6% 85 19.4%
Mean Age	61.2 yrs
Primary Indication: SCD VT SCD/VT	 137 31.2% 268 61.1% 34 7.7%
Coronary Artery Disease	324 73.8%
Mean Ejection Fraction	32.5% (N=390)

Table IB3-5: PCD System Data Summary for Patients with Two Anchoring Sleeves - 2/1/93

Of these 439 patients, 292 have completed their 1 month follow-up and 195 have completed their 3 month follow-up and 17 have completed a 6 month follow-up. Since the introduction of the dual anchoring sleeve the incidence of lead dislodgement has been dramatically reduced. There has been 13 dislodgements in 10 patients for a per patient incidence of dislodgement of 2.3% (10/439).

U.S. versus International

Table IB3-6 contains a summary of the complications and observations for the U.S. patients versus the Internal patients.

4. Summary of Patient Deaths

The positive impact of implantable cardioverter defibrillator (ICD) therapy on sudden cardiac death mortality has been well documented in the medical literature. The use of device therapy for the treatment of recurrent ventricular arrhythmias has become an accepted and important clinical tool. An analysis of the sudden cardiac death and overall survival in the PCD Transvene System patient population was performed based on the categorization by the investigators and subsequently reviewed by the Clinical Event Review Committee (CERC).

For purposes of the clinical study, each of the patient deaths was categorized using the following definitions:

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed.**
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD System component, or as a result of a device induced arrhythmia, or an interaction between a PCD System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD System.

28

All deaths and significant complications have been and will continue to be reviewed by a committee comprised of PCD Transvene System investigators and other physicians. Two committees (Clinical Event Review Committees) have been formed, one to review North American deaths and complications, and the other to review European clinical events. The primary purpose of these reviews was to determine whether the PCD System was related to the deaths or significant complications that have occurred and, if so, what changes may be required to prevent such events in the future.

There have been a total of 51 patient deaths reported in the PCD Transvene System patient population. Table IB4-1 summarizes how these patient deaths have been classified.

PCD Transvene System
Summary of Death Classifications
(n = 757)

Classifications	Number of Deaths
Sudden Cardiac	5
Non-Sudden Cardiac	31
Noncardiac	15
TOTAL	51

Table IB4-1: PCD Transvene System - Summary of Death Classifications - 2/1/93

None of the patient deaths were attributed to a malfunction of the PCD Transvene System.

Actuarial survival analysis on the PCD Transvene System was done on all patients who were either evaluated for implantation or in whom the device was implanted. Thus, the analysis is done from the perspective of **intention to treat.** Those patients in whom the PCD Device was OFF at the time of death or in whom no device was implanted **are** included in the survival analysis. Those patients that were screened for a PCD Transvene System but failed to receive a Transvene system and received a Medtronic Epicardial system are also included in this analysis.

Projected one year survival calculations for the various death classifications are provided in Table IB4-2. **The actuarial projections include perioperative deaths only in the calculation of one year survival from death due to all causes (shown in the row labelled Overall).** The perioperative death rate defined as deaths which occurred within thirty days of implant was 0.7% (5/757) which is considerably less than the perioperative mortality for the PCD System with Epicardial leads (5.3% - 39/742). Included in this table are the projected one year survival calculations for patients who ultimately received a PCD Transvene System (n = 757) and all patients that were screened for a PCD Transvene System (n = 854) regardless of implant outcome. The outcome of the 854 patients screened for a PCD Transvene System are described more fully in section IC2.

PCD Transvene System One Year Actuarial Survival		
	Received a Transvene System (N=757)	**Screened for a Transvene System (n=854)**
Sudden Cardiac Death	99.5%	99.4%
Non-Sudden Cardiac	96.2%	96.6%
All Cardiac	95.8%	96.1%
Noncardiac	98.1%	98.3%
Perioperative	0.7%	1.6%
Overall	93.3%	92.9%

Table IB4-2: PCD Transvene System - One Year Actuarial Survival - 2/1/93

The positive impact of the PCD Transvene System on patient mortality is clearly obvious from this analysis. The sudden cardiac death survival rate in this patient group is 99.5% for those in the patient group that received a Transvene System and 99.4% for those who were screened for a Transvene System. This is marked improvement when compared with the reported survival of similar patient groups treated with drug therapy alone of between 34% and 73% at one year.

Figure 1 contains the survival curve for sudden cardiac and total deaths for the 757 patients that received a PCD Transvene System.

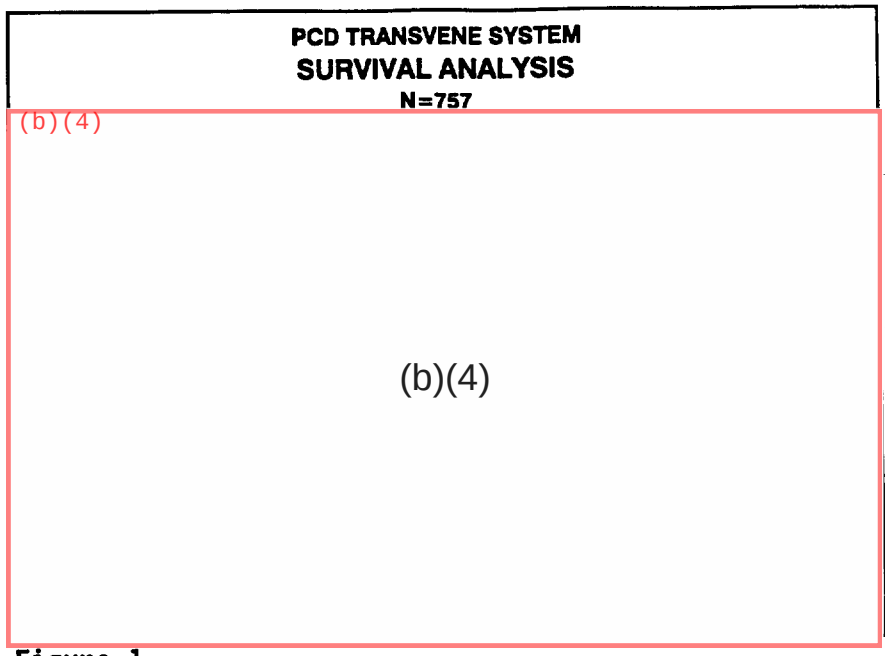

Figure 1

C. Specific Patient Populations

1. Clinical Experience By Primary Indication

Medtronic is requesting approval for use of the PCD Transvene System in the following patient population:

* Patients who have survived at least one episode of cardiac arrest due to a ventricular arrhythmia not caused by an acute myocardial infarction; or

* Patients with recurrent, sustained ventricular tachycardia that remain inducible via programmed electrical stimuli or exercise, or occur spontaneously, despite the most efficacious antiarrhythmic drug therapy that can be tolerated by the patient chronically.

Note: These patient indications are identical to those approved for the Medtronic PCD Epicardial System.

40

Sudden cardiac death without recurrent VT (**SCD**) was the indication for implant in 37.1% of the patients, recurrent ventricular tachycardia without an episode of sudden cardiac death (**VT**) was the indication for implant in 49.8% of the patients, and sudden cardiac death and recurrent VT (**SCD/VT**) was the indication for implant in 13.1% of the patients.

The performance of the PCD Transvene System in these three groups are summarized in Table IC1-1.

In all three patient groups, coronary artery disease was the predominant heart disease and the patients exhibited moderate left ventricular dysfunction as demonstrated by mean ejection fractions of less than 40%. The mean LED at the time of implant was similar among the patient groups as was the mean DFT.

The overall efficacy in terminating spontaneous VT/VF episodes in the SCD patient group was 98.4%, in the VT patient group 98.3%, and in the SCD/VT group 99.1%. Thus, independent of the indication for implant, the PCD Transvene System was highly effective in terminating spontaneous episodes of VT/VF.

The one year sudden cardiac death survival rates for all groups was greater than 98.6%

This analysis indicates that the PCD Transvene System has performed safely and effectively in the indicated patient groups and should be approved for use in the indicated patient population.

PCD Transvene System Data Summary by Primary Indication				
	SCD	VT	SCD/VT	All Patients
# of Patients	281 (37.1%)	377 (49.8%)	99 (13.1%)	757

Table IC1-1: PCD Transvene System Data Summary by Primary Indication - 2/1/93

2. Patients Not Meeting Implant Criteria

a. Overview

For purposes of the PCD Transvene System, the implant criteria was defined as successful VF termination at least 3 times in 4 attempts with the final lead configuration with an output energy of 18 Joules or less.

A total of 897 patients had an evaluation of a PCD Transvene System and are divided into the following groups: (1) patients who received a PCD Transvene System, (2) patients screened for a PCD Transvene System and received a PCD Epicardial System, and (3) patients who received a non-standard lead system. Figure 1 provides an overview of the outcome of these patients.

As can be seen, 88.6% (757/854) of the patients who were screened for a PCD Transvene System ultimately received a 3 lead system. Of these 757 patients, 71.7% (543 patients) met the recommended defibrillation implant criteria, which compares favorably with the predicted success rates published in the literature (Wilber et al). However, 28.3% (214/757) of the patients did not meet the recommended defibrillation efficacy implant criteria and still received the PCD Transvene System.

Ninety-seven (97) patients (10.8%) were screened for a Transvene lead system but received an epicardial system. Forty-three (43) patients (4.8%) were screened for a Transvene lead system but received an non-standard system.

PCD TRANSVENE SYSTEM IMPLANT EVALUATION

MEDTRONIC CONFIDENTIAL

b. Reasons for Not Meeting Implant Criteria

The physician's justification for implanting the PCD Transvene System despite not meeting the recommended defibrillation implant criteria are presented in Table IC2-1. As noted previously, the patients not meeting implant criteria (N=214) were divided into three groups (1) Successful defibrillation at an energy level of equal to or less than 24 Joules (79.4% of the patients); (2) Difficult to induce VF (11.2% of the patients); and (3) Implant procedure terminated due to poor patient condition (9.4% of the patients).

PCD Transvene System Reasons for Not Meeting Implant Criteria Physician Justification	
Reason	**Number of Patients (% of Total)**
Success at $\leq$ 24 Joules	170 (79.4%)
Difficult/Unable to Induce VF	24 (11.2%)
Patient Condition	20 (9.4%)
Total	214

Table IC2-1: PCD Transvene System: Physician Justification for Not Meeting Implant Criteria - 2/1/93

Table IC2-2 contains the patient characteristics of the patients not meeting implant criteria presented by physician justification.

PCD Transvene System Patients Not Meeting Implant Criteria by Justification			
	Success at ≤ 24 Joules	Difficult/Unable to Induce VF	Patient Condition
Number of Patients	170	24	20
Mean Follow-Up	9.6 months	9.8 months	14.4 months

Overall	94.0%	100.0%	85.5%

Table IC2-3: PCD Transvene System: Patients Not Meeting Implant by Justification - Clinical Outcome - 2/1/93

In summary, the physician made an appropriate judgement to implant the PCD Transvene system based on the clinical outcome of the patient especially those patients with a 10 Joule safety margin. Their outcome is clinically equivalent to that of the entire 757 patient population.

1) **Success at $\leq$ 24 Joules**

There were 170 patients in whom the PCD Transvene System was implanted with a defibrillation safety margin of at least 10 Joules. Table IC2-4 provides an overview of these patients clinical experience.

These data indicate that the final implanted PCD Transvene System was evaluated and significant attempts were made to meet the recommended implant criteria. In most of these patients (79.4%), a safety margin of 10 Joules was obtained between the successful defibrillation energy (24 J or less) for ventricular fibrillation and the maximum output of the PCD Device (34 J). The investigators decided in certain circumstances that this was appropriate demonstration of device effectiveness and that the PCD Transvene System could be implanted.

Of these patients, 159 (93.5%) have had VT or VF induced at a chronic follow-up visit and in each case, VT or VF was successfully terminated by the PCD Transvene System. In addition, 65 patients (38.2%) have experienced a spontaneous VF episode with an overall efficacy of 99.4%.

Thus, the clinical outcome in these patients was not adversely affected by not meeting implant criteria since their spontaneous VF episode efficacy was 99.4% and the one year sudden cardiac death actuarial survival was also 99.4%. The duration of follow up, an average of 9.7 months, is similar to that of the entire patient group (11.7 months).

PCD Transvene System Patients Not Meeting Implant Criteria 10J Safety Margin Provided	
Number of Patients	170
Lowest Energy of Defibrillation	
1 Success with 10J Safety Margin	87
2 Success with 10J Safety Margin	58
3 Success with 10J Safety Margin	18
> 3 Success with 10J Safety Margin	7

Table IC2-4: PCD Transvene System: Patients Not Meeting Implant Criteria with 3/4 Successes at ≤ 24 Joules Clinical Experience - 2/1/93

2) Difficult or Unable to Induce VF

There were 24 patients who did not meet the recommended PCD Transvene System implant criteria because at least three episodes of VF were not induced at the time of implant. Of these, 15 patients had ventricular tachycardia induced and successfully reverted. The remaining 9 patients had ventricular flutter induced and successfully reverted. In all 24 patients, the lowest successful energy was equal to or less than 18 Joules.

The indication for implant was sudden cardiac death (SCD) in 6 patients (25%), recurrent ventricular tachycardia (VT) in 13 patients (54.2%) and sudden cardiac death associated with recurrent ventricular tachycardia (SCD/VT) in 5 (20.8%) patients. Thus the majority of the patients, 75%, had documented recurrent ventricular tachycardia as part of their ventricular tachyarrhythmia history. Eight of these patients (33.0%) were on Amiodarone therapy which may have contributed to the inability to induce VF.

Of the 24 patients who did not meet the recommended PCD Transvene System implant criteria because at least three episodes of VF were not induced at the time of implant, 13 patients (54.2%) have experienced a spontaneous VF episode and 21 patients (87.5%) have had VT or VF induced

during a chronic follow-up. In all cases, VF was successfully reverted by the PCD Transvene System.

There has been one reported patient death (b)(6) in this patient group (at xx months) with a resultant one year sudden cardiac death and overall actuarial survival of 100%.

3) **Patient Condition**

There were 20 patients in whom the implant procedure was terminated due to poor patient condition. These patients received a PCD Transvene System without at least a 10 Joule defibrillation safety margin. The implant circumstances of these patients are summarized as follows:

- At least one successful defibrillation was obtained at an energy level greater than 24 Joules but less than 34 Joules (**N = 11 patients**);
- Multiple inductions of VT were performed and successfully reverted with an energy level of 18 Joules or less. However, induced VF was not successfully reverted by an energy level of less than or equal to 34 Joules (**N = 6 patients**); and
- Physician elected to terminate the procedure due to the patient's condition before inductions with the final implanted lead configuration were performed (**N = 3 patients**).

The mean ejection fraction of this group was 26.9%, indicating more severe underlying cardiovascular disease, and may have contributed to the physicians decision to terminate the implant procedure prior to meeting implant criteria. This group had a mean of 6.8 VF inductions, 2.2 lead configurations evaluated and a mean duration of VT/VF for the implant procedure of 220 total seconds. The circumstances of the implant procedures, mainly the duration of induced ventricular tachyarrhythmia and associated hemodynamic compromise, limited the number of inductions that could be performed and whether the recommended implant criteria could be met.

Of these 20 patients, VT or VF has been induced at a chronic follow-up visit in 16 patients (80%) and in all cases successful defibrillation with the implanted PCD Transvene System was documented.

The overall spontaneous VF episode efficacy for this patient group was 96.0%. However, examination of events indicated that one patient experienced multiple episodes of atrial fibrillation that was detected as VF and in whom all four programmed VF therapies were ineffective. This patient's antiarrhythmic drug therapy was modified and there were no further reports of ineffective therapies.

Thus there have been no patients who have experienced an actual spontaneous VF episode where all four programmed VF therapies failed to terminate the episode.

There have been two reported patient deaths, Patient ID (b)(6) which was classified as non-sudden cardiac secondary to end stage heart failure and Patient ID (b)(6) which was also classified as non-sudden cardiac. The one year sudden cardiac death survival in this patient population is 100% while the overall one year survival was 85.5%. This lower overall one year survival may be due to the lower mean ejection fraction of this patient group.

The VF Therapy efficacy and SCD survival in these twenty patients was not adversely affected by not meeting implant criteria since there was no reports of failure to terminate a spontaneous VF episode and the overall one year sudden cardiac death survival was 100%.

c. **Complications and Observations: Patients Not Meeting Implant Criteria**

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following previously described definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Of the 170 patients with successful defibrillation at 24 Joules, as of February 1, 1993, there have been a total of 41 complications reported in 33 patients and 34 observations reported in 31 patients in the PCD Transvene System patient population. Thus, 19.4% (33/170) of the patients had a clinical event reported which was categorized as a complication and 18.2% (31/170) of the patients had a clinical event reported which was categorized as an observation. The percent of patients with complications reported in the overall population of 757 patients was 19.4% (147/757), the same percentage as in this subgroup of 170. There were 23.8% (180/757) of the patients in the overall population with reported observations, a slightly higher percentage than in this subgroup of 170 patients.

Of the 24 patients that did not meet the implant criteria due to difficulty or inability to induce sustained VF, as of February 1, 1993, there have been a total of 4 complications reported in 4 patients and 10 observations reported in 8 patients in the PCD Transvene System patient population. Thus, 16.7% (4/24) of the patients had a clinical event reported which was categorized as a complication and 30.0% (8/24) of the patients had a clinical event reported which was categorized as an observation.

Of the 20 patients that did not meet the implant criteria due to patient condition, as of February 1, 1993, there have been a total of 6 complications reported in 4 patients and 7 observations reported in 5 patients in the PCD Transvene System patient population. Thus, 20.0% (4/20) of the patients had a clinical event reported which was categorized as a complication and 25.0% (5/20) of the patients had a clinical event reported which was categorized as an observation.

Table IC2-5 and IC2-6 summarizes the reported PCD Transvene System complications and observations by category in these 3 patient groups, respectively. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

Table IC2-7: PCD Transvene System: Patients Meeting Implant Criteria vs Not Meeting Implant Criteria - Comparison of Pt Characteristics - 2/1/93

Statistical analysis was completed on the 543 patients that net implant criteria versus the 214 patients that did not meet criteria. Statistical analysis indicated three significant differences between these two patient groups - patient sex, indication for implant and mean ejection fraction.

Patients not meeting implant criteria had a statistically higher percentage of patients who were male ($p = 0.002$). This difference reflects that the majority of patients with coronary disease with concomitant life threatening ventricular arrhythmias are males.

Analysis indicated the patients not meeting the implant criteria had a statistically higher percentage of patients whose primary indication for implant was sudden cardiac death associated with recurrent ventricular tachycardia ($p = 0.002$). This difference reflects the physicians use of the PCD Transvene System.

Finally, patients who did meet the implant criteria had a statistically lower mean ejection fraction ($p = 0.0342$) which reflects a higher degree of underlying cardiovascular disease in these patients.

It should be noted, that none of these differences should be used as predictors for patients who should be screened for a PCD Transvene System.

Implant data obtained in these two patient groups is presented in Table IC2-8. As would be expected the patients not meeting the implant criteria had higher mean DFT and LED values when compared to the patients who did meet the implant criteria. However, the mean DFT (18.8J) and LED (19.5J) values obtained in patients not meeting implant criteria provided at least a 10 Joule defibrillation safety margin between the successful energy and the maximum output of the PCD Device (34J) in nearly all (97.4%) of the patients.

PCD Transvene System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Mean Number of Inductions	7.0	8.2

Mean LED	14.8J	19.5J
Implanted Lead System		
RV-SVC-SQ	351 (64.6%)	145 (67.8%)
RV-CS-SQ	159 (29.3%)	63 (29.4%)
RV-CS-SVC	33 (6.1%)	6 (2.8%)
Defibrillation Pathway		
Sequential	414 (75.7%)	160 (74.4%)
Simultaneous	127 (23.2%)	51 (23.7%)
Single	6 (1.1%)	4 (1.9%)

Table IC2-8: PCD Transvene System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Implant Data - 2/1/93

When the mean number of inductions and the mean number of configurations tested of 8.2 and 2.7, respectively, for those patients that did not meet the implant criteria is compared to those that did meet the implant criteria, 7.0 and 2.0, it is apparent the implanting physicians did induce more VF and were more likely to try more than 1 lead configuration in an attempt to meet the implant criteria.

In order to determine if the patient's not meeting implant criteria had higher risk for morbidity and mortality, a comparison of their clinical outcome was made with those patients who did meet the implant criteria. This comparison is provided in Table IC2-9.

PCD Transvene System Patients Meeting Implant Criteria versus Patients Not Meeting Implant Criteria		
Implant Data		
Data	**Meeting Criteria**	**Not Meeting Criteria**
Number of Patients	543	214
Spontaneous VT Episode Efficacy	98.7%	97.6%
Spontaneous VF Episode Efficacy	98.2%	99.0%
Number of Patient Deaths	37	14
Perioperative Mortality	0.7%	0.5%
One Year Survival		
Sudden Cardiac	99.5%	99.5%
Non-Sudden Cardiac	95.8%	97.2%
All Cardiac	95.4%	96.7%
Noncardiac	98.5%	97.1%
Overall	93.2%	93.5%

Table IC2-9: PCD Transvene System: Patients Not Meeting Implant Criteria versus Patients Meeting Implant Criteria - Comparison of Clinical Outcome - 2/1/93

The two patient groups had similar efficacy in the treatment of spontaneous VT/VF episodes. Importantly, in the patient population who did not meet the implant criteria there were no patients who experienced actual spontaneous VF episodes where all programmed PCD Device therapies failed to terminate the episode.

Five patients experienced 7 episodes in which the PCD® Device was ineffective in terminating a spontaneous episode of VF despite delivery of all four programmed VF therapies. Three patients had 5 reported ineffective VF spontaneous episodes that were due to sinus tachycardia or atrial fibrillation with rapid ventricular response rather than VF. Reprogramming and pharmacologic intervention resolved these problems.

Two patients experienced 2 episodes in which the PCD detected the episodes as VF but were actually episodes due

to extraordinary circumstances. The first patient (b)(6) had incessant episodes of fast VT (cycle length 280 ms) that were eventually resolved by drugs. The second patient (b)(6) was in the hospital and there was an episode of VF detected by the PCD and therapy was delivered. However, the device was interrogated before termination of the episode was detected by the PCD. There was external intervention (transthoracic defibrillation) associated with the terminal event. However, the patient ultimately expired. The device was not interrogated again.

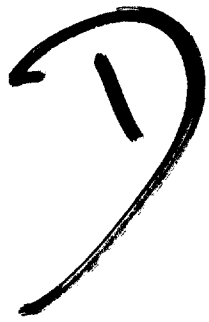
Eighteen patients experienced 68 episodes in which the PCD Device was ineffective in terminating a spontaneous episode of VT despite delivery of all four programmed VT therapies. Nine patients experienced 44 ineffective episodes that were due to sinus tachycardia or atrial fibrillation/flutter (SVT) with a rapid ventricular response that had been detected as VT. These episodes were resolved with either modification of programmed parameters or of antiarrhythmic drug therapy. It should be noted that the PCD Device responded appropriately based on the programmed detection parameters.

The remaining 24 episodes occurred in 8 patients in which the programmed VT therapies were ineffective in terminating a spontaneous VT episode. **No patient deaths occurred as a result of ineffective VT therapy.** Reprogramming and pharmacologic intervention resolved these events.

There was no difference in the one year sudden cardiac survival or the overall survival in the two groups although follow-up was shorter for patients not meeting implant criteria (10.1 vs 12.3 months). This indicates, that despite not meeting the implant criteria these patients were not at higher risk of sudden cardiac death.

Conclusion

In conclusion, 214 patients received the PCD Transvene System despite not meeting the recommended implant criteria. These 214 patients are divided into the following groups:



- successful defibrillation of VF at 24 Joules or less (170/214),
- difficult to induce at least three episodes of VF at implant (24/214), and
- worsening patient condition which prevented further inductions (20/214).

It should be noted that 91% (194/214) of the patients not meeting the recommended implant criteria had at least one successful termination of induced ventricular tachyarrhythmia (VT, VFlutter or VF) at 24 Joules or less. Additionally, their clinical outcome, especially in the 170 patients with successful defibrillation of VF at $\leq$24 Joules is similar and is part of the support to request changing the implant criteria to the following:

* Two consecutive successful defibrillations with the final lead configuration with a stored output of 24 Joules or less; or

* Three successful defibrillations in four attempts with the final lead configuration at a stored output energy of 24 J or less.

D. System Comparison

The efficacy and safety of implantable cardioverter defibrillator (ICD) therapy for recurrent ventricular tachycardia (VT) and ventricular fibrillation (VF) has been well established. The Ventak-P Epicardial System provides cardioversion and defibrillation therapy for VT and hemodynamically unstable VT. However, this type of therapy may not be optimal for patients with stable, well tolerated VT that is amenable to antitachycardia pacing due to the pain associated with cardioversion shock therapy. The need to incorporate programmability, multiple detection and therapeutic options has lead to the development of the PCD Device.

However, the Ventak-P Epicardial System and PCD Epicardial System are implanted only with a defibrillation lead system requiring a thoracotomy. The PCD Transvene System allows the implantation of an ICD System without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy.

In the PCD Transvene System PMA Application a comparison of the PCD Transvene System clinical experience was made to both the Ventak-P Epicardial System and the PCD Epicardial System. (Reference: Clinical Experience Report Section X, Comparison to AICD Clinical Results and Section XI, Comparison to PCD Epicardial System Clinical Results). A comparison to the Ventak-P Epicardial System was done because this was the most similar FDA approved ICD System available at the time of the original submission. A comparison to the PCD Epicardial System was done since this system incorporated the same tiered therapy ICD Device as well as being a concurrent clinical study using the same protocol and clinical investigators.

The comparison between the Ventak-P Epicardial System and the PCD Transvene System was limited in scope due to the limited availability of clinical data from the Ventak-P Epicardial System Summary of Safety and Effectiveness, but included patient characteristics, implant defibrillation thresholds, incidence of spontaneous VT/VF episodes, incidence of complications and one year actuarial survival.

The comparison between the PCD Transvene System and the PCD Epicardial System included patient characteristics, implant data, implant defibrillation thresholds, programmed parameter status, spontaneous VT/VF episode efficacy, incidence of complications and observations and one year actuarial survival.

1. **Comparison to AICD (Ventak-P) Epicardial System**

   The current AICD (Ventak-P) Epicardial System is implanted only with a defibrillation lead system requiring a thoracotomy. The PCD Transvene System allows the implantation of an implantable cardioverter defibrillator (ICD) system without the potential increased perioperative morbidity and mortality associated with a thoracotomy. This allows the application of ICD therapy in patients who may not otherwise be candidates for this type of therapy. Though the PCD Transvene System will have complications and observations that are specific to the lead system, the overall performance should be at least equivalent to that reported with the current AICD Epicardial System.

This section provides a comparison of the PCD Transvene System clinical experience to that of the reported AICD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Clinical performance
- Survival analysis

For purposes of comparison, the Ventak-P Epicardial System patient population described in the Summary of Safety and Effectiveness Data (PMA Application Number P890061) dated May 2, 1991 will be used. A copy of this summary was obtained through the Freedom of Information Act.

a. Patient Characteristics

In comparing the clinical experience with the PCD Transvene System to the reported Ventak-P Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

The characteristics of the patients receiving the PCD Transvene System were compared to the characteristics of patients discussed in the Ventak-P Summary of Safety and Effectiveness Data and are presented in Table ID1-1.

PCD Transvene System Comparison of Patient Characteristics PCD versus AICD		
	PCD	**Ventak-P**
Number of Patients	757	292
Mean Follow-Up Time	11.7 months	6.8 months
% Males **% Females**	610 (81%) 147 (19%)	231 (79%) 61 (21%)
Mean Age	59.4 years	61.5 years
Primary Indication: **SCD** **VT** **SCD/VT**	 281 (37%) 377 (50%) 99 (13%)	 49 (16%) 169 (59%) 73 (25%)
Coronary Artery Disease	561 (74%)	228 (78%)
Mean Ejection Fraction	35.6%	34%
Drug Therapy at Implant	42%	45.0%
Concomitant Surgery	0%	18.0%

Table ID1-1: Comparison of Patient Characteristics, PCD versus Ventak-P 2/1/93

The two patient groups are comparable in mean age and mean ejection fraction. Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34% for the Ventak-P Epicardial System patient group.

Analysis indicated that no statistical differences between the PCD Transvene System and Ventak-P Epicardial System patient populations except in the category of patient indication. There are more patients that had Sudden Cardiac Death as the primary indication in the PCD Transvene population than in the AICD population ($p = 0.001$).

b. Clinical Characteristics

Areas of clinical performance that were compared were implant defibrillation thresholds, incidence of spontaneous VT/VF events, incidence of

67

complications and patient survival. These specific areas were selected in order to evaluate the system performance in the two patient populations.

1) Implant Defibrillation Thresholds

For the purposes of the PCD Transvene System clinical study, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts. For the purposes of this report a defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead system. In a epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

A total of 316 patients had a defibrillation threshold determined at the time of PCD device implant. The mean defibrillation threshold (DFT) for all lead systems was 14.8J. The recommendation for VF Therapy #1 is to program the stored energy to twice the implant DFT or 18 Joules, whichever is greater. Thus an adequate defibrillation safety margin was provided when following the VF therapy programming recommendations.

In the Ventak-P Epicardial System, the mean defibrillation threshold at implant was 13.4J. Thus the two systems had similar defibrillation thresholds at implant despite the fact that one system utilized an epicardial defibrillation lead system while the other utilized a transvenous defibrillation lead system.

These data indicate that the PCD Transvene System had comparable implant defibrillation threshold performance when compared to the reported Ventak-P Epicardial System clinical experience.

2) Incidence of Spontaneous VT/VF Episodes

The incidence of spontaneous VT/VF episodes in the Ventak-P Epicardial System and PCD Transvene System patient population was evaluated by utilizing the stored episode information provided by both devices.

In the Ventak-P device, the total number of shocks delivered to the patient is provided via interrogation of the device. The PCD device provides information on the total number of VT and VF episodes detected by the PCD device and the total number of VT and VF episodes successfully treated by the PCD device as well as the number of VT/VF episodes where the PCD device was ineffective. In addition, the last 20 intervals of the last episode satisfying detection criteria along with the first 10 intervals after the last therapy delivered are recorded by the device. These data assist the physician in evaluating the frequency of VT/VF episodes, the efficacy of the PCD device programmed parameters and the need for reprogramming.

In the Ventak-P Epicardial System experience of 292 patients with a mean follow-up of 6.8 months, 137 (46.9%) received a device countershock in response to a spontaneous

681

ventricular tachyarrhythmia episode as defined by the Ventak-P Device detection criteria.

In the PCD Transvene System experience of 757 patients with a mean follow-up of 11.7 months, 458 patients (60.5%) have received device therapy in response to a spontaneous ventricular tachyarrhythmia episode as defined by the PCD Transvene System detection criteria.

A total of 10,027 spontaneous VT and 1982 spontaneous VF episodes have been recorded by the PCD device episode counters. Of the 9864 successfully treated spontaneous VT episodes, 91.4% were treated with one of the programmed antitachycardia pacing therapies incorporated in the PCD device. The clinical benefit of tiered therapy is the reduction of delivery of high energy shocks for the treatment of stable recurrent ventricular tachycardia that may be responsive to antitachycardia pacing.

3) Incidence of Complications

Table ID1-2 provides a comparison of reported complications and observations. The AICD clinical experience data is from the Winkle, et al Long Term Outcome with Automatic Implantable Cardioverter-Defibrillator; JACC, May 1989; 13(6); 135-161. This article was selected because it provides a detailed clinical complication experience on a large patient population, 270 patients. Note that the percentage reported in the PCD Transvene System includes **both complications and observations**. In the following table, the complications are reported for the categories of Failure to Cardiovert/Defibrillate, Pocket Infection, and Erosion. Observations are reported in the Inappropriate/Problematic VT/VF Therapy Delivery category.

PCD Transvene System Comparison of Complication/Observation Rates PCD versus AICD		
Category	**PCD%**	**AICD%**
Fail to Cardiovert/Defibrillate	2.3%	4.1%
Inappropriate/Problematic VT/VF Therapy Delivery	9.6%*	20%
Pocket Infection (explant)	2.9%	2.2%
Erosion	0.8%	0.7%

* Includes Observations only; there were no Complications in this category.

Table ID1-2: Comparison of Complication/Observation Rates: PCD Transvene System vs AICD Epicardial System - 2/1/93

The incidence of failure to cardiovert and/or defibrillate was lower in the PCD Transvene System patient population. The instances of failure to cardiovert and/or defibrillate in the PCD Transvene System patient population were associated with increased defibrillation requirements during induced episodes, none of which resulted in patient death.

The failures to cardiovert/defibrillate reported in the Winkle, et al article were associated with patch dislodgement, patch crinkling, lead conductor fracture and elevated defibrillation thresholds.

The incidence of inappropriate/problematic VT/VF therapy delivery was lower in the PCD Transvene System patient population. This is to be anticipated since the device incorporates independently programmable detection algorithms for VT and VF. The reasons for inappropriate VT/VF therapy delivery included sinus tachycardia being detected as VT or VF and atrial fibrillation with rapid ventricular response being detected as VT or VF.

The overdetection circumstances reported in Winkle, et al were nonsustained VT, VT, sinus

91

tachycardia, atrial fibrillation with rapid ventricular response, sensing lead fracture and pacemaker interaction. The patients with VT complained of receiving multiple shocks with limited or no symptoms. The incorporation of antitachycardia pacing in the PCD device decreases the need for delivery of cardioversion shocks for the termination of stable VT and increases patient acceptance of ICD therapy.

In the Winkle, et al experience all patients with pocket infection had the devices explanted. In the PCD Transvene System experience, the incidence of device explant secondary to pocket infection was 2.9% which was comparable to Winkle's article.

Thus, the incidence of complications and observations in the categories of ineffective VT/VF therapies, infection requiring explant and erosion was similar to that of the AICD Epicardial System. The incidence of inappropriate delivery of therapy is lower in the PCD Transvene System experience than in the AICD Epicardial System experience, which is clinically significant.

This analysis indicates that the PCD Transvene System offers clinical advantages in reducing the need for a thoracotomy for implantation and reducing the number of shocks due to successful antitachyarrhythmia pacing and inappropriate therapy incidence.

c. Survival Analysis

The Ventak-P Epicardial System produced by Cardiac Pacemaker, Inc, has obtained market approval from the U.S. FDA to date. While there are important differences in the function of the Ventak-P Epicardial System and the PCD Transvene System, the Ventak-P Epicardial system is the most comparable Market Released system. Table ID1-3 summarizes how the

patient deaths have been classified for the PCD Transvene System and the Ventak-P epicardial System.

PCD Transvene System Comparison of Death Classification PCD Transvene System versus Ventak-P Epicardial System		
	PCD Transvene System	Ventak-P Epicardial System
Sudden Cardiac	5	4
Non-Sudden Cardiac	31	8
All Cardiac	15	6
Unknown	0	1
Total	51	19
Perioperative	5 (0.7%)	8 (2.7%)

Table ID1-3: PCD Transvene System - Death Classification- PCD Transvene VS Ventak=P - 2/1/93

A total of 51 deaths (6.7%) were reported in the PCD Transvene System patient population. Of the 35 cardiac deaths, 30 were non-sudden cardiac and 5 were sudden cardiac. Sixteen deaths were classified as noncardiac. Five of the 51 total deaths occurred within the perioperative period (death less than 30 days post implant) with a resultant perioperative mortality of 0.7%.

In the Ventak-P Epicardial System patient population a total of 19 deaths (6.5%) were reported. Of the 12 cardiac deaths, 4 were classified as sudden cardiac and 8 were classified as non-sudden cardiac. Six of the deaths were classified as noncardiac and the cause of one was unknown. Eight of the deaths occurred within the perioperative period with a resultant perioperative mortality of 2.7%. The PCD Transvene System population had a lower perioperative mortality, 0.7% vs 2.7% (p=0.006).

For purposes of this comparison, only the overall actuarial survival rate includes perioperative deaths. All other calculations in both the PCD Transvene System and Ventak-P Epicardial System group exclude perioperative deaths.

For the Ventak-P Epicardial System, patient deaths were **censored** if the Ventak-P device had been either electively deactivated for various reasons prior to the patient's death, thus preventing the device from attempting to convert the arrhythmia or if the pulse generators were known to be nonfunctional and awaiting replacement. For purposes of this comparison, seven patient deaths were **censored** in the PCD Transvene System patient population because the devices were deactivated at the time of patient death.

Table ID1-4 contains the survival comparison of the PCD Transvene System versus the Ventak-P Epicardial System.

PCD Transvene System Survival Comparison PCD versus Ventak-P		
	PCD Transvene System	Ventak-P Epicardial System
Sudden Cardiac	99.7%	98.6%
Overall	94.2%	90.8%

Table ID1-3: PCD Transvene System - Survival Comparison - PCD vs Ventak-P - 2/1/93

The PCD Transvene System sudden cardiac death survival of 99.7% at one year is comparable to that of the Ventak-P Epicardial System sudden cardiac death survival rate of 98.6%. More importantly, the overall one year actuarial survival for the PCD Transvene System was 94.2% as compared to 90.8% for the Ventak-P Epicardial System. This difference was primarily due to the improvement in the reported perioperative mortality in the PCD Transvene System patient population. [Note:

94

Confidence interval analysis was performed indicating that there was a statistical difference in the reported **Overall** mortality. The survival probability at one year for the Transvene population was 95.3%. From the analysis run, using commercially available statistical software package (SAS), the survival standard error was also calculated. The confidence interval was calculated by taking the survival probability (b)(4) (b)(4) (survival standard error). The survival standard error was 1.1, therefore, the confidence interval for (b)(4) (b)(4)

This comparison of actuarial survival rates indicates that the projected sudden cardiac death survival of patients receiving a PCD System patient population is comparable to that reported for the Ventak-P Epicardial System. Thus, the incorporation of programmable VT/VF detection and therapy algorithms has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

In addition, the elimination of a surgical thoracotomy for implant in the PCD Transvene System has improved the perioperative mortality and overall one year survival when compared to the Ventak-P Epicardial System.

2. Comparison to PCD Epicardial Study

The PCD Epicardial System uses the same tiered therapy device that combines features of bradycardia support pacing, antitachycardia pacing, low energy cardioversion as well as defibrillation therapy. This system has incorporated programmability and multiple detection and therapeutic options that allows the titration of device therapy to a patient's specific clinical arrhythmia history.

The PCD Epicardial System requires a thoracotomy for implantation because of the need to insert epicardial patch leads. This exposes the patient to surgical risk and

potentially limits the type of patient who may be considered for implant of the system. The need for a simpler and safer implantation technique is widely recognized. The incorporation of a nonthoracotomy lead system, such as the PCD Transvene System, should decrease the potential perioperative and long term mortality and morbidity associated with current epicardial system implantation approaches.

The PCD Epicardial System and PCD Transvene System are identical except for the implanted defibrillation lead system. Thus, the performance of the PCD device, associated support equipment, is similar in the two systems and therefore a comparison of clinical experience should focus on those areas where the implanted lead system may impact clinical outcome.

This section provides a comparison of the PCD Transvene System clinical experience to the reported PCD Epicardial System clinical experience. The following areas will be discussed:

- Patient characteristics
- Implant Data
- Spontaneous VT/VF Episode Efficacy
- Complications and Observations
- Survival analysis

This analysis will show that the incorporation of a nonthoracotomy defibrillation lead system has maintained the type of therapy available for the treatment of recurrent VT/VF and decreased the potential mortality and morbidity associated with epicardial implant approaches while maintaining the positive impact of ICD therapy on VT/VF episode efficacy and patient survival.

The PCD Epicardial System clinical data was chosen as a control because the patients were being enrolled in the two studies concurrently by the same investigators, and the patient indications, implant criteria, and clinical data requirements were identical for the two patient groups.

a. **Patient Characteristics**

In comparing the clinical experience with the PCD Transvene System to the PCD Epicardial System clinical experience, it is important to determine that the patients who received the device are comparable.

Table ID2-1 contains the characteristics of the 757 patients receiving the PCD Transvene System versus the characteristics of the 742 patients who received the PCD Epicardial System as of 1/5/93.

PCD Transvene System
Comparison of Patient Characteristics

	PCD Transvene System	PCD Epicardial System
Number of Patients	(b)(4) (b)(4)	
Mean Follow-Up Time	11.7 months	16.3 months
% Males* % Females	(b)(4) (b)(4) 80.6% 19.4%	(b)(4) (b)(4) 85.8% 14.2%
Mean Age	59.4 years	59.6 years
Primary Indication* SCD VT SCD/VT	(b)(4) (b)(4) 37.1% 49.8% 13.2%	(b)(4) (b)(4) 28.8% 54.6% 16.6%
Cardiovascular History Coronary Artery Disease Cardiomyopathy	(b)(4) (b)(4) 74.1% 13.1%	(b)(4) (b)(4) 76.7% 29.9%
Mean Ejection Fraction	35.6%	34.0%
Number of Drugs Failed*	2.3	3.0

* Statistically Significant

Table ID2-1: Comparison of Patient Characteristics, PCD Transvene System versus PCD Epicardial System - 2/1/93

Both groups had moderately depressed left ventricular function demonstrated by the mean ejection of 35.6% for the PCD Transvene System patient group and 34.0% for the PCD Epicardial patient group.

77

Analysis indicated that the PCD Transvene System patient population had a higher percentage of patients whose indication for implant was sudden cardiac death ($p = 0.002$) and higher percentage of females ($p = 0.007$). It is not expected that these differences will result in a different clinical outcome in the PCD Transvene System patient population as compared to the PCD Epicardial System. This difference in patient indication is a reflection of the physicians use of the PCD Transvene System.

It is interesting to note, that there was a statistical difference in the number of antiarrhythmic drugs tested between the two patient groups ($p = 0.001$). The PCD Transvene System patient group failed a mean of 2.3 antiarrhythmic drugs prior to implant while the PCD Epicardial System patient group failed a mean of 3.0 antiarrhythmic drugs. This difference is a reflection of the differences in the indications for implant between the two patient groups. The PCD Transvene System patient group had a higher incidence of patients whose primary indication for implant was sudden cardiac death. These patients are not required to have drug therapy screening, therefore, fewer drugs were tested in this group.

b. Implant Data

In both systems, lead system testing was performed to verify that one of the specified lead systems was capable of properly detecting and treating episodes of ventricular fibrillation and, when appropriate ventricular tachycardia. This testing included pacing and sensing thresholds during sinus rhythm, evaluation of VF electrogram amplitudes and defibrillation efficacy evaluation. The implant criteria for both systems was identical and was:

1. Successful VF termination at least 3 times in 4 attempts with an output energy of 18 Joules or less and

2. At least a 2:1 VF sensing safety margin

78

Pace/Sense Performance

In both the PCD Transvene and PCD Epicardial Systems, sensing is performed in a standard bipolar configuration and pacing is performed in the integrated bipolar configuration. The pace/sense implant criteria for both systems was:

Pacing Threshold:
R-Wave Amplitude:
Slew Rate:
Resistance:

(b)(4)

(b)(4)

Table ID2-2 provides a comparison of the mean pace/sense values obtained at the time of implant for the PCD Transvene and Epicardial Systems. It should be noted that the pace/sense values presented for the PCD Epicardial System are for the Model 7217B PCD Device.

PCD Transvene System
Performance Comparison
Implant Pace/Sense Parameters

Parameter	PCD Transvene System	PCD Epicardial System
Pacing Threshold*	(b)(4)	
R Wave Amplitude*		
Slew Rate*		
Resistance*		

* Statistically Significant

Table ID2-2: PCD Transvene System: Comparison of Implant Pace/Sense Parameters - 2/1/93

The implant pace/sense parameters obtained for the PCD Transvene System indicates that the lead system provided adequate pacing and safety margins. There was a statistically significant difference in all of the implant pace/sense parameters ($p = 0.001$). This is anticipated because

endocardial pace/sense parameters are better than epicardial values for bradycardia pacing electrode systems.

Electrogram amplitudes were evaluated at follow-up evaluations of both systems to evaluate the performance of the pace/sense lead system and assure adequate safety margin for detection of both baseline rhythms and ventricular tachyarrhythmias. In addition, pacing thresholds were also evaluated at follow-up evaluations to assure an adequate safety margin for capture during both bradycardia and antitachycardia pacing therapies. A comparison of the chronic pace/sense performance for the two systems is presented in Table ID2-3. It should be noted that there was no statistical difference in the chronic pace/sense performance of the two systems.

PCD Transvene System Performance Comparison Chronic Pace/Sense Parameters		
Parameter	**PCD Transvene System**	**PCD Epicardial System**
Electrogram Amplitude	(b)(4) (b)(4)	
Pulse Width Threshold		

Table ID2-3: PCD Transvene System: Comparison of Chronic Pace/Sense Parameters - 2/1/93

The incidence of loss of capture requiring lead system modification in the PCD Transvene System was 0.8% while the incidence in the PCD Epicardial System was 2.0%. There were no reports of undersensing requiring lead modification in the PCD Transvene System while the incidence in the PCD Epicardial System was 0.8%.

This comparison of implant and chronic pace/sense data performance indicates that the performance of the PCD Transvene System is similar to that reported with the PCD Epicardial System and potentially may be improved over the PCD Epicardial system. The

PCD Transvene System provides appropriate acute and chronic safety margins for sensing of sinus rhythm and ventricular tachyarrhythmia as well as appropriate safety margins for pacing therapy.

Implant Defibrillation Thresholds

For the purposes of both systems, determination of defibrillation threshold was not mandatory. However, the preferred method of evaluating defibrillation efficacy was to determine the defibrillation threshold using a testing sequence of 18J, 15J, 10J, 5J with a failure at any level causing a return to 18 J for the remaining attempts.

A defibrillation threshold was defined as the energy at the lowest successful defibrillation attempt, provided a patient had a failure below their lowest defibrillation success or a success at $\leq$ 5J. The rhythm treated must have been VF to be included in the analysis.

Table ID2-4 provides a comparison of defibrillation thresholds determined at implant for the PCD Transvene and PCD Epicardial Systems.

PCD Transvene System
Performance Comparison
Implant Defibrillation Thresholds

System	Mean DFT
PCD Transvene System*	14.8J
PCD Epicardial System	9.8J

* Statistically Significant ($p \leq 0.05$)

Table ID2-4: PCD Transvene System: Comparison of Implant DFT - 2/1/93

The PCD Transvene System did have a significantly higher mean implant defibrillation threshold ($p = 0.0001$). It should be noted, that it was expected that the PCD Transvene System would have a higher mean defibrillation threshold as compared to a traditional epicardial defibrillation lead

81

system. In a traditional epicardial system, the increased electrode surface area would theoretically decrease defibrillation requirements.

The programmed defibrillation pathways for the two patient populations is presented in Table ID2-5. The implanted PCD Transvene Systems are almost exclusively three lead systems and this explains the decreased use of SINGLE pathway. The use of SIMULTANEOUS pathway is higher in the PCD Transvene System and indicates that in a group of patients the incorporation of multiple defibrillation pathways allowed an increase in the ability to meet the PCD Transvene System implant criteria. Most of the PCD Epicardial System implants used a two patch system resulting in the increased use of the SINGLE pathway.

PCD Transvene System Performance Comparison Programmed Defibrillation Pathway		
Defibrillation Pathway	**PCD Transvene System**	**PCD Epicardial System**
Sequential	(b)(4)	
Simultaneous		
Single		

Table ID2-5: PCD Transvene System: Comparison of Programmed Defibrillation Pathway - 2/1/93

The differences in the programmed status of the PCD device in the PCD Transvene System are a reflection of the type of patients who received the device and the defibrillation energy requirements for each lead system. It is important to note that the PCD device performed safely and effectively in both patient populations.

c. Spontaneous VT/VF Efficacy

The primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular tachyarrhythmias. An

MEDTRONIC CONFIDENTIAL

additional benefit of the PCD Transvene System is the elimination of the need for a thoracotomy for implantation of the defibrillation lead system and the resultant decrease in potential patient morbidity and mortality associated with a thoracotomy. This clinical benefit should not be gained at the expense of providing effective termination of spontaneous VT and VF episodes. Table ID2-6 provides a comparison of the efficacy of the PCD Transvene and PCD Epicardial System in treating spontaneous episodes of VT and VF.

PCD Transvene System Performance Comparison		
Spontaneous VT Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Patients with VT Episodes	316	386
Number of Episodes	10,027	20,061
% Overall Efficacy	9,864/10,027 98.4%	19,726/20,061 98.3%
% Unsuccessful Termination (VT)	68/10,027 0.7%	150/20,061 0.8%
% Unsuccessful Termination (AF,ST)	95/10,027 0.9%	185/20,061 0.9%
Spontaneous VF Episodes		
	PCD Transvene System	**PCD Epicardial System**
Mean Follow-Up	11.7 months	16.3 months
Number of Patients with VF Episodes	317	342
Number of Episodes	1982	2,636
% Overall Efficacy	1951/1982 98.4%	2601/2636 98.7%
% Unsuccessful Termination (VF)	5/1982 0.3%	15/2636 0.5%
% Unsuccessful Termination (AF,ST, Other)	26/1982 1.3%	24/2636 0.8%

Table ID2-6: PCD Transvene System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

The overall success rate of the PCD Transvene System in terminating spontaneous episodes of VT or VF is 98.5%. This success rate compares very favorably with the overall success rate of the PCD Epicardial System which was 98.4%. Therefore, the PCD Transvene System offers the potential of decreased patient morbidity and mortality without decreasing the treatment efficacy of spontaneous VT/VF episodes.

d. Complications and Observations

A comparison of the reported complications and observations was made between the PCD Transvene System and the PCD Epicardial System. The PCD Epicardial System patient population used for comparison included clinical experience as of January 5, 1992 with 742 patients and a mean implant duration of 16.3 months. These two patient groups are similar in the patient demographics and indication for implant of the PCD System. In the PCD Transvene System patient population, 19.4% of the patients experienced a clinical complication and 23.8% of the patients experienced a clinical observation. In the PCD Epicardial System, 14.2% of the patients experienced a clinical complication and 32.9% of the patients experienced a clinical observation.

Table ID2-7 and ID2-8 provide a comparison of the reported complications/observations and their incidence in the two patient populations.

PCD Transvene System PCD Transvene System versus PCD Epicardial System Reported Complications		
Reported Complications	**PCD Transvene System (N = 757)**	**PCD Epicardial System (N = 742)**
Increased Defibrillation Requirements	1.2%	0.5%
Inappropriate Therapy	-	2.2%
Pace/Sense Related	0.8%	3.5%
Infection Related - Explant	2.9%	2.3%
Lead Related	15.1%	3.0%

Table ID2-7: Reported Complications: PCD Transvene System versus PCD Epicardial System - 2/1/93

PCD Transvene System PCD Transvene System versus PCD Epicardial System Reported Observations		
Reported Observations	**PCD Transvene System (N = 757)**	**PCD Epicardial System (N = 742)**
Ineffective Therapy	1.1%	1.1%
Inappropriate Therapy	9.6%	13.6%
Pace/Sense Related	9.0%	14.0%
Infection Related	5.3%	2.6%
Lead Related	2.3%	1.2%
Device Related	-	-

Table ID2-8: Reported Observations: PCD Transvene System versus PCD Epicardial System - 2/1/93

e. Survival Analysis

Despite their excellent clinical performance, epicardial defibrillation lead system have important limitations. The requirement for direct thoracic access contributes significantly to patient morbidity and mortality, patient discomfort and prolonged hospitalization. The availability of reliable nonthoracotomy lead systems should provide

positive clinical impact on these issues while not negatively impacting patient survival. Therefore, a comparison of the one year actuarial survival rates for the PCD Transvene and Epicardial System was performed.

Table ID2-9 provides a summary of the patient deaths reported in the two patient populations by classification. As a reference, the mean follow-up time for the PCD Transvene System patient population was 11.7 months while for the PCD Epicardial System it was 16.3 months. Patients with the device programmed OFF and perioperative deaths are not mutually exclusive.

PCD Transvene System Death Classifications PCD Transvene System versus PCD Epicardial System		
Death Classification	**PCD Transvene System (N=757)**	**PCD Epicardial System (N=742)**
Sudden Cardiac	5 0.7%	24 3.2%
# Off	1 0.1%	3 0.4%
# Perioperative	2 0.3%	9 1.2%
Non-Sudden Cardiac	31 4.1%	54 7.3%
# Off	4 0.5%	12 1.6%
# Perioperative	2 0.3%	18 2.4%
All Cardiac	36 4.8%	78 10.5%
# Off	5 0.7%	15 2.0%
# Perioperative	4 0.5%	27 3.6%
Noncardiac	15 2.0%	34 4.6%
# Off	2 0.3%	7 0.9%
# Perioperative	1 0.1%	12 1.6%
Total	51 6.7%	113 15.2%
# Off	7 0.9%	23 3.1%
# Perioperative	5 0.7%	39 5.3%

Table ID2-9: Death Classifications: PCD Transvene System versus PCD Epicardial System - 2/1/93

Table ID2-10 provides a comparison of actuarial survival rates between the PCD Transvene and PCD Epicardial patient populations. The actuarial survival projections include perioperative deaths only in the calculation of

84

survival from death due to all causes (shown in table row labelled **Overall**). Perioperative mortality includes those deaths which occur in the first thirty days post implant of the PCD System.

PCD Transvene System Comparison of Actuarial Survival PCD Transvene System versus PCD Epicardial System			(b)(4)
One Year Survival	**PCD Transvene System**	**PCD Epicardial System**	
Number of Patients	757	742	
Sudden Cardiac	99.5%	98.9%	
Non-Sudden Cardiac	96.2%	96.7%	(b)(4)
All Cardiac	95.8%	95.7%	
Noncardiac	98.1%	98.0%	
Overall*	93.3%	88.6%	

* (b)(4) (b)(4)

Table ID2-10: Comparison of Actuarial Survival: PCD Transvene System versus PCD Epicardial System - 2/1/93

There was a significant increase in overall survival in the patients receiving a PCD Transvene System. As previously noted, the Overall one year actuarial survival includes death from all causes. The overall one year survival for patients receiving the PCD Transvene System was 93.3%. This is significantly improved as compared to the overall one year actuarial survival for the PCD Epicardial System (88.6%) (b)(4) (b)(4) This improvement in overall survival is primarily due to the marked improvement in perioperative mortality, the PCD Transvene System having a 0.7% (5/757) perioperative mortality versus the a perioperative mortality of 5.3% (39/742) in the PCD Epicardial System. This improvement in perioperative mortality is primarily due to the elimination of the need for a thoracotomy and its associated morbidity and mortality.

3. Patients Followed For ≥ One Year

a. Patient Characteristics

Table ID3-1 provides a data summary on the patients followed for a year or more. This table includes patient characteristics, defibrillation pathway configuration, mean LED and DFT, spontaneous VT and VF experience and efficacy. The characteristics of this subset of patients are similar to the original 757 patient population. Patients followed for a year or more had a similar percentage of patients having a history of coronary artery disease (69.2% vs 74.1%) and a similar mean ejection fraction (38% vs 35.6%). The differences are small and are not suspected to have an impact on implant duration or survival. Note that since by definition all patients have been followed for at least one year, the overall survival probability and the sudden cardiac survival probability is 100% at one year.

PCD Transvene System Data Summary	
	Patients with **12** months of Follow-up
Number of Patients	393
Device Months Follow-up	6454.6
Mean Follow-up Time	16.3 mo
Maximum Follow-up Time	37.4 mo
Number, % Male **Number, % Female**	310 78.9% 83 21.1%

b. Spontaneous VT/VF Efficacy

The primary benefits from the use of the PCD System center on the detection and termination of life-threatening ventricular tachyarrhythmias. Table

life-threatening ventricular tachyarrhythmias. Table ID3-2 provides a comparison of the efficacy of the PCD Transvene System in patients with at least 12 months of follow-up in treating spontaneous episodes of VT and VF.

PCD Transvene System Patients with 12 Mths Follow-up	
Spontaneous VT Episodes	
Number of Episodes	6338
% Overall Efficacy	99.0% 6273/6338
Spontaneous VF Episodes	
Number of Episodes	1105
% Overall Efficacy	98.6% 1090/1105

Table ID3-2: PCD Transvene System: Comparison of Spontaneous VT/VF Episode Efficacy -

c. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following previously described definitions:

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse

effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

As of February 1, 1993, of the 393 patients with implant durations of greater than or equal to one year, there have been a total of 89 complications reported in 76 patients and 122 observations reported in 99 patients in the PCD Transvene System patient population. Thus, 19.3% (76/393) of the patients had a clinical event reported which was categorized as a complication vs 19.4% (147/757) in the overall population and 25.2% (99/393) of the patients had a clinical event reported which was categorized as an observation vs 23.8% (180/757) in the overall population.

Table ID3-3 Summarizes the reported PCD Transvene System complications and observations by category. The reported complications and observations are recognized clinical events that may occur with any of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

PCD Transvene System Reported Complications/Observations in Patients followed for 1 Year or more: By Category		
Category	**Complications**	**Observations**
	Num (% of Pts)	Num (% of Pts)
Increased Defibrillation Requirements	3 (0.8%)	2 (0.5%)
Inappropriate VF Therapy Delivery	-	10 (2.5%)
Inappropriate VT Therapy Delivery	-	40 (10.2%)
Loss of Capture	2 (0.5%)	6 (1.5%)
Oversensing	-	29 (7.4%)
Undersensing	-	-
Skin Erosion	2 (0.5%)	1 (0.3%)
Pocket Infection	5 (1.3%)	7 (1.8%)
Seroma	1 (0.3%)	9 (2.3%)

Total	**89**	**122**

Table ID3-3: PCD Transvene System: Reported Complications and Observations - 2/1/93

Table ID3-4 contains a description of the lead dislodgements that have occurred in less than 30 days and in greater than 30 days.

PCD Transvene System Reported Complications/Observations in Patients followed ≥1 Year Lead Dislodgements <30 days and >30 days N=393			
Complications		Observations	
<30 days	>30 days	<30 days	>30 days
27 (6.9%)	29 (7.4%)	0 (0)	6 (1.5%)

Table ID3-4: PCD Transvene System: Lead Dislodgements occurring <30/>30 days in patients followed for greater than or equal to one year as of 2/1/93

There have been a total of 35 lead dislodgements reported in patients at greater than 30 days. None of the lead dislodgements resulted in an ineffective therapy for a spontaneous VT or VF episode or patient death. Lead dislodgements were documented by fluoroscopic examination during electrophysiologic evaluation, chest x-ray obtained during routine follow-up, or during pacing/sensing threshold evaluation during routine follow-up. In 29 cases, reoperation was required to reposition the lead and reestablish an effective defibrillation lead system. In 6 cases, lead repositioning was not required.

Lead dislodgements are not specific to the PCD Transvene System and have been reported with dual chamber pacemakers and the current market released implantable cardioverter defibrillator (ICD) system. The early history of dual chamber pacemakers witnessed a high lead dislodgement rate of at least 20% (Smyth, PND, et al. Permanent perivenous atrial sensing and pacing with a new J-shaped lead. J Thoracic Cardiovascular Surgery. 1976;72:565-570). Winkle, et al reported that the incidence of dislodgement of the superior vena cava spring leads with the current market release ICD system to be 6.3%. (Winkle, et al. Automatic

93

Implantable Cardioverter-Defibrillator: Efficacy, Complications, and Survival in Patients with Malignant Ventricular Arrhythmias. JACC. June 1988; Vol.11, No.6:1278-86).

In summary, this group represents the majority of the overall population and the characteristics of the 393 patients with implant durations of greater than or equal to one year were similar to the overall population of 757 patients.

d. Survival Analysis

There have been a total of 7 patient deaths reported in this subset of patients. The deaths occurred greater than 12 months from the date of implant. Table ID3-5 summarizes how these patient deaths have been classified.

PCD Transvene System
Summary of Death Classifications
in Patients followed for a Year or more

Classifications	Number of Deaths
Sudden Cardiac	0
Non-Sudden Cardiac	5
Noncardiac	2
TOTAL	7

Table ID3-5: PCD Transvene System - Summary of Death Classifications - 2/1/93

Table ID3-6 summarizes the 18 month and 2 year actuarial survival of the patinets followed for at least 1 year.

PCD Transvene System 18 month and 2 Year Actuarial Survival		
	18 months	2 year
Sudden Cardiac Death	100%	100%
Non-Sudden Cardiac	98.3%	96.7%
All Cardiac	98.3%	96.7%
Noncardiac	99.5%	98.6%
Overall	97.8%	95.4%

Table IB3-6: PCD Transvene System - One Year Actuarial Survival - 2/1/93

4. Non-Standard Lead Configurations

In addition to the 757 patients presented in this report there were 43 patients who received defibrillation lead systems that were different from the three "Standard" systems. Even though these lead systems were different from the majority of systems evaluated they were evaluated by the investigator at time of implant and found to be efficacious.

Seven (7) of the 43 non-standard systems were in patients that had previously received a market released epicardial defibrillation system and one or more Transvene was added to the system to improve defibrillation efficacy. Twenty-four (24) patients had hybrid systems of Medtronic epicardial patches used with one or more Transvene leads. Six patients had two lead Transvene systems implanted. Four patients had Transvene leads placed in "nonstandard" locations (Pulmonary Artery, Right Atrium, and Great Cardiac Vein). Two patients have two Transvene leads connected together with a high voltage Y-adaptor and are programmed to single pathway defibrillation. One of these is a four lead system (SVC/SQ&CS/RV), the other is a three lead system (SVC&SQ/RV).

Table ID4-1 contains the distribution of the non-standard lead systems.

95

PCD Transvene System "Nonstandard" Defibrillation Lead Systems	
Market Released Epicardial-Transvene Hybrid	(b)(4)
Medtronic Epicardial-Transvene Hybrid	
Two Lead Transvene	
"Nonstandard" Anatomic Locations	
"Nonstandard" Electrical Configuration	

Table ID4-1: Non-standard Defibrillation Lead Systems - 2/1/93

These non-standard lead systems have a mean defibrillation threshold similar to the overall patient population and have performed safely and effectively during the follow-up period. The efficacy of termination of spontaneous episodes of ventricular fibrillation is 100%.

(b)(4), (b)(6)

a. Patient Characteristics

Table ID4-2 contains the data summary of the patients that received the standard lead systems and the 757 patients that received a 3 lead Transvene lead system.

PCD Transvene System Data Summary: Non-Standard Lead Systems		
	Non-Standard Lead Systems	**All Patients**

% Unsuccessful Termination (AF,ST)	3/113 2.7%

Table ID4-2: PCD Transvene System: Comparison of Spontaneous VT/VF Episode Efficacy - 2/1/93

c. Complications and Observations

The use of a multiprogrammable implantable cardioverter defibrillator (ICD) device allows the physician to resolve most relevant medical events by noninvasively changing programmed parameters thus, avoiding invasive procedures. However, there will continue to be certain relevant medical events which will require invasive procedures for resolution.

For purposes of this clinical study, reported relevant medical events were divided into complications and observations based on the following previously described definitions:

98

COMPLICATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which can NOT be treated or resolved by reprogramming the device and REQUIRES invasive intervention.

OBSERVATION: A symptomatic or asymptomatic clinical event with potential adverse effects, which either does NOT require invasive intervention, or which CAN be corrected by reprogramming the device.

Table ID4-3 Summarizes the reported PCD Transvene System complications and observations by category for the patients that received a non-standard lead configuration. The reported complications and observations are recognized clinical events that may occur with **any** of the current ICD devices. These complications and observations are discussed in the PCD device and Transvene manual. **None of the reported complications or observations have resulted in a patient death.**

PCD Transvene System Reported Complications/Observations in Patients with Non-Standard Lead Configurations: By Category

d. Survival Analysis

There were 2 patient deaths in the 42 patients that received a non-standard lead system. One was classified as non-sudden cardiac and one was classified as non cardiac. Table ID4-4 containes the one year actuarial survival for the patients with non-standard lead systems.

PCD Transvene System 1 year Actuarial Survival	
Sudden Cardiac Death	100%
Non-Sudden Cardiac	95.2%
All Cardiac	95.2%
Noncardiac	100.0%
Overall	93.0%

Table ID4-4: PCD Transvene System - One Year Actuarial Survival - 2/1/93

E. PCD System Performance

1. Explants; Leads and PCD Devices

Transvene Lead Performance

The Transvene Lead System consists of a Right Ventricular Lead, a Coronary Sinus/Superior Vena Cava lead, and a Subcutaneous Patch lead. There have been a total of 757 Right Ventricular leads (15 with the SP2100 and 742 with the Model 6884/6966), 796 Coronary Sinus/Superior Vena Cava leads (Model 6881/6963), and 718 Subcutaneous Patch leads (Models 6895/10317/6999) implanted with a cumulative implant duration of 8894.8 months. The reported incidence of fracture for the RV lead is 0.9% (7/757) and 0.3% (2/757) for the SQ lead.

A Model 6884, screw-in, right ventricular, pace/sense, cardioversion/ defibrillation lead was returned to Medtronic 27 months post implant. The lead was returned to Medtronic following explant from a patient that was undergoing a heart/lung transplant. Note that the lead had been fully functional while implanted and was found to be fully functional upon explant.

Upon undergoing further analysis at Medtronic, some MIO (metal ion oxidation) was observed on the lumen of the middle insulation approximately 20 cm proximal of the pacing tip electrode, and on the outside of the inner insulation. The MIO was further characterized to be

"cosmetic" in that it had not functionally affected the lead in any way. Cosmetic MIO is defined as any crack that has not breached the insulation.

Initial analysis indicated that the presence of the MIO was in the clavicular region of the body; i.e., the location, 20 cm proximal of the tip, would be in the first rib clavicle region of a small adult. There was no evidence, however, of conductor coil fracture and the lead was fully functional. Given the Model 6884 lead is generally implanted via subclavian vein insertion, this type of observation may occasionally be expected. However, subsequent analysis of the patient X-rays showed that the area of MIO was actually in the right ventricle. The patient's right ventricle was extremely dilated, secondary to pulmonary hypertension. Therefore, 20 cm from the proximal tip electrode located the area of MIO at the point of maximum curvature of the lead, in the right ventricle, rather than in the clavicular region.

Detailed Analysis Results

Visual/Microscopic

Shallow (cosmetic) environmental stress cracking (ESC) was visible. No coil deformation was visible in the first rib/clavicle region. Possible MIO was visible 20 cm proximal of the electrode tip extending approximately 0.5 cm on the middle insulation. Possible MIO was also visible on the innermost insulation starting at 19.3 cm proximal of the electrode tip and extending 5.4 cm proximally.

Scanning Electron Microscopy

MIO was observed on the lumen of the middle insulation and on the outside of the innermost insulation. The MIO penetration was less than five percent of the insulation wall thickness. In addition to the insulation, both the middle and inner coils were evaluated up to 2500 times magnification. There were no anomalies apparent on the inside or outside of the middle coil in the region of the MIO. The innermost coil showed no signs of crush or fatigue in the region of the MIO.

FTIR-ATR

FTIR spectra were obtained for a control area (no MIO) of the inner tubing and the cracked area of the tubing. Relative ratios of key bonds were calculated using the absorption intensities. These ratios indicated that the ether segments were oxidized in the polyurethane, which is characteristic of MIO. In addition, peaks appeared, indicative of carboxylic acids or esters (oxidation byproducts).

Discussion

Contrary to the initial dimensional analysis of this lead that indicated the area of MIO was located to the clavicular region of implant, review of the patient's X-rays revealed that the heart was significantly enlarged due to the advanced disease state. Subsequently, a significant portion of the insulated lead body was located in the heart, including the portion with cosmetic MIO. Typically, 20 cm proximal of the tip electrode approximates the clavicular region.

Consistent with our previous analysis of MIO relative to the 6884/6966 lead, the observed MIO did not, in any way, affect the clinical performance of this lead. Patient data analysis shows that the implanted lead system, inclusive of the 6884 lead, performed appropriately. Of six spontaneous VT/VF episodes reported (4VT/2VF), all were appropriately detected and treated via the implanted PCD Transvene system.

In addition, the presence of MIO on the middle insulation is not entirely unexpected (reference February 18, 1993, Medtronic/FDA meeting). If the middle insulation had been degraded to the point of electrically shorting the sensing ring (middle conductor coil) to the common defibrillation electrode (middle coil), an integrated bipolar sensing system would, in essence, be created. In this type of system, sensing occurs between the unipolar pacing tip and the common defibrillation electrode, versus standard, or true, bipolar sensing between the pace/sense tip and the ring electrodes. This type of sensing system is identical to the CPI Endotak configuration, as well as Medtronic's earlier

04

design of a Transvene RV lead, i.e., the Model SP2100. These types of integrated systems have been shown to be clinically acceptable. Note that canine testing of a shorted, RV cardioversion/defibrillation lead, indicated that this type of failure does not result in the lack of therapy delivery.

If the innermost insulation had degraded such that the pacing tip electrode shorted, this could manifest as intermittent sensing of the brady pace/sense function of the lead. This type of anomalous system performance is expected to be observed at follow-up sessions, given the frequent monitoring of patients (every three months) or as necessary when the patient experiences VT/VF episodes or anything unusual. Similar to brady pacing patients, problems related to pace/sense performance are typically observed at the time of follow-up (pace/sense threshold measurements are standard follow-up procedure for both brady and tachy lead systems) and/or when the patient reports to his/her physician for any unusual events, e.g., intermittent pacing/sensing.

The extensive dilatation of the right ventricle in which this lead was implanted resulted in a large portion of insulated lead body being in the right ventricle, as opposed to primarily just the cardioversion/defibrillation electrode coil. Subsequently, this lead may have been subject to more flexing in the heart than what is typical for the RV lead. Note: this was demonstrated in the videotape that was presented to FDA at the February 18, 1993, Medtronic/FDA meeting.

Clinical data from brady pacing leads indicates that the portion of the lead subject to the flexing motion in the heart may be related to the occurrence of MIO in brady lead bodies. Brady pacing leads, proximal to the tip/ring electrodes are subject to more flexing motion, relative to a cardioversion/defibrillation RV lead, while contained in the heart. On the other hand, cardioversion/defibrillation leads, like the 6884/6966, are comprised of a comparatively stiff portion proximal to the tip/ring electrode. This length of defibrillation electrode, 5 cm, appears to flex less than a typical brady pacing lead while in the heart, as a result of

greater stiffness. However, in the extremely hypertrophic heart, as was the case with this particular RV lead, the lead may be subject to more flexing, similar to that of a brady pacing lead.

Conclusions

As noted, Medtronic cannot assure that MIO, or other lead failure mechanisms will not occur in the 6884/6966 lead. However, one should consider the actual benefits of the lead versus the **potential** for MIO occurrence. Specifically, clinical data to date for the Transvene system show that one year actuarial survival from SCD is 99.5 percent and the average hospital stay for Transvene implant is only seven days (versus ten for an epicardial system)*. Regarding the potential for MIO occurrence, analysis shows this would result in a bipolar integrated sensing system, or in an intermittent pace/sense system. Integrated sensing has been shown to be clinically acceptable, and intermittent pacing/sensing is assessed as part of standard follow-up procedures. Additionally, with postmarket surveillance mechanisms in place, such as returned product analysis and chronic lead monitoring, Medtronic is well positioned to appropriately evaluate and manage potential failure mechanisms of implantable cardiac leads. We are committed to these surveillance mechanisms in the interest of delivering optimal implantable technology products to the health care market.

Based on the clinical data collected, the Transvene leads have performed safely and reliably.

PCD Devices

In the 762 implants, a total of 63 units (8.3%) were explanted secondary to patient deaths, infection, heart transplant, low battery voltage measurement and PCD Device performance issues. Table IE1-1 provides an overview of the units explanted, and returned to Medtronic for analysis and reason for explant.

06

PCD Transvene System Reasons for PCD Device Explant n = 762		
Reason	**All Models**	
	Explanted	Received for analysis
Patient Death	22	17
Infection	22	10
Cardiac Transplant	9	5
Low Battery Voltage Measurement	1	1
PCD Device Performance Issues	4	4
L23	1	1
Lead Issues	4	4
Total	63	42

Table IE1-1 Reasons for PCD Device Explant - 2/1/93

The investigational plan requests that if the patient expires during the course of the clinical study that the PCD device be explanted and returned to Medtronic for analysis. There were 51 reported patient deaths and 22 devices were explanted. Seventeen have been received at Medtronic for analysis. In the 29 deaths where the device was not explanted, the patients expired and were buried before the devices could be explanted.

Results of analysis performed on the 42 explanted devices is presented in Table IE1-2.

PCD Transvene System Final Analysis on Explanted PCD Devices (N = 762)	
Within Normal Specifications	36
Hermetic Leakage at IC	1
Random Component Failure	2
Shorted on Pulse 2 Output	2
L23	1
Analysis Pending	0
Total	42

Table IE1-2: Final Analysis on Explanted PCD Devices - 2/1/93

Of the 42 devices explanted, final analysis on 36 units indicated that the devices were functioning within normal specifications.

Six PCD Devices were explanted for the following device performance issues:

- explanted due to a Power On Reset (POR) condition that was not related to the delivery of external defibrillation or cautery (N=1);
- explanted for lower than expected battery voltage for time in service, includes L23 (N=2);
- explanted secondary to failure to appropriately synchronize and deliver cardioversion therapy for an induced VT episode (N=1); and
- explanted post inappropriate delivery of VF therapy during a manual capacitor charge time (N=2).

These devices are discussed in detail in the discussion that follows.

In the case of the device explanted for PCD Device performance issue (b)(4) (b)(4) the device experienced a Power On Reset (POR) condition that was not related to

08

the delivery of external defibrillation or electrocautery. Under certain conditions, the use of direct defibrillation or electrosurgical cautery in the icinity of a Model 7217B PCD System (i.e., device and electrodes) may cause the device to be set to its reset parameter values (VT/VF detection and therapies disabled and nominal VVI pacing parameters). In the case of this patient, the POR condition occurred during the pre-hospital discharge evaluation and the patient was under no increased risk.

Since external defibrillation or electrocautery had not been used near the device, it was recommended that the device be explanted. The patient received a second PCD Device without difficulties. The explanted PCD Device underwent initial evaluation and was found to be performing within specifications.

Analysis of the device which had the documented short on the Pulse 2 output was found in a device which was explanted secondary to patient death. The death was classified as nonsudden and not related to the implanted PCD Transvene System. It appears that this diode failed post explant of the system probably due to electrocautery being used at the time of explant and was not related to the patient's death.

There was one device (b)(4) that was explanted due to lower than expected battery voltage for time in service. Analysis indicated that hermetic leakage at the input to one of the integrated circuits lead to a voltage drop across a resistor where the voltage measurement is taken. Thus the actual battery voltage was appropriate but the telemetry reading was incorrectly low.

There have been no reports of lower than expected battery voltage for time in service due to failure in an integrated circuit which increases current drain or leakage of tantalum capacitors on the printed circuit board as reported in the PCD Epicardial System experience.

None of these issues are related to the PCD device battery performance. The battery has performed according to

09

specifications and there is no clinical data indicating otherwise.

In the case of the PCD Device (b)(4) which did not appropriately synchronize cardioversion therapy, during the pre-hospital discharge electrophysiology study, VT was induced and cardioversion therapy failed to appropriately synchronize and deliver therapy for the induced episode. The PCD Device was explanted and the patient received a second device without difficulties. Analysis of the explanted PCD Device indicated a random device failure. The manufacturing process was modified to incorporate a screening process to identify any further devices which may exhibit this behavior.

In the PCD Device (b)(4) in which VF therapy was delivered during a capacitor charge time, appropriate function of the Model 7217B PCD Device was documented at the time of implant. At the time of the one month follow-up, the device was interrogated and there were no spontaneous episodes between hospital discharge and the one month follow-up. During the monitor, the capacitors were being charged according to protocol and the patient indicated she felt a sensation in her abdomen. Subsequently, the PCD device did not respond to telemetry.

The patient was monitored again in an effort to assess telemetry. Another programmer was used and various radiofrequency sensitivities were used in attempts to gain telemetry. Still there was no response. The implanted system was assessed via x-ray and device (leads) dislodgement was not seen. Alternative implant, e.g., another commercially available defibrillator, was not considered an option as the Medtronic lead connections were not known to be compatible with other manufacturer's devices. The PCD Device was explanted and a second Model 7217B PCD device was implanted without difficulty. This patient has done well since the second implant procedure. No further device performance issues such as this one have been reported in this patient or other implanted devices.

Analysis of the explanted unit indicated that arcing occurred between the conductors inside the hermetically

170

enclosed brazed ring of the high power hybrid. As a result, high voltage was momentarily applied to the low power circuitry, including the low power hybrid. This low power hybrid lost function including the capability to pace and transmit telemetry due to excessive voltage applied. The mechanism that initiated the arcing could not be identified.

Even though the arcing mechanism could not be identified, it is important to note that the hybrid manufacturing procedure has processing steps to ensure that arcing does not occur. Traceability data on this unit indicated there were no processing anomalies related to this hybrid.

Since this was the only device that exhibited this type of failure in the field and the hybrid manufacturing process has demonstrated that it will screen out infant mortality, this is considered a random component failure.

F. Clinical Conclusions

The overall clinical experience with the PCD Transvene System indicates that the system performed according to design and specification. The reported clinical complications and patient deaths are appropriately addressed in the required labelling for the system and the patient selection criteria for implant of the device is appropriate.

The following can be drawn from this analysis of the data collected in this clinical study from the 757 patients with a mean follow-up of 11.7 months:

Patient Deaths

- The projected one year survival probabilities for Sudden Cardiac Death, Non-Sudden Cardiac Death, all Cardiac Deaths and Noncardiac Death were found to be 99.5%, 96.2%, 95.8%, and 98.1%, respectively.

  The incorporation of programmable VT/VF detection and therapies has improved the type of therapy available for the treatment of recurrent VT/VF while maintaining the positive impact of ICD therapy on survival from sudden cardiac death.

- The sudden cardiac death survival of 99.5% at one year is comparable to that of the AICD patient population 98.0%.

- There have been no deaths due to a PCD Device malfunction.

Complications/Observations

- Complications were reported in 19.4% of the patient population and observations were reported in 23.8% of the patient population.

- The incidence of complications was comparable to that of the market released AICD system in the categories of ineffective VT/VF therapy, pocket infection, and pocket erosion and was lower than the AICD in the category of inappropriate delivery of VT/VF therapy.

Patient Indications

- All of the 757 patients who received a 3 lead system in this clinical evaluation met at least one of the primary indications. Sudden cardiac death (SCD) was the primary indication in 37.1% of the patients, recurrent ventricular tachycardia (VT) was the primary indication in 49.8 % of the patients and SCD/VT was the primary indication in 13.1% of the patients.

- The number of patients (60.5%) receiving VT/VF therapy for spontaneous episodes of ventricular arrhythmias supports the conclusion that the patient selection criteria are appropriate and that the PCD Transvene System was implanted in patients who benefit from this therapy.

- The one year sudden cardiac death survival rates for the SCD patient group was 100.0%, for the VT patient group 99.4% and the SCD/VT patient group 98.6%.

VT/VF Detection and Therapy Performance

- The PCD Transvene System properly detects and treats VT as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VT was 98.4%.

B

- The PCD Transvene System properly detects and treats VF as demonstrated by the spontaneous episode data. The overall success rate for detection and treatment of spontaneous VF was 98.4%.

- There were no reported patient deaths due to the nondetection of a spontaneous VT or VF episode by the PCD Transvene System.

PCD Transvene System Performance

- The PCD Transvene System components (Model 7216A/7217B and Model 6884/6966, 6881/6963, 6895/6999 Transvene leads) have performed according to design and specification and are, therefore, considered safe and effective in the indicated patient population.

Medtronic asserts and the PCD Transvene investigators unanimously agree that the findings of the clinical study support the conclusion that the Medtronic Tachyarrhythmia Control System and the Transvene Cardioversion and Defibrillation Electrodes are safe and effective in the indicated patient population.

III

Death Summaries

A

Complication/ Observation	ID#	Implant Date	Event Date	Resolution/Outcome
Complication	(b)(6), (b)(6), (b)(4)	11/25/91	1/30/92	(b)(6), (b)(6), (b)(4)

III. Death Summaries

A. Perioperative Death Summaries

Perioperative deaths include all deaths occurring within thirty days of implant. The perioperative death summaries are also included in the appropriate sections of this report discussing specific death catagories.

1. Patient (b)(6)

PCD Serial Number: (b)(4), (b)(6)
Date of Implant: (b)(4), (b)(6)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4)

(b)(4)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as periopertive, non-sudden cardiac and related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and felt that the death was related to the implant procedure and not the implanted PCD Transvene System.

2. Patient (b)(6), (b)(4)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	OFF
VT Rx #1	OFF
VT Rx #2	OFF
VT Rx #3	OFF
VT Rx #4	OFF
FDI	320 ms

VF Rx #4	34J/SINGLE

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, sudden cardiac and not related to the implanted PCD Transvene System. The investigator felt that the patient's death was related to her severe left ventricular dysfunction. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

B. Sudden Cardiac Death Summaries

1. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: Sudden Cardiac

(b)(4), (b)(6)

VF Rx #4	34J,Seq

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as Sudden Cardiac (Witnessed) and not related to the implanted PCD Transvene System. The European CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

5. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: Sudden Cardiac

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.6 mV
TDI	350
VT NID	12
VT Rx #1	Burst
VT Rx #2	18J,CV
VT Rx #3	34J,CV
VT Rx #4	34J,CV
FDI	280
VF NID	18
VF Rx #1	34J, Seq
VF Rx #2	34J, Seq
VF Rx #3	34J, Seq
VF Rx #4	34J,Seq

(b)(4), (b)(6)

(b)(4), (b)(6)

Based on the information received the investigator classified the patient death as Sudden Cardiac (Unwitnessed). The European CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

C. **Non-Sudden Cardiac**

1. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as periopertive, non-sudden cardiac and related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and felt that the death was related to the implant procedure and not the implanted PCD Transvene System.

2. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

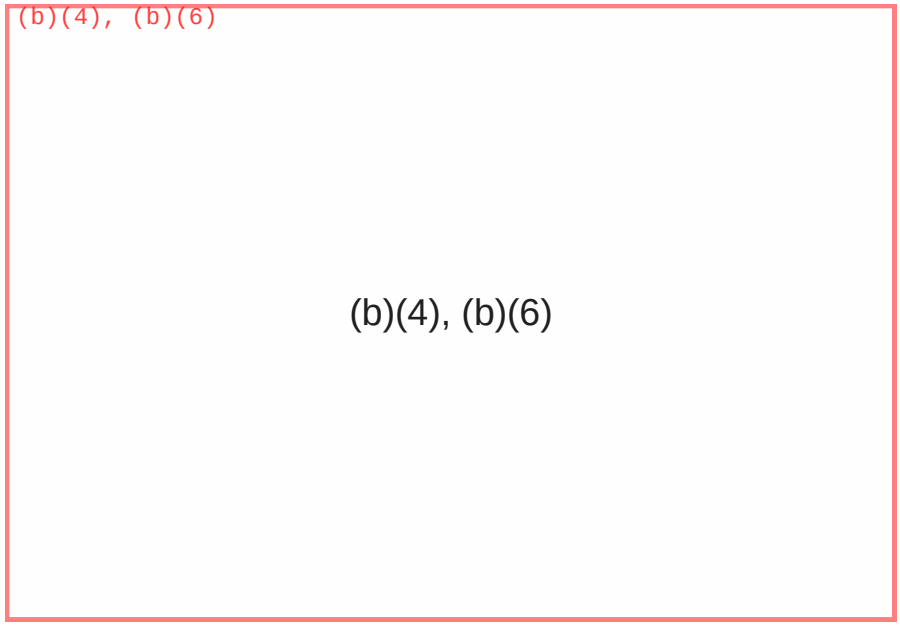
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)



(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as noncardiac secondary to brain carcinoma by the investigator and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

5. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-sudden Cardiac (Non-arrhythmic)

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	off
VT NID	off
VT Rx #1	off
VT Rx #2	off
VT Rx #3	off
VT Rx #4	off
FDI	320

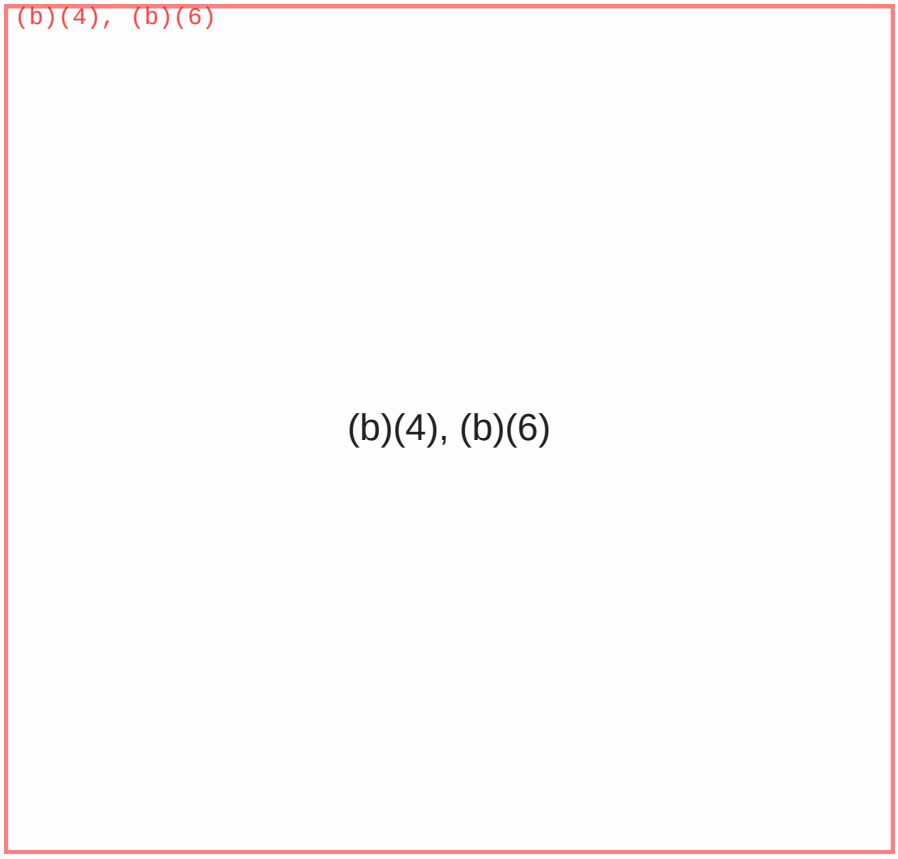
VF Rx #4	34J, sim

(b)(4), (b)(6)



301

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator originally classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. However, the North American CERC commitee recommended reclassification of the death to non-sudden cardiac after full review of the circumstances surrounding the patient's death.

8. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

the last follow-up visit was as follows:

Parameter	Value
Sensitivity	0.6 mV
TDI	350 ms
VT NID	16
VT Rx #1	CV/34J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ

VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as non-sudden cardiac secondary to end stage heart failure by the investigator and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

10. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD device programmed status at the last follow-up visit was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	OFF
VT Rx #1	OFF
VT Rx #2	OFF
VT Rx #3	OFF
VT Rx #4	OFF
FDI	320 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

11. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

09

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD device programmed status at the time of the patient's death was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	480 ms
VT NID	16
VT Rx #1	CV/1.0J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	320 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The CERC reviewed the circumstances of this patient death and classified this patient death as perioperative and

210

procedure related. The CERC also indicated that the increased frequency in spontaneous VT/VF episodes may have been related to the increased number of inductions during the implant procedure.

12. Patient (b)(6)

PCD Serial Number:	(b)(6), (b)(4)
Date of Implant:	
Date of Death:	
Death Classification:	Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD device programmed status at this time was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	380 ms
VT NID	16
VT Rx #1	CV/10J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	290 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

13

(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as non-sudden cardiac secondary to intractable VT by the investigator and not related to the implanted PCD Transvene System. The CERC reviewed the circumstances of the patient death and agreed with the investigator's classification.

13. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	OFF
VT Rx #1	OFF
VT Rx #2	OFF
VT Rx #3	OFF
VT Rx #4	OFF
FDI	320 ms
VF NID	24
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

14. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	500
VT NID	16
VT Rx #1	Burst
VT Rx #2	Burst
VT Rx #3	Burst
VT Rx #4	34J,CV
FDI	320

(b)(4), (b)(6)

The investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

6. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	520 ms
VT NID	16
VT Rx #1	Burst
VT Rx #2	Burst
VT Rx #3	CV,15J,Seq
VT Rx #4	CV,34J,Seq
FDI	320
VF NID	18
VF Rx #1	34J,Seq
VF Rx #2	34J,Seq
VF Rx #3	34J,Seq
VF Rx #4	34J,Seq

The investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

7. Patient (b)(6), (b)(4)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.6 mV
TDI	460 ms
VT NID	16
VT Rx #1	Ramp
VT Rx #2	CV,1J,Seq
VT Rx #3	CV,5J,Seq
VT Rx #4	CV,34J,Seq
FDI	280 ms
VF NID	18
VF Rx #1	34J,Seq
VF Rx #2	34J,Seq
VF Rx #3	34J,Seq
VF Rx #4	34J,Seq

The investigator classified the patient death as non cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

8. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-cardiac

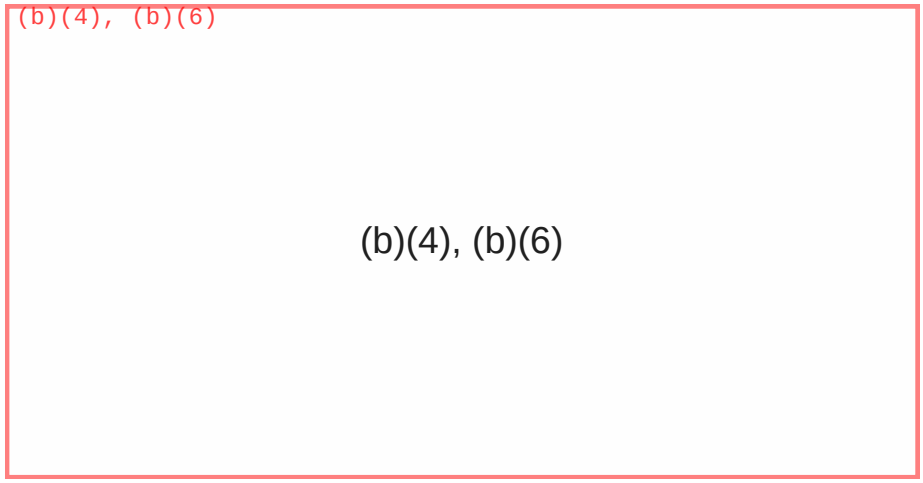
(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	350 ms
VT NID	8
VT Rx #1	Burst
VT Rx #2	CV,34J, Seq
VT Rx #3	CV,34J, Seq
VT Rx #4	CV,34J, Seq
FDI	270 ms
VF NID	12
VF Rx #1	34J, Seq
VF Rx #2	34J, Seq
VF Rx #3	34J, Seq
VF Rx #4	34J, Seq

(b)(4), (b)(6)



The investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

9. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	450 ms
VT NID	20
VT Rx #1	CV/34J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	380 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as perioperative, noncardiac and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

10. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	360 ms
VT NID	20
VT Rx #1	CV, 34J
VT Rx #2	CV, 34J
VT Rx #3	CV, 34J
VT Rx #4	CV, 34J
FDI	300 ms
VF NID	18
VF Rx #1	34J
VF Rx #2	34J
VF Rx #3	34J
VF Rx #4	34J

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

11. Patient (b)(6)

PCD Serial Number:	(b)(6), (b)(4)
Date of Implant:	(b)(6), (b)(4)
Date of Death:	
Death Classification:	Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

device delivered 5 cardioversion therapies of 5 Joules each. The PCD device programmed status was as follows:

Parameter	Value
Sensitivity	0.6 mV
TDI	400 ms
VT NID	16
VT Rx #1	CV/5J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	300 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as non-cardiac, specifically respiratory arrest, by the investigator and not related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

380

12. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	340
VT NID	24
VT Rx #1	OFF
VT Rx #2	34J,CV
VT Rx #3	34J,CV
VT Rx #4	34J,CV
FDI	300
VF NID	18
VF Rx #1	34J, Seq
VF Rx #2	34J, Seq
VF Rx #3	34J, Seq
VF Rx #4	34J,Seq

(b)(4), (b)(6)

(b)(4), (b)(6)

Based on the information received the investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The European CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

13. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	360 ms
VT NID	24
VT Rx #1	CV,18J,Seq
VT Rx #2	CV,18J,Seq
VT Rx #3	CV,18J,Seq
VT Rx #4	CV,18J,Seq
FDI	320 ms
VF NID	18
VF Rx #1	34J,Seq
VF Rx #2	34J,Seq
VF Rx #3	34J,Seq
VF Rx #4	34J,Seq

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as non-cardiac and not related to the implanted PCD Transvene System. The U.S. CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

14. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-cardiac

(b)(6)

(b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 Mv
TDI	400
VT NID	16
VT Rx #1	34J,CV
VT Rx #2	34J,CV
VT Rx #3	34J,CV
VT Rx #4	34J,CV
FDI	320
VF NID	18
VF Rx #1	34J,SIML
VF Rx #2	34J,SIML
VF Rx #3	34J,SIML
VF Rx #4	34J,SIML

(b)(6)

(b)(6)

The investigator classified the patient death as non-cardiac and not related to the PCD system. The European CERC committee reviewed the circumstances of this patient's death and agreed with the investigator's classification.

15. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The programmed parameters at last known follow-up are as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	380
VT NID	16
VT Rx #1	Burst
VT Rx #2	34J,CV
VT Rx #3	34J,CV
VT Rx #4	34J,CV
FDI	300
VF NID	18
VF Rx #1	34J,Siml
VF Rx #2	34J,Siml
VF Rx #3	34J,Siml
VF Rx #4	34J,Siml

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as non-cardiac. The European CERC has reviewed this death.

E

E. Deaths: Non-standard Lead Configurations and Epicardial Implants

Non-Standard:

1. Patient (b)(6)

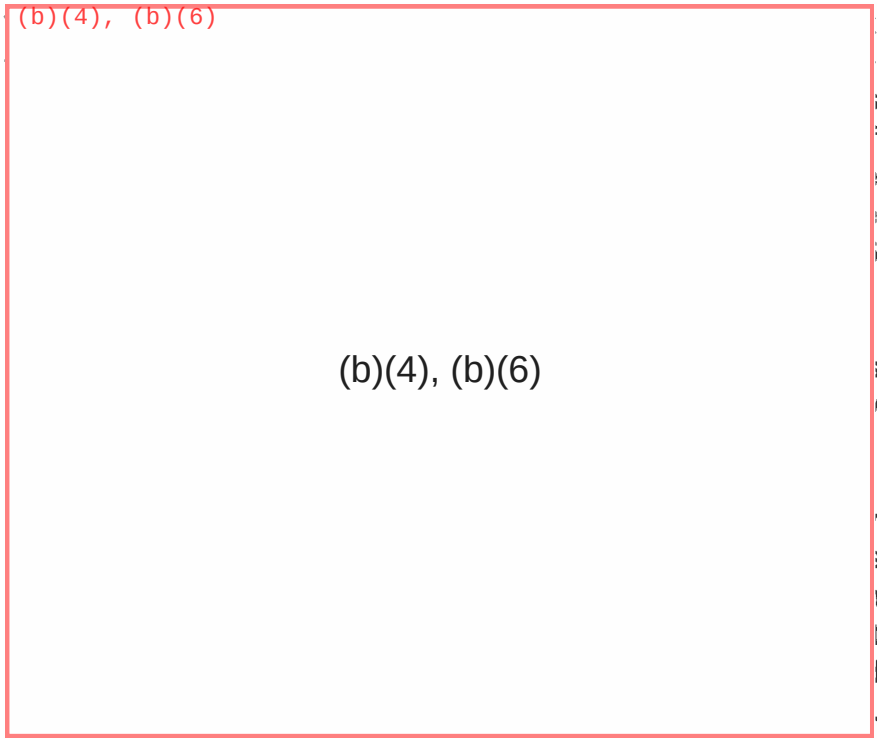
PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.6 mV
TDI	420 ms
VT NID	12
VT Rx #1	Ramp
VT Rx #2	CV/34J/SIM
VT Rx #3	CV/34J/SIM
VT Rx #4	CV/34J/SIM
FDI	300 ms
VF NID	12
VF Rx #1	34J/SIM
VF Rx #2	34J/SIM
VF Rx #3	34J/SIM
VF Rx #4	34J/SIM

(b)(4), (b)(6)



The investigator classified this patient death as non-sudden cardiac and not related to the implanted PCD Transvene

System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

2. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, noncardiac and not related to the implanted

PCD Transvene System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

Epicardial System

1. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	500 ms
VT NID	20
VT Rx #1	Burst
VT Rx #2	CV/5J/SIN
VT Rx #3	CV/34J/SIN
VT Rx #4	CV/34J/SIM
FDI	320 ms
VF NID	12
VF Rx #1	34J/SIN
VF Rx #2	34J/SIN
VF Rx #3	34J/SIN
VF Rx #4	34J/SIN

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, noncardiac and not related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

2. Patient (b)(6)

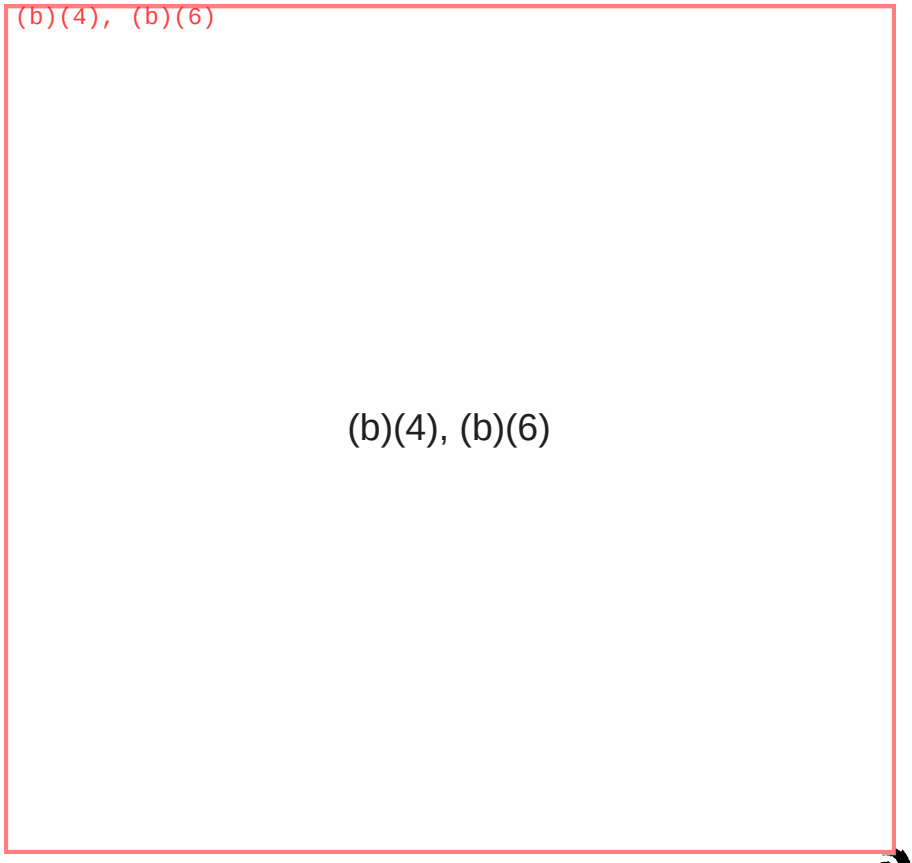
PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	-
VT Rx #1	-
VT Rx #2	-
VT Rx #3	-
VT Rx #4	-
FDI	350 ms
VF NID	12
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)



(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, non-sudden cardiac and related to an ventricular arrhythmia episode. The investigator indicated that the patient death was not related to the implanted PCD System. The CERC reviewed the circumstances of this patient death and agreed with investigator's classification.

3. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

300

Parameter	Value
Sensitivity	0.6 mV
TDI	450 ms
VT NID	16
VT Rx #1	Ramp
VT Rx #2	Burst
VT Rx #3	CV/34/SIN
VT Rx #4	CV/34/SIN
FDI	340 ms
VF NID	18
VF Rx #1	34J/SIN
VF Rx #2	34J/SIN
VF Rx #3	34J/SIN
VF Rx #4	34J/SIN

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, non-sudden cardiac and not related to the implanted PCD System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

4. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The primary investigator classified the death nonsudden cardiac, perioperative and not related to the implanted PCD system. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

5. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The CERC reviewed the circumstances of this patient death and agreed with the primary investigator's classification. In addition, the death was classified as procedure related due to the fact the patient underwent both a nonthoracotomy and epicardial lead evaluation.

6. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The CERC reviewed the circumstances of this patient death and agreed with the primary investigator's classification. In addition, the death was classified as perioperative and procedure related due to cerebrovascular accident that occurred during surgical procedure.

7. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD Device programmed status was:

Parameter	Value
Sensitivity	0.6 mV
TDI	OFF
VT NID	-
VT Therapy #1	OFF
VT Therapy #2	OFF
VT Therapy #3	OFF
VT Therapy #4	OFF
FDI	320 ms
VF NID	18
VF Therapy #1	34J SIM
VF Therapy #2	34J SIM
VF Therapy #3	34J SIM
VF Therapy #4	34J SIM

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The CERC reviewed the circumstances of this patient death and agreed with the primary investigator's classification. In addition, this death was classified as perioperative and procedure related due to both a nonthoracotomy and epicardial lead evaluation being performed.

8. Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Non-Sudden Cardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

The final programmed status of PCD Device was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	-
VT Therapy #1	-
VT Therapy #2	-
VT Therapy #3	-
VT Therapy #4	-
FDI	320 ms
VF NID	18
VF Therapy #1	34J/SIN
VF Therapy #2	34J/SIN
VF Therapy #3	34J/SIN
VF Therapy #4	34J/SIN

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, non-sudden cardiac and not related to the implanted PCD System. The CERC reviewed the circumstances of this patient death and agreed with the investigator's classification.

IX Summary of Additional Implants

C. Patient Deaths

(b)(4)

(b)(4)

Non-Cardiac:	Deaths that occurred where the primary cause of death was determined to be non cardiac in nature, e.g. stroke, cancer, etc.
Cardiac:	Deaths that occurred where the primary cause of death was determined to be cardiac in nature.
Non-Sudden:	Deaths that occur greater than one hour after the onset of symptoms.
Sudden:	Deaths that occur within one hour of the onset of symptoms or where the death is unwitnessed. Sudden cardiac deaths were also categorized as being **Witnessed** or **Unwitnessed**.
Perioperative:	Deaths that occur within thirty days of implant.
System Related:	A death which results from a malfunction (operation not according to design specification) of a PCD System component, or as a result of a device induced arrhythmia, or an interaction between a PCD System component and the patient.
Procedure Related:	A death which occurs as a result of a procedure required to implant, follow or test a PCD System.

Materials Used

The following is a list of materials previously tested and used in the Model 6966 right ventricular lead:

- (b)(4)

(b)(4)

- (b)(4)
- (b)(4)
- (b)(4)
- (b)(4)
- (b)(4)
- (b)(4)

Rationale

(b)(4)

(b)(4)

Conclusion

All materials were found to be biocompatible and therefore are considered suitable for human implant. See the Biocompatibility Table following this section.

BIOCOMPATIBILITY TEST DATA FOR NON-THORACOTOMY (TRANSVENE) LEADS

(b)(4)

(b)(4)

The biocompatibility testing performed on the non-thoracotomy leads was in accordance with the Office of Device Evaluation, Division of Cardiovascular Devices' Implantable Pacemaker Lead Testing Guidance for the Submission of a 510(k) Notification. September 1989. In this guidance, the following biocompatibility tests are stated as being considered necessary to satisfy the biocompatibility of the implanted materials:

- (b)(4)

Therefore, the above-listed tests which were performed are considered adequate to assess the biocompatibility of the material used in the non-thoracotomy leads. This testing performed is consistent with the biocompatibility testing that has been performed for all of Medtronic's pacing lead products.

In addition, the following rationale is provided as to why we did not perform specific tests of the Tripartite Biocompatibility Guidance for Medical Devices:

1. EXECUTIVE SUMMARY OF THE ANIMAL TESTING

The information presented in this section is an accumulation of several studies, some of which FDA has previously reviewed in IDE submissions (G870102). These studies demonstrate the safety of the Transvene lead Models 6963, 6966 and 6999.

A variety of non-thoracotomy leads were evaluated in a series of four canine studies. Descriptions of the leads, as well as the study number(s) (1, 2, 3 or 4) in which they were evaluated, are presented below.

Description: Non-thoracotomy Leads

CORONARY SINUS/SUPERIOR VENA CAVA LEADS

Model 6963, evaluated in Study No. 4, is a silicone, unipolar, coronary sinus or superior vena cava lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies.

Model 6881, evaluated in Study Nos. 2, 3 and 4 is functionally equivalent to the Model 6963 except the 6881 has a 3.2 mm connector.

Model 10285, evaluated in Study No. 1, is the temporary version of the Model 6963/6881.

RIGHT VENTRICULAR LEADS

Model 6966, evaluated in Study No. 4, is a polyurethane, tripolar, extendable/retractable, screw-in lead with a 6.5 mm connector and platinum alloy electrode for delivery of cardioversion and defibrillation therapies. Additionally, the 6966 has a 3.2 mm connector for pacing and sensing.

Model 6884, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6966 except the 6884 has a 3.2 mm connector in place of the 6.5 mm connector for the cardioversion-defibrillation electrode.

Model 10284, evaluated in Study No. 1, is the temporary version of the Model 6966/6884.

SUBCUTANEOUS PATCH LEADS

Model 6999, evaluated in Study No. 4, is a silicone, unipolar, oval, subcutaneous patch with a 6.5 mm connector and platinum alloy electrode coils that are partially embedded in the silicone patch for delivery of cardioversion and defibrillation therapies. Additionally, the patch is embedded with (b)(4) (b)(4)

Model 6895, evaluated in Study Nos. 2 and 3, is functionally equivalent to the Model 6999 except the 6895 has a 3.2 mm connector and is covered with (b)(4) (b)(4)

Model 10317, evaluated in Study No. 3, is functionally equivalent to the 6895 except it is embedded on the outer edge with (b)(4) (b)(4)

Although model numbers differ, all leads in each of the three groups are functionally equivalent. The various model numbers reflect an evolution of temporary to transvenous lead development, as well as minor changes, such as the connector pin modification from 3.2 mm to 6.5 mm.

Additional devices were used to evaluate the non-thoracotomy lead studies in canines. These are described below.

External Devices for Implant Support

Model 5355 External Tachyarrhythmia Control Device (ETCD)

The Model 5355 ETCD provides the same detection capabilities as the implantable Model 7217B PCD Device. Therapies are identical except that the maximum output energy is 40 joules (J) and automatic defibrillation and cardioversion are not available in the Model 5355. The Model 5355 ETCD provides measurement and display of output waveform parameters and ETCD status, an isolated electrogram signal, and passthrough connections of pacing and sensing electrodes to external instrumentation.

Model 2394 External Cardioverter/Defibrillator (ECVD)

The Model 2394 ECVD instrument can deliver: (1) a single stimulation pulse on one output channel, or (2) a pair of pulses, delivered individually on the two different output channels. Monophasic and biphasic pulses are provided, output capacitance can be varied between 10 and 150 microFarads (mf) depending on which external capacitor modules are used, and pulse width can be specified as a fixed duration (0.1-19.9 ms) or "tilt" (10-90%).

between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Model 2376 External Cardioverter/Defibrillator (ECVD)

The output stimulation parameters of the Model 2376 are very similar to those of the Model 2394 except for the following modifications:

- All pulses are monophasic, truncated, exponential waveforms.
- Output capacitance is fixed at 50 microFarads and pulse width is determined by a fixed pulse duration only.
- Pulse output voltages can range between 50 and 1090 volts and may be delivered asynchronously (upon manual command) or synchronized with an intrinsic sensed event.

Study Methods

All canine studies were conducted according to the 1966 and 1970 Animal Welfare Acts, 1985 NIH Laboratory Animal Use and Care Guidelines and GLP regulations. Adult mongrel canines were used for all studies. The dogs weighed 20 kg or more.

Specific details of each study are presented in the following "Animal Studies/Results" section.

Each study is briefly described below. Both acute and chronic studies were performed to assess the toxicity of the non-thoracotomy lead system as well as its stability over time.

Study #1: Acute Toxicity Testing of Non-thoracotomy Leads

The objective of this study was to quantify the amount and nature of shock-induced damage to the myocardial tissue resulting from multiple, high energy defibrillation shocks delivered through transvenous defibrillation leads and a subcutaneous patch. This information has previously been submitted to the agency in the Non-Thoracotomy IDE, reference Document Control Number G870102/S23; FDA Approved October 4, 1990. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results of these studies revealed only minimal shock-induced necrosis (<0.1-0.5 percent by weight), which did not result in functional impairment of the cardiac tissue. Therefore, the use of the Model 6963, 6966 and 6999 leads did not result in significant myocardial damage in canines and could be safely implanted in humans.

Study #2: Model 6881, 6884 and 6895 Chronic Lead Evaluation

The objective of this study was to evaluate the suitability of the lead system for human clinical use. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Study results demonstrate that the performance of the non-thoracotomy lead system when used with the PCD and ETCD devices is in conformance with system design and expected operation.

Study #3: Model 6881, 6884 and 6895 Chronic Lead Defibrillation Study

This study is an evaluation of the chronic stability of the non-thoracotomy lead system via the monitoring of defibrillation and pacing thresholds. In addition, histopathological examinations have been performed to assess the amount and nature of shock-induced damage to the myocardial tissue resulting from defibrillation shocks. Lead models evaluated in this study are functionally equivalent to the Models 6963, 6966 and 6999. Results demonstrate stable pacing, sensing and defibrillation thresholds over time. Additionally, histopathology analysis shows no cardiac tissue damage due to delivery of defibrillation shocks.

Study #4: Model 6963, 6966 and 6999 Chronic Lead Defibrillation Study

This study is an ongoing evaluation of the non-thoracotomy lead system to assess chronic defibrillation threshold stability, pacing thresholds, intracardiac sensing capabilities and tissue damage. Results indicate the lead system performs as intended; DFTs and pacing thresholds have remained stable throughout the study (40 weeks) and intracardiac sensing is appropriate. Additionally there is minimal localized trauma to the cardiac tissue (<0.05 percent by weight).

Conclusion

All of these canine studies have demonstrated that the non-thoracotomy lead system, which includes the Model 6963 CS/SVC lead, 6966 RV lead and 6999 SQ patch lead, functions safely and is therefore appropriate for human use.

2. ANIMAL STUDIES/RESULTS

In this section each study (1-4) is described in detail and includes the study objectives, methods, relevance and conclusions.

A brief abstract prefaces each chronic study report.

Lead length:			
Pacing/sensing rings:			

\+ The Model SP2100-5 is a screw-in lead where the screw acts as the pacing electrode; sensing is achieved from the screw to the defibrillation coil.

* The shadow area is the surface area, or silhouette, covered by the electrode.

Appendix C: Complications and Observations

PCD Transvene System Reported Complications and Observations and Corresponding Treatments

All complications and observations reported as of June 24, 1992 are presented in Tables Appendix C-1 and C-2. A total of 757 patients have received a PCD Transvene System.

Complications have been reported in 138 patients and clinical observations have been reported in 157 patients. The reported clinical complication incidence in this patient population is 18.2% (138/757). The reported clinical observation incidence in this patient population is 20.8% (157/757).

The following tables provide clinical summaries of the complications and observations reported in the PCD Transvene System patient population.

PCD Transvene System Reported Complications/Observations By Category 6/24/92		
Category	**Complications**	**Observations**
Increased Defibrillation Requirements	0.8%	0.5%
Inappropriate Therapy Delivery	-	8.2%
Pace/Sense Performance Related	0.8%	4.1%
Infection Related - Explant Required	2.0%	-
Infection Related	1.5%	4.9%
Lead Related	12.4%	2.6%
Device Related	0.5%	-

Table Appendix C-1: PCD Transvene System Complications and Observations by Category - 6/24/92

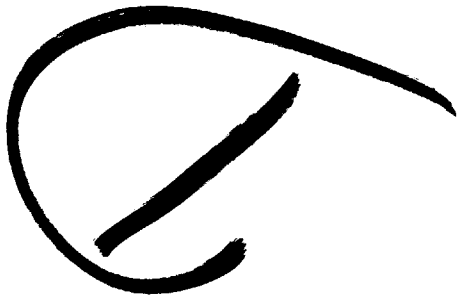
Patient Deaths

5



PCD Transvene System Death Summaries

There have been 34 reported patient deaths in patients who were screened for a PCD Transvene System implant as of June 24, 1992. A description of each of these deaths is provided in the following discussion.

There are **twenty-two (22) patient deaths** in patients who received a PCD Transvene System. Three of these deaths were classified as sudden cardiac; sixteen were classified as non-sudden cardiac; and the remaining three patient deaths were classified as noncardiac. There were 5 perioperative patient deaths in this group.

There have been **two (2) patient deaths** in patients who have received "Other Lead Systems". One death was classified as non-sudden cardiac due to CHF and septicemia and the other was classified as perioperative, noncardiac due to sepsis.

There have been **eight (8) patient deaths** in patients who were screened for a PCD Transvene System but ultimately received a PCD Epicardial System. Two of the deaths were classified as sudden cardiac, four were classified as non-sudden cardiac and the remaining two deaths were classified as noncardiac. All of the patient deaths were classified as perioperative.

There have been **two (2) patient deaths** in patients who were screened for a PCD Transvene System who did not meet the implant criteria and received no PCD System. Both of these deaths were classified as non-sudden cardiac and neither occurred in the perioperative period.

All of the patient deaths have been reviewed by a committee compromised of PCD Device investigators and other physicians (Clinical Event Review Committee). The primary purpose of these reviews was to determine whether the PCD device system was related to the deaths that have occurred, and if so what changes are required to prevent such events in the future.

There have been no patient deaths reported secondary to ineffective defibrillation of a spontaneous episode of VF, lead dislodgement or lead fracture.

Patients Received PCD Transvene System

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant:
Date of Death:
Death Classification: **Noncardiac**

(b)(4), (b)(6)

Device programmed status was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	450 ms
VT NID	20
VT Rx #1	CV/34J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	380 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified the patient death as perioperative, noncardiac and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Sudden Cardiac**

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

Device programmed status was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	490 ms
VT NID	12
VT Rx #1	Burst
VT Rx #2	CV/5J/SIM
VT Rx #3	CV/34J/SIM
VT Rx #4	CV/34J/SIM
FDI	320 ms
VF NID	18
VF Rx #1	18J/SIM
VF Rx #2	34J/SIM
VF Rx #3	34J/SIM
VF Rx #4	34J/SIM

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative and sudden cardiac. The relationship of the death to the implanted PCD Transvene System was classified as unknown. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Sudden Cardiac**

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

programmed status was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	450 ms
VT NID	12
VT Rx #1	Ramp
VT Rx #2	CV/34J/SINGLE
VT Rx #3	CV/34J/SINGLE
VT Rx #4	CV/34J/SINGLE
FDI	300 ms
VF NID	12
VF Rx #1	34J/SINGLE
VF Rx #2	34J/SINGLE
VF Rx #3	34J/SINGLE
VF Rx #4	34J/SINGLE

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as perioperative, sudden cardiac and not related to the implanted PCD Transvene System. The investigator felt that the patient's death was related to her severe left ventricular dysfunction. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Non-Sudden Cardiac**

(b)(4), (b)(6)

(b)(4), (b)(6)

programmed status was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	-
VT Rx #1	OFF
VT Rx #2	-
VT Rx #3	-
VT Rx #4	-
FDI	330 ms
VF NID	12
VF Rx #1	18J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as non-sudden cardiac however it was related to an arrhythmic event. In addition, the investigator indicated that this death was not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Non-Sudden Cardiac**

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

(b)(4), (b)(6)

The investigator classified this patient death as periopertive, non-sudden cardiac and related to the implanted PCD Transvene System. The CERC reviewed the circumstances of this patient death and felt that the death was related to the implant procedure and not the implanted PCD Transvene System.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Non-Sudden Cardiac**

Parameter	Value
Sensitivity	0.3 mV
TDI	420 ms
VT NID	12
VT Rx #1	Burst
VT Rx #2	Burst
VT Rx #3	CV/18J/SIM
VT Rx #4	CV/34J/SIM

VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as non-sudden cardiac secondary to end stage heart failure by the investigator and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Non-Sudden Cardiac**

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD device programmed status at the last follow-up visit was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	OFF
VT NID	OFF
VT Rx #1	OFF
VT Rx #2	OFF
VT Rx #3	OFF
VT Rx #4	OFF
FDI	320 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4), (b)(6)

(b)(4), (b)(6)

The cause of death was reported as non-sudden cardiac secondary to end stage heart failure by the investigator and not related to the implanted PCD Transvene System. The CERC committee reviewed the circumstances of this patient death and agreed with the investigator's classification.

4

Patient (b)(6)

Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: **Non-Sudden Cardiac**

(b)(4), (b)(6)

episodes by the pacing therapy.

(b)(4), (b)(6)

(b)(4), (b)(6)

The PCD device programmed status at the time of the patient's death was as follows:

Parameter	Value
Sensitivity	0.3 mV
TDI	480 ms
VT NID	16
VT Rx #1	CV/1.0J/SEQ
VT Rx #2	CV/34J/SEQ
VT Rx #3	CV/34J/SEQ
VT Rx #4	CV/34J/SEQ
FDI	320 ms
VF NID	18
VF Rx #1	34J/SEQ
VF Rx #2	34J/SEQ
VF Rx #3	34J/SEQ
VF Rx #4	34J/SEQ

(b)(4)

(b)(4)

The CERC reviewed the circumstances of this patient death and

classified this patient death as perioperative and procedure related. The CERC also indicated that the increased frequency in spontaneous VT/VF episodes may have been related to the increased number of inductions during the implant procedure.

Patient (b)(6)

PCD Serial Number: (b)(6), (b)(4)
Date of Implant: (b)(6), (b)(4)
Date of Death:
Death Classification: Noncardiac

(b)(4), (b)(6)

(b)(4), (b)(6)

Parameter	Value
Sensitivity	0.6 mV

MODEL 7217B PCD
PACER-CARDIOVERTER-DEFIBRILLATOR WITH
NON-THORACOTOMY LEAD SYSTEMS

RECEIVED
1993 JAN 30 11
FDA/CDE/DHC

A. STUDY PURPOSE

1. Name and Intended Use of System

The Model 7217B PCD System consists of several components, including a pulse generator; various transvenous, subcutaneous, and epicardial leads; and a dedicated software cartridge used with an existing programmer system.

The Model 7217B PCD (Pacer-Cardioverter-Defibrillator) is an implantable, multiprogrammable, automatic tachyarrhythmia control device designed to detect and treat episodes of ventricular tachycardia (VT) and ventricular fibrillation (VF) using either low energy pacing therapies or higher energy cardioversion or defibrillation therapies.

(b)(4)

(b)(4)

The Model 7217B will be used with two basic types of lead systems -

APPENDIX C

CLINICAL LITERATURE

APPENDIX C

A copy of the Bibliography provided in the original Transvene PMA application (dated March 31, 1992) is included here for convenient reference (listing of literature articles). In addition, copies of the following relevant articles are also provided.

Bardy, G.H., Hofer, B., Johnson, G., Kudenchuk, P.J., Poole, J.E., Dolack, G.L., Gleva, M., Mitchell, R., Kelso, D. "Implantable Transvenous Cardioverter-Defibrillator" Circulation Vol 87, No 4, April 1993, p. 1152-68.

Dunnett, C.W., Tamhane, A.C. "A Step-up Multiple Test Procedure" Journal of the American Statistical Association Vol. 87, No. 417, March 1992, p. 162-70.

Winkle, R.A., Mead, H., Ruder, M., Gaudiani, V.A., Smith, N.A., Buch, W.S., Schmidt, P., Shipman, T. "Long-term Outcome with the Automatic Implantable Cardioverter-Defibrillator" J Am Coll Cardiol 13(6), May 89, p. 1353-61.

Pages removed for the following reason: Copyright Materials.

BIBLIOGRAPHY

Selected articles are marked with an asterick (*), and copies were provided in the original Transvene PMA.

Medtronic® Defibrillation Lead Disclaimer of Warranties 16

Service 17

DESCRIPTION AND INTENDED USE

The Medtronic® TRANSVENE™-SVC Model 6963 Unipolar, Endocardial, Coronary Sinus or Superior Vena Cava Lead is designed for the delivery of cardioversion and defibrillation therapies. It is intended for single long-term use in the coronary sinus or superior vena cava and is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

Silicone insulation surrounds the low resistance conductor coil and the coil electrode is a platinum alloy. The lead also has a 6.5 mm connector.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE™-SVC lead with two non-radiopaque anchoring sleeves, stylet, and stylet guide
- 1 vein lifter
- Extra stylets
- Product literature

CONTRAINDICATIONS

There are no known contraindications for this lead.

WARNINGS

Do not attempt to use this lead with a non-Medtronic Implantable Cardioverter/Defibrillator device.

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning"

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, or whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile surgical gloves that have been rinsed in sterile water or the equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

Using an Anchoring Sleeve

Always use an anchoring sleeve with all leads to secure the lead from moving and to protect the lead insulation and conductor coil from damage. A second anchoring sleeve is provided for additional fixation.

Chronic Repositioning

Chronic repositioning or removal of the lead may be difficult because of the fibrotic tissue. **However, if a lead must be removed or repositioned, proceed with extreme caution.** If a lead is abandoned, it should be capped to avoid transmitting electrical signals. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section titled "Suggested Implantation Procedure."

POTENTIAL COMPLICATIONS

The potential complications related to the use of endocardial leads include, but are not limited to, the following patient-related conditions: fibrillation or other arrhythmias, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax, hemothorax, and tissue necrosis.

Other potential complications related to the lead system, but are not limited to the following: lead dislodgement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of detection, cardioversion, and defibrillation therapies.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable bag and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55° C (130° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

General Instructions

The implantation procedure generally includes using a stylet guide, stylets, and a vein lifter; selecting an insertion site; positioning the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition.

Opening the Package

Open the package according to the instructions. Inspect the lead. Remove the disc from the distal end of the lead. Verify that two anchoring sleeves are present.

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 1).

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness for different lead and stylet flexibility. Each stylet knob is etched with the stylet diameter and length.

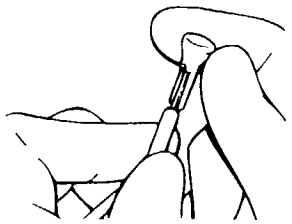

Figure 1. Stylet guide attachment.

If a slight curve is needed for the stylet, refer to instructions in the section titled "Positioning a Lead."

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein. In general, a left venous entry site will aid in maneuvering the lead into the coronary sinus orifice.

CAUTION: Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib (Figure 2). Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g., the cephalic vein.

Use fluoroscopy to facilitate accurate lead placement.

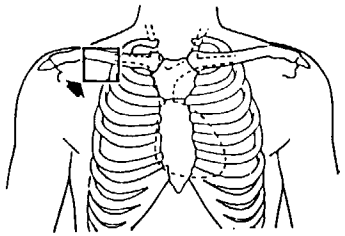

Figure 2. Insertion site.

Using a Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 3). During insertion of the lead into the vein, make sure the anchoring sleeves do not slide off the distal end of the lead.

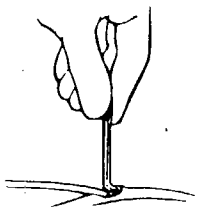

Figure 3. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Lead

For added control in maneuvering the lead tip, the distal end of the lead may be slightly curved by inserting a gently curved stylet as shown in Figure 4. A possible angle of curvature is illustrated in Figures 5 and 6.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 4).

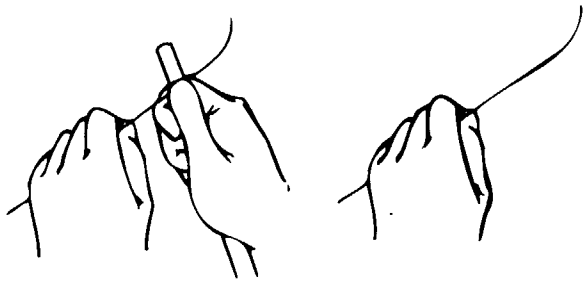

Figure 4. Imparting a curve to the stylet.

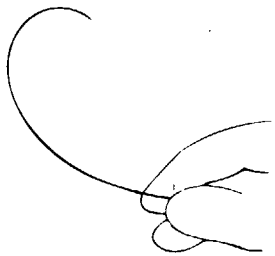

Figure 5. Bend the stylet into a gentle spiral. This gives the lead a gentle curve upward, to the left, and posterior.

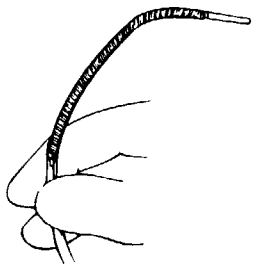

Figure 6. The curve in the stylet is designed to facilitate passage of the lead across the superior surface of the tricuspid valve. The second bend helps to position the lead to the left and posterior toward the coronary sinus ostium.

The electrode may be placed in either the coronary sinus or the superior vena cava.

If placing the electrode in the coronary sinus, advance the lead into the right atrium and rotate the curved stylet to manipulate the tip over the tricuspid valve. Move the tip medially and posteriorly to the coronary sinus ostium and advance the lead into the coronary sinus. Continue advancing the lead through the coronary sinus to the desired position.

If the lead goes through the tricuspid valve opening, retract the lead with a gentle posterior rotation and then advance it toward the coronary sinus ostium.

If the electrode is to be placed in the superior vena cava, advance the tip so that the distal portion of the electrode is approximately 3 to 5 cm proximal to the superior vena cava—right atrial junction.

The electrode for the TRANSVENE™-SVC must be as far as possible from other defibrillation electrodes. Also, the cardiac mass between the electrodes should be as large as possible. Insufficient separation between the electrodes may result in reduced defibrillation efficacy.

Proper positioning of the electrode is essential for defibrillation efficacy. Use fluoroscopy (P-A and lateral position) to ensure that the distal end of the electrode is properly positioned in the superior vena cava or is lodged in the coronary sinus with the proximal end of the electrode advanced beyond the coronary sinus ostium.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

In order to demonstrate reliable defibrillation efficacy, obtain final electrical measurements for the lead system.

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold		
(at 0.5 ms pulse width)	≤ 1.0 V - endocardial	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≤ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Anchoring the Lead

Do not secure the ligatures so tightly that they damage the vein, lead, or anchoring sleeve. Do not tie a ligature directly to the lead body (Figure 7). During anchoring, take care to avoid dislodging the lead tip.

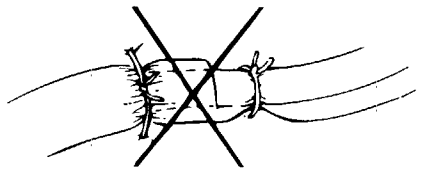

Figure 7. Do NOT secure the sutures too tightly and do NOT tie a suture to the lead body.

Use an anchoring sleeve to secure the lead from moving and to protect the lead insulation and conductor coil from damage caused by tight ligatures. A second anchoring sleeve may be placed in the tunnel entry site or in the pocket area for additional fixation.

Anchor the lead with nonabsorbable sutures.

The TRANSVENE™-SVC uses the triple groove anchoring sleeve illustrated in Figure 8. The triple groove anchoring sleeves are already situated on the lead.

With a triple groove anchoring sleeve, all three grooves should be used with the following procedure (Figure 9).

- Partially insert the distal anchoring sleeve into the vein.
- **Use all three grooves to secure the anchoring sleeve to the lead body.**
- Use the most distal suture groove to secure the anchoring sleeve to the vein.
- Use the middle groove to secure the anchoring sleeve to the fascia and lead. First, create a base by looping a suture through the fascia underneath the middle groove and tying a knot. Continue by firmly wrapping the suture around the middle groove and tying a second knot.

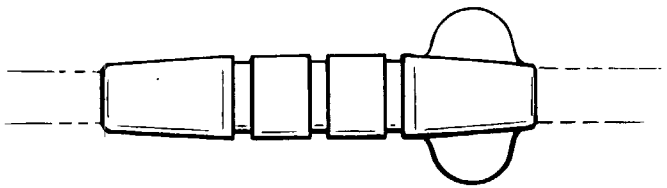

Figure 8. The triple groove anchoring sleeve.

CAUTION: Do not use the anchoring sleeve tabs for suturing.

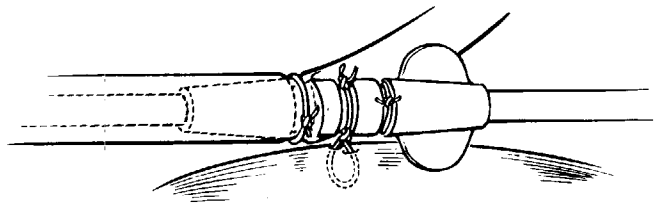

Figure 9. Triple groove anchoring sleeve secured to the lead and fascia using three grooves.

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 10a and 10b for instructions and illustrations showing lead connections to the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Insert the lead connector into the connector block. Refer to the tachyarrhythmia control device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

CAUTION: Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillation Electrodes	Two-Electrode System Connection Diagram
Medtronic® Model 7217B PCD™ Device	2	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE™-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE™-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the connector plug packaged with the pulse generator into the PULSE1 port. **PULSE2** Insert the lead connector of the TRANSVENE™-RV, -SVC, or -SQ lead into the PULSE2 port.

Figure 10b. Connections for three-electrode system leads (simultaneous or sequential pulse) into the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 11). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

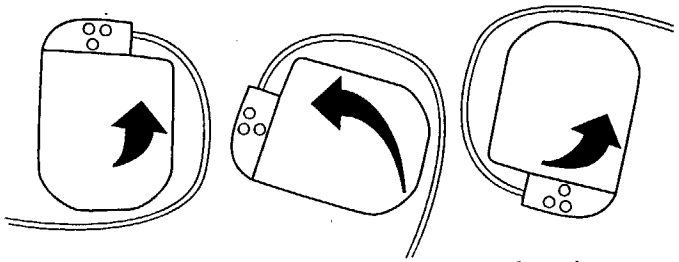

Figure 11. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 12).
- Do NOT grip the lead or pulse generator with surgical instruments.

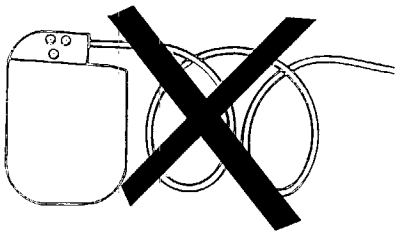

Figure 12. Do not coil or twist the lead body.

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

At the physician's discretion, X-rays may be taken every six months to verify proper lead position and to check for conductor fractures.

SPECIFICATIONS (Nominal)

PARAMETER		MODEL 6963
Type		Unipolar
Position		Coronary Sinus/Superior Vena Cava
Fixation		None. Tip lodges in the Coronary Sinus or is placed in the Superior Vena Cava
Length		20-110 cm
Connector		6.5 mm
Materials	Conductor:	Multifilar MP35N Composite
	Insulator:	Silicone
	Electrode:	Platinum Alloy

PARAMETER		MODEL 6963
Electrode Shadow Area	Coil:	360 mm^2
Electrode Surface Area	Coil:	90 mm^2 (5 cm)
Diameters	Body:	1.7 mm
	Electrode:	2.3 mm
Configuration	Electrode:	Coiled, 48 turns per inch
Unipolar Resistance		3.3 ohms
Lead Introducer (recommended size)		8.0 French

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications (including perforation of the heart) will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

For complete warranty information, see the accompanying card enclosed in the package.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

Service 20

DESCRIPTION AND INTENDED USE

The Medtronic® Model 6966 Tripolar, Endocardial, Screw-In Ventricular Lead is designed for pacing, sensing, and delivering cardioversion and defibrillation therapies. It is intended for single long-term use in the ventricle and is designed to be used only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead.

The TRANSVENE™-RV lead has a helical electrode made of platinum alloy that can be actively fixed in the endocardium. The helix can be extended or retracted by rotating the lead connector pin with a special fixation tool. Active fixation leads are particularly beneficial for patients who have smooth or hypertrophic hearts where lead dislodgement may be a potential problem.

The three electrodes of this lead are: coil, ring, and helix (Figure 1).

The defibrillating coil electrode is most proximal to the pulse generator and connects electrically to the connector PIN of the UNIPOLAR leg of the bifurcation. This UNIPOLAR leg will not accept a stylet.

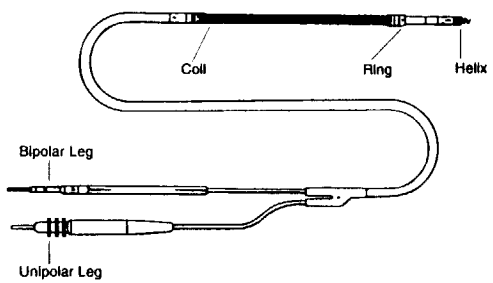

Figure 1. The three electrodes and two connector legs.

The ring electrode is proximal to the helix and connects electrically to the connector RING of the BIPOLAR leg of the bifurcation.

The helix tip electrode is most distal to the pulse generator and provides active fixation in the endocardium. It can be extended or retracted by rotating the lead connector PIN with a special fixation tool. The helix electrode connects electrically to the connector PIN of the BIPOLAR leg of the bifurcation. This BIPOLAR leg is the only one that will accept a stylet.

The coil electrode is intended to be used for delivery of cardioversion and defibrillation pulses. The helix tip electrode and the ring electrode may be used for bipolar

pacing and sensing; however, when used with standard bipolar PCD™ pulse generators, pacing occurs between the helix tip electrode and the coil electrode.

The lead's conductors are in a multifilar configuration and are insulated with polyurethane.

The lead has application where implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE™-RV lead with two non-radiopaque anchoring sleeves, stylet, and stylet guide
- 2 fixation tools
- 1 vein lifter
- Extra stylets
- Product literature

CONTRAINDICATIONS

When tricuspid valvular disease or a mechanical heart valve is present, use of a ventricular endocardial lead is contraindicated.

WARNINGS

Do not attempt to use this lead with a non-Medtronic Implantable Cardioverter/Defibrillator device.

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning"

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, and whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile surgical gloves that have been rinsed in sterile water or equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

The maximum number of revolutions of the electrode fixation tool needed to extend or retract the helix is 20. **Exceeding the maximum revolutions may damage the lead.**

Using an Anchoring Sleeve

Always use an anchoring sleeve with all leads to secure the lead from moving and to protect the lead insulation and conductor coil from damage. A second anchoring sleeve is provided for additional fixation.

Chronic Repositioning

Chronic repositioning or removal of screw-in leads may not be possible because of blood or fibrotic tissue development into the helix mechanism. Removal of the lead could result in avulsion of the endocardium, valve, or vein. In addition, the lead junctions may separate, leaving the lead tip and bare wire in the heart or vein. In most clinical situations, it is preferable to abandon unused leads in place.

However, if a lead must be removed or repositioned, proceed with extreme caution. If a helix does not disengage from the endocardium by rotating the connector pin, rotating the lead body counterclockwise may withdraw the helix and decrease the possibility of damage to the cardiovascular structures during removal.

If a lead is abandoned, it should be capped to avoid transmitting electrical signals from the pin to the heart. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section "Suggested Implantation Procedure."

POTENTIAL COMPLICATIONS

The potential complications related to the use of endocardial leads include, but are not limited to, the following patient-related conditions: fibrillation or other arrhythmias, air embolism, cardiac perforation, heart wall rupture, cardiac tamponade, pericardial rub, infection, myocarditis, constrictive pericarditis, pneumothorax, hemothorax, and tissue necrosis.

Other potential complications related to the lead system, but are not limited to the following: lead dislodgement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of detection, cardioversion, defibrillation, or pacing therapies.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable package and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55° C (130° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

The implantation procedure generally includes checking the mechanical functioning of the lead electrode before it is inserted; using a stylet guide, stylets, and vein lifter; selecting an insertion site; positioning the lead; securing the lead; taking electrical and defibrillation efficacy measurements; anchoring the lead; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition.

Opening the Package

Open the package according to the instructions. Inspect the lead. Remove the disc from the distal end of the lead. Verify that two anchoring sleeves are present.

Verifying the Mechanical Functioning of the Helix Electrode

Before implantation, verify the mechanical functioning of the electrode, as described below.

1. Within the sterile field, remove the lead and the accompanying stylets from the sterile packaging. The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin that accepts the stylet controls the helix mechanism.
2. To attach the fixation tool, first remove the stylet guide. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).

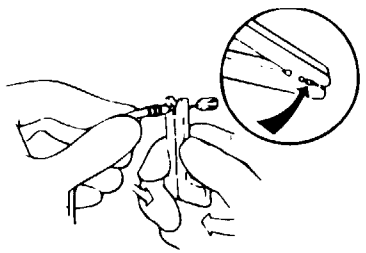

Figure 2. Attachment of the fixation tool to the connector pin.

3. Rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

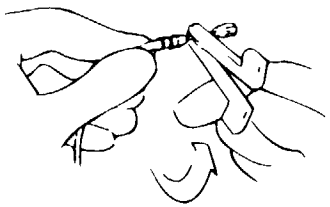

Figure 3. Rotating the fixation tool.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions may damage the lead.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the lead and its conductor coil to unwind.
5. After allowing the lead and its conductor coil to unwind, reattach the fixation tool and turn it counterclockwise until the helix tip is retracted in the sheath.

Using the Stylet Guide and Stylets

The lead is packaged with a stylet guide attached and a stylet already inserted. The connector pin with the stylet in it controls the helix mechanism. Use of the stylet guide is optional. An attached stylet guide may be removed by gently pulling it off. To attach a stylet guide, gently push it as far as possible onto the connector pin that accepts the stylet (Figure 4).

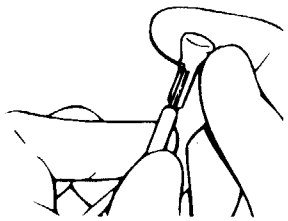

Figure 4. Stylet guide attachment.

A stylet provides additional stiffness and controlled flexibility for maneuvering the lead into position. Stylets vary in stiffness for different lead and stylet flexibility. Each stylet knob is etched with the stylet diameter and length.

If a slight curve is needed for the stylet, refer to instructions in the section titled "Positioning a Lead."

CAUTION: To avoid damage to the lead or body tissue, do not use excessive force or surgical instruments to insert a stylet into the lead. When handling a stylet, avoid overbending, kinking, or blood contact.

CAUTION: Repeated insertions of a stylet increases the chance that blood or other fluids may accumulate on it, which may cause difficulty in passing the stylet through the lead and may cause damage to the lead.

Selecting an Insertion Site

The lead may be inserted by venotomy through several different venous routes, including the right or left cephalic vein or the external or internal jugular vein.

CAUTION: Given the body diameter of transvenous defibrillation leads, insertion via a subclavian approach should be done as far lateral as possible to avoid clamping the lead body between the clavicle and the first rib (Figure 5). Clamping the lead can eventually cause the conductor to fracture, can cause damage to the insulation, or can cause other damage to the lead. This can result in complications such as loss of detection, loss of pacing therapies, or loss of cardioversion/defibrillation therapy. Certain anatomical abnormalities, such as thoracic outlet syndrome, can also precipitate pinching and subsequent fracture of the lead. If the subclavian approach is required, avoid techniques that can damage the lead. Specifically, do not force the lead if significant resistance is encountered. Do not use techniques such as adjusting the patient's posture (i.e., raising the arm or putting a towel behind the person's back) to facilitate the passage of the lead. If resistance is encountered, it is recommended that an alternate venous entry site be used, e.g., the cephalic vein.

Use fluoroscopy to facilitate accurate lead placement.

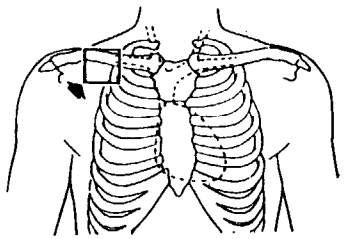

Figure 5. Insertion site.

Using the Vein Lifter

A vein lifter facilitates lead introduction. Insert its tapered end into the incised vein and gently push the lead tip underneath and into the vein (Figure 6).

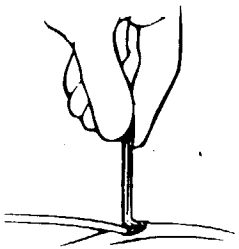

Figure 6. Using the vein lifter.

CAUTION: Avoid placing the lead under extreme tension or angulation to prevent lead dislodgement and possible lead fracture. **Do not grip the lead with surgical instruments.**

Positioning a Lead

Advance the lead into the right atrium. For added control in maneuvering the lead tip through the tricuspid valve, the distal end of the lead may be slightly curved by inserting a gently curved stylet (Figure 7). After the lead tip is passed into the ventricle, the curved stylet may be replaced with a straight stylet. The lead tip may then be advanced to the right ventricular apex while care is taken to avoid perforation of the ventricular wall.

CAUTION: To avoid damage to the stylet, do not use a sharp object to impart a curve to the distal end (Figure 7).

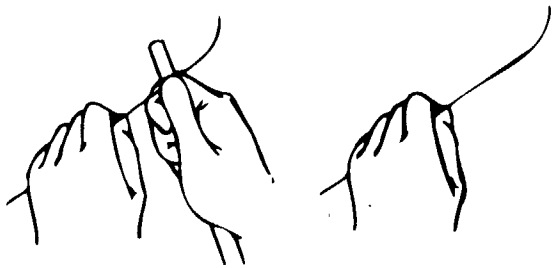

Figure 7. Imparting a curve to the stylet.

Accurate positioning of the electrode is essential for stable endocardial pacing. A satisfactory position is usually

achieved when the lead tip points straight toward the apex, or when the distal end dips or bends slightly.

Use fluoroscopy (lateral position) to ensure that the tip is not in a retrograde position or is not lodged in the coronary sinus.

After the stylet is inserted, gently remove the stylet guide so that it rests alongside the stylet knob.

Securing the Electrode into the Endocardium

The following procedure is recommended for electrode fixation:

1. Press both legs of the fixation tool together and place the most distal hole of the fixation tool on the connector pin that accepts the stylet (Figure 2).
2. Gently press the lead tip against the endocardium by pushing the stylet and the lead at the vein entry site. Then, rotate the tool clockwise until the coiled electrode is completely exposed (Figure 3). Maximum electrode exposure reveals 2 coils.

The maximum number of revolutions of the fixation tool needed to extend or retract the helix is 20.

CAUTION: Exceeding the maximum number of revolutions to extend or retract the helix may damage the lead.

3. Use fluoroscopy to verify helix electrode exposure. Closing of the space between the conductor (A) and the indicator ring (B) implies complete exposure of the helix electrode (Figure 8).

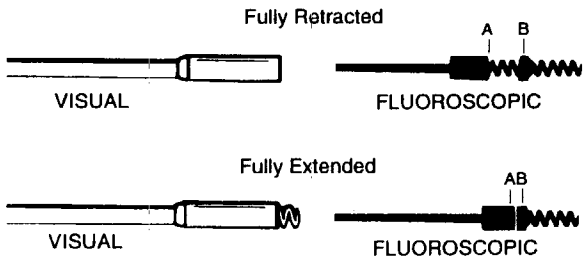

Figure 8. Possible views of the electrode.

4. Disconnect the fixation tool from the connector pin and release the proximal end of the lead body. Allow several seconds for the residual torque in the lead to be relieved.

5. After allowing the residual torque in the lead to be relieved, rotate the whole lead body clockwise approximately one revolution to ensure that the helical electrode is secured to the endocardium.

6. Carefully withdraw the stylet partially.

7. Obtain electrical measurements to verify satisfactory placement and electrode fixation. Refer to the following section, Taking Electrical and Defibrillation Efficacy Measurements, for recommended procedures and values.

8. Verify that the helix is affixed by gently pulling back on the lead and checking for resistance. A properly affixed helix will remain in position. If the helix is not properly affixed, the lead tip may become loose in the right ventricle.

9. If repositioning is required, reattach and rotate the fixation tool counterclockwise until the electrode is withdrawn. Use fluoroscopy to verify withdrawal. Repeat the procedure above.

CAUTION: When retracting the helix, do not rotate the fixation tool more than 20 revolutions. When the electrode is fully retracted, 2 coils of the helix will be visible between the indicator ring and the conductor.

10. Remove the stylet guide and stylet completely. When removing the stylet guide, grip the lead firmly just below the connector pin; this will help prevent possible lead dislodgement.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

In order to demonstrate reliable defibrillation efficacy, obtain final electrical measurements for the lead system.

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold		
(at 0.5 ms pulse width)	≤ 1.0 V - endocardial	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≤ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

Anchoring the Lead

Do not secure the ligatures so tightly that they damage the vein, lead, or anchoring sleeve. Do not tie a ligature directly to the lead body (Figure 9). During anchoring, take care to avoid dislodging the lead tip.

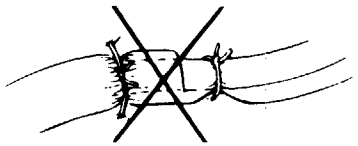

Figure 9. Do NOT secure the sutures too tightly and do NOT tie a suture to the lead body.

Use an anchoring sleeve to secure the lead from moving and to protect the lead insulation and conductor coil from damage caused by tight ligatures. A second anchoring sleeve may be placed in the tunnel entry site or in the pocket area for additional fixation.

Anchor the lead with nonabsorbable sutures.

TRANSVENE™-RV uses a triple groove anchoring sleeve illustrated in Figure 10. The triple groove anchoring sleeves are situated at the connector end of the lead.

Figure 10. The triple groove anchoring sleeve.

With a triple groove anchoring sleeve, all three grooves should be used with the following procedure (Figure 11):

- Partially insert the distal anchoring sleeve into the vein.
- **Use all three grooves to secure the anchoring sleeve to the lead body.**
- Use the most distal suture groove to secure the anchoring sleeve to the vein.

- Use the middle groove to secure the anchoring sleeve to the fascia and lead. First, create a base by looping a suture through the fascia underneath the middle groove and tying a knot. Continue by firmly wrapping the suture around the middle groove and tying a second knot.

CAUTION: Do not use the anchoring sleeve tabs for suturing.

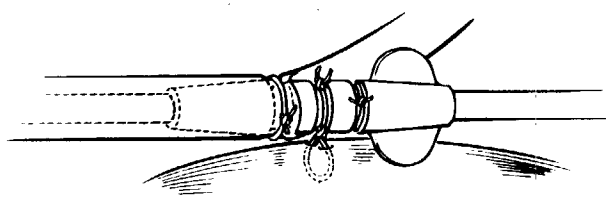

Figure 11. Triple groove anchoring sleeve secured to the lead and fascia using three grooves.

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 12a and 12b for instructions and illustrations showing lead connections to the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Insert the lead connector into the connector block. Refer to the tachyarrhythmia control device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

CAUTION: Always remove the stylet before connecting the lead to the pulse generator. Failure to remove the stylet may result in lead failure.

Tachyarrhythmia Control Device Model	Number of Implanted Defibrillation Electrodes	Two-Electrode System Connection Diagram

Figure 12b. Connections for three-electrode system leads (simultaneous or sequential pulse) into the Medtronic® PCD™ Tachyarrhythmia Control Device 7217B.

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 13). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

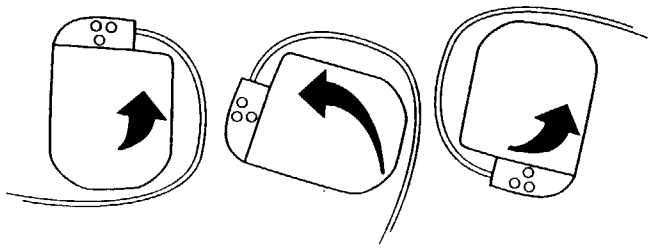

Figure 13. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 14).
- Do NOT grip the lead or pulse generator with surgical instruments.

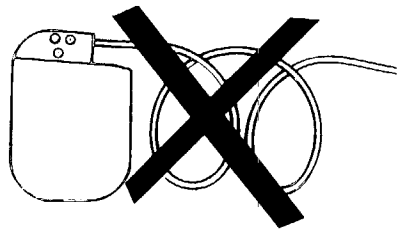

Figure 14. Do not coil or twist the lead body.

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

At the physician's discretion, X-rays may be taken every six months to verify proper lead position and to check for conductor fractures.

	Insulator:	Polyurethane
	Electrode:	Platinum Alloy
Electrode Surface Area	Helix:	10 mm^2
	Ring:	37 mm^2
	Coil:	426 mm^2 (5 cm length)
Electrode Shadow Area		448 mm^2

PARAMETER		MODEL 6966
Diameters	Body:	3.3 mm
	Helix:	1.6 mm
	Maximum Head:	3.5 mm
Helix Length (fully extended)		2 mm
Conductor Resistances	Pacing:	45 ohms (unipolar) 190 ohms (bipolar)
	Defibrillation:	3.5 ohms
Lead Introducer (recommended size)		11 French
Maximum Revolutions that can be used to extend or retract the helix when using a straight style		20

GENERAL WARNING

Medtronic® implantable leads are implanted in the extremely hostile environment of the human body. Leads are necessarily very small in diameter and must still be very flexible, which unavoidably reduces their potential performance or longevity. Leads may fail to function for a variety of causes, including, but not limited to: medical complications, body rejection phenomena, allergic reaction, fibrotic tissue, or failure of leads by breakage or by breach of their insulation covering. In addition, despite the exercise of all due care in design, component selection, manufacture, and testing prior to sale, leads may be easily damaged before, during, or after insertion by improper handling or other intervening acts. Consequently, no representation or warranty is made that failure or cessation of function of leads will not occur or that the body will not react adversely to the implantation of leads or that medical complications (including perforation of the heart) will not follow the implantation of leads or that the lead will, in all cases, restore adequate cardiac function.

SERVICE

Medtronic employs highly trained representatives and engineers located throughout the world to serve you and, upon request, to provide training to qualified hospital personnel in the use of Medtronic products. In addition, Medtronic maintains a professional staff of consultants to provide technical and medical consultation to product users. For supplemental information, contact your local Medtronic representative, or call or write Medtronic at the appropriate address or telephone number listed on the back cover.

DESCRIPTION AND INTENDED USE

The Medtronic® TRANSVENE™-SQ Model 6999 Unipolar, Subcutaneous, Oval Patch Lead is designed for the delivery of cardioversion and defibrillation therapies. It is intended for single long-term use only with a compatible Medtronic implantable tachyarrhythmia control device along with at least one other Medtronic defibrillation lead. A third Medtronic defibrillation lead may also be used.

The lead features a low resistance conductor coil and platinum alloy electrode coils for cardioversion and defibrillation therapies. The outer edge of the lead is used for suturing. The lead also has a 6.5 mm unipolar connector.

There are 3 nodes on one side of the patch, and 2 nodes at the junction of the lead body and patch electrode. These nodes are intended to mark the insulated side of the patch electrode.

The lead has application for patients in which implantable tachyarrhythmia cardioversion or defibrillation systems are indicated.

CONTENTS OF PACKAGE

The leads are supplied sterile. Each package contains:

- 1 TRANSVENE™-SQ lead
- Product literature

CONTRAINDICATIONS

There are no known contraindications for this lead.

WARNINGS

Do not attempt to use this lead with a non-Medtronic Implantable Cardioverter/Defibrillator device.

Use only battery-powered equipment during lead implantation and testing to protect against fibrillation that may be caused by alternating currents. Line-powered equipment used in the vicinity of the patient must be properly grounded. Lead connector pins must be insulated from any leakage currents that may arise from line-powered equipment.

See also the section titled "General Warning"

PRECAUTIONS

Necessary Hospital Equipment

Defibrillation equipment should be kept nearby for immediate use during the acute lead system testing, implantation procedure, or whenever arrhythmias are possible or intentionally induced during post-implant testing.

Inspecting the Package

Carefully inspect the lead sterile package prior to opening; if the seal or package is damaged, contact your local Medtronic representative.

Handling the Lead

Leads should be handled with great care at all times. **Any severe bending, kinking, stretching, or handling with surgical instruments may cause permanent damage to the lead.**

Lead insulators attract small particles such as lint and dust. Therefore, protect the lead from materials shedding these substances. Handle the lead with sterile surgical gloves that have been rinsed in sterile water or the equivalent.

Do not immerse leads in mineral oil, silicone oil, or any other liquid.

Chronic Repositioning

Chronic repositioning or removal of the lead may be difficult because of the fibrotic tissue. **However, if a lead must be removed or repositioned, proceed with extreme caution.** If a lead is abandoned, it should be capped to avoid transmitting electrical signals. Return all removed or unused leads or portions thereof to Medtronic.

See additional cautions in the section titled "Suggested Implantation Procedure."

POTENTIAL COMPLICATIONS

The potential complications related to the use of subcutaneous patch leads include, but are not limited to, the following patient-related conditions: serous fluid accumulation around the patch; infection; and bleeding after placement, after repositioning, or if sutures tear out.

Other potential complications related to the lead system, but are not limited to the following: lead displacement, lead conductor or electrode fracture, insulation failure, and poor connection which may lead to loss of cardioversion and defibrillation therapies.

ENSURING PRODUCT INTEGRITY

Carefully inspect the sterile package before opening. It is not recommended that you use the product after its expiration date.

If the integrity of the sterile package has been compromised prior to the product expiration date, place the contents in a gas-permeable bag and resterilize them with ethylene oxide as described below.

CAUTION: Use ethylene oxide only. Do not resterilize more than one time.

The process should not exceed temperatures of 55° C (130° F). Allow proper aeration of ethylene oxide residues prior to implantation. Use some acceptable method to determine sterilizer effectiveness, such as a biological indicator.

Due to the variability between sterilizers, precise sterilization instructions cannot be provided. Contact your sterilizer manufacturer for more information regarding sterilization procedures.

SUGGESTED IMPLANTATION PROCEDURE

General Instructions

The implantation procedure generally includes selecting an insertion site; positioning the lead; taking electrical and defibrillation efficacy measurements; tunneling the lead; connecting the lead to the pulse generator; and closing the pocket.

Some implantation techniques vary according to physician preference and the patient's anatomy or physical condition.

Opening the Package

Open the package according to the instructions. Inspect the lead. Remove the disc from the distal end of the lead. Verify that two anchoring sleeves are present.

Positioning a Lead

The recommended starting position for the TRANSVENE™-SQ subcutaneous patch lead is along the left chest near the heart. The patch may be repositioned, if necessary, to meet the implant defibrillation efficacy criteria outlined in the following section. The subcutaneous patch may be placed subcutaneously, submuscularly, or directly on the periosteum of the ribs. The patch may be repositioned on the left lateral chest wall, if necessary, to meet the implant defibrillation efficacy criteria.

Place sutures through the outer edge of the patch electrode. It is recommended that two or more sutures be used for fixation.

CAUTION: The patch must be placed such that the nodes are facing away from the heart.

Taking Electrical Measurements and Defibrillation Efficacy Measurements

In order to demonstrate reliable defibrillation efficacy, obtain final electrical measurements for the lead system.

Initial electrical measurements may deviate from the recommendations because of acute cellular trauma. If this occurs, wait five to fifteen minutes and repeat the testing procedure. Values may vary depending upon lead type, pulse generator settings, cardiac tissue condition, and drug interactions. If electrical measurements do not stabilize to acceptable levels, it may be necessary to reposition the lead and repeat the testing procedure.

For more information on obtaining electrical measurements, consult the technical manual supplied with the testing device.

Recommended Pacing/Sensing Measurements at Implant
(when using a pacing system analyzer)

Measurements Required	Acute Lead System	Chronic Lead System
Capture threshold	≤ 1.5 V Epicardial	≤ 3.0 V
(at 0.5 ms pulse width)	≤ 1.0 V - endocardial	≤ 3.0 V
Impedance	200 - 800 ohms	200 - 800 ohms
Filtered R-wave amplitude	≤ 5 mV (during sinus rhythm)	≥ 3 mV (during sinus rhythm)
Slew rate	≥ 0.75 V/s	≥ 0.45 V/s

6999 900[illegible]EN 195420-003/MMC 6/8/93 11:36 PM Page 6

Tunneling the Lead

Before tunneling the lead connector, record each lead's serial number along with the function of the lead. Use of a chest tube is suggested in tunneling the lead connector to the pulse generator to prevent damage to the lead. Tunnel the lead subcutaneously to the pulse generator pocket.

Connecting the Lead to a Tachyarrhythmia Device

Refer to Figures 1a and 1b for instructions and illustrations showing lead connections to the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

CAUTION: Do not use surgical instruments to grasp the lead or connector pin when tunneling.

Insert the lead connector into the connector block. Refer to the tachyarrhythmia control device technical manual for the use of setscrews and setscrew tools.

Before closing the pocket, verify sensing, pacing, and defibrillation efficacy.

Medtronic® Model 7217B PCD™ Device	3	**PACE/SENSE, SENSE2** Insert the Pace/Sense lead connector of the TRANSVENE™-RV into the PACE/SENSE, SENSE2 port. **COMMON** Insert the unipolar lead connector of the TRANSVENE™-RV, -SVC, or -SQ into the COMMON port.  **PULSE1** Insert the lead connector of the TRANSVENE™-RV, -SVC, or -SQ lead into the PULSE1 port. **PULSE2** Insert the lead connector of the TRANSVENE™-RV, -SVC, or -SQ lead into the PULSE2 port.

Figure 1b. Connections for three-electrode system leads (simultaneous or sequential pulse) into the Medtronic® PCD™ Tachyarrhythmia Control Device Model 7217B.

Closing the Pocket

To prevent undesirable twisting of the lead body, wrap the excess lead length loosely under the pulse generator and place both into the subcutaneous pocket (Figure 2). Ensure that the leads do not leave the pulse generator at an acute angle. Sharp angles place undue stress on the lead conductor and insulation.

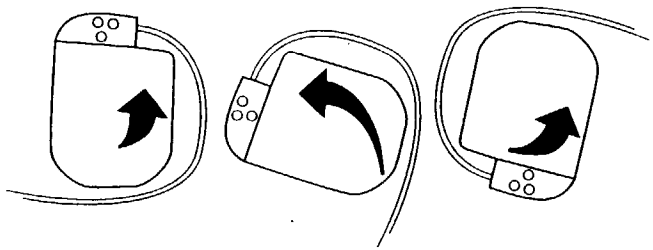

Figure 2. While rotating the pulse generator, loosely wrap the excess lead length and place it under the pulse generator.

To reduce the potential for abrasion on the lead body, it is recommended the PCD be placed in a Parsonnet pouch.

When placing the pulse generator and leads into the subcutaneous pocket:

- Do NOT coil the lead. Coiling the lead can twist the lead body and may result in lead dislodgement (Figure 3).
- Do NOT grip the lead or pulse generator with surgical instruments.

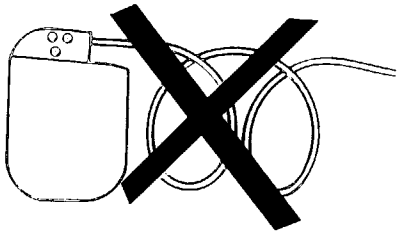

Figure 3. Do not coil or twist the lead body.

After implantation, monitor the patient's electrocardiogram continuously. If a lead dislodges, it usually occurs during the immediate postoperative period.

At the physician's discretion, X-rays may be taken every six months to verify proper lead position and to check for conductor fractures.

SPECIFICATIONS (Nominal)

PARAMETER		MODEL 6999
Type		Unipolar
Position		Subcutaneous chest wall
Fixation		Sutures (may be placed through the outer edge of the patch body)

The Model 7217B PCD Technical Manual has been modified to incorporate the use of Transvene leads.

See section beginning on page 44, Placing Transvene Leads, through page 48.

In addition, the Defibrillation Efficacy Testing section reflects a modified implant criteria consistent with the clinical data, see page 47, Figure 22.

APPENDIX H

EDUCATION OUTLINE:
TRANSVENE PCD IMPLANT

USER EDUCATION PLAN

CONTENT OUTLINE

Medtronic Transvene Lead System

Note: The hours and depth of training will vary based on the experience of the health care professional with the PCD system and transvenous leads.

I. Implant and Expectation Aspects

A. How to access vein

B. Avoiding crush and dislodgements

C. Management of dislodgements

D. Lead Extraction

II. Overview of the Transvene Leads

A. Right Ventricular lead

- Review pacing and sensing measurements
- Lead placement
- Chronic repositioning

B. Superior Vena Cava Lead

- Lead placement options and anchoring

C. Coronary Sinus Lead

- Placement and anchoring

D. Subcutaneous Patch

- Placement options dependent on placement of other leads for optimum defibrillation vectors

III. Implant Procedure

A. Review of Implant steps
- Preprogram PCD in package, set up ETCD and connect to hospital recording/monitoring equipment.
- Place leads and test lead system integrity
- Perform defib efficacy protocol
- Connect PCD and test with lead system

B. Recommended implant criteria for defibrillation efficacy testing.

C. Options if implant criteria is not met
   - Change lead positions
   - Change tilt
   - Change pathways

D. Induction Methods

E. Recommendations for Rescue

F. Hybrid systems
   - Approved/recommended systems
   - When to use

Materials

Workbook with outlines for lecture and discussion
Video demonstrating lead placement options for maximum defib efficacy

Deficiency Responses

P920015/ACIV4

1. **Discuss how the use of a silicone adhesive prevents tissue in-growth in the Model 6963 lead. Where is the adhesive placed? From experience, discuss the use of polyurethane and silicone in leads to prevent tissue in-growth.**

RESPONSE:

The Model 6963 lead has a tight wound electrode coil made of platinum wire. When the lead is constructed, a piece of silicone tubing is fit under the electrode coil. This separates the electrode coil from the conductor coil and prevents fluid penetration from the outside of the lead to the conductor coil, thus permitting free passage of the stylet. The silicone tubing also enhances alignment of the electrode coil. After the electrode coil and silicone tubing are assembled, silicone adhesive is applied between the tight windings of the electrode coil. The silicone adhesive bonds to the silicone tubing and forms a filler between each winding of electrode coil. This filler is intended to minimize the possibility of tissue-growth by filling in some of the space between the electrode coil windings and by eliminating any space between the electrode coil and the silicone tubing underneath.

Medtronic has used both polyurethane and silicone for many years as insulative materials and as fillers for pacing leads. Both polyurethane and silicone perform as well as insulators and as fillers, to discourage tissue in-growth by eliminating gaps. Generally, silicone fillers are used with silicone leads, and urethane fillers are used with urethane leads. This is for ease of manufacturing and is not a requirement, as silicone fillers can be used with urethane leads, and urethane fillers can be used with silicone leads.

2

2. **Please provide the results of mutagenicity testing for the (b)(4) (anchor sleeve). If the tests have not been done please provide a justification for not doing so.**

RESPONSE:

The Model 6999 unipolar patch lead is intended for use subcutaneously, submuscularly, or directly on the periosteum of the ribs. A (b)(4) (The description of the Model 6999 contained in the "Nonclinical Laboratory Testing" on page 482 (of the PMA) inadvertently stated that the (b)(4) covers the patch; actually, (b)(4) and not directly exposed to body tissue or fluids. Note that the Device Description provided on page 93 of the PMA is correct.)

The (b)(4) was not tested by itself because adequate data exists to demonstrate that it is non-mutagenic. Specifically, Ames Mutagenicity testing was performed on the Model 6921L lead. The Model 6921L is a large epicardial patch lead with (b)(4) embedded in the outer (b)(4) inch perimeter of the silicone patch. This is identical to the (b)(4) in the 6999 lead.

The anchoring sleeve on the Transvene leads is comprised of molded silicone rubber/titanium dioxide. The anchoring sleeve was subjected to mutagenicity testing in conjunction with the transvenous leads. A description of the test and results are as follows.

Ames Mutagenicity

(b)(4)

(b)(4)

The lead Model 6921L and anchoring sleeve were extracted in both (b)(4) and (b)(4) All extracts were tested and results show the materials to be non-mutagenic.

3. **Provide a description of the helix electrode fixation tool and of the tests to verify the torsional force for implanting the helix electrode.**

RESPONSE:

The fixation tool is an injection molded tool made of (b)(4) material. The tool depends on the resiliency of the (b)(4) material to apply a consistent gripping force (hence consistent torque) to the connector pin during rotation. The tool is specified to meet a (b)(4) minimum torque output requirement. The tool was tested and qualified to meet this requirement.

The 6884/6966 lead is specified to fully extend and retract the helix mechanism within (b)(4) connector pin revolutions. Testing completed on the 6884/6966 lead shows that an average of (b)(4) is required to rotate the connector pin of the device (b)(4) revolutions. The labeling (Technical Manual) calls out (b)(4) turns maximum to fully extend the mechanism. The (b)(4) turn specification was qualified (b)(4) (b)(4) Each lead manufactured is tested to this requirement.

Extensive experience with bradycardia pacing leads using the identical helix electrode mechanism shows that the number of rotations required to implant the electrode is virtually identical to the number required to extend the helix in-vitro. Furthermore, testing in canines has shown the number of connector pin rotations to be well within the (b)(4) turns specified.

4. Based on your experience, identify the minimum number of flex cycles that a lead should withstand. Also, give the stress level exerted on the Model 6907 lead (from which the median failure time of (b)(4) cycles was observed), and on the Transvene™ leads.

RESPONSE:

Medtronic developed a test protocol which provides a uniform, accelerated method for evaluating lead bodies in terms of the flexural fatigue life of the conductor. This test is used for evaluation and qualification of new lead designs, inclusive of bradycardia pacing and cardioversion/defibrillation leads.

Test Method/Equipment

(b)(4)

(b)(4)

Sample Size/Configuration

(b)(4)

(b)(4)

Pass/Fail Criteria

(b)(4)

(b)(4)

5

For the purpose of data reporting, Medtronic has historically compared lead flex life to the Model 6907. This is the basis for the (b)(4) cycles flex life design requirement. The Model 6907 is a unipolar, silicone, endocardial lead. The Model 6907 has more than 20 years of field experience. Of approximately (b)(4) sold, only (b)(4) coil fractures have been reported in this time (b)(4) Therefore, any lead with flex life equal to or greater than the Model 6907 is considered safe and effective for its intended use.

Endocardial leads experience flexure, especially where the lead is tied or clamped, at a suture site or where it is held between two bones, i.e., first rib and clavicle. Both pacing and cardioversion/defibrillation endocardial leads experience this flexure, as the insertion site and implant technique are equivalent. Thus, the test that is used to evaluate lead body flex life is applicable to both pacing leads and cardioversion/defibrillation leads.

5. **Since the electrode coil is flexed separately from the insulated conductor, discuss the reliability of the section where the electrode is coaxial to the conductor. Is there friction between the electrode and the conductor when the section is flexed?**

RESPONSE:

Both the insulated lead body (conductor coil(s) and insulation(s)) and the non-insulated defibrillation electrode portion of lead Models 6963, 6966 and 6999 were flexed during the Lead System Life Test.

Per the test protocol, the insulated lead body and the non-insulated defibrillation electrode portion of lead Models 6963, 6966 and 6999 were flexed (b)(4) cycles at each of (b)(4) monitors, for a total of (b)(4) flex cycles. All three lead Models met this requirement and were fully functional at the completion of the (b)(4) long test.

Model 6999 leads were not specifically tested beyond the life test requirement of (b)(4) cycles as this has been completed via similarity to the Model 6921 patch lead. The design of the lead Model 6999 is functionally equivalent to the Model 6921 epicardial lead which has demonstrated an electrode flex life in excess of (b)(4) (b)(4) cycles.

(b)(4) Model 6966 and (b)(4) Model 6963 leads were flexed beyond the test requirement of (b)(4) cycles. (b)(4) Model 6921S/L leads were also flexed following completion of the Lead System Life Test run on epicardial leads. The data for the defibrillation electrode segment of each lead model tested at a (b)(4) inch radius is as follows:

Model 6963	Model 6966	Model 6999 (6921S/L)
(b)(4)		

(b)(4)

A coaxial design is used in lead Models 6963 and 6966. The layer of insulation between the conductor coil and the defibrillation coil does offer support to the design, serving to separate the two coils. Since there is no contact there is no friction between the conductor and electrode coils.

6. **The Model 6999's (b)(4) electrode coil fails at a much lower flex cycle than the (b)(4) electrode coil. Discuss the reliability of the (b)(4) (b)(4) electrode coil, and the effects of its failure on the performance of the lead.**

7. **Please discuss how patient treatment is affected if one or two of the electrode coils of the Model 6999 patch lead becomes damaged.**

RESPONSE:

These deficiencies are addressed together due to similarity.
