

Macroeconomic Activity Module

THIS PAGE INTENTIONALLY LEFT BLANK

The Macroeconomic Activity Module (MAM) represents interactions between the U.S. economy and energy markets. The rate of growth of the economy, measured by the growth in gross domestic product (GDP), is a key determinant of growth in the demand for energy. Associated economic factors, such as interest rates and disposable income, strongly influence various elements of the supply and demand for energy. At the same time, reactions to energy markets by the aggregate economy, such as a slowdown in economic growth resulting from increasing energy prices, are also reflected in this module. A detailed description of the MAM is provided in the EIA publication, Model Documentation Report: Macroeconomic Activity Module (MAM) of the National Energy Modeling System, (2012), (Washington, DC, October 2012).

Key assumptions

The output of the U.S. economy, measured by GDP, is expected to increase by 2.5 percent between 2011 and 2040 in the Reference case. Two key factors help explain the growth in GDP: the growth rate of nonfarm employment and the rate of productivity change associated with employment. As Table 2.1 indicates, in the Reference case, real GDP grows by 2.5 percent for the next ten years and 2.4 percent growth for the final fifteen years of the projection. Both the high and low macroeconomic growth cases show roughly 0.5 percentage point differences in growth as compared to the Reference case. Non-farm employment shows higher growth in the first five years of the projection period and then returns to its long-run trend growth. In the Reference case, nonfarm employment grows by 1.0 percent from 2011 to 2040 as compared to 1.2 percent and 0.8 percent in the High Growth and Low Growth cases, respectively. In the Reference case, productivity (measured as output per hour in nonfarm businesses) grows by 1.9 percent from 2011 to 2040; showing slower growth than the 2.0 percent growth experienced during the previous 30 years. Business fixed investment as a share of nominal GDP is expected to grow over the last 10 years of the projection. The resulting growth in the capital stock and the technology base of that capital stock helps to sustain productivity growth of 1.9 percent from 2011 to 2040.

The Census Bureau's middle series population projection is used as a basis for population growth in the AEO2013. Total population is expected to grow by 0.9 percent per year between 2011 and 2040, and the share of population over 65 is expected to increase over time. However, the share of the labor force in the population over 65 is also projected to increase in the projection period.

To achieve the Reference case's long-run 2.5 percent economic growth, there is an anticipated steady growth in labor productivity. The improvement in labor productivity reflects the positive effects of a growing capital stock as well as technological change over time. Nonfarm labor productivity is expected to remain between 1.7 and 2.2 percent for the remainder of the projection period from 2015 through 2040.

Table 2.1. Growth in gross domestic product, nonfarm employment and productivity

Assumptions	2011-2015	2015-2025	2025-2040	2011-2040
Real GDP (Billion Chain-Weighted \$2005)				
High Growth	2.7%	3.2%	2.7%	2.9%
Reference	2.5%	2.6%	2.4%	2.5%
Low Growth	2.0%	1.7%	2.1%	1.9%
Nonfarm Employment				
High Growth	1.7%	1.3%	0.9%	1.1%
Reference	1.6%	0.9%	0.8%	1.0%
Low Growth	1.3%	0.9%	0.7%	0.8%
Productivity				
High Growth	1.0%	2.2%	2.2%	2.1%
Reference	0.9%	2.0%	2.0%	1.9%
Low Growth	0.6%	1.4%	1.7%	1.4%

Source: U.S. Energy Information Administration, AEO2013 National Energy Modeling system runs: AEO2013.d102312A, LM2013.d110912A, and HM2013.d110912A.

To reflect uncertainty in the projection of U.S. economic growth, the *AEO2013* uses High and Low Economic Growth cases to project the possible impacts of alternative economic growth assumptions on energy markets. The High Economic Growth case incorporates higher population, labor force and productivity growth rates than the Reference case. Due to the higher productivity gains, inflation and interest rates are lower than the Reference case. Investment, disposable income and industrial production are greater. Economic output is projected to increase by 2.9 percent per year between 2011 and 2040. The Low Economic Growth case assumes lower population, labor force, and productivity gains, with resulting higher prices and interest rates and lower industrial output growth. In the Low Economic Growth case, economic output is expected to increase by 1.9 percent per year over the projection horizon.
