Carlos M. Gutierrez, Secretary

National Institute of Standards and Technology
Patrick Gallagher, Acting Director

FOREWORD

The Federal Information Processing Standards Publication Series of the National Institute of Standards and Technology (NIST) is the official series of publications relating to standards and guidelines adopted and promulgated under the provisions of the Federal Information Security Management Act (FISMA) of 2002.

Comments concerning FIPS publications are welcomed and should be addressed to the Director, Information Technology Laboratory, National Institute of Standards and Technology, 100 Bureau Drive, Stop 8900, Gaithersburg, MD 20899-8900.

Cita Furlani, Director
Information Technology Laboratory

Abstract

This standard specifies five hash algorithms that can be used to generate digests of messages. The digests are used to detect whether messages have been changed since the digests were generated.

Key words: computer security, cryptography, message digest, hash function, hash algorithm, Federal Information Processing Standards, Secure Hash Standard.

October 2008

Announcing the

SECURE HASH STANDARD

Federal Information Processing Standards Publications (FIPS PUBS) are issued by the National Institute of Standards and Technology (NIST) after approval by the Secretary of Commerce pursuant to Section 5131 of the Information Technology Management Reform Act of 1996 (Public Law 104-106), and the Computer Security Act of 1987 (Public Law 100-235).

1. **Name of Standard**: Secure Hash Standard (SHS) (FIPS PUB 180-3).

2. **Category of Standard**: Computer Security Standard, Cryptography.

3. **Explanation**: This Standard specifies five secure hash algorithms - SHA-1, SHA-224, SHA-256, SHA-384, and SHA-512 - for computing a condensed representation of electronic data (message). When a message of any length less than 2^{64} bits (for SHA-1, SHA-224 and SHA-256) or less than 2^{128} bits (for SHA-384 and SHA-512) is input to a hash algorithm, the result is an output called a message digest. The message digests range in length from 160 to 512 bits, depending on the algorithm. Secure hash algorithms are typically used with other cryptographic algorithms, such as digital signature algorithms and keyed-hash message authentication codes, or in the generation of random numbers (bits).

The five hash algorithms specified in this Standard are called secure because, for a given algorithm, it is computationally infeasible 1) to find a message that corresponds to a given message digest, or 2) to find two different messages that produce the same message digest. Any change to a message will, with a very high probability, result in a different message digest. This will result in a verification failure when the secure hash algorithm is used with a digital signature algorithm or a keyed-hash message authentication algorithm.

This Standard supersedes FIPS 180-2 [FIPS 180-2].

4. **Approving Authority**: Secretary of Commerce.

5. **Maintenance Agency**: U.S. Department of Commerce, National Institute of Standards and Technology (NIST), Information Technology Laboratory (ITL).

6. **Applicability**: This Standard is applicable to all Federal departments and agencies for the protection of sensitive unclassified information that is not subject to Title 10 United States Code

Section 2315 (10 USC 2315) and that is not within a national security system as defined in Title 44 United States Code Section 3502(2) (44 USC 3502(2)). This standard shall be implemented whenever a secure hash algorithm is required for Federal applications, including use by other cryptographic algorithms and protocols. The adoption and use of this Standard is available to private and commercial organizations.

7. Specifications: Federal Information Processing Standard (FIPS) 180-3, Secure Hash Standard (SHS) (affixed).

8. Implementations: The secure hash algorithms specified herein may be implemented in software, firmware, hardware or any combination thereof. Only algorithm implementations that are validated by NIST will be considered as complying with this standard. Information about the validation program can be obtained at http://csrc.nist.gov/groups/STM/index.html.

9. Implementation Schedule: Guidance regarding the testing and validation to FIPS 180-3 and its relationship to FIPS 140-2 can be found in IG 1.10 of the Implementation Guidance for FIPS PUB 140-2 and the Cryptographic Module Validation Program at http://csrc.nist.gov/groups/STM/cmvp/index.html.

10. Patents: Implementations of the secure hash algorithms in this standard may be covered by U.S. or foreign patents.

11. Export Control: Certain cryptographic devices and technical data regarding them are subject to Federal export controls. Exports of cryptographic modules implementing this standard and technical data regarding them must comply with these Federal regulations and be licensed by the Bureau of Export Administration of the U.S. Department of Commerce. Information about export regulations is available at: http://www.bis.doc.gov/index.htm.

12. Qualifications: While it is the intent of this Standard to specify general security requirements for generating a message digest, conformance to this Standard does not assure that a particular implementation is secure. The responsible authority in each agency or department shall assure that an overall implementation provides an acceptable level of security. This Standard will be reviewed every five years in order to assess its adequacy.

13. Waiver Procedure: The Federal Information Security Management Act (FISMA) does not allow for waivers to Federal Information Processing Standards (FIPS) that are made mandatory by the Secretary of Commerce.

14. Where to Obtain Copies of the Standard: This publication is available electronically by accessing http://csrc.nist.gov/publications/. Other computer security publications are available at the same web site.

**Federal Information
Processing Standards Publication 180-3**

Specifications for the

SECURE HASH STANDARD

Table of Contents

1. INTRODUCTION

This Standard specifies five secure hash algorithms, SHA-1, SHA-224, SHA-256, SHA-384, and SHA-512. All five of the algorithms are iterative, one-way hash functions that can process a message to produce a condensed representation called a *message digest*. These algorithms enable the determination of a message's integrity: any change to the message will, with a very high probability, result in a different message digest. This property is useful in the generation and verification of digital signatures and message authentication codes, and in the generation of random numbers or bits.

Each algorithm can be described in two stages: preprocessing and hash computation. Preprocessing involves padding a message, parsing the padded message into m-bit blocks, and setting initialization values to be used in the hash computation. The hash computation generates a *message schedule* from the padded message and uses that schedule, along with functions, constants, and word operations to iteratively generate a series of hash values. The final hash value generated by the hash computation is used to determine the message digest.

The five algorithms differ most significantly in the security strengths that are provided for the data being hashed. The security strengths of these five hash functions and the system as a whole when each of them is used with other cryptographic algorithms, such as digital signature algorithms and keyed-hash message authentication codes, can be found in [SP 800-57] and [SP 800-107].

Additionally, the five algorithms differ in terms of the size of the blocks and words of data that are used during hashing. Figure 1 presents the basic properties of these hash algorithms.

Algorithm	Message Size (bits)	Block Size (bits)	Word Size (bits)	Message Digest Size (bits)
SHA-1	$< 2^{64}$	512	32	160
SHA-224	$< 2^{64}$	512	32	224
SHA-256	$< 2^{64}$	512	32	256
SHA-384	$< 2^{128}$	1024	64	384
SHA-512	$< 2^{128}$	1024	64	512

Figure 1: Secure Hash Algorithm Properties

2. DEFINITIONS

2.1 Glossary of Terms and Acronyms

Bit   A binary digit having a value of 0 or 1.

Byte   A group of eight bits.

FIPS   Federal Information Processing Standard.

NIST   National Institute of Standards and Technology.

SHA   Secure Hash Algorithm.

SP   Special Publication

Word   A group of either 32 bits (4 bytes) or 64 bits (8 bytes), depending on the secure hash algorithm.

2.2 Algorithm Parameters, Symbols, and Terms

2.2.1 Parameters

The following parameters are used in the secure hash algorithm specifications in this Standard.

a, b, c, ..., h   Working variables that are the *w*-bit words used in the computation of the hash values, $H^{(i)}$.

$H^{(i)}$ The ith hash value. $H^{(0)}$ is the *initial* hash value; $H^{(N)}$ is the *final* hash value and is used to determine the message digest.

$H_j^{(i)}$ The jth word of the ith hash value, where $H_0^{(i)}$ is the left-most word of hash value *i*.

K_t Constant value to be used for the iteration *t* of the hash computation.

k   Number of zeroes appended to a message during the padding step.

ℓ Length of the message, *M*, in bits.

m   Number of bits in a message block, $M^{(i)}$.

M   Message to be hashed.

$M^{(i)}$	Message block i, with a size of m bits.
$M_j^{(i)}$	The jth word of the ith message block, where $M_0^{(i)}$ is the left-most word of message block i.
n	Number of bits to be rotated or shifted when a word is operated upon.
N	Number of blocks in the padded message.
T	Temporary w-bit word used in the hash computation.
w	Number of bits in a word.
W_t	The tth w-bit word of the message schedule.

2.2.2   Symbols and Operations

The following symbols are used in the secure hash algorithm specifications; each operates on w-bit words.

$\wedge$	Bitwise AND operation.
$\vee$	Bitwise OR ("inclusive-OR") operation.
$\oplus$	Bitwise XOR ("exclusive-OR") operation.
$\neg$	Bitwise complement operation.
$+$	Addition modulo 2^w.
$<<$	Left-shift operation, where $x << n$ is obtained by discarding the left-most n bits of the word x and then padding the result with n zeroes on the right.
$>>$	Right-shift operation, where $x >> n$ is obtained by discarding the right-most n bits of the word x and then padding the result with n zeroes on the left.

The following operations are used in the secure hash algorithm specifications:

$ROTL^n(x)$	The *rotate left* (circular left shift) operation, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by $ROTL^n(x) = (x << n) \vee (x >> w - n)$.
$ROTR^n(x)$	The *rotate right* (circular right shift) operation, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by $ROTR^n(x) = (x >> n) \vee (x << w - n)$.

SHRⁿ(x)   The *right shift* operation, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by $SHR^n(x) = x >> n$.

3.   NOTATION AND CONVENTIONS

3.1   Bit Strings and Integers

The following terminology related to bit strings and integers will be used.

1. A *hex digit* is an element of the set {0, 1,…, 9, a,…, f}. A hex digit is the representation of a 4-bit string. For example, the hex digit "7" represents the 4-bit string "0111", and the hex digit "a" represents the 4-bit string "1010".

2. A *word* is a *w*-bit string that may be represented as a sequence of hex digits. To convert a word to hex digits, each 4-bit string is converted to its hex digit equivalent, as described in (1) above. For example, the 32-bit string

        1010 0001 0000 0011 1111 1110 0010 0011

    can be expressed as "a103fe23", and the 64-bit string

        1010 0001 0000 0011 1111 1110 0010 0011
        0011 0010 1110 1111 0011 0000 0001 1010

    can be expressed as "a103fe2332ef301a".

    Throughout this specification, the "big-endian" convention is used when expressing both 32- and 64-bit words, so that within each word, the most significant bit is stored in the left-most bit position.

3. An *integer* may be represented as a word or pair of words. A word representation of the message length, ℓ, in bits, is required for the padding techniques of Sec. 5.1.

    An integer between 0 and 2^{32}-1 *inclusive* may be represented as a 32-bit word. The least significant four bits of the integer are represented by the right-most hex digit of the word representation. For example, the integer $291=2^8 + 2^5 + 2^1 + 2^0=256+32+2+1$ is represented by the hex word "00000123".

    The same holds true for an integer between 0 and 2^{64}-1 *inclusive*, which may be represented as a 64-bit word.

    If *Z* is an integer, $0 \leq Z < 2^{64}$, then $Z=2^{32}X + Y$, where $0 \leq X < 2^{32}$ and $0 \leq Y < 2^{32}$. Since *X* and *Y* can be represented as 32-bit words *x* and *y*, respectively, the integer *Z* can be represented as the pair of words (*x*, *y*). This property is used for SHA-1, SHA-224 and SHA-256.

If Z is an integer, $0 \leq Z < 2^{128}$, then $Z = 2^{64}X + Y$, where $0 \leq X < 2^{64}$ and $0 \leq Y < 2^{64}$. Since X and Y can be represented as 64-bit words x and y, respectively, the integer Z can be represented as the pair of words (x, y). This property is used for SHA-384 and SHA-512.

4. For the secure hash algorithms, the size of the *message block* - m bits - depends on the algorithm.

   a) For **SHA-1, SHA-224** and **SHA-256**, each message block has **512 bits**, which are represented as a sequence of sixteen **32-bit words**.

   b) For **SHA-384** and **SHA-512**, each message block has **1024 bits**, which are represented as a sequence of sixteen **64-bit words**.

3.2   Operations on Words

The following operations are applied to w-bit words in all five secure hash algorithms. SHA-1, SHA-224 and SHA-256 operate on 32-bit words (w=32), and SHA-384 and SHA-512 operate on 64-bit words (w=64).

1. Bitwise *logical* word operations: $\wedge$, $\vee$, $\oplus$, and $\neg$ (see Sec. 2.2.2).

2. Addition modulo 2^w.

   The operation $x + y$ is defined as follows. The words x and y represent integers X and Y, where $0 \leq X < 2^w$ and $0 \leq Y < 2^w$. For positive integers U and V, let $U \bmod V$ be the remainder upon dividing U by V. Compute

   $$Z = (X + Y) \bmod 2^w.$$

   Then $0 \leq Z < 2^w$. Convert the integer Z to a word, z, and define $z = x + y$.

3. The *right shift* operation $\textbf{\textit{SHR}}^{\,n}(\textbf{\textit{x}})$, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by

   $$SHR^{\,n}(x) = x \gg n.$$

   This operation is used in the SHA-224, SHA-256, SHA-384, and SHA-512 algorithms.

4. The *rotate right* (circular right shift) operation $\textbf{\textit{ROTR}}^{\,n}(\textbf{\textit{x}})$, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by

   $$ROTR^{\,n}(x) = (x \gg n) \vee (x \ll w - n).$$

Thus, $ROTR^n(x)$ is equivalent to a circular shift (rotation) of x by n positions to the right.

This operation is used by the SHA-224, SHA-256, SHA-384, and SHA-512 algorithms.

5. The *rotate left* (circular left shift) operation, $\textbf{ROTL}^{\textbf{n}}(\textbf{x})$, where x is a w-bit word and n is an integer with $0 \leq n < w$, is defined by

$$ROTL^n(x) = (x << n) \lor (x >> w - n).$$

Thus, $ROTL^n(x)$ is equivalent to a circular shift (rotation) of x by n positions to the left.

This operation is used only in the SHA-1 algorithm.

6. Note the following equivalence relationships, where w is fixed in each relationship:

$$ROTL^n(x) \approx ROTR^{w-n}(x)$$

$$ROTR^n(x) \approx ROTL^{w-n}(x)$$

4. FUNCTIONS AND CONSTANTS

4.1 Functions

This section defines the functions that are used by each of the algorithms. Although the SHA-224, SHA-256, SHA-384, and SHA-512 algorithms all use similar functions, their descriptions are separated into sections for SHA-224 and SHA-256 (Sec. 4.1.2) and for SHA-384 and SHA-512 (Sec. 4.1.3), since the input and output for these functions are words of different sizes. Each of the algorithms include $Ch(x, y, z)$ and $Maj(x, y, z)$ functions; the exclusive-OR operation ($\oplus$) in these functions may be replaced by a bitwise OR operation ($\vee$) and produce identical results.

4.1.1 SHA-1 Functions

SHA-1 uses a sequence of logical functions, $f_0, f_1,\ldots, f_{79}$. Each function f_t, where $0 \le t < 79$, operates on three 32-bit words, x, y, and z, and produces a 32-bit word as output. The function f_t (x, y, z) is defined as follows:

$$
f_t(x, y, z) = \begin{cases}
Ch(x, y, z)=(x \wedge y) \oplus (\neg x \wedge z) & 0 \le t \le 19 \\[1em]
Parity(x, y, z)=x \oplus y \oplus z & 20 \le t \le 39 \\[1em]
Maj(x, y, z)=(x \wedge y) \oplus (x \wedge z) \oplus (y \wedge z) & 40 \le t \le 59 \\[1em]
Parity(x, y, z)=x \oplus y \oplus z & 60 \le t \le 79.
\end{cases} \tag{4.1}
$$

4.1.2 SHA-224 and SHA-256 Functions

SHA-224 and SHA-256 both use six logical functions, where *each function operates on 32-bit words*, which are represented as x, y, and z. The result of each function is a new 32-bit word.

$$
\begin{aligned}
Ch(x, y, z) &= (x \wedge y) \oplus (\neg x \wedge z) && (4.2) \\
Maj(x, y, z) &= (x \wedge y) \oplus (x \wedge z) \oplus (y \wedge z) && (4.3)
\end{aligned}
$$

$$
\begin{aligned}
\Sigma_0^{\{256\}}(x) &= ROTR^2(x) \oplus ROTR^{13}(x) \oplus ROTR^{22}(x) && (4.4) \\
\Sigma_1^{\{256\}}(x) &= ROTR^6(x) \oplus ROTR^{11}(x) \oplus ROTR^{25}(x) && (4.5) \\
\sigma_0^{\{256\}}(x) &= ROTR^7(x) \oplus ROTR^{18}(x) \oplus SHR^3(x) && (4.6) \\
\sigma_1^{\{256\}}(x) &= ROTR^{17}(x) \oplus ROTR^{19}(x) \oplus SHR^{10}(x) && (4.7)
\end{aligned}
$$

4.1.3 SHA-384 and SHA-512 Functions

SHA-384 and SHA-512 both use six logical functions, where *each function operates on 64-bit words*, which are represented as x, y, and z. The result of each function is a new 64-bit word.

$$
\begin{aligned}
Ch(x, y, z) &= (x \wedge y) \oplus (\neg x \wedge z) & (4.8) \\
Maj(x, y, z) &= (x \wedge y) \oplus (x \wedge z) \oplus (y \wedge z) & (4.9)
\end{aligned}
$$

$$
\begin{aligned}
\textstyle\sum_0^{\{512\}}(x) &= ROTR^{28}(x) \oplus ROTR^{34}(x) \oplus ROTR^{39}(x) & (4.10) \\
\textstyle\sum_1^{\{512\}}(x) &= ROTR^{14}(x) \oplus ROTR^{18}(x) \oplus ROTR^{41}(x) & (4.11) \\
\sigma_0^{\{512\}}(x) &= ROTR^{1}(x) \oplus ROTR^{8}(x) \oplus SHR^{7}(x) & (4.12) \\
\sigma_1^{\{512\}}(x) &= ROTR^{19}(x) \oplus ROTR^{61}(x) \oplus SHR^{6}(x) & (4.13)
\end{aligned}
$$

4.2   Constants

4.2.1   SHA-1 Constants

SHA-1 uses a sequence of eighty constant 32-bit words, $K_0, K_1, \ldots, K_{79}$, which are given by

$$
K_t =
\begin{cases}
\texttt{5a827999} & 0 \le t \le 19 \\[6pt]
\texttt{6ed9eba1} & 20 \le t \le 39 \\[6pt]
\texttt{8f1bbcdc} & 40 \le t \le 59 \\[6pt]
\texttt{ca62c1d6} & 60 \le t \le 79
\end{cases}
\qquad (4.14)
$$

4.2.2   SHA-224 and SHA-256 Constants

SHA-224 and SHA-256 use the same sequence of sixty-four constant 32-bit words, $K_0^{\{256\}}, K_1^{\{256\}}, \ldots, K_{63}^{\{256\}}$. These words represent the first thirty-two bits of the fractional parts of the cube roots of the first sixty-four prime numbers. In hex, these constant words are (from left to right)

5.   PREPROCESSING

Preprocessing shall take place before hash computation begins. This preprocessing consists of three steps: padding the message, M (Sec. 5.1), parsing the padded message into message blocks (Sec. 5.2), and setting the initial hash value, $H^{(0)}$ (Sec. 5.3).

5.1   Padding the Message

The message, M, shall be padded before hash computation begins. The purpose of this padding is to ensure that the padded message is a multiple of 512 or 1024 bits, depending on the algorithm.

5.1.1   SHA-1, SHA-224 and SHA-256

Suppose that the length of the message, M, is ℓ bits. Append the bit "1" to the end of the message, followed by k zero bits, where k is the smallest, non-negative solution to the equation $\ell + 1 + k \equiv 448 \bmod 512$. Then append the 64-bit block that is equal to the number ℓ expressed using a binary representation. For example, the (8-bit ASCII) message "**abc**" has length $8 \times 3 = 24$, so the message is padded with a one bit, then $448 - (24 + 1) = 423$ zero bits, and then the message length, to become the 512-bit padded message

$$\underbrace{01100001}_{\text{"a"}} \quad \underbrace{01100010}_{\text{"b"}} \quad \underbrace{01100011}_{\text{"c"}} \quad 1 \quad \overbrace{00...00}^{423} \quad \overbrace{00...\underbrace{011000}_{\ell=24}}^{64}$$

The length of the padded message should now be a multiple of 512 bits.

5.1.2   SHA-384 and SHA-512

Suppose the length of the message M, in bits, is ℓ bits. Append the bit "1" to the end of the message, followed by k zero bits, where k is the smallest non-negative solution to the equation $\ell + 1 + k \equiv 896 \bmod 1024$. Then append the 128-bit block that is equal to the number ℓ expressed using a binary representation. For example, the (8-bit ASCII) message "**abc**" has length $8 \times 3 = 24$, so the message is padded with a one bit, then $896 - (24 + 1) = 871$ zero bits, and then the message length, to become the 1024-bit padded message

$$\underbrace{01100001}_{\text{"a"}} \quad \underbrace{01100010}_{\text{"b"}} \quad \underbrace{01100011}_{\text{"c"}} \quad 1 \quad \overbrace{00...00}^{871} \quad \overbrace{00...\underbrace{011000}_{\ell=24}}^{128}$$

The length of the padded message should now be a multiple of 1024 bits.

5.2   Parsing the Padded Message

After a message has been padded, it must be parsed into N m-bit blocks before the hash computation can begin.

5.2.1   SHA-1, SHA-224 and SHA-256

For SHA-1, SHA-224 and SHA-256, the padded message is parsed into N 512-bit blocks, $M^{(1)}$, $M^{(2)},\ldots, M^{(N)}$. Since the 512 bits of the input block may be expressed as sixteen 32-bit words, the first 32 bits of message block i are denoted $M_0^{(i)}$, the next 32 bits are $M_1^{(i)}$, and so on up to $M_{15}^{(i)}$.

5.2.2   SHA-384 and SHA-512

For SHA-384 and SHA-512, the padded message is parsed into N 1024-bit blocks, $M^{(1)}$, $M^{(2)},\ldots,$ $M^{(N)}$. Since the 1024 bits of the input block may be expressed as sixteen 64-bit words, the first 64 bits of message block i are denoted $M_0^{(i)}$, the next 64 bits are $M_1^{(i)}$, and so on up to $M_{15}^{(i)}$.

5.3   Setting the Initial Hash Value ($H^{(0)}$)

Before hash computation begins for each of the secure hash algorithms, the initial hash value, $H^{(0)}$, must be set. The size and number of words in $H^{(0)}$ depends on the message digest size.

5.3.1   SHA-1

For SHA-1, the initial hash value, $H^{(0)}$, shall consist of the following five 32-bit words, in hex:

$$H_0^{(0)} = \texttt{67452301}$$
$$H_1^{(0)} = \texttt{efcdab89}$$
$$H_2^{(0)} = \texttt{98badcfe}$$
$$H_3^{(0)} = \texttt{10325476}$$
$$H_4^{(0)} = \texttt{c3d2e1f0}$$

5.3.2   SHA-224

For SHA-224, the initial hash value, $H^{(0)}$, shall consist of the following eight 32-bit words, in hex:

$$H_0^{(0)} = \texttt{c1059ed8}$$
$$H_1^{(0)} = \texttt{367cd507}$$
$$H_2^{(0)} = \texttt{3070dd17}$$
$$H_3^{(0)} = \texttt{f70e5939}$$
$$H_4^{(0)} = \texttt{ffc00b31}$$
$$H_5^{(0)} = \texttt{68581511}$$

$$H_6^{(0)} = \text{64f98fa7}$$

$$H_7^{(0)} = \text{befa4fa4}$$

5.3.3   SHA-256

For SHA-256, the initial hash value, $H^{(0)}$, shall consist of the following eight 32-bit words, in hex:

$$H_0^{(0)} = \text{6a09e667}$$
$$H_1^{(0)} = \text{bb67ae85}$$
$$H_2^{(0)} = \text{3c6ef372}$$
$$H_3^{(0)} = \text{a54ff53a}$$
$$H_4^{(0)} = \text{510e527f}$$
$$H_5^{(0)} = \text{9b05688c}$$
$$H_6^{(0)} = \text{1f83d9ab}$$
$$H_7^{(0)} = \text{5be0cd19}$$

These words were obtained by taking the first thirty-two bits of the fractional parts of the square roots of the first eight prime numbers.

5.3.4   SHA-384

For SHA-384, the initial hash value, $H^{(0)}$, shall consist of the following eight 64-bit words, in hex:

$$H_0^{(0)} = \text{cbbb9d5dc1059ed8}$$
$$H_1^{(0)} = \text{629a292a367cd507}$$
$$H_2^{(0)} = \text{9159015a3070dd17}$$
$$H_3^{(0)} = \text{152fecd8f70e5939}$$
$$H_4^{(0)} = \text{67332667ffc00b31}$$
$$H_5^{(0)} = \text{8eb44a8768581511}$$
$$H_6^{(0)} = \text{db0c2e0d64f98fa7}$$
$$H_7^{(0)} = \text{47b5481dbefa4fa4}$$

These words were obtained by taking the first sixty-four bits of the fractional parts of the square roots of the ninth through sixteenth prime numbers.

5.3.5   SHA-512

For SHA-512, the initial hash value, $H^{(0)}$, shall consist of the following eight 64-bit words, in hex:

$$H_0^{(0)} = \text{6a09e667f3bcc908}$$

$$H_1^{(0)} = \text{bb67ae8584caa73b}$$
$$H_2^{(0)} = \text{3c6ef372fe94f82b}$$
$$H_3^{(0)} = \text{a54ff53a5f1d36f1}$$
$$H_4^{(0)} = \text{510e527fade682d1}$$
$$H_5^{(0)} = \text{9b05688c2b3e6c1f}$$
$$H_6^{(0)} = \text{1f83d9abfb41bd6b}$$
$$H_7^{(0)} = \text{5be0cd19137e2179}$$

These words were obtained by taking the first sixty-four bits of the fractional parts of the square roots of the first eight prime numbers.

6.   SECURE HASH ALGORITHMS

In the following sections, the hash algorithms are not described in ascending order of size. SHA-256 is described before SHA-224 because the specification for SHA-224 is identical to SHA-256, except that different initial hash values are used, and the final hash value is truncated to 224 bits for SHA-224. The same is true for SHA-512 and SHA-384, except that the final hash value is truncated to 384 bits for SHA-384.

For each of the secure hash algorithms, there may exist alternate computation methods that yield identical results; one example is the alternative SHA-1 computation described in Sec. 6.1.3. Such alternate methods may be implemented in conformance to this standard.

6.1   SHA-1

SHA-1 may be used to hash a message, M, having a length of ℓ bits, where $0 \le \ell < 2^{64}$. The algorithm uses 1) a message schedule of eighty 32-bit words, 2) five working variables of 32 bits each, and 3) a hash value of five 32-bit words. The final result of SHA-1 is a 160-bit message digest.

The words of the message schedule are labeled W_0, W_1,…, W_{79}. The five working variables are labeled a, b, c, d, and e. The words of the hash value are labeled $H_0^{(i)}, H_1^{(i)}, \ldots, H_4^{(i)}$, which will hold the initial hash value, $H^{(0)}$, replaced by each successive intermediate hash value (after each message block is processed), $H^{(i)}$, and ending with the final hash value, $H^{(N)}$. SHA-1 also uses a single temporary word, T.

6.1.1   SHA-1 Preprocessing

1. Pad the message, M, according to Sec. 5.1.1;

2. Parse the padded message into N 512-bit message blocks, $M^{(1)}$, $M^{(2)}$, …, $M^{(N)}$, according to Sec. 5.2.1; and

3. Set the initial hash value, $H^{(0)}$, as specified in Sec. 5.3.1.

6.1.2   SHA-1 Hash Computation

The SHA-1 hash computation uses functions and constants previously defined in Sec. 4.1.1 and Sec. 4.2.1, respectively. Addition (+) is performed modulo 2^{32}.

After preprocessing is completed, each message block, $M^{(1)}$, $M^{(2)}$, …, $M^{(N)}$, is processed in order, using the following steps:

For i=1 to N:
{
    1. Prepare the message schedule, $\{W_t\}$:

$$
W_t = \begin{cases} M_t^{(i)} & 0 \le t \le 15 \\ \\ ROTL^1(W_{t-3} \oplus W_{t-8} \oplus W_{t-14} \oplus W_{t-16}) & 16 \le t \le 79 \end{cases}
$$

2. Initialize the five working variables, a, b, c, d, and e, with the $(i\text{-}1)^{\text{st}}$ hash value:

$$a = H_0^{(i-1)}$$
$$b = H_1^{(i-1)}$$
$$c = H_2^{(i-1)}$$
$$d = H_3^{(i-1)}$$
$$e = H_4^{(i-1)}$$

3. For t=0 to 79:
   {
$$T = ROTL^5(a) + f_t(b,c,d) + e + K_t + W_t$$
$$e = d$$
$$d = c$$
$$c = ROTL^{30}(b)$$
$$b = a$$
$$a = T$$
   }

4. Compute the ith intermediate hash value $H^{(i)}$:

$$H_0^{(i)} = a + H_0^{(i-1)}$$
$$H_1^{(i)} = b + H_1^{(i-1)}$$
$$H_2^{(i)} = c + H_2^{(i-1)}$$
$$H_3^{(i)} = d + H_3^{(i-1)}$$
$$H_4^{(i)} = e + H_4^{(i-1)}$$

}

After repeating steps one through four a total of N times (i.e., after processing $M^{(N)}$), the resulting 160-bit message digest of the message, M, is

$$H_0^{(N)} \| H_1^{(N)} \| H_2^{(N)} \| H_3^{(N)} \| H_4^{(N)}$$

6.1.3   Alternate Method for Computing a SHA-1 Message Digest

The SHA-1 hash computation method described in Sec. 6.1.2 assumes that the message schedule W_0, W_1,…, W_{79} is implemented as an array of eighty 32-bit words. This is efficient from the standpoint of the minimization of execution time, since the addresses of W_{t-3},…, W_{t-16} in step (2) of Sec. 6.1.2 are easily computed.

However, if memory is limited, an alternative is to regard $\{W_t\}$ as a circular queue that may be implemented using an array of sixteen 32-bit words, W_0, W_1,…, W_{15}. The alternate method that is described in this section yields the same message digest as the SHA-1 computation method described in Sec. 6.1.2. Although this alternate method saves sixty-four 32-bit words of storage, it is likely to lengthen the execution time due to the increased complexity of the address computations for the $\{W_t\}$ in step (3).

For this alternate SHA-1 method, let *MASK*=`0000000f` (in hex). As in Sec. 6.1.1, addition is performed modulo 2^{32}. Assuming that the preprocessing as described in Sec. 6.1.1 has been performed, the processing of $M^{(i)}$ is as follows:

For *i*=1 to *N*:
{

    1. For *t*=0 to 15:
       {

$$W_t = M_t^{(i)}$$

       }

    2. Initialize the five working variables, *a*, *b*, *c*, *d*, and *e*, with the $(i\text{-}1)^{\text{st}}$ hash value:

$$a = H_0^{(i-1)}$$
$$b = H_1^{(i-1)}$$
$$c = H_2^{(i-1)}$$
$$d = H_3^{(i-1)}$$
$$e = H_4^{(i-1)}$$

    3. For *t*=0 to 79:
       {

$$s = t \wedge MASK$$

       If $t \geq 16$ then
       {

$$W_s = ROTL^1(W_{(s+13)\wedge MASK} \oplus W_{(s+8)\wedge MASK} \oplus W_{(s+2)\wedge MASK} \oplus W_s)$$

       }

$$T = ROTL^5(a) + f_t(b,c,d) + e + K_t + W_s$$

$$e = d$$

$$d = c$$

$$c = ROTL^{30}(b)$$

$$b = a$$

$$a = T$$

  }

4. Compute the ith intermediate hash value $H^{(i)}$:

$$H_0^{(i)} = a + H_0^{(i-1)}$$

$$H_1^{(i)} = b + H_1^{(i-1)}$$

$$H_2^{(i)} = c + H_2^{(i-1)}$$

$$H_3^{(i)} = d + H_3^{(i-1)}$$

$$H_4^{(i)} = e + H_4^{(i-1)}$$

}

After repeating steps one through four a total of N times (i.e., after processing $M^{(N)}$), the resulting 160-bit message digest of the message, M, is

$$H_0^{(N)} \| H_1^{(N)} \| H_2^{(N)} \| H_3^{(N)} \| H_4^{(N)}$$

6.2   SHA-256

SHA-256 may be used to hash a message, M, having a length of ℓ bits, where $0 \le \ell < 2^{64}$. The algorithm uses 1) a message schedule of sixty-four 32-bit words, 2) eight working variables of 32 bits each, and 3) a hash value of eight 32-bit words. The final result of SHA-256 is a 256-bit message digest.

The words of the message schedule are labeled W_0, W_1,…, W_{63}. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled $H_0^{(i)}, H_1^{(i)}, \ldots, H_7^{(i)}$, which will hold the initial hash value, $H^{(0)}$, replaced by each successive intermediate hash value (after each message block is processed), $H^{(i)}$, and ending with the final hash value, $H^{(N)}$. SHA-256 also uses two temporary words, T_1 and T_2.

6.2.1   SHA-256 Preprocessing

1. Pad the message, M, according to Sec. 5.1.1;

2. Parse the padded message into N 512-bit message blocks, $M^{(1)}$, $M^{(2)}$, ..., $M^{(N)}$, according to Sec. 5.2.1; and

3. Set the initial hash value, $H^{(0)}$, as specified in Sec. 5.3.3.

6.2.2 SHA-256 Hash Computation

The SHA-256 hash computation uses functions and constants previously defined in Sec. 4.1.2 and Sec. 4.2.2, respectively. Addition (+) is performed modulo 2^{32}.

After preprocessing is completed, each message block, $M^{(1)}$, $M^{(2)}$, ..., $M^{(N)}$, is processed in order, using the following steps:

For i=1 to N:
{
    1. Prepare the message schedule, $\{W_t\}$:

$$W_t = \begin{cases} M_t^{(i)} & 0 \le t \le 15 \\ \\ \sigma_1^{\{256\}}(W_{t-2}) + W_{t-7} + \sigma_0^{\{256\}}(W_{t-15}) + W_{t-16} & 16 \le t \le 63 \end{cases}$$

    2. Initialize the eight working variables, a, b, c, d, e, f, g, and h, with the $(i\text{-}1)^{\text{st}}$ hash value:

$$a = H_0^{(i-1)}$$
$$b = H_1^{(i-1)}$$
$$c = H_2^{(i-1)}$$
$$d = H_3^{(i-1)}$$
$$e = H_4^{(i-1)}$$
$$f = H_5^{(i-1)}$$
$$g = H_6^{(i-1)}$$
$$h = H_7^{(i-1)}$$

    3. For t=0 to 63:
      {

$$T_1 = h + \sum_1^{\{256\}}(e) + Ch(e, f, g) + K_t^{\{256\}} + W_t$$

$$T_2 = \sum_0^{\{256\}}(a) + Maj(a, b, c)$$

$$h = g$$

$$g = f$$

$$f = e$$

$$e = d + T_1$$

$$d = c$$

$$c = b$$

$$b = a$$

$$a = T_1 + T_2$$

    }

4. Compute the ith intermediate hash value $H^{(i)}$:

$$H_0^{(i)} = a + H_0^{(i-1)}$$

$$H_1^{(i)} = b + H_1^{(i-1)}$$

$$H_2^{(i)} = c + H_2^{(i-1)}$$

$$H_3^{(i)} = d + H_3^{(i-1)}$$

$$H_4^{(i)} = e + H_4^{(i-1)}$$

$$H_5^{(i)} = f + H_5^{(i-1)}$$

$$H_6^{(i)} = g + H_6^{(i-1)}$$

$$H_7^{(i)} = h + H_7^{(i-1)}$$

}

After repeating steps one through four a total of N times (i.e., after processing $M^{(N)}$), the resulting 256-bit message digest of the message, M, is

$$H_0^{(N)} \Vert H_1^{(N)} \Vert H_2^{(N)} \Vert H_3^{(N)} \Vert H_4^{(N)} \Vert H_5^{(N)} \Vert H_6^{(N)} \Vert H_7^{(N)}$$

6.3   SHA-224

SHA-224 may be used to hash a message, M, having a length of ℓ bits, where $0 \leq \ell < 2^{64}$. The function is defined in the exact same manner as SHA-256 (Section 6.2), with the following two exceptions:

1. The initial hash value, $H^{(0)}$, shall be set as specified in Sec. 5.3.2; and

2. The 224-bit message digest is obtained by truncating the final hash value, $H(N)$, to its left-most 224 bits:

$$H_0^{(N)} \| H_1^{(N)} \| H_2^{(N)} \| H_3^{(N)} \| H_4^{(N)} \| H_5^{(N)} \| H_6^{(N)}$$

6.4   SHA-512

SHA-512 may be used to hash a message, M, having a length of ℓ bits, where $0 \le \ell < 2^{128}$. The algorithm uses 1) a message schedule of eighty 64-bit words, 2) eight working variables of 64 bits each, and 3) a hash value of eight 64-bit words. The final result of SHA-512 is a 512-bit message digest.

The words of the message schedule are labeled W_0, W_1,…, W_{79}. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled $H_0^{(i)}, H_1^{(i)}, \ldots, H_7^{(i)}$, which will hold the initial hash value, $H^{(0)}$, replaced by each successive intermediate hash value (after each message block is processed), $H^{(i)}$, and ending with the final hash value, $H^{(N)}$. SHA-512 also uses two temporary words, T_1 and T_2.

6.4.1   SHA-512 Preprocessing

1. Pad the message, M, according to Sec. 5.1.2;

2. Parse the padded message into N 1024-bit message blocks, $M^{(1)}$, $M^{(2)}$, …, $M^{(N)}$, according to Sec. 5.2.2; and

3. Set the initial hash value, $H^{(0)}$, as specified in Sec. 5.3.5.

6.4.2   SHA-512 Hash Computation

The SHA-512 hash computation uses functions and constants previously defined in Sec. 4.1.3 and Sec. 4.2.3, respectively. Addition (+) is performed modulo 2^{64}.

After preprocessing is completed, each message block, $M^{(1)}$, $M^{(2)}$, …, $M^{(N)}$, is processed in order, using the following steps:

For i=1 to N:
{

1. Prepare the message schedule, $\{W_t\}$:

$$W_t = \begin{cases} M_t^{(i)} & 0 \le t \le 15 \\ \\ \sigma_1^{\{512\}}(W_{t-2}) + W_{t-7} + \sigma_0^{\{512\}}(W_{t-15}) + W_{t-16} & 16 \le t \le 79 \end{cases}$$

2. Initialize the eight working variables, a, b, c, d, e, f, g, and h, with the $(i\text{-}1)^{\text{st}}$ hash value:

$$a = H_0^{(i-1)}$$
$$b = H_1^{(i-1)}$$
$$c = H_2^{(i-1)}$$
$$d = H_3^{(i-1)}$$
$$e = H_4^{(i-1)}$$
$$f = H_5^{(i-1)}$$
$$g = H_6^{(i-1)}$$
$$h = H_7^{(i-1)}$$

3. For t=0 to 79:
{

$$T_1 = h + \sum_1^{\{512\}}(e) + Ch(e,f,g) + K_t^{\{512\}} + W_t$$
$$T_2 = \sum_0^{\{512\}}(a) + Maj(a,b,c)$$
$$h = g$$
$$g = f$$
$$f = e$$
$$e = d + T_1$$
$$d = c$$
$$c = b$$
$$b = a$$
$$a = T_1 + T_2$$

}

4. Compute the ith intermediate hash value $H^{(i)}$:

$$H_0^{(i)} = a + H_0^{(i-1)}$$
$$H_1^{(i)} = b + H_1^{(i-1)}$$
$$H_2^{(i)} = c + H_2^{(i-1)}$$
$$H_3^{(i)} = d + H_3^{(i-1)}$$
$$H_4^{(i)} = e + H_4^{(i-1)}$$
$$H_5^{(i)} = f + H_5^{(i-1)}$$
$$H_6^{(i)} = g + H_6^{(i-1)}$$
$$H_7^{(i)} = h + H_7^{(i-1)}$$

}

After repeating steps one through four a total of N times (i.e., after processing $M^{(N)}$), the resulting 512-bit message digest of the message, M, is

$$H_0^{(N)} \| H_1^{(N)} \| H_2^{(N)} \| H_3^{(N)} \| H_4^{(N)} \| H_5^{(N)} \| H_6^{(N)} \| H_7^{(N)}$$

6.5   SHA-384

SHA-384 may be used to hash a message, M, having a length of ℓ bits, where $0 \le \ell < 2^{128}$. The algorithm is defined in the exact same manner as SHA-512 (Sec. 6.4), with the following two exceptions:

1. The initial hash value, $H^{(0)}$, shall be set as specified in Sec. 5.3.4; and

2. The 384-bit message digest is obtained by truncating the final hash value, $H^{(N)}$, to its left-most 384 bits:

$$H_0^{(N)} \| H_1^{(N)} \| H_2^{(N)} \| H_3^{(N)} \| H_4^{(N)} \| H_5^{(N)}$$

7.   TRUNCATION OF A MESSAGE DIGEST

Some application may require a hash function with a message digest length different than those provided by the hash functions in this Standard. In such cases, a truncated message digest may be used, whereby a hash function with a larger message digest length is applied to the data to be hashed, and the resulting message digest is truncated by selecting an appropriate number of the leftmost bits. For guidelines on choosing the length of the truncated message digest and information about its security implications for the cryptographic application that uses it, see SP 800-107.

APPENDIX A: Additional Information

A.1   Security of the Secure Hash Algorithms

The security of the five hash algorithms, SHA-1, SHA-224, SHA-256, SHA-384, and SHA-512 is discussed in [SP 800-107].

A.2   Implementation Notes

Examples of SHA-1, SHA-224, SHA-256, SHA-384 and SHA-512 are available at http://csrc.nist.gov/groups/ST/toolkit/examples.html.

A.3   Object Identifiers

Object identifiers (OIDs) for the SHA-1, SHA-224, SHA-256, SHA-384 and SHA-512 algorithms are posted at http://csrc.nist.gov/groups/ST/crypto_apps_infra/csor/algorithms.html.
