Quality

The U.S. Energy Information Administration is committed to quality products and service. To ensure that this report meets the highest standards for quality, please forward your comments or suggestions about this publication to Orhan M. Yildiz at 202/586-5410, or email: email: orhan.yildiz@eia.doe.gov

For general inquiries about energy data, please contact the National Energy Information Center at 202/586-8800. Internet users may contact the center at: infoctr@eia.doe.gov

Preface

The *Electric Power Annual 2008* summarizes electric power industry statistics at the national level. The publication provides industry decision-makers, government policymakers, analysts, and the general public with historical data that may be used in understanding U.S. electricity markets. The *Electric Power Annual* is prepared by the Electric Power Division; Office of Coal, Nuclear, Electric and Alternate Fuels; U.S. Energy Information Administration (EIA); U.S. Department of Energy.

Data in this report can be used in analytic studies for public policy and business decisions. The chapters present information and data in the following areas: electricity generation; electric generating capacity; demand, capacity resources, and capacity margins; fuel, consumption and receipts; emissions; electricity trade; retail electric customers, sales, revenue and average retail price; electric utility revenue and expense statistics; and demand-side management.

Monetary values in this publication are expressed in nominal terms.

Data published in the *Electric Power Annual* are compiled from four surveys completed annually or monthly by electric utilities and other electric power producers and submitted to the EIA and five surveys administered by other government organizations[1]. The EIA forms are described in detail in the "Technical Notes."

An important note to the reader: In this edition of the *Electric Power Annual*, changes have been made to the order of chapters, to improve the flow of the publication. Furthermore, a new Chapter 5 has been added to display selected characteristics of the electric power industry. For the convenience of the reader, a crosswalk list between the chapters, tables and illustrations of the 2007 and 2008 *Electric Power Annual* publications is provided in the Preface.

Electric Power Industry 2008: Year in Review

Overview

In 2008, electricity generation and sales were adversely affected by the weakening economy. Annual net electric power generation decreased for the first time since 2001, dropping 0.9 percent from 4,157 million megawatthours (MWh) in 2007 to 4,119 million MWh in 2008. Summer peak load (noncoincident) fell by 3.8 percent, from 782,227 megawatts (MW) in 2007 to 752,470 MW in 2008. Winter peak load (noncoincident), which is always smaller than summer peak load, increased in 2008 by 0.9 percent, from 637,905 MW in 2007 to 643,557 MW in 2008. Nationally, the contiguous U.S. experienced an average temperature that was the coolest in more than ten years.[1]

Fossil fuel prices showed significant volatility during 2008. Natural gas spot prices as delivered to electric plants were $8.27 per MMBtu in January, rose to $12.14 per MMBtu in June, and fell to $6.36 per MMBtu in November. The overall 27.2-percent increase in average fossil fuel costs delivered to electric plants from 2007 contributed to the 6.7-percent increase in average retail electricity prices, from 9.1 to 9.7 cents per kilowatthour (kWh). Between 2004 and 2008, the average price of fossil fuels delivered to electric plants increased a cumulative 65.7 percent. Over the same time period, the national average retail price of electricity increased 28.0 percent, from 7.6 cents per kWh in 2004 to 9.7 cents per kWh in 2008.

While electricity generation from the primary fuel sources decreased in 2008 (coal by 1.5 percent, natural gas by 1.5 percent, and nuclear by 0.03 percent), generation from all renewable sources increased, with the exception of wood and wood derived fuels. Most notably, wind generation increased 60.7 percent, from 34.5 million MWh in 2007 to 55.4 million MWh in 2008. For the first time, wind generation constituted a larger share of total electric generation than either petroleum or wood and wood-derived fuels. At the time of this writing, 24 States have put in place Renewable Portfolio Standards and five additional States have nonbinding goals for renewable energy[2]. Several pieces of recently enacted Federal legislation have also offered substantial financial incentives for renewable electricity production.

In 2008, total net summer generating capacity increased 15,283 MW, a gain of 1.5 percent over 2007. New wind capacity accounted for 53.2 percent of that increase, with 8,136 MW installed during 2008. Wind net summer capacity increased 49.3 percent from 2007 to 2008. New natural gas-fired capacity of 4,556 MW accounted for 29.8 percent of the total net capacity increase. Natural-gas fired capacity additions have been declining since a peak in 2002.

The capacity factor for combined cycle natural gas units increased from 33.5 percent in 2003 to 42.0 percent in 2007, and then fell slightly to 40.7 percent in 2008. The overall improvement in the average capacity factor since 2003 reflects both the increased reliance on combined cycle generation to meet energy requirements and further efficiency gains in combined cycle generation technology. Nuclear and coal-fired generation had the highest average capacity factors at 91.1 percent and 72.2 percent, respectively, in 2008.

Estimated U.S. electric power plant carbon dioxide emissions fell 2.5 percent from 2007 to 2008, from 2,540 million metric tons to 2,477 million metric tons, largely due to decreased fuel consumption. Sulfur dioxide (SO_2) emissions fell 13.4 percent, from 9.0 to 7.8 million metric tons, between 2007 and 2008. This amounts to the largest year-over-year decline since 1995. The large reductions in SO_2 in 2008 result in part from a decline in fuel consumption but mostly from the installation of emissions reduction equipment in response to the Environmental Protection Agency's Clean Air Interstate Rule (see Emissions section). 2008 data also show significant reductions to emissions of nitrogen oxides (NO_x), which dropped 8.8 percent, - from 3.7 to 3.3 million metric tons. Since 1997, sulfur dioxide and nitrogen oxide emissions declined by 41.9 percent and 48.8 percent, respectively.

Generation

Net generation of electric power fell 0.9 percent in 2008, to 4,119 million megawatthours (MWh) from 4,157 million MWh in 2007 (Figure ES1). According to the Bureau of Economic Analysis, the real U.S. gross domestic product increased 0.4 percent in 2008.[3] The Federal Reserve Board, however, reported a 2.2 percent decrease in total industrial production.[4] The National Oceanic and Atmospheric Administration (NOAA) reported that 2008 was the "coolest year in more than ten years." Heating degree days in 2008 were 5.6 percent higher, while cooling degree days were 8.7 percent lower than they were in 2007. NOAA's Residential Demand Temperature Index[5] was 33.0 percent higher in 2008 than it was in 2007. The combination of weak economic activity and reduced summer electricity demand for cooling appears to have contributed to the 0.9 percent decrease in net generation, as compared with the 2.3 percent increase observed in 2007.

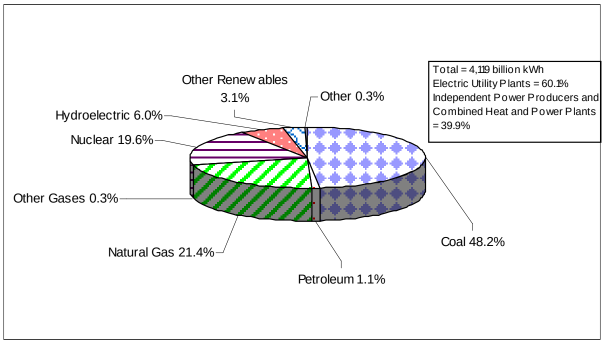
Figure ES1. U.S. Electric Power Industry Net Generation, 2008



Source: U.S. Energy Information Administration, Form EIA-923, "Power Plant Operations Report."

The three primary energy sources for generating electric power in the United States, coal, natural gas, and nuclear energy, consistently provided between 85.0 and 89.5 percent of total net generation during the period 1997 through 2008 (Table 2.1). Petroleum's relative share of total net generation was down to 1.1 percent in 2008. Although conventional hydroelectric power's share of generation was up slightly in 2008, the general trend of this share is one of decline. In 2008, generation from conventional hydroelectric plants accounted for 6.2 percent of total net generation, as compared to 10.2 percent in 1997. Excluding conventional hydroelectric, renewable energy sources contributed 3.1 percent of total net electric generation in 2008, up from 2.5 percent in 2007. This marks the fifth consecutive year in which this category's share of total net generation has increased, and the first time it crossed the three percent threshold. The largest portion of this increase comes from wind generation, which increased from 0.8 percent to 1.3 percent of total net electric generation.

In 2008, electricity generation from coal-fired capacity fell 1.5 percent. Coal-fired generation decreased from 2,016 million MWh in 2007 to 1,986 million MWh in 2008, the lowest coal-fired generation total since 2004. Declines in Pennsylvania, Georgia, North Carolina, and Virginia accounted for 57.8 percent of the national decline. Issues involving individual plants played a key role in the regional decline. In Pennsylvania, 45.4 percent of the drop in coal-fired generation can be attributed to the Homer City plant. Generation at Homer City was down 17.1 percent from its total in 2007, due in part to maintenance outages and economic dispatch. In North Carolina, the Marshall plant's coal-fired generation level was 13.9 percent lower than it was in 2007. This drop accounted for almost half – 49.4 percent – of the decrease in North Carolina's coal-fired electricity production.

Coal's share of total net generation continued its downward trend, accounting for 48.2 percent in 2008 as compared to 48.5 percent in 2007 and 52.8 percent in 1997. Nevertheless, providing 1,986 million MWh, it remains the primary source of baseload generation in the United States.

Following a decade of solid growth, natural gas has increased its share of the electricity market from 13.7 percent in 1997 to 21.4 percent in 2008. Net generation from natural gas-fired capacity fell 1.5 percent, from 897 million MWh in 2007 to 883 million MWh in 2008, the first drop in natural gas-fired generation since 2003. Natural gas-fired generation accounted for 21.4 percent of total net generation in 2008, down from 21.6 percent in 2007. Despite the decrease, natural-gas fired generation was the second leading contributor to total net generation for the third consecutive year, surpassing nuclear generation, which had a 19.6 percent share of total net generation.

Net generation at nuclear plants was down fractionally in 2008 to 806.2 million MWh from 806.4 million MWh. Between 1997 and 2008, the nuclear share of total net generation ranged from a low of 18.0 percent to a high of 20.6 percent, with an annual average growth of 2.3 percent, despite the fact that no new nuclear units have been constructed. Since 1997, average capacity factors for nuclear plants increased from 72.0 percent to 91.8 percent in 2007 (Table 5.3). In 2008, however, the capacity factor for nuclear plants was down slightly to 91.1 percent. In past years, growth in nuclear generation was the result of both improved capacity factors and uprates of existing plants. The net summer capacity of nuclear plants increased due to uprates in 2008 by 489 MW, continuing the overall upward trend. From 1998 through 2008, net summer capacity of existing nuclear plants increased by 3,685 MW.

Net generation from renewable energy sources, excluding conventional hydroelectric generation, increased 19.9 percent in 2008, following an increase of 9.0 percent in 2007 (Table 2.1a). A large part of this growth was due to increased wind generation, which totaled 55.4 million MWh, or 1.3 percent of total net generation. For the first time, wind generation constituted a larger share than biomass, and also a larger share than petroleum. The top 5 wind-generating States were Texas, California, Minnesota, Iowa, and Washington. Texas, where wind generation was up 80.2 percent in 2008, was by far the largest source of wind generation with more than three times that of

California, the Nation's second-largest provider. Nationally, wind generation increased 60.7 percent from its 2007 level. 72.6 percent of the national increase was accounted for by increases in Texas, Colorado, Minnesota, Illinois, Oregon, and Iowa. Wood and wood-derived fuels, representing 0.9 percent of total net generation, accounted for 37 million MWh, down 4.4 percent from 2007. Geothermal power plants supplied 15 million MWh of net generation and other biomass plants generated 18 million MWh; each of these renewable sources accounted for approximately 0.4 percent of total net generation in 2008. Generation from solar thermal and photovoltaic sources was up 41.2 percent from 2007, at 864 thousand MWh. Wood and wood derived fuels and geothermal have maintained fairly stable output levels since 1997, averaging 38 million MWh and 15 million MWh per year, respectively. Other biomass generation has declined from a 23 million MWh peak in 2000 to 18 million MWh in 2008.

Net generation from conventional hydroelectric plants was up 3.0 percent from 248 million MWh in 2007 to 255 million MWh in 2008. Declines in California and Washington were offset by increases in Alabama, New York, and Arkansas. According to the National Climatic Data Center (NCDC), Arkansas had its sixth wettest spring on record in 2008. The largest increase in hydroelectric generation at a single plant in the United States was at the Bull Shoals facility in Arkansas. The absolute rise in hydroelectric generation at the Bull Shoals plant alone exceeded the increase at any other plant nationwide, as well as the increase in every other State (outside of Arkansas), except for Alabama and New York. In the West, March-October 2008 was the driest such eight-month period on record for California and Nevada, according to the NCDC. The largest drop at a single hydroelectric plant in the United States occurred at California's Edward C. Hyatt plant. The absolute decrease at Edward C. Hyatt exceeded the decreases in hydroelectric generation in every other State outside of California, other than Washington.

Largely due to a sharp rise in oil prices, petroleum-fired generation fell 29.7 percent, to 46 million MWh. Its share of total net generation dropped to 1.1 percent.

Fossil Fuel Stocks at Electric Power Plants

End-of-year coal stocks for 2008 increased 6.9 percent from 151 million tons to 162 million tons (Table 3.4). The 2008 build in coal stocks was similar to the 7.3 percent increase that occurred in 2007, with both considerably less than the 39.4 percent increase in 2006. The increase in 2008 appears to be the result of the decrease in coal-fired generation and the concomitant drop in coal consumption compared to 2007, as well as an increase in receipts of coal at electric power sector facilities The increase in end-of-year stocks is consistent with the finding in the North American Electric Reliability Corporation's (NERC) *2008/2009 Winter Reliability Assessment*[6] that power plant inventories "appear[ed] to be sufficient going into the winter, particularly with the softening of the international markets that will reduce exports and make importing coal economic again."

Inventories of petroleum fell 5.7 percent from 47.2 million barrels at the end of 2007 to 44.5 million barrels at the end of 2008. This was the lowest end-of-year petroleum stock level since 2000, when stocks plummeted 24.4 percent from their 1999 year-end level.

Fuel Consumption

Consumption of fossil fuels for electricity generation decreased 0.4 percent (coal), 28.1 percent (petroleum), and 2.7 percent (natural gas) in 2008 (Table 3.1). This tracks with the similar pattern of decreases in generation for the same year: a 1.5 percent decrease in coal generation, 29.7 percent decrease in generation from petroleum, and 1.5 percent decrease in natural gas generation.

Consumption of fossil fuels by combined heat and power plants for useful thermal output is shown in Table 3.2[7]. Industrial and commercial power producers generally constitute a larger share of fuel consumption for useful thermal output than consumption for electricity generation. Commercial and industrial concerns showed more sensitivity to the weakened economy in 2008 than utilities: fossil fuel consumption for useful thermal output decreased 2.8 percent for coal, 39.2 percent for petroleum, and 9.1 percent for natural gas.

Capacity

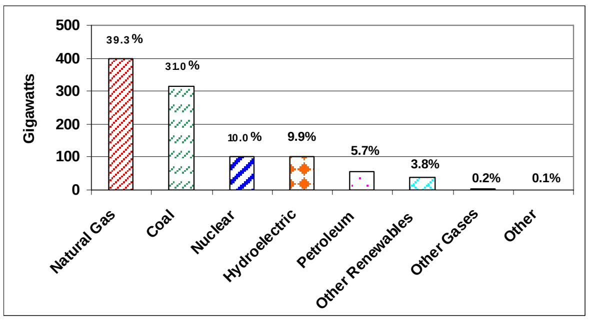
Total U.S. net summer generating capacity as of December 31, 2008 was 1,010,171 MW (Figure ES2, Table 1.1), an increase of 1.5 percent from December 31, 2007. During the year, net summer generating capacity increased 15,283 MW, after accounting for

[6] http://www.nerc.com/files/Winter2008-09.pdf

[7] Please note that a new method of allocating fuel consumption between electricity generation and useful thermal output was applied to combined heat and power generators from 2004 forward. In the historical data, this results in the appearance of an increase in the efficiency of electricity generation after 2003.

retirements, deratings (reductions in power plant generating capability) and other adjustments. For the second year in a row, the net increase to renewable, non-hydroelectric capacity exceeded the net increase to fossil fuel capacity (counting retirements). New wind capacity made up the majority (53.2 percent) of the net summer capacity increase, at 8,136 MW. More new wind capacity came online in 2008 than in the prior two years combined. For most of the past decade, natural gas has been the preferred fuel for new generating capacity. However, in 2008, natural gas-fired generating units accounted for 4,556 MW, or 29.8 percent of the net increase in capacity.

Figure ES2. U.S. Electric Power Industry Net Summer Capacity, 2008



Source: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report."

As of December 31, 2008, wind generating capacity totaled 24,651 MW, a 49.3 percent increase over the 16,515 MW in operation at the end of 2007 (Table 1.1a). Texas continues to lead the Nation in wind power development with 2,938 MW of new wind capacity placed in service during 2008, increasing its share of the Nation's wind capacity currently in operation to 30.1 percent. Iowa has the second highest share of total installed wind generating capacity at 2,635 MW. The remainder of the top five wind-producing States are California at 9.6 percent, Minnesota at 5.9 percent and Washington at 5.5 percent of the Nation's total installed wind generating capacity. Collectively, 15,255 MW or 61.9 percent of total wind generating capacity is located in these 5 States. The States with the biggest increases in wind capacity in 2008 over 2007 include Michigan, South Dakota, Wisconsin, and West Virginia, all with a more than 200-percent increase. The States reporting wind capacity for the first time in 2008 include Indiana, New Hampshire, and Utah, with 130.5, 24.0, and 18.9 MW, respectively. Over the last three years 15,945 MW of wind generating capacity has been placed in service. The overall electric generating capacity from non-hydroelectric renewable energy sources increased 28.0 percent in 2008 to 38,493 MW (Figure ES2), with the additional wind capacity of 8,136 MW accounting for 96.6 percent of the increase.

Natural gas-fired generating capacity represented 397,432 MW or 39.3 percent of total net summer generating capacity in 2008. Although new natural gas-fired combined-cycle plants produce electricity more efficiently than older fossil-fueled plants, high natural gas prices can work against full utilization of these plants if such prices adversely affect economic dispatch. Since 1997, net summer natural gas-fired capacity increased by 220,961 MW, net of retirements and adjustments. As a result, natural gas capacity additions were almost equivalent to the 231,522 MW total increase in net summer capacity over the same time period. In contrast, coal, petroleum and nuclear capacity realized a combined decrease of 14,281 MW over the same time period. The net capacity increase of 24,843 MW from renewables, including hydro, other gases, and other sources accounts for the remainder of the additions since 1997.

Coal-fired generating capacity increased slightly in 2008 to 313,322 MW, or 31.0 percent of total generating capacity. This share of total capacity represents a 0.4 percentage point decline from 2007 (31.4 percent). Retirements of existing coal-fired net summer capacity reported by operators totaled 764 MW, while 1,482 MW were added during the year. This additional capacity is attributed to 2 existing plants and 3 new plants placed in service in 2008. Since 1997, net summer coal-fired capacity has declined 302 MW, after accounting for new additions, upgrades and other adjustments. Nevertheless, net generation from the Nation's coal-fired plants continues to increase due to gains in operating efficiency.

Nuclear net summer generating capacity totaled 100,755 MW or 10.0 percent of total capacity. Uprates totaling 383 MW of nameplate capacity were completed at the Three Mile Island plant in Pennsylvania, the Clinton Power Station and the Braidwood Generation Station in Illinois, as well as the Prairie Island and Monticello plants in Minnesota. Nuclear plant operators reported that net summer capacity increased by 489 MW and net winter capacity increased by 729 MW.

Conventional hydroelectric generating capacity accounted for 7.7 percent of total capacity with a summer net generating capacity of 77,930 MW. Pumped storage hydroelectric generating capacity totaled 21,858 MW. Combined, conventional and pumped storage generating capacity accounted for 9.9 percent of total capacity. Like coal and nuclear, hydroelectric generating capacity has remained relatively unchanged over the last 10 years.

Petroleum-fired capacity totaled 57,445 MW, up 1,377 MW (or 2.5 percent) from 2007. Petroleum-fired capacity accounted for 5.7 percent of all generating capacity.

As of December 31, 2008, additions with a total nameplate capacity of 87,966 MW are scheduled to start commercial operation between 2009 and 2013 (Table 1.4). This compares with 92,996 MW of planned capacity reported on December 31, 2007, for the 5-year period through 2012. The data also show that over the next two years there will be a notable increase in planned additions relative to the past 2 years, if additions are completed as planned. In 2007 and 2008, the industry added 34,088 MW of nameplate capacity. Planned capacity additions to be placed in service during calendar years 2009 and 2010 total 46,940 MW. However, the weak economy, which has limited access to credit and capital, and lower demand may defer the installation of some of this capacity.

Capacity planning data also reveal an ongoing shift in the fuel mix. Natural gas, coal, and wind additions are projected to play a significant role over the next 5 years. The industry reports that it is planning to add 45,541 MW of natural-gas fired capacity. These planned additions account for 51.8 percent of planned additions over the next 5 years, and are projected to increase the overall natural gas-fired capacity by 10.0 percent. Over the same period, 21,340 MW of coal-fired capacity are planned. This amount represents 24.3 percent of total planned additions and is equivalent to 6.3 percent of existing coal-fired capacity. The Watts Bar Unit 2 nuclear reactor is planned for operation in 2012, adding 1,270 MW of nuclear capacity. This will be the first new reactor to go online since 1995[8]. Planned wind additions are projected to be 13,650 MW, or 15.5 percent of total additions, and would increase 2008 installed wind capacity by 54.6 percent. Planned solar additions, though only 2.2 percent of total planned additions, are notable in that the projected increase of 1,938 MW will expand the 2008 installed solar capacity by 360 percent.

As expected, nuclear and coal-fired plants have the highest average capacity factors at 91.1 percent and 72.2 percent, respectively (Figure ES3, Table 5.3)). This is consistent with the economies of scale that these forms of capital-intensive baseload generating plants provide. The average capacity factor for coal-fired generation reflects a 1.4-percentage point decrease from the 73.6 percent average capacity factor achieved in 2007. The average capacity factor for nuclear generation decreased from 91.8 percent to 91.1 percent. This compares to the 90.4 percent average over the past five years and the low of 72.0 percent that occurred in 1997. Because the industry continues to rely on new combined cycle natural gas generation to meet rising demand, the average capacity factor[9] rose from 33.5 percent in 2003 to 42.0 percent in 2007, falling off slightly to 40.7 percent in 2008. The 8.5 percentage point improvement in the average capacity factor reflects both the increased reliance on combined cycle generation to meet energy requirements and further efficiency gains in combined cycle generation technology. In 2008 the average capacity factor for simple cycle natural gas-fired generation was 10.6 percent.

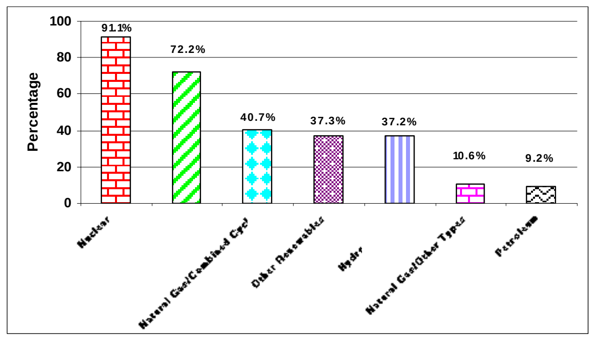
Figure ES3. Average Capacity Factor by Energy Source, 2008



Sources: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report;" Form EIA-923, "Power Plant Operations Report."

The increases in installed wind capacity are reflected in the reduced performance of renewable resources in aggregate, as measured by a composite capacity factor. The variable, intermittent nature of wind as an energy source leads to a low capacity factor relative to biomass, as wind is only available for generation subject to prevailing wind conditions. Renewable generation other than hydroelectric had a 37.3-percent capacity factor in 2008. This is a significant decrease from the 59.1 percent achieved in 2000, at which time the category was dominated by wood, wood-derived fuels, and other biomass, all of which are dispatchable energy sources. The continuous decline in the average capacity factor for all non-hydroelectric renewable resources is consistent with the significant growth of wind capacity relative to other forms of renewable electricity generation.

[9] Average capacity factors for natural gas generation have been calculated for both combined cycle generation and simple cycle generation. The required data was obtained from plant-specific capacity and energy data from the Form EIA-860, Form EIA-923, Form EIA-906 and Form EIA-920.

Fuel Switching Capacity

The total amount of net summer capacity reporting natural gas as the primary fuel in 2008 was 397,432 MW, of which 119,899 MW (30.2 percent) reported the operational capability as "switchable" between natural gas and oil. The requirement for this operational capability is that the capacity had (in working order) all necessary fuel switching equipment, including fuel storage. However, most of this capacity is subject to environmental regulatory limits on the use of oil, e.g., a restriction on how many hours per year a unit is allowed to burn oil. Of the 119,899 MW of gas-fired capacity that reported the ability to switch to oil, only 38,020 MW (31.7 percent) reported no environmental regulatory constraints or other factors limiting oil-fired operations (Table 1.9).

Fuel-switchable capacity is spread across the major generating technologies. Combustion turbine peaking units account for 44.9 percent (53,859 MW) of this net summer capacity. Steam generators (28,766 MW) and combined cycle units (36,339 MW) account for 24.0 percent and 30.3 percent of total switchable capacity, respectively. Internal combustion engines make up the remaining 0.8 percent. Of the total steam-electric switchable generating capacity, 16,777 MW can burn oil with no limiting factors. Similarly, for gas turbines, 15,167 MW of the total switchable capacity can switch fuels to oil without restriction.

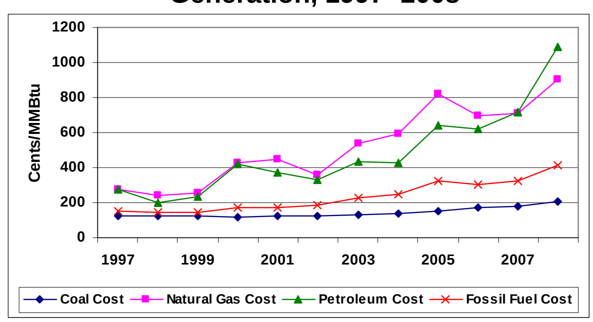
Interconnection Costs

During 2008, 356 generators representing a total nameplate capacity of 16,947 MW were connected for the first time to the electric grid. Interconnection costs are presented by producer type (Table 1.11) and by voltage class (Table 1.12). Total cost for each individual generator interconnection varies based on its components. In turn, the components of the total cost may vary based on whether or not interconnection infrastructure was already in place, the type of equipment for which costs were incurred, or other factors associated with the relevant generator technology. Though the amount of capacity connected to the grid was about the same for both independent power producers (IPP) and electric utilities, the total cost for the IPP sector, as well as the cost per MW, was significantly greater. This was due in part to the high interconnection costs from new wind plants, which are typically sited in relatively remote locations, thereby requiring the construction of longer transmission line extensions than might be required for conventional power plants.

Fuel Costs

The 2008 average delivered cost for all fossil fuels used at electric power plants (coal, petroleum, and natural gas combined) for electricity generation was $4.11 per million British thermal units (MMBtu) (Figure ES4, Table 3.5), an increase of 27.2 percent over the average delivered cost of $3.23 per MMBtu in 2007. This is the largest increase since 2005. All fossil fuel prices increased in 2008. The cost of natural gas delivered to electric power plants increased 26.9 percent, from $7.11 per MMBtu in 2007 to $9.02 per MMBtu in 2008. Annually, there have been larger increases (e.g., the 51.4 percent increase between 2002 and 2003), but 2008 was a particularly volatile year for natural gas prices, which spiked in the summer of 2008. The average daily spot price at Henry Hub[10] peaked at $13.28 per MMBtu on July 2, and was down to $5.71 per MMBtu by December 31st. Petroleum costs followed a similar pattern in 2008, with a nationwide annual increase of 51.5 percent, from $7.17 MMBtu in 2007 to $10.87 per MMBtu in 2008. As a result, petroleum-fired generation was down 29.6 percent in 2008.

Figure ES4. Fuel Costs for Electricity Generation, 1997- 2008



Sources: U.S. Energy Information Administration, Form EIA-423, "Monthly Cost and Quality of Fuels for Electric Plants Report," Federal Energy Regulatory Commission (FERC), Form 423, "Monthly Report of Cost and Quality of Fuels for Electric Plants," Form EIA-860, "Annual Electric Generator Report;" Form EIA-923, "Power Plant Operations Report."

The 2008 delivered cost of coal increased 16.9 percent nationwide, from $1.77 per MMBtu in 2007 to $2.07 MMBtu in 2008. This marked the eighth straight year that coal prices have increased. Since 2000 the delivered cost of coal has increased 72.5 percent (Figure ES4). Every Census Division saw increases in coal costs in 2008, with the exception of the Pacific Noncontiguous Division, as Alaska produces its own coal while Hawaii relies on imported coal. The South Atlantic and East South Central Divisions, which rely heavily on the higher-price Appalachian coal, saw the largest coal cost increases. In the South Atlantic, the delivered cost of

[10] Natural gas price data from www.theice.com

coal increased 22.1 percent, from $2.38 per MMBtu in 2007 to $2.91 per MMBtu in 2008. In the East South Central, costs increased to $2.41 per MMBtu in 2008.

Emissions

The estimated carbon dioxide (CO_2), sulfur dioxide (SO_2), and nitrogen oxide (NO_x) emissions for electricity are based on the type and quantity of fossil fuels consumed by electric power plants for the generation of electric power and associated useful thermal output. In the case of SO_2 and NO_x, boiler configurations and pollution abatement equipment also play a role. The emissions factors used in the estimation methodology are described in the discussion of Air Emissions in the Technical Notes, and are summarized in Tables A1, A2, and A3.

Emissions estimates for CO_2, SO_2, and NO_x all declined in 2008 relative to the previous year, affected by the weak U.S. economy and the decline in electricity production (Table 3.9). SO_2 and NO_x emissions were further reduced due to increased installations of emission control devices.

Estimated carbon dioxide emissions by U.S. electric generators and combined heat and power facilities fell 2.5 percent from 2007 to 2008 (from 2,540 million metric tons to 2,477 million metric tons), largely due to a fall in fuel consumption at electric power plants. Emissions from coal-fired power plants typically account for four-fifths of CO_2 emissions by electric power plants. Coal-fired generation fell 1.5 percent in 2008.

SO_2 emissions fell 13.4 percent, from 9.0 to 7.8 million metric tons, between 2007 and 2008. This amounts to the largest year-over-year decline since 1995. There are multiple ways to reduce sulfur emissions in electricity production. One is to change the type of coal burned to a coal rank with lower sulfur content. Other methods are to switch fuels (typically to natural gas) or to shut down plants with high SO_2 emissions. The large reductions in SO_2 in 2008 mostly resulted from the installation of emissions reduction equipment (flue gas desulfurization (FGD) units) in response to recently-implemented emission reduction legislation.

In March 2005, the Environmental Protection Agency issued its Clean Air Interstate Rule (CAIR), which was intended to achieve the largest reduction in certain air pollutants in more than a decade. CAIR covers 28 Eastern States and the District of Columbia, a region that historically burned high-sulfur coal. CAIR calls for a 70-percent reduction in SO_2 (from 2003 levels) by 2015. Although CAIR was vacated and remanded to the EPA by a U.S. Court of Appeals for the District of Columbia in July 2008, it was later reinstated by the same court in December of 2008. The temporary remand of CAIR in 2008 may have put off some SO_2 abatement investments; however, much of the planned SO_2 control retrofits were already in the pipeline, as indicated by the elevated level of FGD installations in 2008. Furthermore, several States and the EPA have taken actions to reduce SO_2 outside of CAIR.

The recent reduction in SO_2 emissions is traceable to a significant increase in FGD unit installations during 2008. Nationwide, the count of FGD units increased from 279 to 330, reflecting the largest increase in installations since 1995[11]. Use of other SO_2 reduction methods was not significant enough to produce a sizable decline in SO_2 in 2008. Most of the decline in SO_2 emissions between 2007 and 2008 can be traced to coal-related SO_2 emissions, but coal consumption did not significantly change (decrease of 0.5 percent). Petroleum represents a small share of electricity generation and due to its smaller carbon content (relative to coal), its contribution to the decline in SO_2 emissions was far less significant than coal. Finally, between 2007 and 2008, the average sulfur content of coal used to fire electric power showed a marginal increase, while there was little switching among coal ranks during this time period.

2008 data also show significant reductions in NO_x emissions. This too can be traced to the installation of pollution abatement equipment such as low-NO_x burners and selective catalytic reduction devices. NO_x emissions decreased 8.8 percent (from 3.7 to 3.3 million metric tons) from 2007 to 2008.

Trade

Total wholesale purchases of electric power in the United States increased 4.0 percent to 5,613 million MWh (Table 6.1), reversing a four-year downward trend. Almost half the volume of sales for resale was provided by energy-only providers (i.e., power marketing companies, a class of electric entities authorized by the Federal Energy Regulatory Commission (FERC) to transact at market-based rates, which came into being during the late 1990s with the deregulation of the wholesale power markets). Wholesale sales by wholesale power marketers and retail energy service providers increased from 2,477 million MWh in 2007 to 2,719 million MWh in 2008, which represented 47.9 percent of the wholesale market (Table 6.2). Independent power producers and

[11]Title IV of the Clean Air Act Amendments of 1990 set a goal of reducing annual SO_2 emissions by 10 million tons below 1980 levels. Phase I of Title IV, which began in 1995, identified 110 mostly coal-burning electric power plants.

combined heat and power (CHP) plants accounted for 24.4 percent of wholesale sales in 2008 compared to 25.5 percent in 2007.

The Nation's only international trade in electric power is with bordering nations Canada and Mexico, with the vast majority of that trade conducted with Canada. Most Mexican electric power trade is conducted with the State of California, while transactions with Canada are conducted through several bordering states. Much of the electricity provided from Canada is hydroelectric generation available for sale as the result of heavy seasonal river flows. On an annual basis, the U.S. is a net importer of electricity.

Total international net imports of electric power in 2008 increased 5.4 percent, from 31.3 million MWh in 2007 to 32.9 million MWh (Table 6.3). Imports to the U.S. increased 5.6 million MWh in 2008 from 51.4 million MWh in 2007 to 57.0 million MWh, while exports increased by 3.9 million MWh. Imports from Canada increased from 50.1 million MWh in 2007 to 55.7 million MWh in 2008, and U.S. exports to Canada increased from 19.6 million MWh to 23.5 million MWh. Electricity trade with Mexico followed a similar pattern of net imports, increasing only fractionally from 2007.

Electricity Prices and Sales

In 2008, the average retail price for all customers rose 0.61 cents per kWh to 9.74 cents per kWh (Table 7.4). This amounted to a 6.7-percent increase over the 9.13 cents per kWh average retail price paid in 2007. Year-over-year, the average retail price for all customers increased in 47 of the 50 States as well as the District of Columbia, with the exceptions being California, Maine, and Nevada. From 2007 to 2008, the average price of electricity increased 10 percent or more in 15 States. Most of the increases were in the 10 to 13 percent range, with the largest increase, 22.0 percent, occurring in Rhode Island. The average retail electric price for all customers declined in only 3 States compared to 11 States in 2007, and only Maine and California had decreases of more than 1 percent. The average retail price of electricity to all customers increased by 4 percent or more in all Census Divisions of the country—except the Pacific Contiguous, which was led by a 2.0 percent decrease in California. In New Jersey the average retail rate for all customers increased 11.0 percent. In the District of Columbia the average price increased 13.4 percent and in Texas it increased 8.7 percent. In Louisiana, the average electricity price for all customers increased 12.5 percent. Most Census Divisions experienced increases of 4 to 9 percent in the average retail price for all customers, with the exception of the East South Central Census Division, which experienced an increase of 12.3 percent. The highest regional price increase was in the Pacific Non-Contiguous Census Division (Alaska and Hawaii), where the average electricity price to all customers increased 29.7 percent over 2007. While both States rely heavily on oil and refined oil products, the regional price increase was primarily driven by increases in Hawaii. Hawaii's primary fuel for electricity is petroleum, and petroleum prices to that State increased 42.0 percent in 2008.

In 2008, residential prices increased to 11.26 cents per kWh, or 5.7 percent over 2007. The average residential price increased by 10 percent or more in 8 States and the District of Columbia. Most of these jurisdictions have implemented retail competition and the investor-owned utilities operating within these States participate in organized, competitive wholesale markets operated by independent system operators. Residential prices in Rhode Island increased 24.1 percent, from 14.05 cents per kWh in 2007 to 17.43 cents per kWh in 2008. The average residential price in Maryland increased 16.4 percent, from 11.89 cents per kWh in 2007 to 13.84 cents per kWh in 2008. The largest increase in average residential prices was in Hawaii, at 34.7 percent. The increases in Rhode Island and Maryland are the result of the transition to market based rates for the wholesale electricity portion of retail electric service. In order to mitigate the impact of higher retail prices, the Maryland Public Service Commission approved a plan for the largest investor-owned utility in the State that gave customers two payment options. The first option provided for retail prices based on the full market price of wholesale electricity prices, effective June 1, 2008. This option resulted in approximately a 50-percent increase in the average electric bill. The second option provided that the cost of electricity would be phased in over time. Deferred costs would be recovered by December 31, 2009.[12]

The District of Columbia had the fourth largest increase in residential prices, at 13.2 percent, followed by New Jersey (10.8 percent). On a regional basis, the highest average residential price increase was observed in the East South Central Division. New England, Mid-Atlantic, East North Central, South Atlantic, and West South Central all observed increases of between 6 percent and 7 percent. Average residential prices in the New England and Mid-Atlantic Census Divisions increased 6.0 percent and 6.8 percent respectively.

[12] In the Matter of Baltimore Gas and Electric Company's Proposal to Implement a Rate Stabilization Plan Pursuant to Section 7-548 of the Public Utility companies Article and the Commission's Inquiry into Factors Impacting Wholesale Electricity Prices, Source: Maryland Public Service Commission, Order No. 81423. Case No. 9099, May 23, 2008.

Average residential prices fell 1.9 percent in Maine and 4.2 percent in California. These were the only two States to realize a decrease in the residential average retail price of electricity in 2008.

Nationally, average commercial prices increased from 9.65 to 10.36 cents per kWh, a 7.5 percent increase over 2007. The largest regional price increase was in the Pacific Noncontiguous Census Division, at 28.0 percent, followed by a 14.8 percent increase in the East North Central Census Division. By State, the largest increase in average commercial prices was in Illinois, where prices increased 37.6 percent as result of some Illinois utilities reclassifying higher-priced industrial transactions as commercial in 2008. Illinois was followed by increases in Hawaii (35.7 percent), Rhode Island (21.2 percent), Virginia (14.7 percent), Georgia (12.4 percent) and the District of Columbia (12.1 percent). The average commercial price in the East North Central Census Division was 9.75 cents per kWh in 2008, up from 8.49 in 2007. In 2007, the West South Central Census Division was unchanged at 9.26 cents per kWh but increased 9.2 percent in 2008 to 10.11 cents per kWh. The average commercial price declined less than 1 percent in Nevada and 2.2 percent in California. In the Pacific Contiguous Census Division, the average commercial price declined from 11.19 cents per kWh in 2007 to 11.03 cents per kWh in 2008. This was the only region where average commercial prices declined.

Average industrial prices increased 6.9 percent from 6.39 cents per kWh in 2007 to 6.83 cents per kWh in 2008. The largest regional price increase in the industrial sector was in the Pacific Noncontiguous Census Division, at 36.1 percent, with Hawaii observing an increase of 41.7 percent from 18.38 cents per kWh to 26.05 cents per kWh in 2008. Average industrial prices in the District of Columbia increased 33.7 percent followed by increases in Louisiana and Tennessee (both at 21.2 percent), and Georgia (20.6 percent). The average industrial rate in the East North Central Census Division was 5.79 cents per kWh in 2008, a 1.9 percent decrease from 5.90 cents per kWh in 2007. This was driven by a 31.3-percent decrease in Illinois industrial prices, as a result of reclassifying data.

Total U.S. retail sales of electricity were 3,733 million MWh in 2008, a 0.8 percent decrease from 2007 to 2008. Comparatively, the annual growth in electricity sales in 2007 was 2.6 percent, and the average annual growth rate since 1997 was 1.6 percent. The 2008 decrease in annual sales from 2007 marks the first time since 2001 that annual sales decreased from the prior year. This decrease was driven by the residential and industrial sectors, with sales decreases of 0.9 percent and 1.8 percent, respectively. Commercial sales were essentially flat between 2007 and 2008. Since 1997, annual industrial sales have declined four times and overall, load continues to gradually shift away from the industrial sector. The industrial sector accounted for 33.0 percent of total retail sales in 1997, but by 2008 it had declined to 27.0 percent. Over that same time period, the commercial sector's share of retail sales increased from 29.5 percent to 35.8 percent, while retail sales to the residential sector grew from 34.2 percent to 37.0 percent.

Demand-Side Management

In 2008, electricity providers reported total peak-load reductions of 32,741 MW resulting from demand-side management (DSM) programs, an 8.2 percent increase from the amount reported in 2007 (Table 9.1). Reported DSM costs increased $1.2 billion, up 47.4 percent from the $2.5 billion reported in 2007. DSM costs can vary significantly from year to year because of business cycle fluctuations and regulatory changes. Since costs are reported as they occur, while program effects may appear in future years, DSM costs and effects may not always show a direct relationship. In the five years since 2003, nominal DSM expenditures have increased at a 22.9-percent average annual growth rate. During the same period, actual peak load reductions have grown at a 6.17-percent average annual rate from, 22,904 MW to 32,741 MW. The divergence between the growth rates of load reduction and expenditures is driven in large measure by 2008 expenditures, which are in response to higher overall energy prices. The full effect of these expenditures may appear in additional load reductions in the coming years. The combined DSM energy savings programs (i.e., load management and energy efficiency) increased to 87.8 million MWh in 2008 from 69.0 million MWh in 2007.

Table ES1. Summary Statistics for the United States, 1997 through 2008

Description	2008	2007	2006	2005	2004	2003	2002	2001	2000	1999	1998	1997
Net Generation (thousand megawatthours)

[1] Includes anthracite, bituminous, subbituminous and lignite coal. Waste and synthetic coal are included starting in 2002.

[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology) and waste oil.

[3] Includes a small number of generators for which waste heat is the primary energy source.

[4] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.

[5] Conventional hydroelectric power excluding pumped storage facilities.

[6] Other renewables represents the summation of the sub-categories of Wind, Solar Thermal and Photovoltaic, Wood and Wood Derived Fuels, Geothermal, and Other Biomass.

[7] Wood/wood waste solids (including paper pellets, railroad ties, utility poles, wood chips, bark, and wood waste solids), wood waste liquids (red liquor, sludge wood, spent sulfite liquor, and other wood-based liquids), and black liquor.

[8] Biogenic municipal solid waste, landfill gas, sludge waste, agricultural byproducts, other biomass solids, other biomass liquids, and other biomass gases (including digester gases, methane, and other biomass gases).

[9] Pumped storage is the capacity to generate electricity from water previously pumped to an elevated reservoir and then released through a conduit to turbine generators located at a lower level. The generation from a hydroelectric pumped storage facility is the net value of production minus the energy used for pumping..

[10] Non-biogenic municipal solid waste, batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.

[11] Municipal solid waste, landfill gas, sludge waste, agricultural byproducts, other biomass solids, other biomass liquids, and other biomass gases (including digester gases, methane, and other biomass gases).

[12] Batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.
[13] Anthracite, bituminous, subbituminous, lignite, and synthetic coal; excludes waste coal.
[14] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology). Data prior to 2004 includes small quantities of waste oil.
[15] For 2002 through 2007, includes data from the Form EIA-423 for independent power producers, and commercial and industrial power-producing facilities. Beginning in 2008, data are collected on the Form EIA-923 for utilities, independent power producers, and commercial and industrial power-producing facilities. Receipts, cost, and quality data are collected from plants above a 50 MW threshold, and imputed for plants between 1 and 50 MW. Therefore, there may be a notable increase in fuel receipts beginning with 2008 data.
[16] Natural gas, including a small amount of supplemental gaseous fuels that cannot be identified separately.
[17] SO_2 and NO_x 2008 values are preliminary.
[18] Data presented are reflective of large utilities.

NA = Not available.

R = Revised.

Note: ·See Glossary reference for definitions.·See Technical Notes Table A5 for conversion to different units of measure.·Capacity by energy source is based on the capacity associated with the energy source reported as the most predominant (primary) one, where more than one energy source is associated with a generator.·Dual-fired capacity returned to respective fuel categories for current and all historical years. New fuel switchable capacity tables have replaced dual-fired breakouts.·Totals may not equal sum of components because of indep

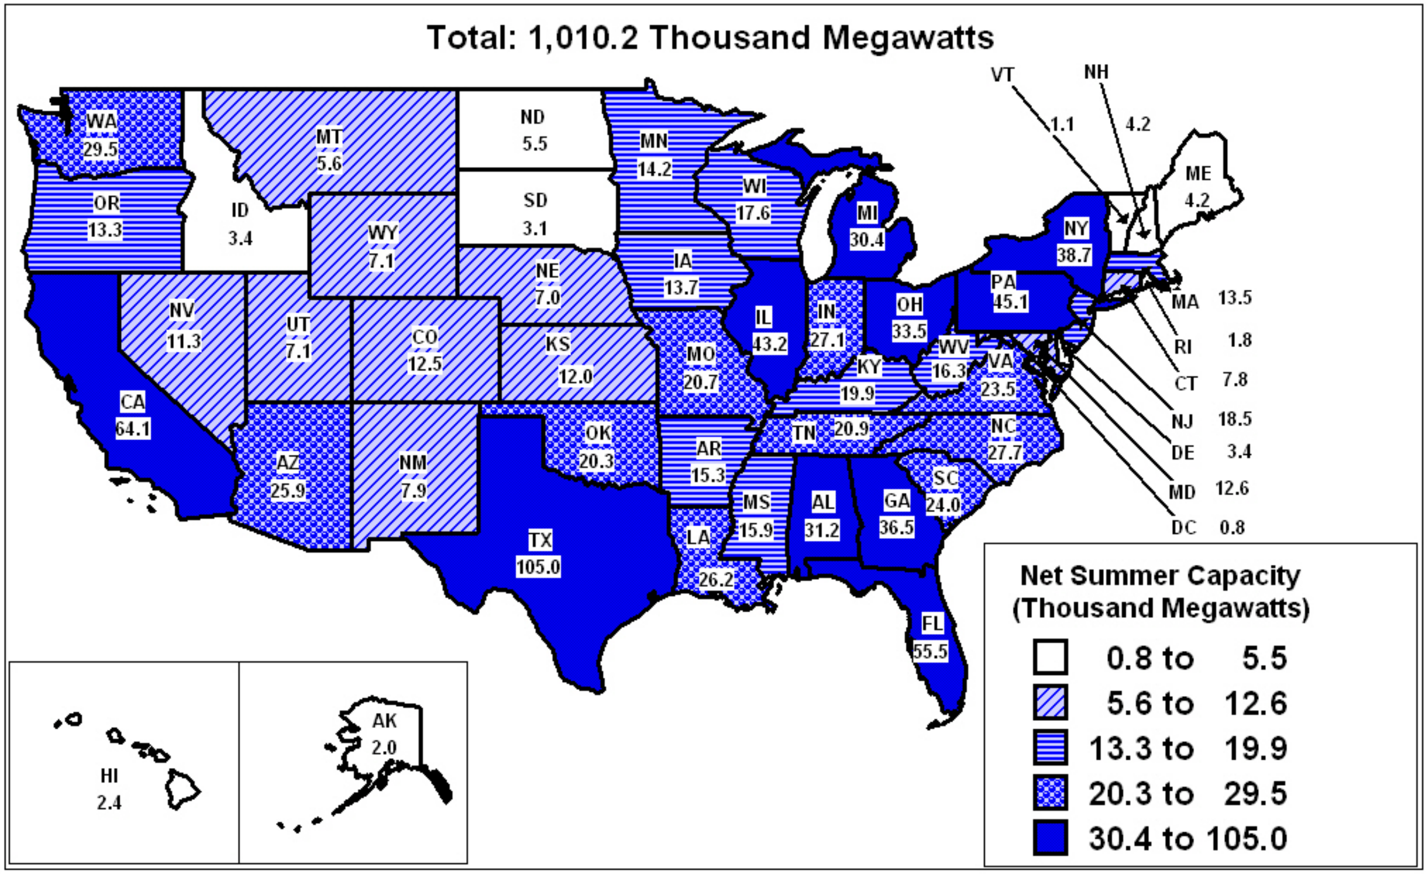
[1] Anthracite, bituminous coal, subbituminous coal, lignite, and waste coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Includes a small number of generators for which waste heat is the primary energy source.
[4] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[5] Conventional hydroelectric power excluding pumped storage facilities.
[6] Wood, black liquor, other wood waste, municipal solid waste, landfill gas, sludge waste, agriculture byproducts, other biomass, geothermal, solar thermal, photovoltaic energy, and wind.
[7] Pumped storage capacity generates electricity from water pumped to an elevated reservoir and then released through a conduit to turbine generators located at a lower level.
[8] Batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.
[9] Small number of electricity-only, non-Combined Heat and Power plants may be included.
R = Revised.
Notes: • See Glossary reference for definitions. • Capacity by energy source is based on the capacity associated with the energy source reported as the most predominant (primary) one, where more than one energy source is associated with a generator. • Totals may not equal sum of components because of independent rounding.

Figure 1.1. U.S. Electric Industry Generating Capacity by State, 2008



Note: Data are displayed as 5 groups of 10 States and the District of Columbia.

Table 1.2. Existing Capacity by Energy Source, 2008
(Megawatts)

Energy Source	Number of Generators	Generator Nameplate Capacity	Net Summer Capacity	Net Winter Capacity
Coal[1]	1,445	337,300	313,322	315,461
Petroleum[2]	3,768	63,655	57,445	61,538
Natural Gas[3]	5,467	454,611	397,432	427,703
Other Gases[4]	102	2,262	1,995	1,958
Nuclear	104	106,147	100,755	102,494
Hydroelectric Conventional[5]	3,996	77,731	77,930	77,694
Wind	494	24,980	24,651	24,698
Solar Thermal and Photovoltaic	89	539	536	455
Wood and Wood Derived Fuels[6]	353	7,730	6,864	6,905
Geothermal	228	3,281	2,256	2,409
Other Biomass[7]	1,412	4,854	4,186	4,263
Pumped Storage	151	20,355	21,858	21,768
Other[8]	49	1,042	942	968
Total	**17,658**	**1,104,486**	**1,010,171**	**1,048,313**

[1] Anthracite, bituminous coal, subbituminous coal, lignite, and waste coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Includes a small number of generators for which waste heat is the primary energy source.
[4] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[5] The net summer capacity and/or the net winter capacity may exceed nameplate capacity due to upgrades to and overload capability of hydroelectric generators.
[6] Wood/wood waste solids (including paper pellets, railroad ties, utility poles, wood chips, bark, and wood waste solids), wood waste liquids (red liquor, sludge wood, spent sulfite liquor, and other wood-based liquids), and black liquor.
[7] Municipal solid waste, landfill gas, sludge waste, agricultural byproducts, other biomass solids, other biomass liquids, and other biomass gases (including digester gases, methane, and other biomass gases).
[8] Batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.

Notes: • Capacity by energy source is based on the capacity associated with the energy source reported as the most predominant (primary) one, where more than one energy source is associated with a generator. • Totals may not equal sum of components because of independent rounding. • In some reporting of capacity data, such as for wind, solar and wave energy sites, the capacity for multiple generators is reported in a single generator record and is presented as a single generator in the count of number of generators.

[1] Anthracite, bituminous coal, subbituminous coal, lignite, and waste coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[4] Conventional hydroelectric power excluding pumped storage facilities; includes ocean power technology (wave energy).
[5] Wood/wood waste solids (including paper pellets, railroad ties, utility poles, wood chips, bark, and wood waste solids), wood waste liquids (red liquor, sludge wood, spent sulfite liquor, and other wood-based liquids), and black liquor.
[6] Municipal solid waste, landfill gas, sludge waste, agricultural byproducts, other biomass solids, other biomass liquids, and other biomass gases (including digester gases, methane, and other biomass gases).
[7] Batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.

Notes: • Projected data are updated annually, so revision superscript is not used. • Capacity by energy source is based on the capacity associated with the energy source reported as the most predominant (primary) one, where more than one energy source is associated with a generator. These data reflect plans as of December 31, 2008. • Totals may not equal sum of components because of independent rounding. • In some reporting of capacity data, such as for wind, solar and wave energy sites, the capacity for multiple generators is reported in a single generator record and is presented as a single generator in the count of number of generators.

Table 1.6.A. Capacity of Dispersed Generators by Technology Type, 2004 through 2008
(Count, Megawatts)

Period	Internal Combustion (MW)	Combustion Turbine (MW)	Steam Turbine (MW)	Hydroelectric (MW)	Wind and Other (MW)	Total	
						Number of Generators	(MW)
2004	3,366[R]	210	552	26	2	11,123	4,156
2005	4,290[R]	335[R]	126	2	13	11,373	4,766
2006	6,524[R]	346[R]	157[R]	3[R]	8	9,536	7,037
2007	7,866[R]	268[R]	102[R]	31	30[R]	11,057	8,297
2008	9,335	86	248	34	70	12,262	9,773

R = Revised.

Note: Dispersed generators are commercial and industrial generators which are not connected to the grid. They may be installed at or near a customer`s site, or at other locations. They may be owned by either the customers of the distribution utility or by the utility. Other includes generators for which technology is not specified.

Source: U.S. Energy Information Administration, Form EIA-861, "Annual Electric Power Industry Report."

Table 1.6.B. Capacity of Distributed Generators by Technology Type, 2004 through 2008
(Count, Megawatts)

Period	Internal Combustion (MW)	Combustion Turbine (MW)	Steam Turbine (MW)	Hydroelectric (MW)	Wind and Other (MW)	Total	
						Number of Generators	(MW)
2004	2,168[R]	1,028	1,085[R]	1,004[R]	138[R]	5,863	5,423
2005[1]	4,025[R]	1,917	1,830[R]	999[R]	995[R]	17,371	9,766
2006	3,646[R]	1,298[R]	2,582[R]	806	1,081[R]	5,044	9,411[R]
2007	4,624[R]	1,990[R]	3,596[R]	1,051[R]	1,441[R]	7,103	12,702
2008	5,112	1,949	3,060	1,154	1,588	9,591	12,863

[1] Distributed generator data in 2005 include a significant number of generators reported by one respondent, which may be for residential applications.

R = Revised.

Note: Distributed generators are commercial and industrial generators which are connected to the grid. They may be installed at or near a customer`s site, or at other locations. They may be owned by either the customers of the distribution utility or by the utility. Other includes generators for which technology is not specified.

Table 1.6.C. Total Capacity of Dispersed and Distributed Generators by Technology Type, 2004 through 2008
(Count, Megawatts)

Period	Internal Combustion (MW)	Combustion Turbine (MW)	Steam Turbine (MW)	Hydroelectric (MW)	Wind and Other (MW)	Total	
						Number of Generators	(MW)
2004	5,534[R]	1,238	1,637[R]	1,030[R]	140[R]	16,986	9,579
2005[1]	8,315[R]	2,252[R]	1,956[R]	1,001[R]	1,008[R]	28,744	14,532
2006	10,169[R]	1,644[R]	2,739[R]	809[R]	1,088[R]	14,580	16,448[R]
2007	12,490[R]	2,258[R]	3,698[R]	1,082[R]	1,471[R]	18,160	20,999
2008	14,447	2,035	3,308	1,188	1,658	21,853	22,636

[1] Distributed generator data in 2005 include a significant number of generators reported by one respondent, which may be for residential applications.

R = Revised.

Note: Dispersed and distributed generators are commercial and industrial generators. Dispersed generators are not connected to the grid. Distributed generators are connected to the grid. Both types of generators may be installed at or near a customer`s site, or at other locations, and both types of generators may be owned by either the customers of the distribution utility or by the utility. Other includes generators for which technology is not specified.

Table 1.11. Interconnection Cost and Capacity for New Generators, by Producer Type, 2007 and 2008

Sector	Units[1]	Nameplate Capacity (megawatts)[1]	Cost (thousand dollars)[1]
2007			
Total	269	14,061	397,921
Electric Utilities[2]	97	8,527	184,813
Independent Power Producers[3]	162	5,413	208,733
Commercial[4]	6	10	421
Industrial[4,R]	4	111	3,954
2008			
Total	356	16,947	523,846
Electric Utilities[2]	108	8,479	185,955
Independent Power Producers[3]	243	8,456	337,145
Commercial[4]	4	10	745
Industrial[4]	1	3	1

[1] Cost is the total cost incurred for the direct, physical interconnection of generators that started commercial operation in the respective years. These generator-specific costs may include costs for transmission or distribution lines, transformers, protective devices, substations, switching stations and other equipment necessary for interconnection. Units and Nameplate Capacity represent the number of units and associated capacity for which interconnection costs were incurred and reported.
[2] Electric utility CHP plants are included in Electric Generators, Electric Utilities.
[3] Includes only independent power producers` combined heat and power facilities.
[4] Small number of electricity-only, non-Combined Heat and Power plants may be included.
R = Revised.
Notes: • See Glossary reference for definitions. • Totals may not equal sum of components because of independent rounding. • In some reporting of capacity data, such as for wind, solar and wave energy sites, the capacity for multiple generators is reported in a single generator record and is presented as a single generator in the count of number of generators.
Source: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report."

Table 1.12. Interconnection Cost and Capacity for New Generators, by Grid Voltage Class, 2007 and 2008

Voltage Class	Units[1]	Nameplate Capacity (megawatts)[1]	Cost (thousand dollars)[1]
2007			
Total	269	14,061	397,921
Distribution (< 35 kV)[R]	104	556	20,462
SubTransmission (35 kV - 138 kV)[R]	103	3,773	131,840
Transmission (> 138 kV)	62	9,731	245,619
2008			
Total	356	16,947	523,846
Distribution (< 35 kV)	101	497	25,198
SubTransmission (35 kV - 138 kV)	178	6,677	181,061
Transmission (> 138 kV)	77	9,773	317,587

[1] Cost is the total cost incurred for the direct, physical interconnection of generators that started commercial operation in the respective years. These generator-specific costs may include costs for transmission or distribution lines, transformers, protective devices, substations, switching stations and other equipment necessary for interconnection. Units and Nameplate Capacity represent the number of units and associated capacity for which interconnection costs were incurred and reported.

R = Revised.

kV=Kilovolt=1000 volts.

Notes: • See Glossary reference for definitions. • Totals may not equal sum of components because of independent rounding. • In some reporting of capacity data, such as for wind, solar and wave energy sites, the capacity for multiple generators is reported in a single generator record and is presented as a single generator in the count of number of generators.

[1] Anthracite, bituminous coal, subbituminous coal, lignite, waste coal, and synthetic coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[4] Conventional hydroelectric power excluding pumped storage facilities.
[5] Other renewables represents the summation of the sub-categories of Wind, Solar Thermal and Photovoltaic, Wood and Wood Derived Fuels, Geothermal, and Other Biomass.
[6] The quantity of output from a hydroelectric pumped storage facility represents production minus energy used for pumping.
[7] Non-biogenic municipal solid waste, batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.
[8] Electric utility CHP plants are included in Electricity Generators, Electric Utilities.
[9] Small number of electricity-only, non-Combined Heat and Power plants may be included.

* = Value is less than half of the smallest unit of measure.

Note: Totals may not equal sum of components because of independent rounding

[1] Anthracite, bituminous coal, subbituminous coal, lignite, waste coal, and synthetic coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology) and waste oil.
[3] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[4] Other renewables represents the summation of the sub-categories of Wind, Solar Thermal and Photovoltaic, Wood and Wood Derived Fuels, Geothermal, and Other Biomass.
[5] Non-biogenic municipal solid waste, batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, tire-derived fuels and miscellaneous technologies.

Notes: • The methodology to allocate fuel use by combined heat and power plants to electric power generation and useful thermal output was modified beginning in 2007, and retroactively applied to data from 2004 to 2006. For more information, please see the Technical Notes in the Appendices. • Totals may not equal sum of components because of independent rounding.

[1] Includes anthracite, bituminous, subbituminous and lignite coal. Waste and synthetic coal were included starting in 2002.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Blast furnace gas, propane gas, and other manufactured and waste gases derived from fossil fuels.
[4] Electric utility CHP plants are included in Electricity Generators, Electric Utilities.
[5] Small number of electricity-only, non-Combined Heat and Power plants may be included.
* = Value is less than half of the smallest unit of measure.
Notes: • See Glossary reference for definitions • A new method of allocating fuel consumption between electric power generation and useful thermal output (UTO) was implemented with publication of the preliminary 2008 data, and retroactively applied to 2004-2007 data. The new methodology evenly distributes a combined heat and power (CHP) plant`s losses between

the two output products (electric power and UTO). In the historical data, UTO was consistently assumed to be 80 percent efficient and all other losses at the plant were allocated to electric power. This change results in the fuel for electric power to be lower while the fuel for UTO is higher than the prior set of data as both are given the same efficiency. This results in the appearance of an increase in efficiency of production of electric power after 2003.

2004	1,002,032	136	27.42	.97	186,655	429	26.56	1.66	5,734,054	596	248
2005	1,021,437	154	31.20	.98	194,733	644	39.65	1.61	6,181,717	821	325
2006	1,079,943	169	34.09	.97	100,965	623	37.66	2.31	6,675,246	694	302
2007	1,054,664	177	35.48	.96	88,347	717	43.50	2.10	7,200,316	711	323
2008	1,069,709	207	41.14	.97	96,341	1,087	64.89	2.21	7,879,046	902	411

[1] Anthracite, bituminous, subbituminous, lignite, waste coal, and synthetic coal.
[2] Distillate fuel oil (all diesel and No. 1, No. 2, and No. 4 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil), jet fuel, kerosene, petroleum coke (converted to liquid petroleum, see Technical Notes for conversion methodology), and waste oil.
[3] Natural gas, including a small amount of supplemental gaseous fuels that cannot be identified separately. Natural gas values for 2001 forward do not include blast furnace gas or other gas.
[4] Beginning in 2006, receipts of petroleum liquids went down substantially, while the receipts of petroleum coke remained the nearly the same. The Average Sulfur Percent by Weight is higher beginning in 2006 as a result the greater influence by petroleum coke receipts, which has higher sulfur content, than the petroleum liquid receipts.
[5] Beginning in 2002, data from the historical Form EIA-423 for independent power producers and combined heat and power producers are included in this table. Prior to 2002, these data were not collected; the data for 2001 and previous years include only data collected from electric utilities via the historical FERC Form 423.

Notes: • Mcf equals 1,000 cubic feet. Totals may not equal sum of components because of independent rounding. • Beginning in 2008 with the Form EIA-923, receipts, cost, and quality data are imputed for plants between 1 and 50 MW, in addition to the data collected from plants above the 50 MW threshold. Therefore, there may be a notable increase in fuel receipts beginning with 2008 data.

[1] ECAR, MAAC, and MAIN dissolved at the end of 2005. Utility membership joined other reliability regional councils. Also, see Footnote 3.
[2] Regional name has changed from Mid-Continent Area Power Pool to Midwest Reliability Organization.
[3] ReliabilityFirst Corporation (RFC) came into existence on January 1, 2006, and submitted a consolidated filing covering the historical NERC regions of ECAR, MAAC, and MAIN. Many of the former utility members joined RFC.
NA = Not available.
Notes: • Projected data are updated annually, so revision superscript is not used. • Nerc Regions are provided in Appendix A., Technical Notes. • Represents an hour of a day during the associated peak period. • The summer peak period begins on June 1 and extends through September 30. • The winter peak period begins on December 1 and extends through the end of February of the following year • The MRO, SERC, and SPP regional boundaries were altered as a variety of utilities changed reliability organizations. The historical data series have not been adjusted. • Totals may not equal sum of components because of independent rounding.

[1] ECAR, MAAC, and MAIN dissolved at the end of 2005. Utility membership joined other reliability regional councils. Also, see Footnote 6.
[2] Net Internal Demand represent the system demand that is planned for by the electric power industry`s reliability authority and is equal to Internal Demand less Direct Control Load Management and Interruptible Demand.
[3] Capacity Resources: Utility- and IPP-owned generating capacity that is existing or in various stages of planning or construction, less inoperable capacity, plus planned capacity purchases from other resources, less planned capacity sales.
[4] Capacity Margin is the amount of unused available capability of an electric power system at peak load as a percentage of capacity resources.
[5] Regional name has changed from Mid-Continent Area Power Pool to Midwest Reliability Organization.
[6] ReliabilityFirst Corporation (RFC) came into existence on January 1, 2006, and submitted a consolidated filing covering the historical NERC regions of ECAR, MAAC, and MAIN. Many of the former utility members joined RFC.

NA = Not available.
R = Revised.

Notes: • Nerc Regions are provided in Appendix A., Technical Notes. • Represents an hour of a day during the associated peak period. • The summer peak period begins on June 1 and extends through September 30. • The MRO, SERC, and SPP regional boundaries were altered as a variety of utilities changed reliability organizations. The historical data series have not been adjusted. • Totals may not equal sum of components because of independent rounding.

Contiguous U.S.	**652,909**	**988,316**	**33.9**	**661,874**	**993,649**	**33.4**

[1] Net Internal Demand represent the system demand that is planned for by the electric power industry`s reliability authority and is equal to Internal Demand less Direct Control Load Management and Interruptible Demand.

[2] Capacity Resources: Utility- and IPP-owned generating capacity that is existing or in various stages of planning or construction, less inoperable capacity, plus planned capacity purchases from other resources, less planned capacity sales.

[3] Capacity Margin is the amount of unused available capability of an electric power system at peak load as a percentage of capacity resources.

[4] Regional name has changed from Mid-Continent Area Power Pool to Midwest Reliability Organization.

[5] ReliabilityFirst Corporation (RFC) came into existence on January 1, 2006, and submitted a consolidated filing covering the historical NERC regions of ECAR, MAAC, and MAIN. Many of the former utility members joined RFC.

Notes: • Actual data are final. • Projected data are updated annually, so revision superscript is not used. • Represents an hour of a day during the associated peak period. • The winter peak period begins on December 1 and extends through the end of February of the following year. For example, winter 2004/2005 begins December 1, 2004, and extends to February 28, 2005 • The MRO, SERC, and SPP regional boundaries were altered as a variety of utilities changed reliability organizations. The historical data series have not been adjusted. • Totals may not equal sum of components because of independent rounding.

2007	87	72	251	39	--	48	133	--	22
2008	85	66	240	39	--	47	133	--	25

[1] Small number of electricity-only, non-Combined Heat and Power plants may be included.

Note: The number of power plants for each energy source is the number of sites for which the respective energy source was reported as the most predominant energy source for at least one of its generators. If all generators for a site have the same energy source reported as the most predominant, that site will be counted once under that energy source. However, if the most predominant energy source is not the same for all generators within a site, the site is counted more than once, based on the number of most predominant energy sources for generators at a site. In general, this table translates the number of generators by energy source (Table 1.2) into the number of sites represented by the generators for an energy source. Therefore, the count for Total (All Sectors) is the sum of the counts for each sector by energy source and does not necessarily represent unique sites

Source: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report."

Table 5.2. Average Capacity Factors by Energy Source, 1997 through 2008
(Percent)

Year	Coal	Petroleum	Natural Gas CC[1]	Natural Gas Other	Nuclear	Hydroelectric Conventional	Other Renewables	All Energy Sources
1997	67.2	14.6	--	31.6	72.0	51.2	57.4	52.4
1998	67.7	22.2	--	34.2	79.2	46.6	57.0	54.6
1999	68.1	22.4	--	33.2	85.3	45.9	56.9	54.9
2000	71.0	20.5	--	37.1	87.7	39.5	59.1	54.6
2001	69.2	21.5	--	35.7	89.4	31.4	50.2	51.4
2002	70.0	18.1	--	38.2	90.3	38.0	54.0	49.7
2003	72.0	22.4	33.5	12.1	87.9	40.0	50.0	47.7
2004	71.9	23.3	35.5	10.7	90.1	39.4	50.5	47.9
2005	73.3	23.8	36.8	10.6	89.3	39.8	47.0	48.3
2006	72.6	12.6	38.8	10.7	89.6	42.4	45.7	48.0
2007	73.6	13.4	42.0	11.4	91.8	36.3	40.0	48.7
2008	72.2	9.2	40.7	10.6	91.1	37.2	37.3	47.4

[1] Prior to 2003, the generation collected on Form EIA-906 did not have a distinction for combined cycle (CC) prime movers. All natural gas-fired plants of all types are included in "Natural Gas Other" for 1997 to 2002.

Technical Note: Average Capacity Factor is the ratio of actual generation to maximum potential output, expressed as a percent.
Average Capacity Factor = [(Net Generation)/(Net Summer Capacity* Number of Hours in the Year)] * 100
for the respective energy source and year

Source: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report;" Form EIA-923, Power Plant Operations Report," and predecessor forms.

Table 5.3. Average Operating Heat Rate for Selected Energy Sources, 2001 through 2008
(Btu per Kilowatthour)

Year	Coal[1]	Petroleum[2]	Natural Gas	Nuclear
2001	10,378	10,742	10,051	10,443
2002	10,314	10,641	9,533	10,442
2003	10,297	10,610	9,207	10,421
2004	10,331	10,571	8,647	10,427
2005	10,373	10,631	8,551	10,436
2006	10,351	10,809	8,471	10,436
2007	10,375	10,794	8,403	10,485
2008	10,378	11,015	8,305	10,453

[1] Includes anthracite, bituminous, subbituminous and lignite coal. Waste coal and synthetic coal are included starting in 2002.
[2] Includes distillate fuel oil (all diesel and No. 1 and No. 2 fuel oils), residual fuel oil (No. 5 and No. 6 fuel oils and bunker C fuel oil, jet fuel, kerosene, petroleum coke, and waste oil.

Notes: • Included in the calculation for coal, petroleum, and natural gas average operating heat rate are electric power plants in the utility and independent power producer sectors. • Combined heat and power plants, and all plants in the commercial and industrial sectors are excluded from the calculations. • The nuclear average heat rate is the weighted average tested heat rate for nuclear units as reported on the Form EIA-860.

Technical Note: The average operating heat rate for coal, petroleum and natural gas displayed in Table 5.3 is calculated by dividing the energy consumed (in BTUs) to generate electricity by the kilowatthours of power generated as reported on the Form EIA-923 and its predecessor forms. Included in the calculation for coal, petroleum and natural gas are utility and independent power producer plants. The calculation excludes combined heat and power plants, industrial plants, and commercial sector plants. The nuclear heat rate is a weighted average (by capacity) of the tested heat rate as reported on the Form EIA-860.

Source: U.S. Energy Information Administration, Form EIA-923, "Power Plant Operations Report," and predecessor form(s) including U.S. Energy Information Administration, Form EIA-906, "Power Plant Report;" and Form EIA-920, "Combined Heat and Power Plant Report;" Form EIA-860, "Annual Electric Generator Report."

Table 5.4. Average Heat Rates by Prime Mover and Energy Source, 2008
(Btu per Kilowatthour)

Prime Mover	Coal	Petroleum	Natural Gas	Nuclear
Steam Turbine	10,138	10,360	10,389	10,453
Gas Turbine	--	13,322	11,526	--
Internal Combustion	--	10,271	10,014	--
Combined Cycle	W	11,044	7,598	--

W = Withheld to avoid disclosure of individual company data.

Notes: • See Glossary reference for definitions. • Totals may not equal sum of components because of independent rounding. • Heat rate is reported at full load conditions for electric utilities and independent power producers.

Technical Note: The heat rates reported on Form EIA-860 are weighted by Net Summer Capacity.
Average Heat Rate = Sum of [Reported Heat Rate * (NSC/Total Capacity)] where
NSC = Net Summer Capacity, and
Total Capacity = Sum of [NSC] of units for the respective prime mover and energy source categories.

Source: U.S. Energy Information Administration, Form EIA-860, "Annual Electric Generator Report."

Table 5.5. Planned Transmission Capacity Additions, by High-Voltage Size, 2009 through 2015
(Circuit Miles of Transmission)

Voltage		Circuit Miles						
Type	**Operating (kV)**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**
AC	230	1,028	1,523	958	1,308	991	365	478
AC	345	276	1,039	877	519	4,069	1,005	1,017
AC	500	32	296	574	1,013	2,181	4,281	1,917
AC	765	--	--	--	--	285	--	--
AC Total		**1,336**	**2,858**	**2,409**	**2,839**	**7,525**	**5,651**	**3,412**
DC	100-299	--	--	--	--	1	--	--
DC	300-399	--	--	--	--	--	--	--
DC	400-599	--	--	--	--	--	--	1,300
DC Total		**--**	**--**	**--**	**--**	**1**	**--**	**1,300**
Grand Total		**1,336**	**2,858**	**2,409**	**2,839**	**7,526**	**5,651**	**4,712**
Lines taken out of service		**5**	**265**	**--**	**--**	**311**	**45**	**116**

Notes: • Circuit miles do not equal physical miles on the ground; the reference terminology for that concept is structural mile. • More than one circuit can be present on a structure. • Some structures were designed and then built to carry future transmission circuits in order to handle expected growth in new capability requirements. • Lines are taken out of service for a variety of reasons including intentional changes to the right-of-way to better use available land for different levels of voltage and types of poles and towers.

[1] Pursuant to applicable Texas statutes establishing competitive electricity markets within the Electric Reliability Council of Texas, all customers served by Retail Energy Providers must be provided bundled energy and delivery services, so they are included under "Full-Service Providers."

NA = Not available.

Notes: • See Technical Notes reference for definitions. • Full-Service Providers sell bundled electricity services (e.g., both energy and delivery) to end users. Full-Service Providers may purchase electricity from others (such as Independent Power Producers or other Full-Service Providers) prior to delivery. Direct sales from independent facility generators to end use consumers are reported under Full-Service Providers. Energy-Only Providers sell energy to end use customers; incumbent utility distribution firms provide Delivery-Only Services for these customers.

2007	1,007	5,647	1,565	102	NA	8,322
2008	1,131	6,281	1,422	121	NA	8,956

[1] Sum of Full-Service Providers and Restructured Retail Service Providers.
[2] Pursuant to applicable Texas statutes establishing competitive electricity markets within the Electric Reliability Council of Texas, all customers served by Retail Energy Providers must be provided bundled energy and delivery services, so are included under "Full-Service Providers."
[3] Sum of Energy-Only Providers and Delivery-Only Service.
[4] From 1996 to 1999, revenue was estimated based on retail sales reported on the Form EIA-861.
NA = Not available.
Notes: • See Technical Notes reference for definitions. • Full-Service Providers sell bundled electricity services (e.g., both energy and delivery) to end users. Full-Service Providers may purchase electricity from others (such as Independent Power Producers or other Full-Service Providers) prior to delivery. Direct sales from independent facility generators to end use consumers are reported under Full-Service Providers. Energy-Only Providers sell energy to end use customers; incumbent utility distribution firms provide Delivery-Only Services for

these customers. Data reported under Restructured Retail Service Providers represent the sum of Energy-Only and Delivery-Only Services. • For historical data, see the State of California discussion in Technical Notes. • Totals may not equal sum of components because of independent rounding.

2006[1]	606,919	35,937	642,856	30,689	2,930	33,619
2007............	773,391	62,260	835,651	44,886	3,943	48,829[R]
2008............	918,284	64,711	982,995	64,400	5,609	70,009

[1] In 2006 the single largest provider of green pricing services in the country discontinued service in two States. More than 297,600 customers in green pricing programs reverted to standard service tariffs, predominantly in Ohio and Pennsylvania.

R = Revised.

Notes: • Green Pricing programs allow electricity customers the opportunity to purchase electricity generated from renewable resources, thereby encouraging renewable energy development. Renewable resources include solar, wind, geothermal, hydroelectric power, and wood. • Net Metering arrangements permit facilities and residences (using a meter that reads inflows and outflows of electricity) to sell any excess power generated over its load requirement back to the distributor to offset consumption.

Appendices

Appendix A.
Technical Notes

This appendix describes how the U.S. Energy Information Administration (EIA) collects, estimates, and reports electric power data in the *Electric Power Annual*. Following is a description of the ongoing data quality efforts and sources of data for the *Electric Power Annual*.

Data Quality

The *Electric Power Annual* (EPA) is prepared by the Electric Power Division (EPD), Office of Coal, Nuclear, Electric and Alternate Fuels (CNEAF), U.S. Energy Information Administration (EIA), U.S. Department of Energy (DOE). EPD performs routine reviews of the data collected and the forms on which they are collected. Additionally, to assure that the data are collected from the complete set of respondents, CNEAF routinely reviews the frames for each data collection.

Unified Data Submission Process

Data are entered directly by respondents into the EPD e-filing system. A small number of hard copy forms are keyed by EPD. All data are subject to review via edits built into the system, additional quality assurance reports, and review by subject matter experts. Questionable data values are verified through contacts with respondents. Also, survey non-respondents are identified and contacted.

Initial edit checks of the data are performed through the system by the respondent. Other program edits include both deterministic checks, in which records are checked for the presence of data in required fields, and statistical checks, in which the data are checked against a range of values based on historical data values and for logical or mathematical consistency with data elements reported in the survey. Discrepancies found in the data, as a result of these checks, are resolved either by the processing staff or by further information obtained from a telephone call to the respondent company.

Those respondents unable to use the electronic reporting method provide the data in hard copy, typically via fax and e-mail. These data are manually entered into the computerized database and are subjected to the same data edits as those that are electronically submitted. Resolution of questionable data is accomplished via telephone or e-mail contact with the respondents.

Reliability of Data

Annual survey data have nonsampling errors. Nonsampling errors can be attributed to many sources: (1) inability to obtain complete information about all cases (i.e., nonresponse); (2) response errors; (3) definitional difficulties; (4) differences in the interpretation of questions; (5) mistakes in recording or coding the data; and (6) other errors of collection, response, coverage, and estimation for missing data.

Although no direct measurement of the biases due to nonsampling errors can be obtained, precautionary steps were taken in all phases of the frame development and data collection, processing, and tabulation processes, in an effort to minimize their influence.

Imputation. If the reported values appeared to be in error and the data issue could not be resolved with the respondent, or if the facility was a nonrespondent, a regression methodology was used to impute for the facility.[1,2,3,4,5] The regression methodology relies on other data to make estimates for erroneous or missing responses.

The basic technique employed is described in the paper "Model-Based Sampling and Inference[12]," on the EIA website. Additional references can be found on the InterStat website. The basis for the current methodology involves a 'borrowing of strength' technique for small domains.[1,6,7]

Data Revision Procedure

CNEAF has adopted the following procedures with respect to the revision of data disseminated in energy data products:

- Annual survey data are disseminated either as preliminary or final when first appearing in a data product. Data initially released as preliminary will be so noted in the data

[7] Knaub, J.R., Jr. (2001), "Using Prediction-Oriented Software for Survey Estimation - Part III: Full-Scale Study of Variance and Bias," InterStat, June 2001, http://interstat.statjournals.net/

product. These data are typically released as final by the next dissemination of the same product; however, if final data are available at an earlier interval they may be released in another product.

- After data are disseminated as final, further revisions will be considered if they make a difference of 1 percent or greater at the national level. Revisions for differences that do not meet the 1 percent or greater threshold will be determined by the Office Director. In either case, the proposed revision will be subject to the EIA revision policy concerning how it affects other EIA products.
- The magnitudes of changes due to revisions experienced in the past will be included periodically in the data products, so that the reader can assess the accuracy of the data.

The *Electric Power Annual* presents the most current annual data available to the EIA. The statistics may differ from those published previously in EIA publications due to corrections, revisions, or other adjustments to the data subsequent to its original release.

Sensitive Data (Formerly Identified as Data Confidentiality). Most of the data collected on the electric power surveys are not considered business sensitive. However, the data that are classified as sensitive are handled by EPD consistent with EIA's “Policy on the Disclosure of Individually Identifiable Energy Information in the Possession of the EIA” (45 Federal Register 59812 (1980)).

Rounding and Percent Change Calculations

Rounding Rules for Data. To round a number to n digits (decimal places), add one unit to the nth digit if the (n+1) digit is 5 or larger and keep the nth digit unchanged if the (n+1) digit is less than 5. The symbol for a number rounded to zero is (*).

Percent Change. The following formula is used to calculate percent differences.

$$\text{Percent Change} = \left(\frac{x\,(t_2) - x\,(t_1)}{x\,(t_1)}\right) x\,100,$$

where $x\ (t_1)$ and $x\ (t_2)$ denote the quantity at year t_1 and subsequent year t_2.

Data Sources for *Electric Power Annual*

Data published in the *Electric Power Annual* are compiled from forms filed annually or aggregated to an annual basis from monthly forms by electric utilities and electricity generators (see figure on EIA Electric Industry Data Collection on the next page.) The EIA forms used are:

- Form EIA-411, “Coordinated Bulk Power Supply Program Report;”
- Form EIA-423, “Monthly Cost and Quality of Fuels for Electric Plants Report;” [Replaced]
- Form EIA-767, “Steam-Electric Plant Operation and Design Report;” [Replaced]
- Form EIA-860, “Annual Electric Generator Report;” [Modified]
- Form EIA-861, “Annual Electric Power Industry Report;”
- Form EIA-906, “Power Plant Report;” [Replaced] and
- Form EIA-920, “Combined Heat and Power Plant Report.” [Replaced]
- Form EIA-923, "Power Plant Operations Report,"

These forms can be found on the EIA Internet website at: http://www.eia.doe.gov/cneaf/electricity/page/forms.html.

The purpose of each form is summarized below.

Survey data from other Federal sources is also utilized for this publication. They include:

- Department of Energy Form OE-781R, “Annual Report of International Electric Export/Import Data” (Office of Electricity Delivery and Energy Reliability);
- Federal Energy Regulatory Commission Form 1, “Annual Report of Major Electric Utilities, Licensees, and Others;”
- Rural Utility Service Form 7, “Financial and Statistical Report;” and
- Rural Utility Service Form 12, “Operating Report – Financial.”

In addition to the above-named forms, the historical data published in the EPA are compiled from the following sources:

- Form EIA-412, “Annual Electric Industry Financial Report,”

- Federal Energy Regulatory Commission Form 423, "Cost and Quality of Fuels for Electric Plants,"
- Form EIA-759, "Monthly Power Plant Report,"
- Form EIA-860A, "Annual Electric Generator Report–Utility,"
- Form EIA-860B, "Annual Electric Generator Report–Nonutility,"
- Form EIA-900, "Monthly Nonutility Power Report,"

Additionally, some data reported in this publication were acquired from the National Energy Board of Canada.

Issues within Non-EIA Historical Data Series: Restructuring of the electric power industry has dramatically increased trade in various locations and altered trends. In California, with the changes initiated to establish electricity markets, the electricity imports and exports data are found on the California's Independent System Operator's web site[8] and are not reported to DOE.

Meanings of Symbols Appearing in Tables

Some symbols appearing in the data tables have further standardized to describe all data collected by the Electric Power Division of EIA. The meanings are indicated in footnotes on the applicable tables and include the following:

* The value reported is less than half of the smallest unit of measure, but is greater than zero.

P Usage of this symbol indicates a preliminary value. The P is defined in endnotes as "P=Preliminary data."

NM Data value is not meaningful when compared to the same value for the previous month or the previous year. This symbol is also used to indicate a data value is not meaningful due to having a high Relative Standard Error (RSE).

Form EIA-411

The Form EIA-411 is filed as a mandatory report except for Schedule 7 (Transmission Outages) that is still voluntary reported. The information reported includes: (1) actual energy and peak demand for the preceding year and five additional years; (2) existing and future generating capacity; (3) scheduled capacity transfers; (4) projections of capacity, demand, purchases, sales, and scheduled maintenance; and (5) bulk power system maps. The report presents various North American Electric Reliability Corporation (NERC) regional council aggregate totals for their member electric utilities, with some nonmember information included. The eight NERC councils submit data for the Form EIA-411 to NERC. A joint response, through the NERC Headquarters, is filed annually on July 15. The forms are compiled from data furnished by electricity generators and electric utilities (members, associates, and nonmembers) within the council areas.

Instrument and Design History. The Form EIA-411 program was initiated under the Federal Power Commission Docket R-362, Reliability and Adequacy of Electric Service, and Orders 383-2, 383-3, and 383-4. The Department of Energy, established in October 1977, assumed the responsibility for this activity. Until 2008, this form was considered voluntary under the authority of the Federal Power Act (Public Law 88-280), The Federal Energy Administration Act of 1974 (Public Law 93-275), and the Department of Energy Organization Act (Public Law 95-91). The responsibility for collecting these data had been delegated to the Office of Emergency Planning and Operations within the Department of Energy and was transferred to EIA for the reporting year 1996.

Issues within Historical Data Series

The Florida Reliability Coordinating Council (FRCC) separated itself from the Southeastern Electric Reliability Council (SERC) in the mid-1990s and all time series data have been adjusted. In 1998, several utilities realigned from Southwest Power Pool (SPP) to SERC. Adjustments were made to the information to account for the separation and to address the tracking of shared reserve capacity that was under long-term contracts with multiple members. Name changes altered both the Mid-Continent Area Power Pool (MAPP) to the Midwest Reliability Organization (MRO) and the Western Systems Coordinating Council (WSCC) to the Western Electricity Coordinating Council (WECC). The MRO membership boundaries have altered over time, but WECC membership boundaries have not. The utilities in the associated regional entity identified as the Alaska System Coordination Council (ASCC)

[8] For the reporting year 2001, California - ISO reported electricity purchases from Mexico of 98,645 MWh. They exported 65,475 MWh, thereby having a total net trade of 33,170 MWh of imported electricity in 2001. For the reporting year 2002, California - ISO reported electricity purchases from Mexico of 143,948 MWh. They exported 196,923 MWh, thereby having a total net trade of 52,975 MWh of exported electricity in 2002. In 2003, California - ISO reported electricity purchases of 971,278 MWh and sold 22,510 MWh. For 2004, California - ISO reported electricity purchases of 1,103,928 MWh and sold 48,074 MWh. For 2005, California ISO reported electricity purchases of 1,498,622 MWh and sales of 103,051 MWh. For 2006, California - ISO reported electric purchases of 1,048,610 MWh and sales of 498, 268 MWh. In 2007, the California – ISO reported electric purchases on 1,178,996 MWh and 216,496 MWh sales with Mexico. In 2008, the California - ISO reported electriciy purchases on 1,189,504 MWh and 216,321 MWh sales with Mexico.

dropped their formal participation in NERC. Both the States of Alaska and Hawaii are not contiguous with the other continental States and have no electrical interconnections. At the close of calendar year 2005, the following reliability regional councils were dissolved: East Central Area Reliability Coordination Agreement (ECAR), Mid-Atlantic Area Council (MAAC), and Mid-America Interconnected Network (MAIN).

On January 1, 2006, the Reliability*First* Corporation (RFC) came into existence as a new regional reliability council. Individual utility membership in the former ECAR, MAAC, and MAIN councils mostly shifted to RFC. However, adjustments in membership as utilities joined or left various reliability councils impacted MRO, SERC, and SPP. The Texas Regional Entity (TRE) was formed from a delegation of authority from NERC to handle the regional responsibilities of the Electric Reliability Council of Texas (ERCOT). The revised delegation agreements covering all the regions were approved by the Federal Energy Regulatory Commission on March 21, 2008. Reliability Councils that are unchanged include: Florida Reliability Coordinating Council (FRCC), Northeast Power Coordinating Council (NPCC), and the Western Electricity Coordinating Council (WECC). The historical time series have not been adjusted to account for individual membership shifts.

The new NERC Regional Entity names are as follows:

- Florida Reliability Coordinating Council (FRCC),
- Midwest Reliability Organization (MRO),
- Northeast Power Coordinating Council (NPCC),
- Reliability*First* Corporation (RFC),
- Southeastern Electric Reliability Council (SERC),
- Southwest Power Pool (SPP),
- Texas Regional Entity (TRE), and
- Western Electricity Coordinating Council (WECC).

<u>Concept of Demand within the EIA-411</u>: Historically, the Form EIA-411 has used the electric power industry's methodology for examining aggregated supply and demand. To get to the megawatts of power that are determined to be available for planning purposes each year, different categories are subtracted from the theoretical true totals. The definitions for demand are as follows:

- **Net Internal Demand**: Internal Demand less Direct Control Load Management and Interruptible Demand.
- **Internal Demand**: To collect these data, NERC develops a Total Internal Demand that is the sum of the metered (net) outputs of all generators within the system and the metered line flows into the system, less the metered line flows out of the system. The demand of station service or auxiliary needs (such as fan motors, pump motors, and other equipment essential to the operation of the generating units) is not included nor are any requirement customer (utility) load or capacity found behind the line meters on the system.
- **Direct Control Load Management**: Demand-Side Management that is under the direct control of the system operator. DCLM may control the electric supply to individual appliances or equipment on customer premises; it does not included Interruptible Demand.
- **Interruptible Demand**: The magnitude of customer demand that, in accordance with contractual arrangements, can be interrupted as the time of the NERC Council or Reporting party seasonal peak by direct control of the system operator. In some instances, the demand reduction may be effected by direct action of the system operator (remote tripping) after notice to the customer in accordance with contractual provisions.

Sensitive Data (Formerly Identified as Data Confidentiality). Power flow cases and maps are considered business sensitive.

Form EIA-412 [Terminated]

The Form EIA-412 was used annually to collect accounting, financial, and operating data from major publicly owned electric utilities in the United States. Those publicly owned electric utilities engaged in the generation, transmission, or distribution of electricity which had 150,000 megawatthours of sales to ultimate consumers and/or 150,000 megawatthours of sales for resale for the two previous years, as reported on the Form EIA-861, “Annual Electric Utility Report,” were required to submit the Form EIA-412. The Form EIA-412 was made available in January to collect data as of the end of the preceding calendar year. The completed surveys were due to EIA on or before April 30.

Instrument and Design History. The Federal Power Commission (FPC) created the FPC Form 1M in 1961 as a mandatory survey. It became the responsibility of the EIA in October 1977 when the FPC was merged with DOE. In 1979, the FPC Form 1M was superseded by the Economic Regulatory Administration (ERA) Form ERA-412, and in January 1980 by the Form EIA-412.

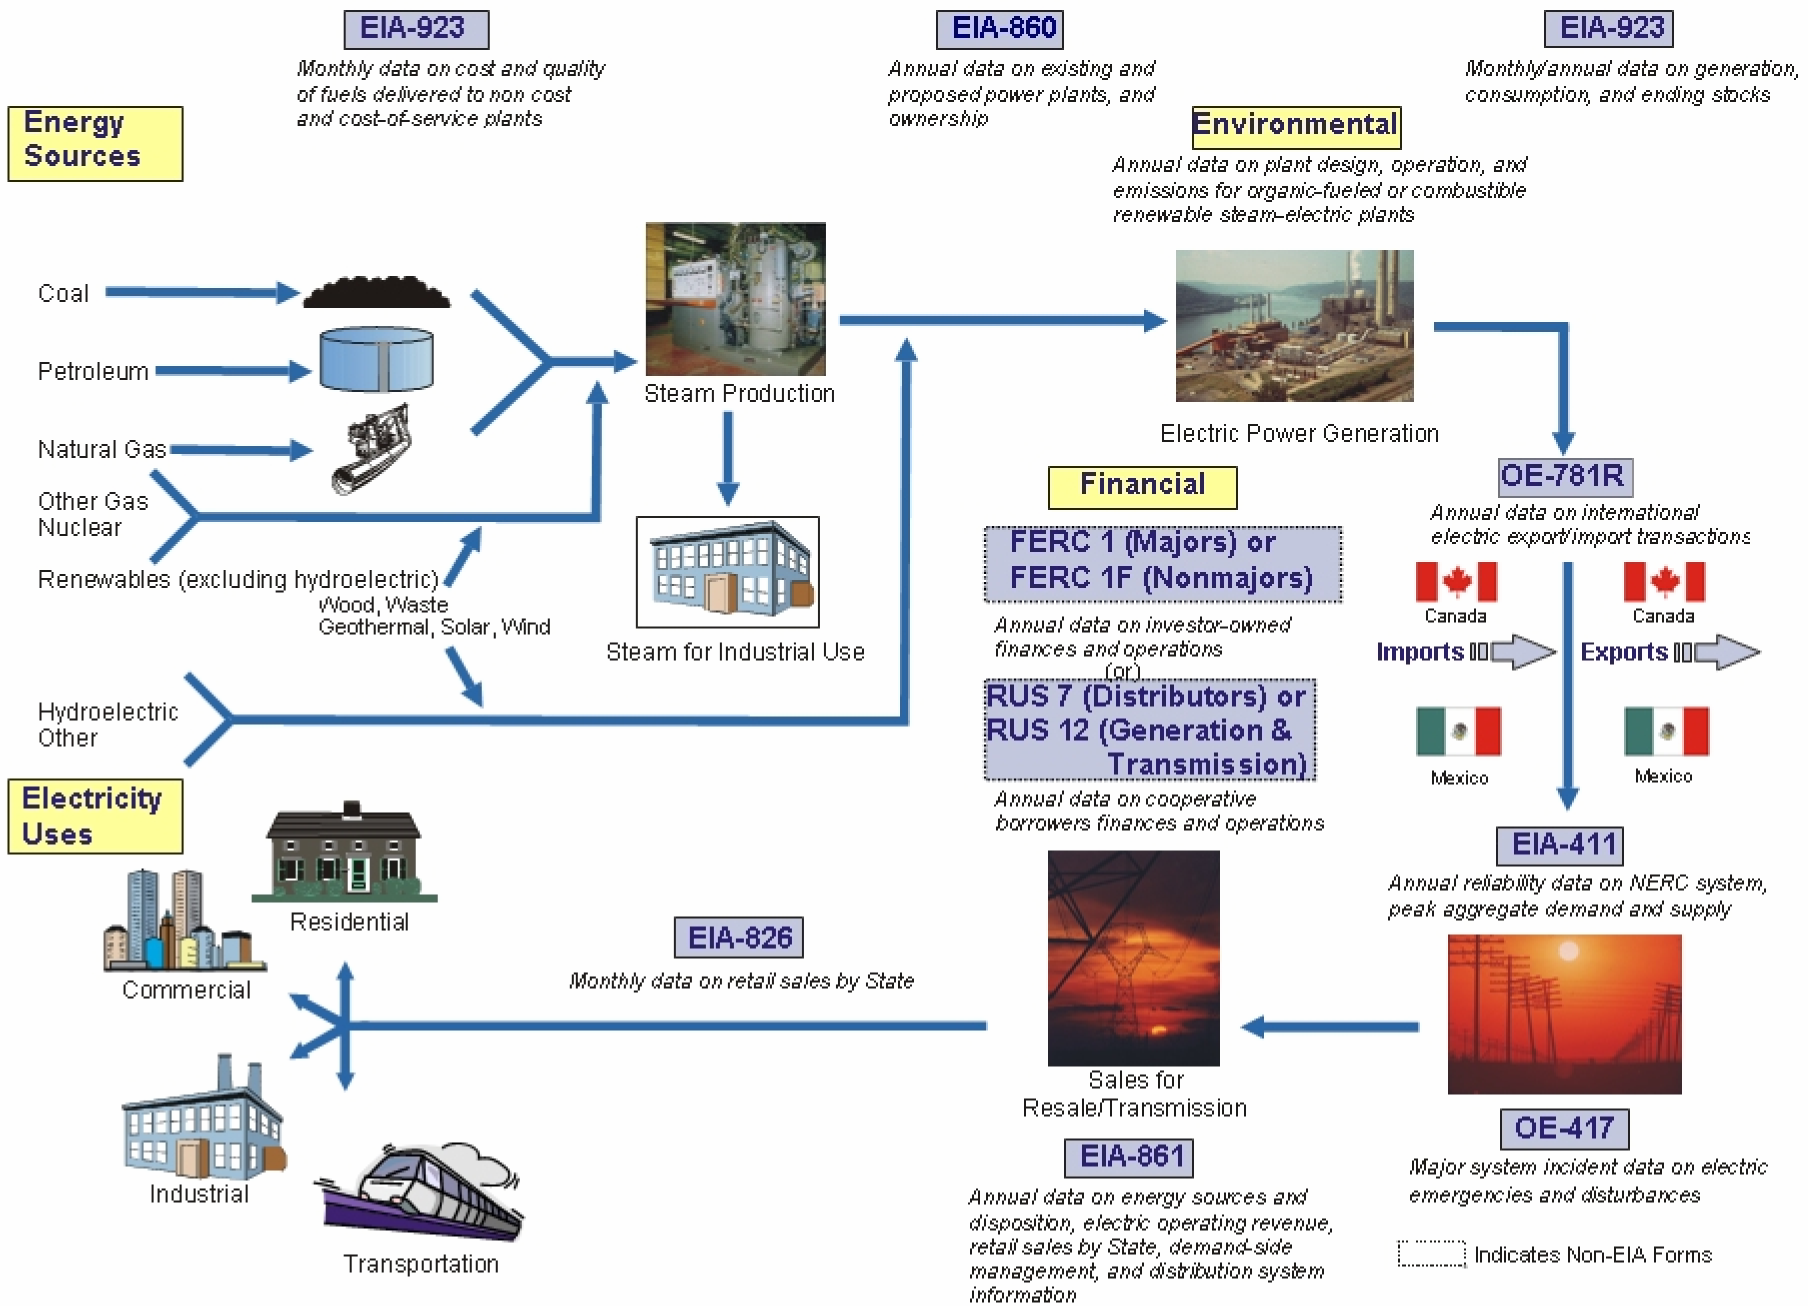
The 1996-1997 data represent those electric utilities meeting a threshold of 120,000 megawatthours for ultimate consumers' sales and/or resales. The criteria used to select the respondents for this survey fit approximately 500 publicly owned electric utilities. Federal electric utilities are required to file the Form EIA-412. The financial data for the U.S. Army Corps of Engineers (except for Saint Mary's Falls at Sault Ste. Marie, Michigan); the U.S. Department of Interior, Bureau of Reclamation; and the U.S. International Boundary and Water Commission were collected on the Form EIA-412 from the Federal power marketing administrations. The form was terminated after the 2003 data year.

Issues within Historical Data Series

Beginning with the 2001 data collection, the plant statistics reported on Schedule 9 were also collected from unregulated entities that own plants with a nameplate capacity of 10 megawatts or greater. Also beginning with the 2003 collection, the transmission data reported in Schedules 10 and 11 were collected from each generation and transmission cooperative owning transmission lines having a nominal voltage of 132 kilovolts or greater.

For 2001 - 2003, California Department of Water Resources - Electric Energy Fund data were included in the EIA-412 data tables. In response to the energy shortfall in California, in 2001 the California State legislature authorized the California Department of Water Resources, using its undamaged borrowing capability, to enter the wholesale markets on behalf of the California retail customers effective on January 17, 2001 and for the period ending December 31, 2002. Their 2001 revenue collected was $5,501,000,000 with purchased power costs of $12,055,000,000. Their 2002 revenue collected was $4,210,000,000 with purchased power costs of $3,827,749,811. Their 2003 revenue collected was $4,627,000,000 with purchased power costs of $4,732,000,000. The California Public Utility Commission was required by statute to establish the procedures for retail revenue recovery mechanisms for their purchase power costs in the future.

EIA Electric Industry Data Collection



Sensitive Data (Formerly Identified as Data Confidentiality). The nonutility data collected on Schedule 9 "Electric Generating Plant Statistics" for "Cost of Plant" and "Production Expenses," are considered business sensitive.

Form EIA-423 [Replaced in 2008 by the Form EIA-923]

The Form EIA-423, "Monthly Cost and Quality of Fuels for Electric Plants Report," collected information from selected electric generating plants in the United States. The data collected on this survey included the cost and quality of fossil fuels delivered to nonutility plants to produce electricity. These plants included independent power producers (including those facilities that formerly reported on the FERC Form 423) and commercial and industrial combined heat and power producers whose total fossil-fueled nameplate generating capacity is 50 or more megawatts.

Instrument and Design History. The Form EIA-423[1] was originally implemented in January 2002 to collect monthly cost and quality data for fossil fuel receipts from owners or operators of nonutility electricity generating plants. It was terminated on January 1, 2008, and replaced by the Form EIA-923, "Power Plant Operations Report."

Issues within Historical Data Series

Natural gas values for 2001 forward do not include blast furnace gas or other gas.

Sensitive Data (Formerly Identified as Data Confidentiality). Plant fuel cost data collected on the survey are considered business sensitive. State and national level aggregations will be published in this report if sufficient data are available to avoid disclosure of individual company and plant level costs.

FERC Form 423 [Replaced in 2008 by Form EIA-923]

The Federal Energy Regulatory Commission (FERC) Form 423, "Monthly Report of Cost and Quality of Fuels for Electric Plants," was administered by FERC. The data were downloaded from the Commission's website into an EIA database. The Form was filed by approximately 600 regulated plants. To meet the old criteria for filing, a plant must have had a total steam turbine electric generating capacity and/or combined-cycle (gas turbine with associated steam turbine) generating capacity of 50 or more megawatts. Only fuel delivered for use in steam-turbine and combined-cycle units was reported. Fuel received for use in gas-turbine or internal-combustion units that was not associated with a combined-cycle operation is not reported. The 2007 data collection represents the last year where the information came from the FERC Form 423.

Instrument and Design History. On July 7, 1972, the Federal Power Commission (FPC) issued Order Number 453 enacting the New Code of Federal Regulations, Section 141.61, legally creating the FPC Form 423. Originally, the form was used to collect data only on fossil-steam plants, but was amended in 1974 to include data on internal-combustion and combustion-turbine units. The FERC Form 423 replaced the FPC Form 423 in January 1983. The FERC Form 423 eliminated peaking units, for which data were previously collected on the FPC Form 423. In addition, the generator nameplate capacity threshold was changed from 25 megawatts to 50 megawatts. This reduction in coverage eliminated approximately 50 utilities and 250 plants. All historical FPC Form 423 data in this publication were revised to reflect the new generator-nameplate-capacity threshold of 50 or more megawatts reported on the FERC Form 423. In January 1991, the collection of data on the FERC Form 423 was extended to include combined-cycle units. Historical data have not been revised to include these units. Starting with the January 1993 data, the FERC began to collect the data directly from the respondents. On January 1, 2008, EIA assumed took responsibility for collection and the information is now under the Form EIA-923, "Power Plant Operations Report."

Formulas and Methodologies. Data for the FERC Form 423 were collected at the plant level. These data were then used in the same formulas used by the Form EIA-423 to produce aggregates and averages for each fuel type at the State, Census division, and U.S. levels.

Issues within Historical Data Series. The FERC Form 423 data published by EIA have been reviewed for consistency between volumes and prices and for their consistency over time.

Receipts data for regulated utilities were compiled by EIA from data collected by the Federal Energy Regulatory Commission (FERC) on the FERC Form 423. These data were collected by FERC for regulatory rather than statistical and publication purposes. EIA did not attempt to resolve any late

[1] Due to the restructuring of the electric power industry, many plants which had historically submitted this information for utility plants on the FERC Form 423 (see subsequent section) were being transferred to the nonutility sector. As a result, a large percentage of fossil fuel receipts were no longer being reported. The Form EIA-423 was implemented to fill this void and to capture the data associated with existing nonregulated power producers. Its design closely follows that of the FERC Form 423.

filing issues in the FERC Form 423 data. Due to the estimation procedure discussed previously, 2003 and later data cannot be directly compared to previous years' data.

Sensitive Data (Formerly Identified as Data Confidentiality). Data collected on FERC Form 423 are not considered to be business sensitive.

Form EIA-767 [Replaced by Forms EIA-860 and EIA-923]

The Form EIA-767 was used to collect data annually on plant operations and equipment design, including boiler, generator, cooling system, air pollution control equipment, and stack characteristics. Data were collected from a mandatory restricted-universe census of all electric power plants with a total existing or planned organic-fueled or combustible renewable steam-electric generator nameplate rating of 10 or more megawatts. The entire form was filed by approximately 800 power plants with a nameplate capacity of 100 or more megawatts. An additional 600 power plants with a nameplate capacity under 100 megawatts submitted information only on fuel consumption and quality, boiler and generator configuration, and nitrogen oxides, mercury, particulate matter, and sulfur dioxide controls.

Instrument and Design History. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data. The predecessor form, FPC-67, "Steam-Electric Plant Air and Water Quality Control Data," was used to collect data from 1969 to 1980, when the form number was changed to Form EIA-767. In 1982, the form was completely redesigned and retitled Form EIA-767, "Steam-Electric Plant Operation and Design Report." In 1986, the respondent universe of 700 was increased to 900 to include plants with nameplate capacity from 10 megawatts to 100 megawatts. In 2002, the respondent universe was increased by almost 1,370 plants with the addition of non-utility plants. Collection of data via the form was suspended for the 2006 data year. Starting for the collection of 2007 calendar year data, most of the Form EIA-767 information is now collected on either the revised Form EIA-860, "Annual Electric Generator Report" or the new Form EIA-923, "Power Plant Operations Report."

Estimation of EIA-767 Data. No estimation of Form EIA-767 data was performed, as 100 percent of the forms were collected.

Issues within Historical Data Series

None.

Sensitive Data (Formerly Identified as Data Confidentiality). Historical latitude and longitude data collected on the Form EIA-767 are considered business sensitive.

Form EIA-860

The Form EIA-860 is a mandatory census of all existing and planned electric generating facilities in the United States with a total generator nameplate capacity of 1 or more megawatts. The survey is used to collect data on existing power plants and 5-year plans for constructing new plants, generating unit additions, modifications, and retirements in existing plants. Data on the survey are collected at the individual generator level. Certain power plant environmental related data are now collected at the boiler level. These data include environmental equipment design parameters and boiler air emission standards and boiler emission controls. The Form EIA-860 is made available in January to collect data for the previous year and is due to EIA by February 15 of each year.

Instrument and Design History. The Form EIA-860 was originally implemented in January 1985 to collect plant data on electric utilities as of year-end 1984. In January 1999, the Form EIA-860 was renamed the Form EIA-860A and was implemented to collect data as of January 1, 1999.

In 1989, the Form EIA-867, "Annual Nonutility Power Producer Report," was initiated to collect plant data on unregulated entities with a total generator nameplate capacity of 5 or more megawatts. In 1992, the reporting threshold of the Form EIA-867 was lowered to include all facilities with a combined nameplate capacity of 1 or more megawatts. Previously, data were collected every 3 years from facilities with a nameplate capacity between 1 and 5 megawatts. In 1998, the Form EIA-867, was renamed Form EIA-860B, "Annual Electric Generator Report – Nonutility." The Form EIA-860B was a mandatory survey of all existing and planned nonutility electric generating facilities in the United States with a total generator nameplate capacity of 1 or more megawatts.

Beginning with data collected for the year 2001, the infrastructure data collected on the Form EIA-860A and the Form EIA-860B were combined into the new Form EIA-860 and the monthly and annual versions of the Form EIA-906. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Starting with the 2007 data,, design parameters data formerly collected on Form EIA-767 are collected on Form EIA-860. These include design parameters associated with certain steam-electric plants' boilers, cooling systems, flue gas particulate collectors, flue gas desulfurization units and stacks and flues.

Estimation of EIA-860 Data. Of the 17,658 existing generators in the 2008 Form EIA-860 frame, imputation was performed on 2 generators. These 2 generators account for less than 0.01 percent of the existing capacity. Imputation was performed at the respondent-plant-generator levels, using the 2007 data for the respondent.

Issues within Historical Data Series

Categorization of Capacity by Business Sector: There is a small number of electric utility combined heat and power plants, as well as a small number of industrial and commercial generating facilities that are not combined heat and power. For the purposes of this report the data for these plants is included, respectively, in the following categories: "Electricity Generators, Electric Utilities," "Combined Heat and Power, Industrial," and "Combined Heat and Power, Commercial."

Some capacity in 2001 through 2004 is classified based on the operating company's classification as an electric utility or an independent power producer. Starting in the *Electric Power Annual 2006*, capacity by producer type was determined at the generating plant level for 2005 and 2006, based on whether the plant is an electric utility plant or an electric nonutility plant. Therefore, the revised capacity by producer type for 2005 is comparable to the capacity for 2006 and later years, by producer type. The previously published 2005 capacity by producer type was determined based on the operating company's classification of electric utility or electric nonutility.

Planned Capacity: Delays and cancellations may have occurred subsequent to respondent data reporting as of December 31 of the data year.

Capacity by Energy Source: Prior to the *Electric Power Annual* 2005, the capacity for generators for which natural gas or petroleum was the most predominant energy source was presented in the categories "petroleum only," "natural gas only" and "dual-fired." The "dual-fired" category, which was EIA's effort to infer which generators could fuel-switch between natural gas and fuel oil, included only the capacity of generators for which the most predominant energy source and second most predominant energy source were reported as natural gas or petroleum. Beginning with the *Electric Power Annual* 2005 capacity is assigned to energy source based solely on the most predominant (primary) energy source reported for a generator. The "dual-fired" category was eliminated. Separately, summaries of capacity associated with generators with fuel-switching capability are presented for 2005 and later years.. These summaries are based on data collected from new questions added to the Form EIA-860 survey that directly address the ability of generators to switch fuels and co-fire fuels.

In the *Electric Power Annual 2005*, certain petroleum-fired capacity was misclassified as natural gas-fired capacity for 1995 – 2003. This has been corrected in the *Electric Power Annual 2006*. Corrections were noted as revised data.

Sensitive Data (Formerly Identified as Data Confidentiality). The tested heat rate data collected on the Form EIA-860 are considered business sensitive.

Form EIA-861

The Form EIA-861 is a mandatory census of electric power industry participants in the United States. The survey is used to collect information on power production and sales data from approximately 3,300 respondents. About 3,200 are electric utilities, and the remainder is nontraditional entities such as energy service providers, or the unregulated subsidiaries of electric utilities and power marketers. The data collected are used to maintain and update the EPD electric power industry participant frame database. The Form EIA-861 is made available in January of each year to collect data as of the end of the preceding calendar year and is due by April 30.

Transportation Sector. Prior to 2003, sales of electric power to the Transportation sector of the U. S. economy were included in the Other sector, along with sales to customers for public buildings, traffic signals, public street lighting, and sales to irrigation consumers. Beginning with the 2003 collection cycle, sales to the Transportation sector are collected separately. Sales to public-sector customers for public buildings, traffic signals and street lighting, previously reported in the Other sector, were reclassified as Commercial sector sales. Sales to irrigation customers, where separately identified, were reclassified to the Industrial sector.

On the Form EIA-861, the Transportation sector is defined as electrified rail, primarily urban transit, light rail, automated guideway, and other rail systems whose primary propulsive energy source is electricity.

Electricity sales to transportation sector consumers whose primary propulsive energy source is not electricity (i.e., gasoline, diesel fuel, etc.) are not included.

Benchmark statistics were reviewed from outside surveys, most notably the U.S. Department of Transportation, Federal Transit Administration's National Transportation Database, a source previously used by EIA to estimate electricity transportation consumption. The U.S. Department of Transportation (DOT) survey indicated the State and city locations of expected respondents. The EIA-861 survey methodology assumed that sales, revenue, and customer counts associated with these mass transit systems would be provided by the incumbent utilities in these areas, relying on information drawn routinely from rate schedules and classifications designed to serve the sector separately and distinctly. In 2007, 72 respondents reported transportation data in 28 States.

Imputation. The *Electric Power Annual* (EPA) reports total retail sales volumes (megawatthours) and customer counts in States with deregulated markets as the sum of bundled sales reported by full-service providers and delivery reported by transmission and distribution utilities. EPD has concluded that the retail sales data reported by delivery utilities are more reliable than data reported by power marketers and Energy Service Providers (ESPs).

The reporting methodology change uses sales volumes and customer counts reported by distribution utilities, and add only an incremental revenue value, representing revenue associated with missing sales assumed to be attributable to the ESPs that were under-represented in the survey frame. In some cases, adjustments are also made to retail sales, revenue, and customer counts associated with underreporting of delivery volumes by one or more of the distribution utilities. In those cases, EIA assumes that total load served by those utilities is accurate, and that any underreporting of delivery volumes resulted from misclassifying actual delivery volumes as bundled sales. Therefore, in those instances EIA adjusted upwards the delivery volumes, revenues, and customer counts and made a corresponding equivalent offset (reduction) to the bundled sales by State and end-use sector.

Data for 2007 reflect imputed retail sales data to account for non-respondents on Form EIA-861. The imputation methodology used is the same as that used in preparing the *Electric Power Monthly* (whose retail sales data are drawn from Form EIA-826). Form EIA-826 is a monthly stratified sample of approximately 454 investor-owned and public utilities, as well as a census of energy service providers and power marketers. If an EIA-861 respondent did not file an annual form for 2007, their data were assumed to be the amount imputed during the year using the EIA-826 sample form collection and imputation process.

Instrument and Design History. The Form EIA-861 was implemented in January 1985 for collection of data as of year-end 1984. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Data Reconciliation. The EPA reports total retail sales volumes (megawatthours) and customer counts in States with deregulated markets as the sum of bundled sales reported by full-service providers and delivery reported by transmission and distribution utilities. EPD has concluded that the retail sales data reported by delivery utilities are more reliable than data reported by power marketers and ESPs.

Average Retail Price of Electricity. This represents the cost per unit of electricity sold and is calculated by dividing retail electric revenue by the corresponding sales of electricity. The average retail price of electricity is calculated for all consumers and for each end-use sector. State-level weighted average prices per unit of sales are calculated as the ratio of revenue to sales.

The electric revenue used to calculate the average retail price of electricity is the operating revenue reported by the electric power industry participant. Operating revenue includes energy charges, demand charges, consumer service charges, environmental surcharges, fuel adjustments, and other miscellaneous charges. Electric power industry participant operating revenues also include ratepayer reimbursements for State and Federal income taxes and taxes other than income taxes paid by the utility.

The average retail price of electricity reported in this publication by sector represents a weighted average of consumer revenue and sales within sectors and across sectors for all consumers, and does not reflect the per kWh rate charged by the electric power industry participant to the individual consumers. Electric utilities typically employ a number of rate schedules within a single sector. These alternative rate schedules reflect the varying consumption levels and patterns of consumers and their associated impact on the costs to the electric power industry participant for providing electrical service.

Issues within Historical Data Series

Beginning in 2003 the Other sector has been eliminated. Data previously assigned to the Other sector have been reclassified as follows: lighting for public buildings, streets, and highways, interdepartmental sales, and other sales to public authorities are now included in the Commercial sector; agricultural and irrigation sales where separately identified are now included in the Industrial sector; and a new sector, Transportation, includes electrified rail and various urban transit systems (such as automated guideway, trolley, and cable) where the principal propulsive energy source is electricity. Comparisons of data across years should include consideration of these reclassification changes.

Changes from year to year in consumer counts, sales and revenues, particularly involving the commercial and industrial consumer sectors, may result from respondent implementation of changes in the definitions of consumers, and reclassifications. Utilities and energy service providers may classify commercial and industrial customers based on either NAICS codes or demands or usage falling within specified limits by rate schedule. Also, the number of ultimate customers is an average of the number of customers at the close of each month.

Demand-Side Management: The following definitions are supplied to assist in interpreting Tables 9.1 through 9.5. Utility costs reflect the total cash expenditures for the year, in nominal dollars, that flow out to support demand-side management (DSM) programs.

- **Actual Peak Load Reduction.** The actual reduction in annual peak load achieved by all program participants during the reporting year, at the time of annual peak load, as opposed to the installed peak load reduction capability (Potential Peak Load Reduction). Actual peak load reduction is reported by large utilities only.
- **Energy Savings.** The change in aggregate electricity use (measured in megawatthours) for consumers that participate in a utility DSM program. These savings represent changes at the consumer's meter (i.e., exclude transmission and distribution effects) and reflect only activities that are undertaken specifically in response to utility-administered programs, including those activities implemented by third parties under contract to the utility.
- **Large Utilities.** Those electric utilities with annual sales to ultimate customers or sales for resale greater than or equal to 150 million kilowatthours in 1998-2008 and, for years prior, the threshold was set at 120 million kilowatthours.
- **Potential Peak Load Reductions.** The potential peak load reduction as a result of load management, and also the actual peak load reduction achieved by energy efficiency programs.

Wholesale Trade: Alaska and Hawaii are not included.

Sensitive Data (Formerly Identified as Data Confidentiality). Data collected on the Form EIA-861 are not considered to be business sensitive.

Form EIA-906 [Replaced in 2007 by Form EIA-923]

The Form EIA-906 was used to collect plant-level data on generation, fuel consumption, stocks, and fuel heat content, from electric utilities and nonutilities. Data were collected monthly from a model-based sample of approximately 1,700 utility and nonutility electric power plants. The form was also used to collect these statistics from another 2,667 plants (i.e., all other generators 1 MW or greater) on an annual basis. The 2007 data collection represents the last year where the information came from the Form EIA-906. Starting with the collection of 2008 calendar year data, the Form EIA-906 information is now collected on a replacement form (the Form EIA-923). The monthly data for Form EIA-906 is now being collected on the replacement form starting in January of 2008.

Instrument and Design History. The Bureau of Census and the U.S. Geological Survey collected, compiled, and published data on the electric power industry prior to 1936. After 1936, the Federal Power Commission (FPC) assumed all data collection and publication responsibilities for the electric power industry and implemented the Form FPC-4. The Federal Power Act, Section 311 and 312, and FPC Order 141 defined the legislative authority to collect power production data. The Form EIA-759 replaced the Form FPC-4 in January 1982. In 1996, the Form EIA-900 was initiated to collect sales for resale data from unregulated entities. In 1998, the form was modified to collect sales for resale, gross generation, and sales to end user data. In 1999, the form was modified to collect net generation, consumption, and ending stock data. In 2000, the form was modified to include useful thermal output data.

In January 2001, Form EIA-906 superseded Forms EIA-759 and EIA-900. In January 2004, Form EIA-920 superseded Form EIA-906 for those plants defined as combined heat and power plants; all other plants that generate electricity continue to report on Form EIA-906. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data. In January 2008, the Form EIA-923 superseded this form.

Issues within Historical Data Series

There were a small number of electric commercial and industrial- only plants that are included in the combined heat and power category. For the purposes of this report the data for these plants were included, respectively, in the following categories: "Electricity Generators, Electric Utilities," "Combined Heat and Power, Industrial," and "Combined Heat and Power, Commercial." No information on the production of Useful Thermal Output (UTO) or fuel consumption for UTO was collected or estimated for the electric utility combined heat and power plants.

Sensitive Data (Formerly Identified as Data Confidentiality). The only business sensitive data element collected on the Form EIA-906 is fuel stocks at the end of the reporting period.

Form EIA-920 [Replaced in 2007 by Form EIA-923]

The Form EIA-920, "Combined Heat and Power Plant Report" was used to collect plant-level data on generation, fuel consumption, stocks, and fuel heat content of combined heat and power (CHP) plants. Data were collected monthly from a sample of plants. The form was also used to collect the statistics from combined heat and power plants on an annual basis.

Instrument and Design History. In January 2004, Form EIA-920 superseded Form EIA-906 for those plants defined as combined heat and power plants; all other plants that generate electricity continue to report on Form EIA-906. Starting with the collection of 2007 calendar year data, the Form EIA-920 information is now collected on a replacement form (the Form EIA-923). The monthly data for Form EIA-920 began collection on the replacement form in January of 2008. (For further information on predecessor forms, see the discussion of the EIA-906 survey, above.) The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Issues within Historical Data Series

There are a small number of electric commercial and industrial only plants that are included in the combined heat and power category. For the purposes of this report the data for these plants are included, respectively, in the following categories: "Electricity Generators, Electric Utilities," "Combined Heat and Power, Industrial," and "Combined Heat and Power, Commercial." No information on the production of UTO or fuel consumption for UTO was collected or estimated for the electric utility combined heat and power plants.

Sensitive Data (Formerly Identified as Data Confidentiality). The only business sensitive data element collected on the Form EIA-920 were fuel stocks at the end of the reporting period.

Form EIA-923

Form EIA-923, "Power Plant Operations Report," is used to collect information on receipts and cost of fossil fuels, fuel stocks, generation, consumption of fuel for generation, and environmental data (e.g., emission controls and cooling systems). Data are collected from a monthly sample of approximately 1,600 plants, which includes a census of nuclear and pumped storage hydroelectric plants. The plants in the monthly sample report their receipts, cost and stocks of fossil fuels, electric power generation, and the total consumption of fuels for both electric power generation and, if a combined heat and power plant, useful thermal output. At the end of the year, the monthly respondents report their annual source and disposition of electric power (nonutilities only), and if applicable, the environmental data on the Form EIA-923 Supplemental Form (Schedules 6, 7, and 8A to 8F). Approximately 3,300 plants, representing all generators not included in the monthly sample and with a nameplate capacity of 1 MW or more, report data on the entire form (Schedules 1 to 8F, as applicable) annually. In addition to electric power generating plants, respondents include fuel storage terminals without generating capacity that receives shipments of fossil fuels for eventual use in electric power generation. The monthly data are due by the last day of the month following the reporting period.

Receipts of fossil fuels, fuel cost and quality information, and fuel stocks at the end of the reporting period are all reported at the plant level. Fuel receipts and costs are collected from plants with a nameplate capacity of 50 MW or more and burn fossil fuels. Plants that burn organic fuels and have a steam turbine capacity of at least 10 megawatts report consumption at the boiler level and generation at the generator level for each month, regardless of whether the plant reports in the monthly sample or reports once a year (annually). For all other plants, consumption is reported at the prime-mover level. For these plants, generation is reported either at the prime-mover level or, for noncombustible sources (e.g., wind, nuclear), at the prime-move and energy source level (including generating unit for nuclear only). The source and disposition of electricity is reported annually for nonutilities at the plant level, as is revenue from sales for resale. Additional operational data, including environmental data, are collected annually from facilities that have a steam turbine capacity of at least 10 megawatts.

Instrument and Design History:

Receipts and Cost and Quality of Fossil Fuels

On July 7, 1972, the Federal Power Commission (FPC) issued Order Number 453 enacting the New Code of Federal Regulations, Section 141.61, legally creating the FPC Form 423. Originally, the form was used to collect data only on fossil-steam plants, but was amended in 1974 to include data on internal-combustion and combustion-turbine units. The FERC Form 423 replaced the FPC Form 423 in January 1983. The FERC Form 423 eliminated peaking units, for which data were previously collected on the FPC Form 423. In addition, the generator nameplate capacity threshold was changed from 25 megawatts to 50 megawatts. This reduction in coverage eliminated approximately 50 utilities and 250 plants. All historical FPC Form 423 data in this publication were revised to reflect the new generator-nameplate-capacity threshold of 50 or more megawatts reported on the FERC Form 423. In January 1991, the collection of data on the FERC Form 423 was extended to include combined-cycle units. Historical data have not been revised to include these units. Starting with the January 1993 data, the FERC began to collect the data directly from the respondents.

The Form EIA-423 was originally implemented in January 2002 to collect monthly cost and quality data for fossil fuel receipts from owners or operators of nonutility electricity generating plants. Due to the restructuring of the electric power industry, many plants which had historically submitted this information for utility plants on the FERC Form 423 (see above) were being transferred to the nonutility sector. As a result, a large percentage of fossil fuel receipts were no longer being reported. The Form EIA-423 was implemented to fill this void and to capture the data associated with existing non-regulated power producers. Its design closely followed that of the FERC Form 423.

Both the Form EIA-423 and FERC-423 were superseded by Form EIA-923 (Schedule 2) in January of 2008. The EIA-923 maintains the same 50 megawatt threshold for these data. However, not all data are collected monthly on the new form. Beginning with 2008 data, a sample of the respondents will report monthly, with the remainder reporting annually (monthly values will be imputed via regression). For 2007, Schedule 2 annual data will not be collected or imputed. Most of the plants required to report on Schedule 2 already submitted their 2007 receipts data on a monthly basis.

Generation and Consumption

The Bureau of Census and the U.S. Geological Survey collected, compiled, and published data on the electric power industry prior to 1936. After 1936, the Federal Power Commission (FPC) assumed all data collection and publication responsibilities for the electric power industry and implemented the Form FPC-4. The Federal Power Act, Section 311 and 312, and FPC Order 141 defined the legislative authority to collect power production data. The Form EIA-759 replaced the Form FPC-4 in January 1982.

In 1996, the Form EIA-900 was initiated to collect sales for resale data from unregulated entities[10]. In 1998, the form was modified to collect sales for resale, gross generation, and sales to end user data. In 1999, the form was modified to collect net generation, consumption, and ending stock data[11]. In 2000, the form was modified to include useful thermal output data.

In January 2001, Form EIA-906 superseded Forms EIA-759 and EIA-900. In January 2004, Form EIA-920 superseded Form EIA-906 for those plants defined as combined heat and power plants; all other plants that generate electricity continue to report on Form EIA-906. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Forms EIA-906 and EIA-920 were superseded by survey form EIA-923 beginning in January 2008 with the collection of annual 2007 data and monthly 2008 data.

Steam Electric Plant Operational Data

The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data. The predecessor form, FPC-67, “Steam-Electric Plant Air and Water Quality Control Data,” was used to collect data from 1969 to 1980, when the form number was changed to Form EIA-767. In 1982, the form was completely redesigned and retitled Form EIA-767, “Steam-Electric Plant Operation and Design Report.” In 1986, the respondent universe of 700 was increased to 900 to include plants with nameplate capacity from 10 megawatts to 100 megawatts. In 2002, the respondent universe increased to above 1,370 plants plus the addition of non-utility plants. Collection of data via the Form EIA-767 was suspended for the 2006 data year, but was resumed on the Form EIA-923 for data year 2007. For respondents selected to be in the monthly sample for Form EIA-906 or EIA-920 in 2007, and were thus were not annual filers for Form EIA-923, this data was collected for 2007 via a one-time supplemental filing in 2008.

Data Processing and Data System Editing. Respondents are encouraged to enter data directly into a computerized database via the e-filing system. A variety of automated quality control mechanisms are run during this process, such as range checks and comparisons with historical data. These edit checks were performed as the data were provided, and many problems that are encountered are resolved during the reporting process. Those plants that are unable to use the electronic reporting medium provide the data in hard copy, typically via fax. These data were manually entered into the computerized database. The data were subjected to the same edits as those that were electronically submitted.

If the reported data appeared to be in error and the data issue could not be resolved by follow up contact with the respondent, or if a facility was a nonrespondent, a regression methodology was used to impute for the facility.

Imputation. For data collected monthly, regression prediction, or imputation, is done for all missing data including non-sampled units and any nonrespondents. For data collected annually, imputation is done for nonrespondents.

For gross generation and total fuel consumption, multiple regression is used for imputation. For gross generation, the regressors are prior year average generation for the same fuel, prior year average generation from other fuels, and nameplate capacity. Regressors for total fuel consumption are prior year average fuel consumption from the same fuel, prior year average consumption from other fuels, and nameplate capacity. For stocks, a linear combination of the prior month's ending stocks value and the current month's consumption and receipts values is used.

Only approximately 0.02% of the national total gross generation for 2007 reported here is imputed, although this will vary by State and energy source.

Net generation, where not reported, is estimated by using a fixed ratio to gross generation by prime-mover type.

Receipts of Fossil Fuels. Note that for 2007, this data was collected on Form EIA-423 and FERC Form 423.

Receipts data, including cost and quality of fuels, are collected at the plant level from selected electric generating plants and fossil-fuel storage terminals in the United States. These plants include independent power producers, electric utilities, and commercial and industrial combined heat and power producers whose total fossil-fueled nameplate capacity is 50 megawatts or more (excluding storage terminals, which do not produce electricity). The data on cost and quality of fuel shipments are then used in the following formulas to produce aggregates and averages for each fuel type at the State, Census division, and U.S. levels. For these formulas, receipts and average heat content are at the plant level. For each geographic region, the summation sign, $\sum$, represents the sum of all facilities in that geographic region.

For coal, units for receipts are in tons and units for average heat contents (A) are in million Btu per ton.

For petroleum, units for receipts are in barrels and units for average heat contents (A) are in million Btu per barrel.

For gas, units for receipts are in thousand cubic feet (Mcf) and units for average heat contents (A) are in million Btu per thousand cubic foot.

For each of the above fossil fuels:

$$\text{Total Btu} = \sum_i (R_i \ x \ A_i),$$

where i denotes a facility; R_i = receipts for facility i;

A_i = average heat content for receipts at facility i;

$$\text{Weighted Average Btu} = \frac{\sum_i (R_i \ x \ A_i)}{\sum_i R_i},$$

where i denotes a facility; R_i = receipts for facility i; and, A_i = average heat content for receipts at facility i.

The weighted average cost in cents per million Btu is calculated using the following formula:

$$\text{Weighted Average Cost} = \frac{\sum_i (R_i \ x \ A_i \ x \ C_i)}{\sum_i (R_i \ x \ A_i)},$$

where i denotes a facility; R_i = receipts for facility i;

A_i average heat content for receipts at facility i;

and C_i = cost in cents per million Btu for facility i.

The weighted average cost in dollars per unit (i.e., tons, barrels, or Mcf) is calculated using the following formula:

$$\text{Weighted Average Cost} = \frac{\sum_i (R_i \ x \ A_i \ x \ C_i)}{10^2 \sum_i R_i},$$

where i denotes a facility; R_i = receipts for facility i;

A_i = average heat content for receipts at facility i;

and, C_i = cost in cents per million Btu for facility i.

Power Production, Fuel Stocks, and Fuel Consumption Data. The Bureau of Census and the U.S. Geological Survey collected, compiled, and published data on the electric power industry prior to 1936. After 1936, the Federal Power Commission (FPC) assumed all data collection and publication responsibilities for the electric power industry and implemented the Form FPC-4. The Federal Power Act, Section 311 and 312, and FPC Order 141 defined the legislative authority to collect power production data. The Form EIA-759 replaced the Form FPC-4 in January 1982.

In 1996, the Form EIA-900 was initiated to collect sales for resale data from unregulated entities. In 1998, the form was modified to collect sales for resale, gross generation, and sales to end user data. In 1999, the form was modified to collect net generation, consumption, and ending stock data. In 2000, the form was modified to include useful thermal output data.

In January 2001, Form EIA-906 superseded Forms EIA-759 and EIA-900. In January 2004, Form EIA-920 superseded Form EIA-906 for those plants defined as combined heat and power plants; all other plants that generate electricity continue to report on Form EIA-906. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

In January 2004, Form EIA-920 superseded Form EIA-906 for those plants defined as combined heat and power plants; all other plants that generate electricity continue to report on Form EIA-906. In January 2008, Form EIA-923 superseded both the EIA-906 and EIA-920 forms for the collection of these data.

Methodology to Estimate Biogenic and Non-biogenic Municipal Solid Waste. Municipal Solid Waste (MSW) consumption for generation of electric power is split into its biogenic and non-biogenic components beginning with 2001 data by the following methodology:

> The reported tonnage of MSW is reported on the Form EIA-923. The composition of MSW and categorization of the components were obtained from the Environmental Protection Agency publication, *Municipal Solid Waste in the United States: 2005 Facts and Figures.* The Btu contents of the components of MSW were obtained from various sources.[2]
>
> The potential quantities of combustible MSW discards (which include all MSW material available for combustion with energy recovery, discards to landfill, and other disposal) were multiplied by their respective Btu contents. The EPA-based categories of MSW were then classified into renewable and non-renewable groupings. From this, EIA calculated how much of the energy potentially consumed from MSW was attributed to biogenic components and how much to non-biogenic components (see Table 1 and 2, below).[3]

[3] Biogenic components include newsprint, paper, containers and packaging, leather, textiles, yard trimmings, food wastes, and wood. Non-biogenic components include plastics, rubber and other miscellaneous non-biogenic waste.

These values are used to allocate the net and gross generation published in the *Electric Power Monthly* and *Electric Power Annual* generation tables. The tons of biogenic and non-biogenic components were estimated with the assumption that glass and metals were removed prior to combustion. The average Btu/ton for the biogenic and non-biogenic components is estimated by dividing the total Btu consumption by the total tons. Published net generation attributed to biogenic MSW and non-biogenic MSW is classified under Other Renewables and Other, respectively.

Table 1. Btu Consumption for Biogenic and Non-biogenic Municipal Solid Waste (percent)

	2001	2002	2003	2004	2005	2006
Biogenic	57	56	55	55	56	56
Non-biogenic	43	44	45	45	44	44

Non-biogenic	23	23	24	24	25	25

Useful Thermal Output. With the implementation of the Form EIA-923, "Power Plant Operations Report," in 2008, combined heat and power (CHP) plants are required to report total fuel consumed and electric power generation4. Beginning with preliminary January 2008 data, EIA estimated the allocation of the total fuel consumed at CHP plants between electric power generation and useful thermal output.

The estimated allocation methodology is summarized in the following paragraphs. The methodology was retroactively applied to 2004-2007 data. Prior to 2004, useful thermal output was collect on the Form EIA-906 and an estimated allocation of fuel for electricity was not necessary.

First, an efficiency factor is determined for each plant and prime mover type. Based on data for electric power generation and useful thermal output (UTO) collected in 2003 (on Form EIA-906, "Power Plant Report") efficiency was calculated for each prime mover type at a plant. The efficiency factor is the total output in Btu, including electric power and useful thermal output (UTO), divided by the total input in Btu. Electric power is converted to Btu at 3,412 Btu per kilowatthour.

Second, to calculate the amount of fuel for electric power, the gross generation in Btu is divided by the efficiency factor. The fuel for UTO is the difference between the total fuel reported and the fuel for electric power generation. UTO is calculated by multiplying the fuel for UTO by the efficiency factor.

In addition, if the total fuel reported is less than the estimated fuel for electric power generation, then the fuel for electric power generation is equal to the total fuel consumed, and the UTO will be zero.

Issues within Historical Data Series

Receipts and Cost and Quality of Fossil Fuels

Values for receipts of natural gas for 2001 forward do not include blast furnace gas or other gas.

Historical data collected on FERC Form 423 and published by EIA have been reviewed for consistency between volumes and prices and for their consistency over time. However, these data were collected by FERC for regulatory rather than statistical and publication purposes. EIA did not attempt to resolve any late filing issues in the FERC Form 423 data. In 2003, EIA introduced a procedure to estimate for late or non-responding entities who were required to report on the FERC Form 423. Due to the introduction of this procedure, 2003 and later data cannot be directly compared to previous years' data.

Prior to 2008, regulated plants reported receipts data on the FERC Form 423. These plants, along with unregulated plants, now report receipts data on Schedule 2 of Form EIA-923. Because FERC issued waivers to Form 423 filing requirements to some plants who met certain criteria, and because not all types of generators were required to report (only steam turbines and combined cycle units reported), a significant number of plants either did not submit fossil fuel receipts data or submitted only a portion of their fossil fuel receipts. Since Form EIA-923 does not have exemptions based on generator type, or reporting waivers, receipts data from 2008 and later cannot be directly compared to previous years' data for the regulated sector. Furthermore, there may be a notable increase in fuel receipts beginning with January 2008 data.

Also beginning with January 2008 data, tables for total receipts will include imputed quantities for plants with capacity one megawatt or more, to be consistent with other electric power data. Previous published receipts data were from plants over a 50 megawatt threshold, which was a legacy of their original collection as information for a regulatory agency, not as a survey to provide more meaningful estimates of totals for statistical purposes. Totals appeared to become smaller as more electric production came from unregulated plants, until the EIA-423 was created to help fill that gap. As a further improvement, estimation of all receipts for the universe normally depicted in the EPA (*i.e.,* one megawatt and above), with associated relative standard errors, provides a more complete assessment of the market.

Generation and Consumption

Beginning in 2008, a new method of allocating fuel consumption between electric power generation and useful thermal output (UTO) was implemented (see above). This new methodology evenly distributes a combined heat and power (CHP) plant's losses between the two output products (electric power and UTO). In the historical data, UTO was consistently assumed to be 80 percent efficient and all other losses at the plant were allocated to electric power. This change causes the fuel for electric power to be lower while the fuel for UTO is higher as both are given the same efficiency. This results in the appearance of an increase in efficiency of production of electric power between periods.

Steam Electric Plant Operational Data

Due to suspension of Form EIA-767 in 2007, there is a one year break in this data series as data year 2006 could not be collected.

Sensitive Data (Formerly identified as Data Confidentiality). Most of the data collected on the Form EIA-923 are not considered business sensitive. However, the total delivered cost of fuel delivered to nonutilities, commodity cost of fossil fuels, and reported fuel stocks at the end of the reporting period are considered business sensitive. The release of these data must adhere to EIA's "Policy on the Disclosure of Individually Identifiable Energy Information in the Possession of the EIA" (45Federal Register 59812 (1980)).

Air Emissions

This section describes the methodology for calculating estimated emissions of carbon dioxide (CO_2) from electric generating plants for 1989 through 2008, as well as the estimated emissions of sulfur dioxide (SO_2) and nitrogen oxides (NO_x) from electric generating plants for 2001 through 2008. For a description of the methodology used for other years, see the technical notes to the *Electric Power Annual 2003*.

Methodology Overview

Initial estimates of uncontrolled SO_2 and NO_x emissions for all plants are made by applying an emissions factor to fuel consumption data collected by EIA on the Form EIA-923. An emission factor is the average quantity of a pollutant released from a power plant when a unit of fuel is burned, assuming no use of pollution control equipment. The basic relationship is:

Emissions = Quantity of Fuel Consumed x Emission Factor

Quantity is defined in physical units (e.g., tons of solid fuels, million cubic feet of gaseous fuels, and thousands of barrels of liquid fuels) for determining NO_x and SO_2 emissions. As discussed below, physical quantities are converted to millions of Btus for calculating CO_2 emissions.

For some fuels, the calculation of SO_2 emissions requires including in the formula the sulfur content of the fuel measured in percentage of weight. Examples include coal and fuel oil. In these cases the formula is:

Emissions = Quantity of Fuel Consumed x Emission Factor x Sulfur Content

The fuels that require the percent sulfur as part of the emissions calculation are indicated in Table A1, which lists the SO_2 emission factors used for this report.

In the case of SO_2 and NO_x emissions, the factor applied to a fuel can also vary with the combustion system: either a steam-producing boiler, a combustion turbine, or an internal combustion engine. In the case of boilers, NO_x emissions can also vary with the firing configuration of a boiler and whether or not the boiler is a wet-bottom or dry-bottom design.[4] These distinctions are shown in Tables A1 and A2.

For SO_2 and NO_x, the initial estimate of uncontrolled emissions is reduced to account for the plant's operational pollution control equipment, when data on control equipment are available from the historical Form EIA-767 survey (i.e., data for the years 2005 and

[4] A boiler's firing configuration relates to the arrangement of the fuel burners in the boiler, and whether the boiler is of conventional or cyclone design. Wet and dry-bottom boilers use different methods to collect a portion of the ash that results from burning coal. For information on wet and dry bottom boilers, see the EIA Glossary at http://www.eia.doe.gov/glossary/index.html. Additional information on wet and dry-bottom-boilers and on other aspects of boiler design and operation, including the differences between conventional and cyclone designs, can be found in Babcock and Wilcox, *Steam: Its Generation and Use*, 41st Edition, 2005.

earlier) and the EIA-860 survey for the years 2007 and 2008. A special case for removal of SO_2 is the fluidized bed boiler, in which the sulfur removal process is integral with the operation of the boiler. The SO_2 emission factors shown in Table A1 for fluidized bed boilers already account for 90 percent removal of SO_2 since, in effect, the plant has no uncontrolled emissions of this pollutant.

Although SO_2 and NO_x emission estimates are made for all plants, in many cases the estimated emissions can be replaced with actual emissions data collected by the U.S. Environmental Protection Agency's Continuous Emissions Monitoring System (CEMS) program. (CEMS data for CO_2 are incomplete and are not used in this report.) The CEMS data account for the bulk of SO_2 and NO_x emissions from the electric power industry. For those plants for which CEMS data are available, the EIA estimates of SO_2 and NO_x emissions are employed for the limited purpose of allocating emissions by fuel, since the CEMS data itself do not provide a detailed breakdown of plant emissions by fuel. For plants for which CEMS data are unavailable, the EIA-computed values are used as the final emissions estimates.

There are a number of reasons why the historical data are periodically revised. These include data revisions, revisions in emission and technology factors, and changes in methodology. For instance, the 2008 EPA report features a revision in historic CO_2 values. This revision occurred due to a change in the accepted methodology regarding adjustments made for the percentage combustion of fuels.

The emissions estimation methodologies are described in more detail below.

CO_2 Emissions. CO_2 emissions are estimated using the information on fuel consumption in physical units and the heat content of fuel collected on the Forms EIA-923 (data for combined heat and power plants) and EIA-906 (all other power plants) for the years 1989 through 2006. In 2007, a new form was introduced, the Power Plant Operations Survey (Form EIA-923), which includes information on fuel consumption previously part of the Form EIA-906/EIA-920 Surveys. Fuel consumption data from the Form EIA-923 was used to estimate CO_2. The heat content information is used to convert physical units to millions of Btu (MMBtu) consumed. To estimate CO_2 emissions, the fuel-specific emission factor from Table A3 is multiplied by the fuel consumption in MMBtu.

The estimation procedure calculates uncontrolled CO_2 emissions. CO_2 control technologies are currently in the early stages of research and there are no operational systems installed. Therefore, no estimates of controlled CO_2 emissions are made.

SO_2 and NO_x Emissions. To comply with environmental regulations controlling SO_2 emissions, many coal-fired generating plants have installed flue gas desulfurization (FGD) units. Similarly, NO_x control regulations require many plants to install low-NO_x burners, selective catalytic reduction systems, or other technologies to reduce emissions. It is common for power plants to employ two or even three NO_x control technologies; accordingly, the NO_x emissions estimation approach accounts for the combined effect of the equipment (Table A4). However, control equipment information is available only for plants that reported on the Form EIA-923 and for historical data from the Form EIA-767. Both the EIA-923 and the historical EIA-767 surveys are limited to plants with boilers fired by combustible fuels[5] with a minimum generating capacity of 10 megawatts (nameplate). Pollution control equipment data are unavailable from EIA sources for plants that did not report on the historical EIA-767 survey, or the EIA-923.

The following method is used to estimate SO_2 and NO_x emissions:

- For steam electric plants, uncontrolled emissions are estimated using the emission factors shown in Tables A1 and A2 as well as reported data on fuel consumption, sulfur content, and boiler firing configuration. Controlled emissions are then determined when pollution control equipment is present. Although information on control equipment was unreported for the years 2006 and 2007, updates for new installations during this period were made based upon Environmental Protection Agency data. For 2008, this data was collected on the Form EIA-923. For SO_2, the reported efficiency of the plant's FGD units is used to convert uncontrolled to controlled emission estimates. For NO_x, the reduction percentages shown in Table A4 are applied to the uncontrolled estimates.

- For plants and prime movers not reported on the historical Form EIA-767 survey or EIA-923, uncontrolled emissions are estimated using the Table A1 and Table A2 emission factors and the following data and assumptions:
    - Fuel consumption is taken from the Form EIA-923 (for historical data, from the Form EIA-920 - for combined heat and power

[5] Boilers that rely entirely on waste heat to create steam, including the heat recovery portion of most combined cycle plants, did not report on the historical Form EIA-767 or EIA-923.

plants) or the Form EIA-906 - all other power plants).

- o The sulfur content of the fuel is estimated from fuel receipts for the plant reported the Form EIA-923 (for historical data, from either the Form EIA-423 or the FERC Form 423). When plant-specific sulfur content data are unavailable, the national average sulfur content for the fuel, computed from the Form EIA-923 (for historical data, from the Form EIA-423 and the FERC Form 423), is applied to the plant.
- o As noted earlier, the emission factor for plants with boilers depends in part on the type of combustion system, including whether a boiler is wet-bottom or dry-bottom, and the boiler firing configuration. However, this boiler information is unavailable for steam electric plants that did not report on the historical Form EIA-767 or EIA-860. For these cases, the plant is assumed to have a dry-bottom, non-cyclone boiler using a firing method that falls into the "All Other" category shown on Table A1.[6]
- o For the plants that did not report on the historical Form EIA-767 or EIA-860, pollution control equipment data are unavailable and the uncontrolled estimates are not reduced.

- If actual emissions of SO_2 or NO_x are reported in EPA's CEMS data, the EIA estimates are replaced with the CEMS values, using the EIA estimates to allocate the CEMS plant-level data by fuel. If CEMS data are unavailable, the EIA estimates are used as the final values.

Conversion of Petroleum Coke to Liquid Petroleum

The quantity conversion is 5 barrels (of 42 U.S. gallons each) per short ton (2,000 pounds). Coke from petroleum has a heating value of 6.024 million Btu per barrel.

Relative Standard Error

The relative standard error (RSE) statistic, usually given as a percent, describes the magnitude of sampling error that might reasonably be incurred. The RSE is the square root of the estimated variance, divided by the variable of interest. The variable of interest may be the ratio of two variables, or a single variable.

The sampling error may be less than the nonsampling error. In fact, large RSE estimates found in preliminary work with these data have often indicated nonsampling errors, which were then identified and corrected. Nonsampling errors may be attributed to many sources, including the response errors, definitional difficulties, differences in the interpretation of questions, mistakes in recording or coding data obtained, and other errors of collection, response, or coverage. These nonsampling errors also occur in complete censuses. In a complete census, this problem may become unmanageable.

Using the Central Limit Theorem, which applies to sums and means such as are applicable here, there is approximately a 68-percent chance that the true total or mean is within one RSE of the estimated total. Note that reported RSEs are always estimates, themselves, and are usually, as here, reported as percents. As an example, suppose that a net generation from coal value is estimated to be 1,507 total million kilowatthours with an estimated RSE of 4.9 percent. This means that, ignoring any nonsampling error, there is approximately a 68-percent chance that the true million kilowatthour value is within approximately 4.9 percent of 1,507 million kilowatthours (that is, between 1,433 and 1,581 million kilowatthours). Also under the Central Limit Theorem, there is approximately a 95-percent chance that the true mean or total is within 2 RSEs of the estimated mean or total.

Note that there are times when a model may not apply, such as in the case of a substantial reclassification of sales, when the relationship between the variable of interest and the regressor data does not hold. In such a case, the new information represents only itself, and such numbers are added to model results when estimating totals. Further, there are times when sample data may be known to be in error, or are not reported. Such cases are treated as if they were never part of the model-based sample, and values are imputed.

Business Classification

Nonutility power producers consist of corporations, persons, agencies, authorities, or other legal entities that own or operate facilities for electric generation

[6] The "All Other" firing configuration category includes, for example, arch firing and concentric firing. For a full list of firing method options for reporting on the historical Form EIA-767, see the form instructions, page xi, at http://www.eia.doe.gov/cneaf/electricity/forms/eia767/eia767instr.pdf.

but are not required to meet all filing obligations of electric utilities to the Federal Energy Regulatory Commission. Included in this category are qualifying cogenerators, small power producer, and independent power producers. Furthermore, nonutility power producers do not have a designated franchised service area. In addition to entities whose primary business is the production and sale of electric power, entities with other primary business classifications can and do sell electric power. These can consist of manufacturing, agricultural, forestry, transportation, finance, service and administrative industries, based on the Office of Management and Budget's Standard Industrial Classification (SIC) Manual.17 In 1997, the SIC Manual name was changed to North American Industry Classification System (NAICS). The following is a list of the main classifications and the category of primary business activity within each classification.

Agriculture, Forestry, and Fishing

111	Agriculture production-crops
112	Agriculture production, livestock and animal specialties
113	Forestry
114	Fishing, hunting, and trapping
115	Agricultural services

Mining

211	Oil and gas extraction
2121	Coal mining
2122	Metal mining
2123	Mining and quarrying of nonmetallic minerals except fuels

Construction

23

Manufacturing

311	Food and kindred products
3122	Tobacco products
314	Textile and mill products
315	Apparel and other finished products made from fabrics and similar materials
316	Leather and leather products
321	Lumber and wood products, except furniture
322	Paper and allied products (other than 322122 or 32213)
322122	Paper mills, except building paper
32213	Paperboard mills
323	Printing and publishing
325	Chemicals and allied products (other than 325188, 325211, 32512, or 325311)
32512	Industrial organic chemicals
325188	Industrial Inorganic Chemicals
325211	Plastics materials and resins
325311	Nitrogenous fertilizers
324	Petroleum refining and related industries (other than 32411)
32411	Petroleum refining
326	Rubber and miscellaneous plastic products
327	Stone, clay, glass, and concrete products (other than 32731)
32731	Cement, hydraulic
331	Primary metal industries (other than 331111 or 331312)
331111	Blast furnaces and steel mills
331312	Primary aluminum
332	Fabricated metal products, except machinery and transportation equipment
333	Industrial and commercial equipment and components except computer equipment
3345	Measuring, analyzing, and controlling instruments, photographic, medical, and optical goods, watches and clocks
335	Electronic and other electrical equipment and components except computer equipment
336	Transportation equipment
337	Furniture and fixtures
339	Miscellaneous manufacturing industries

Transportation and Public Utilities

22	Electric, gas, and sanitary services
2212	Natural gas transmission
2213	Water supply
22131	Irrigation systems
22132	Sewerage systems
481	Transportation by air
482	Railroad transportation
483	Water transportation
484	Motor freight transportation and warehousing
485	Local and suburban transit and interurban highway passenger transport
486	Pipelines, except natural gas
487	Transportation services
491	United States Postal Service
513	Communications
562212	Refuse systems

Wholesale Trade

421 to 422

Retail Trade

441 to 454

Finance, Insurance, and Real Estate

521 to 533

Services

512 Motion pictures
514 Business services
514199 Miscellaneous services
541 Legal services
561 Engineering, accounting, research, management, and 611 Education services
622 Health services
624 Social services
712 Museums, art galleries, and botanical and zoological gardens
713 Amusement and recreation services
721 Hotels
811 Miscellaneous repair services
8111 Automotive repair, services, and parking
812 Personal services
813 Membership organizations related services
814 Private households

Public Administration

Note: * For these fuels, emissions are estimated by multiplying the emissions factor by the physical volume of fuel and the sulfur percentage of the fuel (other fuels do not require the sulfur percentage in the calculation). Note that EIA data do not provide the sulfur content of TDF. The value used (1.56 percent) is from U.S. EPA, *Control of Mercury Emissions from Coal-Fired Electric Utility Boilers*, April 2002, EPA-600/R-01-109, Table A-11 (available at:http://www.epa.gov/appcdwww/aptb/EPA-600-R-01-109A.pdf).
** Although Sludge Waste and Black Liquor consist substantially of liquids, these fuels are measured and reported to EIA in tons.

Table A4. Nitrogen Oxides Control Technology Emissions Reduction Factors

Nitrogen Oxides Control Technology	EIA-Code(s)	Reduction Factor (Percent)
Advanced Overfire Air	AA	30[1]
Alternate Burners	BF	20
Flue Gas Recirculation	FR	40
Fluidized Bed Combustor	CF	20
Fuel Reburning	FU	30
Low Excess Air	LA	20
Low NO_x Burners	LN	30[1]
Other (or Unspecified)	OT	20
Overfire Air	OV	20[1]
Selective Catalytic Reduction	SR	70
Selective Catalytic Reduction With Low Nitrogen Oxide Burners	SR and LN	90
Selective Noncatalytic Reduction	SN	30
Selective Noncatalytic Reduction With Low NO_x Burners	SN and LN	50
Slagging	SC	20

1. Starting with 1995 data, reduction factors for advanced overfire air, low NO_x burners, and overfire air were reduced by 10 percent.

Table A5. Unit-of-Measure Equivalents

Unit	Equivalent	Unit
Kilowatt (kW)	1,000 (One Thousand)	Watts
Megawatt (MW)	1,000,000 (One Million)	Watts
Gigawatt (GW)	1,000,000,000 (One Billion)	Watts
Terawatt (TW)	1,000,000,000,000 (One Trillion)	Watts
Gigawatt	1,000,000 (One Million)	Kilowatts
Thousand Gigawatts	1,000,000,000 (One Billion)	Kilowatts
Kilowatthours (kWh)	1,000 (One Thousand)	Watthours
Megawatthours (MWh)	1,000,000 (One Million)	Watthours
Gigawatthours (GWh)	1,000,000,000 (One Billion)	Watthours
Terawatthours (TWh)	1,000,000,000,000 (One Trillion)	Watthours
Gigawatthours	1,000,000 (One Million)	Kilowatthours
Thousand Gigawatthours	1,000,000,000(One Billion)	Kilowatthours
U.S. Dollar	1,000 (One Thousand)	Mills
U.S. Cent	10 (Ten)	Mills
