INTRODUCTION

During 18 - 28 May 1993, a cruise was conducted on Georges Bank as part of a pilot project for the U.S. GLOBEC Northwest Atlantic Study entitled: stratification variability on Georges Bank and its effect on larval fish survival. The objectives of the cruise were to: 1) acquire information on the abundance and distribution of ichthyoplankton and zooplankton on the southern flank of Georges Bank in relation to water column conditions; 2) deploy and recover a mooring to measure the physical conditions at a fixed site; 3) make repeated observations of the plankton at the fixed site and within a drifting patch of water tagged by a transmitting buoy; and 4) make these observations in close cooperation with the R/V COLUMBUS ISELIN which was working in the same area as part of the same study.

The intent of this report is to document data collected by the Woods Hole National Marine Fisheries Service scientists during the R/V ALBATROSS IV cruise ALB9306. The sampling systems are described and the data are summarized in the form of basic tables and figures.

SAMPLING SYSTEMS

Shipboard

The primary shipboard sampling systems used during this cruise to accomplish the above objectives were:

MOCNESS: Multiple Opening/Closing Net and Environmental

Sensing System with 1 m² (0.333 mm mesh nets) and 1/4 m² (0.064 mm mesh nets) mouth openings. They are identified as MOC1 MOC1/4, respectively. Both were equipped with 9 nets and conductivity/temperature/depth measuring packages. The MOCNESS systems were deployed on the port side of the ship using the boom.

Seabird Electronics Seacat Model 19 CTD (Profiler): a conductivity, temperature, and depth measuring instrument with a sampling rate of 2 observations per second. During a bongo haul, the Profiler was attached above the bongo frame and was towed double - obliquely through the water.

Neil Brown Mark V CTD (MK5): a conductivity/temperature/depth measuring system equipped with a fluorometer and rosette water sampler. The MK5 was deployed from the starboard hydrographic A-frame for both vertical profiles while the vessel was stationary and for "tow-yo" sampling while the vessel steamed at 2.5 knots.

Near real time satellite imagery: Satellite derived SST data were sent to the ship via INMARSAT C from the NMFS Narragansett R.I. Laboratory.

Moored

A physical oceanographic mooring with instruments to measure the

temperature, salinity, and current in the upper 45 meters was deployed to monitor the vertical structure of the water column during the sampling period.

VMCM: Vector Measuring Current Meters were attached at 15m and 45m to record current velocity and temperature 16 times per hour.

RBR Temperature Loggers (TPODS): Single channel temperature loggers (model series XL-105) were used in fixed mode of operation as part of the moored array. Temperature observations were recorded every 2 minutes of their deployment. Instruments were attached at 5, 25, and 35 meters.

Seabird Electronics Seacat Model 16: Internally recording temperature / conductivity instruments, intended for fixed mooring operations, recorded temperature and conductivity observations every 2 minutes of their deployment. Instruments were attached at 1, 10, 20, 30, and 40 meters.

Drifting

Loran-C Marker Buoy: This instrument, manufactured by Seimac Limited and loaned to us by Art Allen of USCG Research and Development Lab, received Loran radio signals at a user defined setting (30 minutes was chosen) and transmitted the

time delays via VHF radio to the ship.

CRUISE NARRATIVE

During the first three days of the cruise (19 - 21 May) a bongo survey of the southern flank of Georges Bank was conducted to locate cod and haddock larvae and to provide an indication of the hydrographic conditions in the region (Figures 1a and 1b). A bongo net (61-cm diameter, 0.333-mm and 0.505-mm mesh nets) equipped with a Seabird CTD Profiler was used on 47 stations between the 50 and 100 meter isobaths.

Based on the survey information, a site was chosen for the deployment of the physical oceanographic mooring. This site was selected to be in the region of the bank which would characteristically have a stratified water column and where larval cod and haddock would be found. The mooring was deployed on May 21 at 40° 38.96'N 67° 37.42'W. After deployment of the mooring, MOCNESS tows did not find cod and haddock larvae in the area in sufficient numbers to warrant continued sampling at that site. A second site was sampled further to the west but, again, larval catches were low. An acceptable site was located at 40° 43'N, 68° 02'W and became the "stratified site" for the study.

Another site was selected to the north in the characteristically well-mixed, shallow portion of Georges Bank, and where the bongo survey indicated a high concentration of cod and haddock larvae. This site is referred to as the "Mixed" site (M) and was

located at 40° 59'N, 68° 02'W (Figure 2).

At the stratified site, a drifting Loran-C buoy was deployed to indicate the water movement during the sampling operations. The buoy had a 6 m long "holey sock" drogue tethered at 10m depth. An initial 6 hour time series of CTD casts and MOCNESS tows were conducted from 18:34 GMT May 22 - 00:42 GMT May 23, using the buoy as a reference. MOCNESS operations included both the 1 m and 1/4m systems, with a tow (using either of the two systems) every 2 - 3 hours. Fish larvae were removed from the MOC1 nets and were preserved in alcohol or frozen for further analyses. Samples from the MOC1/4 were preserved in formalin. A CTD cast was done before each tow.

During 02:30 - 06:45 GMT May 23, CTD tow-yo #1 was conducted from the stratified site toward the mixed site. The ship steamed at 2.5 knots and the CTD was lowered every 8 minutes to give a spatial resolution of about 0.7 km between casts. The termination on the sea cable failed during this transect and the section could not be completed before a previously scheduled rendezvous with the R/V COLUMBUS ISELIN at the mixed site at 10:00 GMT on May 23.

At the mixed site, a high-flyer drifter (without a Loran-C buoy) was deployed with a holey sock as a reference marker for sampling. A 24 hour time series of CTD casts and MOCNESS tows began at 10:52 GMT on May 23. The drifter moved into an area of large sand ridges northwest of the original site, making MOCNESS operations difficult. The remainder of the operations at the mixed site were conducted at the original site location. The drifter was

recovered at 23:30 GMT May 23, after a full tidal cycle had brought it back to near its original deployment site. The CTD and MOCNESS time series were continued until 14:00 GMT on May 24.

The R/V COLUMBUS ISELIN profiled the water column with a plankton pump and an acoustic profiling system (TAPS - Tracor acoustic Profiling System) in the vicinity of the 1/4m MOCNESS tows made by the ALBATROSS IV. These systems each measure the size spectrum of the larval prey organisms. The data collected will allow for a comparison of the results from the different systems.

The ALBATROSS IV then returned to the stratified site to conduct a second CTD and MOCNESS time series. No Signals were received from the Loran-C buoy that had earlier been deployed there. The time series was conducted at the stratified site from 16:20 GMT May 24 to 23:00 GMT May 25. The R/V Columbus Iselin worked closely with the ALBATROSS IV until 03:00 GMT May 25.

From 01:00 - 05:00 GMT May 26, a search was conducted for the Loran-C drifter. The search involved steaming a trackline which the buoy was expected to have followed, given its initial drift and the subsequent forcing by winds and tidal currents. No signal was received. Since the buoy's signal had previously been received at a range of up to 15 miles, it was concluded that the buoy had either been lost or had been picked up by another vessel.

At 07:55 GMT May 26, a CTD cast was made next to the mooring. The purpose of this cast was to compare the data from the CTD with that being recorded by the instruments on the mooring.

From 10:08 - 14:00 GMT May 26, CTD tow-yo #2 was conducted

from near the stratified site to the mixed site. From 16:00 - 20:00 GMT May 26, CTD tow-yo #3 was conducted from the mixed site toward the stratified site. From 23:20 GMT May 26 - 01:30 GMT May 27, CTD tow-yo #4 was conducted from the stratified site toward the mixed site. The tow-yo's were timed to sample at either the on-bank (tow-yo #2 and #4) or off-bank (tow-yo #1 and #3) extreme of the tidal ellipse. From 04:00 - 07:48 GMT May 27, a series of CTD casts were made between the stratified site and the shelf/slope front to determine the water properties to the southeast of the study area.

The mooring was recovered 11:00 - 13:00 GMT on May 27. All instruments were recovered and appeared in good condition.

During 14:37 GMT May 27 - 03:00 GMT May 28, a final series of CTD and MOCNESS tows were made at the stratified site. During a 1/4m MOCNESS tow (#1048), the nets were caught by the ship's propeller. The nets and cod-ends were lost and the instrument suffered modest damage. Tow-yo #5 was conducted during 06:00 - 07:00 GMT May 28, on the eastern side of Great South Channel.

A chronological listing of the operations conducted during this cruise, with time and position information is provided in Table 1.

RESULTS

Biology

1) Bongo Survey:

A total of 47 bongo hauls were made during the first three days of the cruise (Figure 1a and 1b). The distributions of larval cod and haddock (number per 100m³) from the initial bongo survey are shown in Figure 3a & b. Both species had higher numbers in depths shallower than 75m.

2) MOCNESS

41 MOCNESS hauls were accomplished on the cruise and a summary of these is found in Table 2. Approximately 1200 samples of larval fish and *Calanus* were collected for RNA/DNA ratio studies and other molecular analyses to be conducted at the Northeast Fisheries Science Center, Narragansett, Rhode Island (L. Buckley and E. Calderone). Approximately 1400 samples of larval fish and zooplankton were collected for enzyme analysis. Eighty time series of respiration rates were made on *Calanus* samples. Enzyme analysis of larval fish and zooplankton samples will be conducted at the University of Miami, Florida (E. Clarke). Measurements of the respiration rates of zooplankton will be analyzed at the University of South Florida, St. Petersburg, Florida (J. Torres).

Vertical distributions of cod, haddock and eggs from the MOCNESS (1m) hauls are presented in Figures 4 - 12. Length frequency distributions of the cod and haddock larvae sorted from the MOCNESS (1m) hauls are shown in Figures 13 - 14. A summary of the MOCNESS data is found in Table 3.

Physical Oceanography:

The physical oceanographic program consisted of 1) using a Seabird Profiler during the initial bongo survey, 2) deploying a mooring to measure the water column structure during the study period, 3) making MK5 CTD profiles to measure the water column structure in connection with the other sampling programs of the cruise, 4) deploying drifters to track during repeated sampling of the same water parcel and 5) collecting data using the Shipboard Computing System (SCS) aboard the ALBATROSS IV. Results are presented in that order.

1) Seabird Profiler

Contoured horizontal sections of temperature and salinity during the initial bongo survey are presented in Figures 15 - 17. In the case of temperature, anomalies are relative to MARMAP observations (Mountain and Holzwarth, 1989). The vertical sections are labelled as either cross bank (C.B.) or along-bank (A.B.) and are shown in Figures 18 - 23. An influx of Scotian Shelf water along the outer edge of the bank had been observed in satellite imagery before and during the period of this study and was present during a few of the CTD casts (Profiler) made during the bongo survey.

2) Mooring

The physical oceanographic mooring consisted of 2 VMCM current meters, 5 SEACAT conductivity / temperature recorders and 3 Branker

temperature recorders (Figure 24). The deployment and recovery of the mooring were accomplished without problems and all instruments collected good data.

The initial processing of the VMCM records was done by Fran Hotchkiss at USGS. This included the standard WHOI editting and checking routines (Tarbell et al., 1988). The output was stored in BUOY format on the VAX. The data were transferred to ascii format and post-processed using UNIX based MATLAB routines. Low-pass filtering was done using a 33-hr (pl33) filter (Flagg, 1979). The five SEACAT records and the three Branker temperature probe records were hourly averaged. The hourly averaged time series of temperature, salinity, and sigma - t are shown in Figures 25 - 27.

Observations at the mooring showed that changes in water properties occurred during a tidal period. Most of this variability is believed to be due to the strong horizontal gradient associated with the shelf/slope front being advected past the observation location with the tidal oscillations.

3) MK5 CTD

A total of 332 MK5 profiles (167 down casts, 165 up casts) were successfully completed during ALB9306. The 4 vertical sections of the tow-yo operations between the mixed and stratified sites are shown in Figures 28 - 31. The tow-yo sections suggest that the highest fluorescence values are found within the tidal front (Mountain and Taylor, submitted). This finding is similar to conditions observed during the May 1992 Marine Ecosystem Response

study (Manning et al., 1995).

4) Loran - C

The Loran-C buoy data received on the vessel was automatically (every 30 minutes) stored on disk at sea using Procomm software. This file was used to monitor the drifter track. However, since the record was less than half of a full tidal cycle, further processing and analysis was not necessary.

5) Shipboard Computing System

A data acquisition system called the Scientific Computing System (SCS), developed by the engineers at the NOAA Atlantic Marine Center (AMC), was in its second year of operation on the ALBATROSS IV. It provides the scientists with continuous records of position, ship speed and direction, wind speed and direction, air temperature, and several other variables (Figure 32). This dataset was processed back at the Lab. Wind speed was converted to wind stress using the method of Large and Pond (1981). A log-layer correction of anemometer height to 10 meters above the sea surface was first made. Figure 33 shows the time series of this wind record (top panels) along with the de-tided current data measured by the VMCMS on the mooring. Figures 34a & b show air and sea surface temperature records from NOAA buoys 44008 ($40^{\circ}30' N$, $69^{\circ}24' W$) and 44011 ($41^{\circ}06' N$, $66^{\circ}36' W$) during the cruise period.

Acknowledgements

The authors would like to acknowledge the Officers and Crew of the R/V Albatross IV for their helpful assistance and cooperation throughout the cruise.
