ABSTRACT

This report presents water-column temperature data collected in the Middle Atlantic Bight and Gulf of Maine for 1993 and 1994, and extends a similar compilation for data collected during 1978-1992 of the Northeast Fisheries Service Ships of Opportunity Program (Benway *et al.* 1993a). Data were collected by expendable bathythermographs deployed by merchant vessels during monthly transects within both bodies of water. Data are presented as contoured vertical sections. Methods of data collection, management, and portrayal are discussed.

INTRODUCTION

In 1970, the National Marine Fisheries Service (NMFS) and the Maritime Administration (MARAD) initiated a cooperative expendable bathythermograph (XBT) survey to identify and describe seasonal and year-to-year variations of temperature, salinity and circulation in major currents of the Gulf of Mexico and western North Atlantic. This survey, conducted in support of the NMFS's Marine Resources Monitoring, Assessment, and Prediction (MARMAP) Program, used merchant ships, cooperating in MARAD's Ship of Opportunity Program (SOOP), as inexpensive collection platforms, and relied on Kings Point Maritime Academy cadets to gather the XBT data.

In the mid-1970s, the continuous plankton recorder (CPR) survey (Glover 1967; Jossi *et al.* 1982), also using ships of opportunity, merged with the XBT survey. The combined surveys concentrated on water masses, circulation, and plankton of the Middle Atlantic Bight and Gulf of Maine, with particular interest in the continental shelf and slope waters.

This report portrays monthly water-column thermal conditions along MARMAP Routes MB (Middle Atlantic Bight) and MC (Gulf of Maine) for 1993 and 1994. During hte monthly cruises, CPR data were also collected, but are not presented here because of delays in data processing. Analyses of SOOP hydrographic data regarding long-term mean conditions and interannual variability in surface temperature, surface salinity, and bottom temperature are presented in Benway *et al.* (1993b). Additional analyses of the data collected in 1993 are presented in Benway *et al.* 1994.

METHODS

STUDY AREA

Ship routes were selected in regions of interest to fisheries research to provide regular sampling and to allow the characterization of oceanographic conditions. Repeated coverage is important for comparative analyses, so ships with the most regular schedules were chosen whenever possible. The cooperating ship's included research, commercial, and U.S. Coast Guard vessels outfitted with data sampling hardware and software from the National Marine Fisheries Service Narragansett (Rhode Island) Laboratory; The National Ocean Service Office of Ocean Observations, Washington D.C.; and the Environmental Research Laboratory, Atlantic Oceanographic and Meteorological Laboratory, Miami, Florida.

Track lines varied on different occupations of a route. This variability made it necessary to develop route polygons with shapes such that only variations along the long axis were considered significant relative to program goals (Figures 1a and 1b).

The Middle Atlantic Bight sampling originates at Ambrose Light (40°27.5'N, 73°49.6'W) and extends offshore 500 km (270 nm) towards Bermuda (Figure 1a). The route polygon is termed MARMAP Route MB, the corners of which are: 40°34'N, 74°00'W; 40°20'N, 74°00'W; 38°30'N, 69°00'W; and 34°44'N, 70°30'W. This route traverses waters of the continental shelf, continental slope, and Gulf Stream.

The Gulf of Maine sampling extends from Boston, Massachusetts, on the western side, to Cape Sable, Nova Scotia on the eastern portion (Figure 1b), for approximately 452 km (244 nm). This route polygon is termed MARMAP Route MC, the corners of which are: 43°30'N, 71°00'W; 43°30'N, 65°37'W; 43°00'N, 65°37'W; and 42°00'N, 71°00'W. This route traverses waters of Massachusetts Bay, Wilkinson Basin, the central gulf ledges, Crowell Basin, southern Jordan Basin and western Scotian Shelf.

DATA AND SAMPLE PROCESSING

On all SOOP vessels, XBT and meteorological data were recorded and logged following the methods of Benway *et al.* (1993a). Temporal coverage by data type is shown in Tables 1 and 2. Middle Atlantic Bight SOOP vessels cast XBT's at 1 hr

intervals (about each 26 km or 14 nm), whereas Gulf of Maine SOOP vessels dropped XBT's at 2-hr intervals (about each 44 km or 24 nm). In both regions, surface temperature was recorded hourly via bucket thermometer, and surface salinity was sampled whenever an XBT was deployed. In the Gulf of Maine, however, at the end of 1993 the *C/V Yankee Clipper* was replaced by the *C/V Skogafoss* and surface salinity sampling ceased. A thermosalinograph has been installed on the *C/V Skogafoss* and is currently going through calibration.

Temperature and depth data collected aboard SOOP vessels were processed and quality controlled by personnel at the NMFS Narragansett Laboratory, following the methods in Benway *et al.* (1993a).

The CPR data were collected and processed following the methods of Thomas (1992). In brief, CPRs were towed at a fixed depth of 10m. Seawater entering the front of the CPR was filtered through a mechanically driven belt of Swiss bolting silk with a wet mesh aperture of 225 microns x 234 microns. In the laboratory, the silk was divided into sections ("stations") corresponding to 10 nautical-mile segments (18.52 km) of a tow track. Geographic position and reference distance were calculated for each geometric center of each silk section, and successive silk sections were assigned sequential station numbers. Zooplankton and phytoplankton atlases are in preparation for both MB and MC Routes.

GENERATION OF CONTOURED VERTICAL SECTIONS

The method of generating contoured vertical sections, or grids, was designed at the NMFS Narragansett Laboratory to overcome problems associated with irregular sampling in time and space (Thomas 1992). Both XBT and bucket data from a single cruise were used to create a contoured grid of monthly, interpolated water-column temperatures.

All contoured sections of water-column temperatures (in degrees Celsius) have been constructed with route polygon reference distances (in kilometers) along the x-axis, and water-column depths along the y-axis. Grid intersections were chosen at intervals of 17.38 km distance and 10 m depth.

A search was performed of the elliptical space (100 km by 50 m) around every grid intersection, and all raw data values within the search ellipses were fitted to the grid by interpolation, using inverse distance squared weighting. In the event of fewer than four raw data values within the search ellipse at a given grid intersection, no interpolation was performed, resulting in a blank region within the interpolated surface.

RESULTS

During 1993 and 1994 the total number of cruises conducted was 29 for the Middle Atlantic Bight and 26 for the Gulf of Maine. Cruises are listed in Table 1 (Middle Atlantic Bight) and Table 2 (Gulf of Maine) along with information on the types of data collected on each cruise.

Portrayals of monthly water-column temperatures for the Middle Atlantic Bight(Route MB) are shown in Figures 2-13, and for the Gulf of Maine (Route MC) in Figures 14-21. *Not* included in these portrayals are the locations of concomitant CPR stations.

Temperature data for any SOOP transect are available from the National Oceanographic Data Center (NODC) in a variety of forms. Requests for and inquiries about SOOP data held by NODC, as well as data products, should be directed to:
