EXECUTIVE SUMMARY

Between 1984 and 1986, the baseline phase of the National Status and Trends Program was conducted at approximately 50 estuarine and coastal sites around the nation. Numerous histopathological observations of fish tissues and measurements of concentrations of chemical contaminants in sediments and fish tissues were made to quantify the status of United States coastal habitats with respect to environmental contamination. One of the products of this effort is a large data set containing information on concentrations of contaminants that possibly may threaten the health of the nation's coastal ecosystems. This body of data is useful to environmental scientists and managers. The purpose of this document is to make the chemical contaminant data available to the environmental community. Data summaries are presented in both graphical and tabular form.

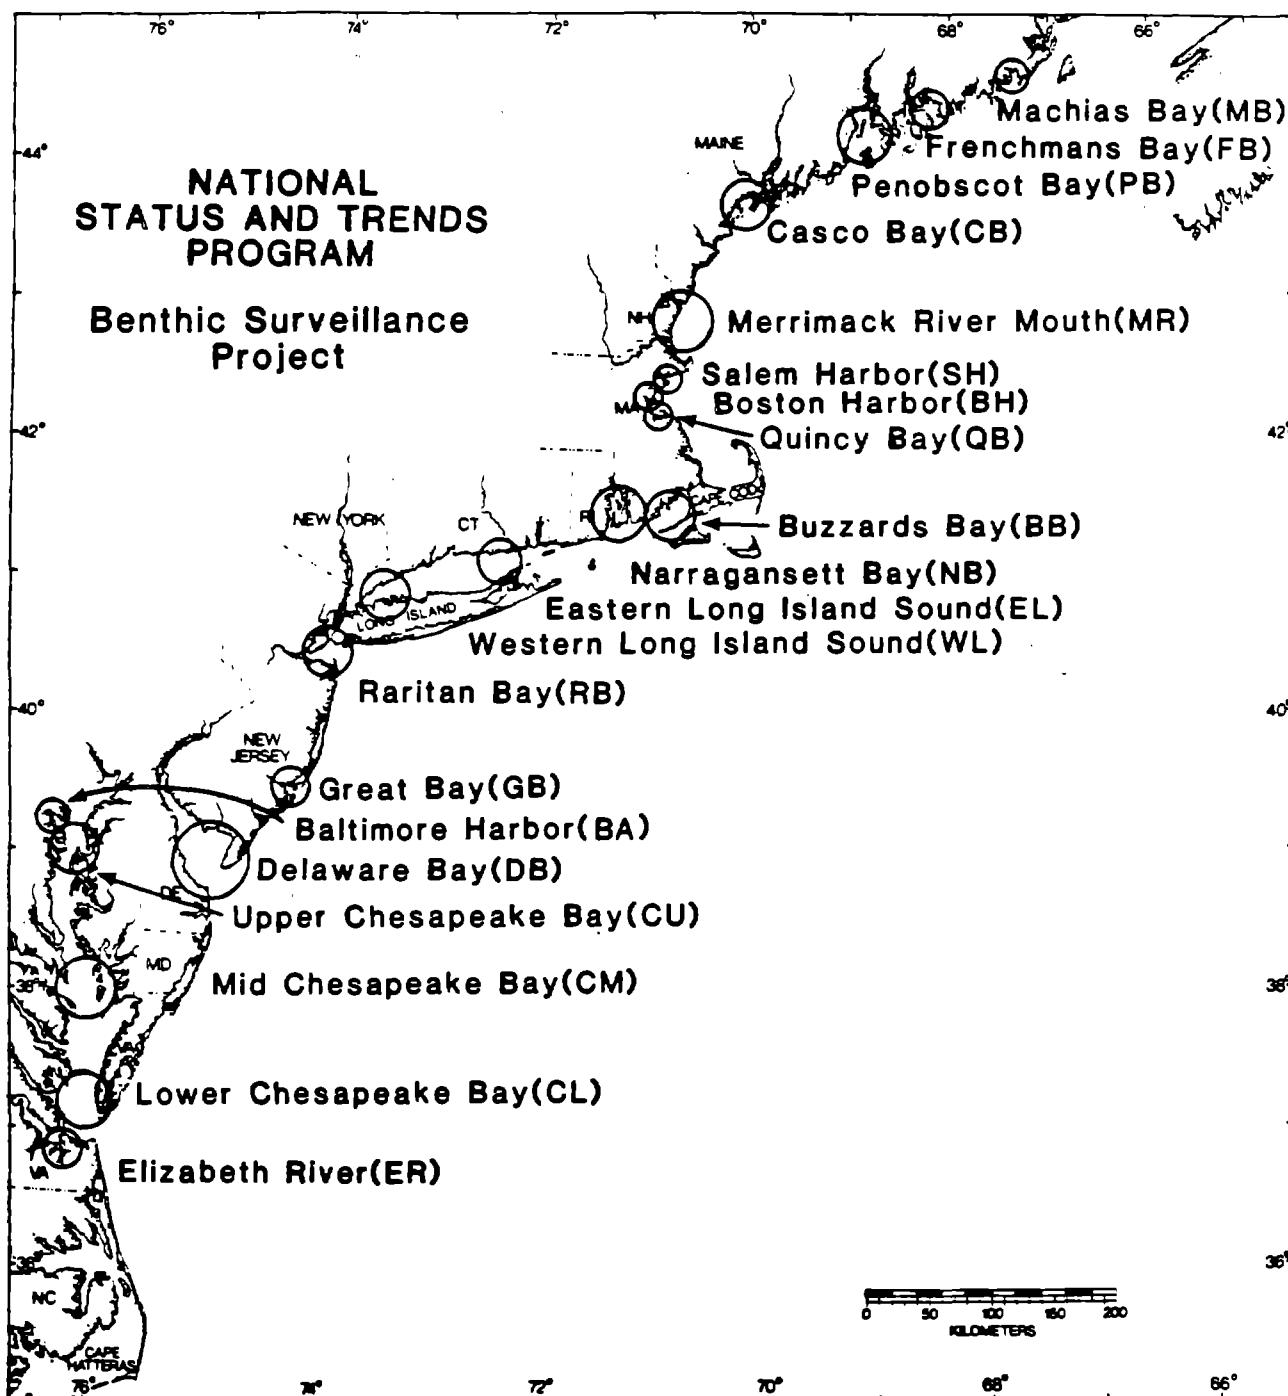

Figure 1. Sites sampled in the northeastern United States during 1984-86 as part of the National Status and Trends Program's Benthic Surveillance Project. Site codes in parentheses.

INTRODUCTION

The National Status and Trends (NS&T) Program is an ongoing federal program initiated in 1984 to establish and maintain an information base needed to quantify the status of, and temporal and spatial trends in, concentrations of selected chemical contaminants, as well as indicators of potential biological effects, in the nation's coastal and estuarine ecosystems (National Ocean Service 1989). A nationally uniform set of measurement techniques is used to obtain comprehensive, high quality data on environmental quality. A rigorous quality assurance program is an integral part of the NS&T Program.

One of the NS&T Program's major components is the Benthic Surveillance Project, the objectives of which include quantifying baseline levels of selected chemical compounds at approximately 50 sites in estuarine and coastal areas around the nation, and detecting trends in habitat contamination by monitoring levels of selected chemicals in sediments and fish tissues.

During 1984-86, personnel of the Northeast Fisheries Center (NEFC) participated in the baseline phase of the Benthic Surveillance Project, collecting and analyzing samples of sediments and fish tissues from 20 sites throughout the northeastern region.

The purpose of this document is to make available the large body of chemical data resulting from NEFC participation in the baseline phase of the NS&T Benthic Surveillance Project.

METHODS

Twenty sites were sampled in the northeastern region (Figure 1). A list of station locations, samples collected, and site codes used in the figures in the Analyte Summary section is given in Table 1. A list of variables measured, the matrices in which they were measured, and analyte codes used in the figures in the Site Summary section is given in Table 2.

Sites were selected to encompass a range of environmental conditions. Field methods and sample collection protocols are detailed in a report by Shigenaka and Lauenstein (1988).

All sediment and tissue samples were collected and stored individually. Depending on the matrix, however, samples were analyzed either individually or as composites. Sediments for both hydrocarbon and metal analyses were composites of the 0-3 cm layer of surface sediment from each of three bottom samples at each of 3-5 stations in each site; one composite per station was analyzed. Thirty specimens of each targeted fish species were collected at each site. Stomach content samples for both hydrocarbon and metal analyses were composites of 10 individual specimens; one composite per site was analyzed. Liver samples for hydrocarbon analyses were composites of 10 individual

specimens; three composites per site were analyzed. Liver samples for metal analyses were not composited; 10 individual specimens per site were analyzed.

Methods used for analyses of hydrocarbons in tissues and sediments are described by MacLeod *et al.* (1985) and Krahm *et al.* (1988). Hydrocarbon analyses were performed under the direction of D. Gadbois of the National Marine Fisheries Service (NMFS) Gloucester (Massachusetts) Laboratory.

Methods used for analyses of metals in tissues were developed at the NMFS Beaufort (North Carolina) Laboratory under the direction of P. Hanson, based on a procedure described by Okamoto and Fuwa (1984). Methods used for analyses of metals in sediments were developed at the NMFS Sandy Hook (New Jersey) Laboratory under the direction of V. Zdanowicz, based on a procedure described by Bernas (1968). Metal analyses were performed under the direction of V. Zdanowicz of the Sandy Hook Laboratory.

Sediment grain size determinations employed a modification of a U.S. Environmental Protection Agency procedure (Plumb 1981). Total organic carbon (TOC) determinations were performed using the method described by Hedges and Stern (1984). Grain size and TOC analyses were performed under the direction of P. Hanson of the Beaufort Laboratory.

DATA PRESENTATION

Data presented in the figures in the Site Summary and Analyte Summary sections are mean values for each analyte for each site over the 1984-86 period. When calculating means, "less than" values were used as best estimates of the actual concentrations. Since "less than" values estimate maximum concentrations, a positive bias is introduced into the calculated means.

The Site Summary section is a graphical summary of data from each site, presenting distributions of analytes in each sample matrix (Figures 2-21). Due to the wide range of concentrations observed, data are presented on a common log scale.

The Analyte Summary section is a graphical summary of data for each analyte by sample matrix, showing distributions of analytes at all sites (Figures 22-28).

No fish specimens were obtained at the Mid Chesapeake (CM) or Baltimore Harbor (BA) sites; therefore, no data appear at those sites in figures of hydrocarbons or metals in stomach contents and livers. In addition, metals were not measured in stomach contents in samples collected in 1986 (see Table 1); consequently, no data appear at the Quincy Bay (QB) or Elizabeth River (ER) sites in figures of metals in stomach contents. Also, stations sampled at the Casco Bay (CB) site in 1984 were located at the mouth of the bay rather than the interior, so those data were not included in the means shown in the figures. Finally, 1984 tissue data from the Lower Chesapeake (CL) site were not included in any figures, as a different species was collected in 1985 and

1986.

Analytical data are presented in the Analytical Data section (Tables 3-9).

ACKNOWLEDGEMENTS

The authors thank E. Leimburg and P. Fournier for producing the graphics, R. Murchelano for suggestions on presentation format, and R. Reid, F. Steimle, A. Draxler, and J. E. O'Reilly for critical review.

The following NOAA personnel made completion of this project possible through their dedication and their participation in field work, laboratory analyses or project administration: Gloucester Laboratory--C. Auld, P. Chen, B. Dockum, A. Humason, L. Karohl, A. Khan, and R. Tremblay; Oxford Laboratory--J. Evans, S. Everline, S. McLaughlin, S. MacLean, R. Murchelano, M. Newman, A. Rosenfield, and D. Spitzer; Sandy Hook Laboratory--K. Fedosh, T. Finneran, R. Kothe, S. Leftwich, K. McNulty, J. Pearce, J. Vitaliano, S. Wilk, and J. Ziskowski; and the officers and crews of the research vessels *Albatross IV*, *Ferrell*, *Gloria Michelle*, and *Kyma*.
