Acknowledgments

Global Population Profile: 2002 was prepared in the International Programs Center (IPC), Population Division, U.S. Census Bureau, under a Participating Agency Service Agreement through the MEASURE Results Package of the U.S. Agency for International Development (PASA HRN-P-00-97-00016-00).

The report was produced under the general direction of **James C. Gibbs**, Assistant Chief for Demographic and Economic Studies. **Patricia M. Rowe**, Chief of the Population Studies Branch, supervised its preparation and provided valuable contributions to its content and design. **Thomas McDevitt** coordinated the 2002 revision effort.

Many persons on the Center's staff shared in the preparation of the demographic estimates and projections, as well as other activities, upon which this report is based.

The demographic estimates and projections underlying the report were prepared by **Matthew Christenson, John Dunlop, Timothy Fowler, Daniel Goodkind, Fern Greenwell, Laura Heaton, Linda Hooper, Caribert Irazi, Ward Kingkade, Lucy Litz, Thomas McDevitt, Andrea Miles, Nancy Murray, Patricia Rowe, Cheryl Sawyer, William Wannall, Karla Yoder,** and **David Zaslow**.

Peter Johnson, Special Assistant for International Demographic Methods, provided guidance in determining the methods to use for evaluating each country's statistics and reviewed the demographic estimates and projections used in the report. He also coordinated the

data capture, aggregation, and retrieval of information from IPC's International Data Base.

Patricia Rowe, Timothy Fowler, and **William Wannall** prepared the Appendix A tables, drawing from the International Data Base. William Wannall also assisted in the revision of the description of data availability in Appendix B and updated the information on married women. **Lucy Litz** updated IPC's statistics on contraceptive prevalence for this report.

The discussion in Appendix C of the methodology for incorporating AIDS mortality into projections was written by **Peter O. Way** and **Karen A. Stanecki**. The HIV/AIDS Surveillance Data Base, which provides the basis for incorporating AIDS mortality into population projections, is maintained by IPC's Health Studies Branch.

Special thanks are due to the data entry and verification support staff, **Joseph Reil, Kathy Caban, Iris Poe,** and **Patricia Dickerson,** and to **Jennifer Fortado**, who helped with consistency issues.

Marjorie Hanson, Population Division's editor, provided valuable comments on an earlier version of the report.

Gregory Carroll, Nelsa D. Brown, Barbara Adams, Jan Sweeney, and **Everett Dove** of the Administrative and Customer Services Division, **Walter C. Odom**, Chief, provided publications and printing management, graphics design and composition, and editorial review for print and electronic media. General

direction and production management were provided by **James L. Clark**, Assistant Division Chief of the Administrative and Customer Services Division and **Susan L. Rappa**, Chief, Publications Services Branch.

We are grateful to the national statistical offices and other national and international organizations worldwide, without whose generous collaboration this kind of report would not be possible. Recognition is due to the Population Division of the United Nations, and its Population Projections section in particular, for sharing data and ideas. As always, we appreciate the assistance of our MEASURE partners Macro International, Inc., which makes the data from the Demographic and Health Surveys available to us on a timely basis, and the Centers for Disease Control and Prevention, which provides copies of and information about its reproductive health surveys.

Finally, we wish to express our gratitude to colleagues at the U.S. Agency for International Development for their support throughout the various stages of this project. We acknowledge with thanks the contributions of **Margaret Neuse**, Director, Office of Population and Reproductive Health; **Scott Radloff**, Deputy Director; and **Ellen Starbird**, Chief, Policy, Evaluation and Communication Division. Special thanks are due to **Joanne Bennett Jeffers** and **Naomi Blumberg**, who served as the Senior Technical Officers on this project and provided helpful guidance in the development and preparation of the report.

HIGHLIGHTS

Global Population Profile: 2002 summarizes the most important trends in global population at the dawn of the 21st century. The presentation is organized around four themes: Global Population Growth, Global Population Composition, Contraceptive Prevalence in the Developing World, and the AIDS Pandemic in the 21st Century.

Global Population Growth

A little more than 4 years ago, in 1999, global population surpassed 6 billion. At midyear 2002, it stood at 6.2 billion and just over two people were being added each second. As rapid as this may seem, the pace at which global population was growing had already peaked more than a decade earlier. In absolute terms, approximately 74 million people were added to the world's population in 2002 compared to a high of 87 million in 1989-90. Similarly, the annual average growth rate was approximately 1.2 percent in 2002, down from a high of 2.2 percent in 1963-64. It is expected that this slowdown in population growth will continue into the foreseeable future.

The slowdown in the growth of the world's population can be traced primarily to declines in fertility. In 2002, the world's women, on average, were giving birth to 2.6 children over their lifetime. This was less than one-half of a child more than the level needed to assure the replacement of the population. Although fertility rates in some parts of the world are expected to remain above replacement level for quite some time (e.g., in Sub-Saharan Africa), Census Bureau projections suggest that the level

of fertility for the world as a whole will drop below replacement level before 2050.

It is important to note that these declines in fertility will not translate directly into equivalent declines in the growth of the population, because the numbers of women in their childbearing years are increasing relative to the rest of the population. This increase was responsible for about three-fourths of global population growth in 2002. Census Bureau projections suggest that by 2050 virtually all of global population increase will be due to this age-sex compositional effect.

Global Population Composition

The age and sex composition of the globe's population in 2002 reflected two historical trends: relatively high but declining fertility on the one hand, and moderate but declining mortality on the other. As a result, the age groups with the largest numbers of people were the very young (under age 15), with each successively older age group being slightly smaller.

With respect to specific populations, the breakdown was as follows. Children (0-14 years of age) made up 29 percent of the world's population. Youth (15-29 years of age) and women of childbearing age (15-49 years of age) each comprised 26 percent of the population. The population of labor force age (15-64 years of age) made up 64 percent of the total. The elderly (65 years of age and older) made up only 7 percent of the globe's population. Finally, the number of men and women on the planet was approximately the same: 101 men for every 100 women.

Over the next 25 years, while the absolute number of children is expected to remain relatively stable, the size of the child population relative to the total population is expected to decline. The numbers of youth and women in their childbearing years are projected to experience modest increases but their proportions of the total population are expected to decrease modestly. The population of labor force age is expected to grow steadily; its proportion of the total, to stay approximately the same. Finally, the elderly population is projected to grow considerably in both absolute and relative terms.

Contraceptive Prevalence in the Developing World

High fertility remains the dominant factor dictating the future size, growth, and composition of the populations of many developing nations. Contraceptive use, in turn, is one of the primary determinants of the level of fertility in a population and of differences in fertility between populations. Contraceptive use is also important as an indicator of the extent to which couples have access to reproductive health services. For these reasons, the levels and trends of contraceptive prevalence, particularly in the world's developing countries, have important implications for both global population change and reproductive health.

As a result of both delayed marriage and use of contraception within marriage, the number of births a woman has during her lifetime has fallen dramatically over the past few decades throughout the

developing world. At the same time, over 100 million women in the world's developing countries would like to space or limit their births but are not using contraception. These women, considered to have "unmet need" for family planning, are found in greater numbers in Asia than in other world regions but make up higher proportions of the populations of Sub-Saharan African countries than of countries in other parts of the world.

The AIDS Pandemic in the 21st Century

At the beginning of the 21st century, Human Immunodeficiency Virus (HIV), which causes the Acquired Immune Deficiency Syndrome (AIDS), continues to have its greatest impact in the developing world. Although the full demographic impact will not be felt for several more years, the emerging downward trends in life expectancy and population growth, the distortions in age structures, and the breakdowns in support systems are already being seen in some countries. At the extreme, Botswana is thought to be experiencing negative population growth due to AIDS mortality.

Since the onset of the AIDS pandemic two decades ago, more than 20 million people have died of

AIDS. Twice that many — 40 million — are now living with HIV, the virus that causes AIDS. Barring some major breakthrough, most of these people are expected to die during the next 10 years or so.

The pandemic continues to have its greatest impact in the developing countries of Africa, Asia, and Latin America, with Sub-Saharan Africa at its epicenter. In 2002, AIDS was the fourth leading cause of death globally but the number one cause of death in Africa.

The U.S. Census Bureau's modeling and projections work indicates that severe distortions in age-sex structures are likely in severely affected countries. In these countries, AIDS mortality is expected to produce age structures that have never been seen before.

Life expectancies in HIV/AIDS-affected countries are projected to decline, negating gains achieved during the past several decades. By 2010, many countries in Southern Africa are expected to see life expectancies fall to near 30 years of age, levels not seen since the beginning of the 20th century.

In 2010, populations in the majority of affected Sub-Saharan African countries are projected to increase, despite high levels of mortality. The exceptions are Botswana,

Lesotho, Mozambique, South Africa, and Swaziland.

It is commonly known that young adults feel the effect of the AIDS pandemic most keenly. However, countries with high infection rates are also experiencing rising rates of infant and child mortality. Over 30 percent of all children born to HIV infected mothers in Sub-Saharan Africa will be HIV positive as a result of mother-to-child transmission, either through the birth process or due to breastfeeding. Because of AIDS, infant mortality rates in some Sub-Saharan African countries are now higher than they were in 1990. In four countries of Sub-Saharan Africa, more infants are projected to die from AIDS in 2010 than from all other causes.

The news is not all bad, however. While child mortality rates in 2010 are projected to continue to be much higher with AIDS than they would have been without AIDS, if prevention of mother-to-child transmission programs are dramatically scaled up then the course of future child mortality rates can be changed. Moreover, several countries have managed to stem the tide of the pandemic. These examples give hope that the AIDS pandemic can be successfully curtailed in other countries.

INTRODUCTION

GLOBAL POPULATION IN PROFILE

A profile of global population at the dawn of the 21st century entails an exploration of some remarkable phenomena. At midyear 2002, the size of global population was about 6.2 billion people. During 2002, the globe experienced a net increase of approximately 74 million people. This growth is due, in part, to an average level of global fertility that has couples producing more children than are needed to replace them despite precipitous fertility declines in recent years. A more important determinant of this growth, however, is the age-sex composition of the population that has a large number of women in their childbearing years relative to

the size of the rest of the population. Finally, although mortality on a global level has also fallen, the anticipated effects of the HIV/AIDS pandemic are of serious concern to the populations of numerous countries. Together, these trends create a composite profile of global population that is worthy of consideration.

Global Population Profile: 2002 provides an opportunity to reflect on the state of the world's population. In this report, we look forward into the next 50 years to consider a wide range of demographic phenomena. The first two sections provide a brief overview

of current understanding and expectations of the growth and composition of global population. The third section draws attention to the contribution of contraceptive use to fertility change in the less developed world. The fourth section of the report reviews current knowledge about the demographic impacts of the HIV/AIDS pandemic. Finally, the appendices that conclude this volume present detailed data and other supporting information upon which our estimates and projections are based. In this way, we profile the most important and interesting trends in global population at the beginning of the 21st century.

Data in this report include summary demographic information for the world, major regions, and countries and territories with a population of at least 5,000 in 2002. For the most part, estimates and projections are based on the evaluation of national data available as of early 2002. As a result, this report does not reflect data from the 2000 round of censuses for many countries.

This year's report covers 227 countries and territories. In most of the text and figures, they are grouped as follows: Sub-Saharan Africa, the Near East and North Africa, China (including Hong Kong, Taiwan, and Macau), India, the Rest of Asia (Asia excluding Japan, China and India) and Oceania (excluding Australia and New Zealand), Latin America and the Caribbean, Eastern Europe and the New Independent States of the former Soviet Union (NIS), and a majority of the world's

industrialized countries referred to here as "Developed World" (North America [excluding Latin America and the Caribbean], Western Europe, Japan, Australia, and New Zealand). In the detailed tables (Appendix A), countries are listed, and regional subtotals are provided, according to a more traditional geographic perspective: Africa (Sub-Saharan and North Africa), the Near East, Asia (including China and Japan), Europe (Western, Eastern) and the NIS, Latin America and the Caribbean, North America (excluding Latin America and the Caribbean), and Oceania.

In addition to these country groupings, references are made in the text to "more developed" countries and "less developed" (or "developing") countries. The first group includes the countries of North America (excluding Latin America and the Caribbean), Europe, the Baltics and the four

European republics of the NIS (Russia, Ukraine, Belarus and Moldova), Japan, Australia, and New Zealand. All other countries are considered to be less developed, following the convention used by the United Nations.

The data in **Global Population Profile: 2002** replace the data issued in earlier volumes in this series. Therefore, they should not be used in conjunction with data from earlier reports to derive time series.

The estimates and projections presented in the report are taken from the October 10, 2002, update of the International Data Base (IDB) of the U.S. Census Bureau. Detailed notes are maintained by the International Programs Center (IPC) to document the data used and the procedures followed in deriving the numbers for each country.

Questions about the estimates and projections presented in this report or about the methodology used in making them should be directed to: Chief, Population Studies Branch, International Programs Center, U.S. Census Bureau, Washington, DC, 20233-8860, e-mail pop.ipc.population.studies@census.gov. Comments on the report are invited. Questions about the demographic impact of the HIV/AIDS pandemic or about the methodology employed in estimating those impacts may be directed to: Chief, Health Studies Branch, International Programs Center, U.S. Census Bureau, Washington, DC, 20233-8860, e-mail ipc-hiv@census.gov.

Most of the data presented in this report, including the data found in the detailed tables of Appendix A, are available to users in computer-readable format. The entire report is available for downloading from the World Wide Web site of the International Programs Center (IPC). The text of the report, including all figures, is stored in pdf format. Tables from Appendices A and B are stored in Excel format. The Web site address for **Global Population Profile: 2002** is:

www.census.gov/ipc/www/wp02/

The data presented in this report draw upon information stored in two databases maintained and regularly updated by the International Programs Center. The *International Data Base* contains statistical tables providing demographic and socioeconomic data for all countries of the world. IPC's Health Studies Branch maintains the *HIV/AIDS Surveillance Data Base*, a compilation of epidemiological information on HIV prevalence.

- The *International Data Base* (IDB) contains information derived from censuses, surveys (for example, population by age and sex, labor force, and contraceptive use), and administrative records (for example, registered births and deaths) for selected years from 1950 to the present. Some variables are available by urban/rural residence. The IDB contains IPC's current estimates and projections of fertility, mortality, migration, and population on a single-year basis to the year 2050. IDB estimates and projections may be more recent than those presented in this report, which are current to October 2002.

Direct access and further information about the IDB are available through the Internet at:

www.census.gov/ipc/www/idbnew.html

Requests for specific data items from, or questions about, the IDB should be directed to:

Senior Information Specialist for the IDB
International Programs Center
Washington Plaza II, Room 109
U.S. Census Bureau
Washington, DC 20233-8860 USA
Telephone: 301-763-6180;
FAX: 301-457-1539;
e-mail: idb@census.gov

- The *HIV/AIDS Surveillance Data Base* includes all available epidemiological information on HIV/AIDS seroprevalence and incidence for countries in Africa, Asia, Latin America, Eastern Europe, and from selected New Independent States taken from the scientific literature and from unpublished reports prepared for international conferences and various workshops. The current update of the database contains over 65,000 individual data records drawn from 6,200 publications and presentations.

The HIV/AIDS Surveillance Data Base can be obtained free of charge on CD-ROM from the Health Studies Branch or downloaded from the Internet at:

www.census.gov/ipc/www/hivaidn.html

Requests for specific data items, CD-ROM or questions about the HIV/AIDS Surveillance Data Base should be directed to:

GLOBAL POPULATION GROWTH

The absolute size of the population of the globe and the pace at which it grows can be difficult to grasp. Similarly, the mechanisms that drive change in population size are often not fully appreciated.

*This section on **Global Population Growth** provides a series of essays that shed some light on these topics. First, two pieces put into*

context the current size and rate of growth of the globe's population. We then discuss the mechanics that drive change in the size of populations and summarize the current trends around the globe in fertility, mortality, and migration. Finally, we examine our projections about the future of population growth around the globe.

BILLIONS AND BILLIONS

In 2002, 5 Billion More People Inhabited the Globe Than in 1800

According to the U.S. Census Bureau, world population hit the 6-billion mark in June of 1999. This figure is over 3.5 times the size of the earth's population at the beginning of the 20th century and roughly double its size in 1960. Never before has the earth sustained such a large human population.

The time required for global population to grow from 5 to 6 billion was shorter than the interval between any of the previous billions. As depicted in Figure 1, it took just 12 years for this to occur, just slightly less time than the 13 years between the fourth and fifth billion, but considerably less time than the 118 years between the first and second billion.

Current Census Bureau projections indicate that it will take increasingly longer periods of time to reach the seventh, eighth, and ninth billion markers of world population. Those engaged in long-term projections suggest that the current run up of world population may peak before it reaches 10 billion (United Nations, 1999b; NRC, 2000).

Asia-Oceania Has Held Over Half of the World's Population Since Before 1950 and Is Expected to Continue to Do So Through 2050

In 2002, China was not only the most populous country in the world, it was also more populous than most of the world's regions (Table 1). This situation has existed at least since 1950 (Figure 2).

India, the second most populous country in the world, has been gaining rapidly on China in both absolute and relative terms (Figure 2). According to Census Bureau projections, India will eclipse China in total population in 2037.

The less developed countries in Asia and Oceania excluding India and China are expected to be more populous than any other region by 2050 (Figure 2). This is due, in part, to growth in top-ten countries such as Indonesia, Pakistan, and Bangladesh (Table 1).

Figure 2.
**Regional Distribution of Global Population:
 1950, 2002, and 2050**
**Population rankings of major world regions
 continue to shift in favor of developing regions.**

* "Developed World" refers to North America (excluding Latin America and the Caribbean), Western Europe, Japan, Australia, and New Zealand. Rest of Asia and Oceania refers to Asia excluding Japan, China, and India plus Oceania excluding Australia and New Zealand. NIS indicates the New Independent States of the former Soviet Union.

Projected Growth in Sub-Saharan Africa Differs Markedly From That for the Developed World and Eastern Europe

The largest percentage increase in population size over the next five decades (from 2002 to 2050) is projected to occur in Sub-Saharan

Africa. Over 800 million people are expected to be added to this region, with Congo (Kinshasa) joining Nigeria on the list of the ten most populous countries (Table 1). Sub-Saharan Africa, which was one-third the size of China in 1950 and one-half its size in 2002, is likely to surpass it in size by 2050 (Figure 2).

At the opposite end of the spectrum, more than half of the world's more developed countries (MDCs), including those in Eastern Europe and the former Soviet Union, are expected to experience population declines over the next 50 years. The United States is the only MDC expected to be among the ten most populous countries in 2050.

REMARKABLE POPULATION GROWTH

World Population Increase in 2002 Was More Than the Population of All but the 14 Largest Nations

In 2002, the world's population increased by 74 million people. If all of these people formed a new country, it would be the fifteenth

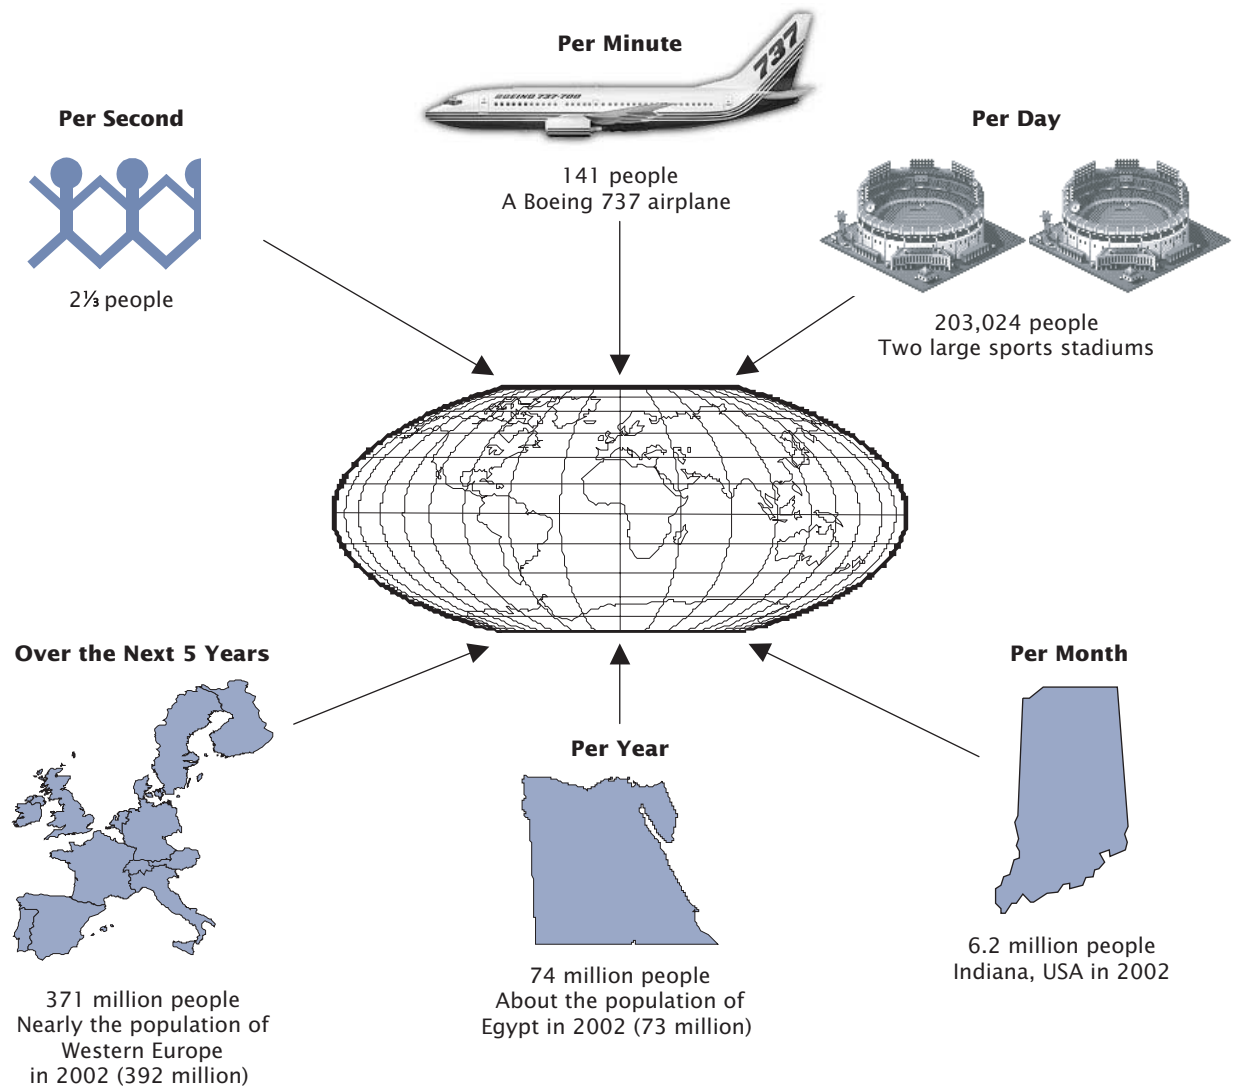

largest country in the world, just larger than Egypt and just smaller than Vietnam. As shown in Figure 3, adding people at this rate is equivalent to:

- 2 $\frac{1}{3}$ people per second,
- 141 people per minute,

- 200,000+ people per day,
- 6.2 million per month.

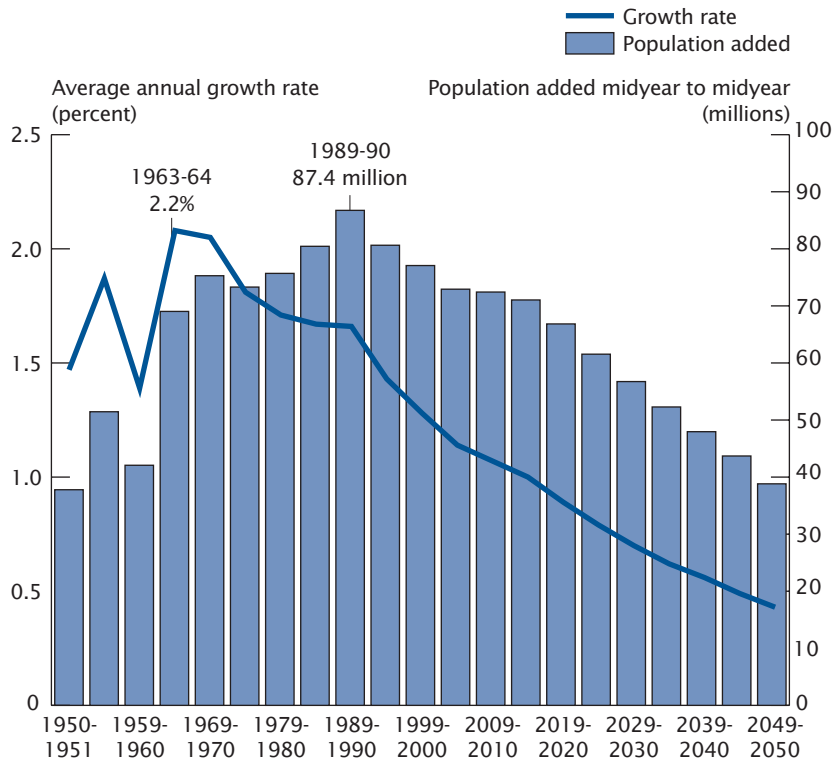

At this rate of growth, the world would add nearly the equivalent of the population of Western Europe (392 million persons in 2002) in 5 years.

Figure 3.

Figure 4.
Annual Additions and the Annual Growth Rate of Global Population: 1950-2050
By 2002, the pace of global population growth was on the decline.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

The Single Largest Annual Increase in World Population Is Estimated to Have Occurred in 1989-90

As Figure 4 shows, however, the average annual rate of growth for the globe's population peaked in 1963-64.¹ Then, in 1989-90, the absolute annual increase to global population reached its apex and began to decline. According to Census Bureau projections, the pace of global population growth will continue to decline into the foreseeable future.

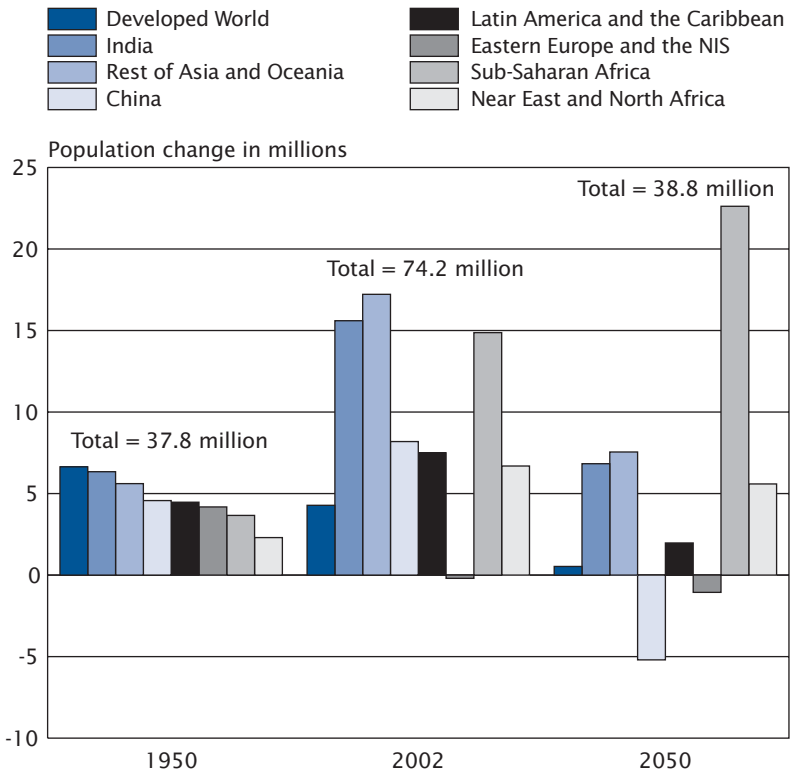

¹ In Figure 4, the dip in population growth during 1959-60 was due to a severe famine in China.

Asia and Sub-Saharan Africa Are Responsible for Most Current and Future World Population Increase

Since 1950, India has contributed more people to the world than any other country (Table 2). It also rivaled regional contributions to population increase during this time period (Figure 5). The rest of less developed Asia and Oceania was also a key contributor to annual population growth in the last half century (Figure 5).

Over the next 50 years, Sub-Saharan Africa is expected to become the primary source of global population increase (Figure 5). Countries such as Nigeria, Congo (Kinshasa), Madagascar, and Uganda are likely to rise quickly in the rankings of the largest contributors to population growth (Table 2). China, conversely, is expected to begin to lose population in larger numbers than any other country or region of the globe by 2050 (Figure 5, Table 2).

Figure 5.

Sub-Saharan Africa is projected to become the primary contributor to world population increase by 2050.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

China and the More Developed Regions of the Globe Are Projected to Experience Consistent Population Declines by 2050

In 1950, more developed countries were major contributors to annual global population increase (Figure

5). By 2002, however, their contribution was dwarfed by that of less developed countries. Only the United States retained a position in the list of the top ten largest contributors (Table 2).

During the next 50 years, more developed countries are expected

to contribute fewer and fewer people to world population increase. Again, only the United States is projected to retain a position in the list of the top ten largest contributors to global population growth in 2050 (Table 2).

THE MECHANICS OF POPULATION CHANGE

The Size of a Population Will Stay Constant When Mortality Is Constant, Fertility Is Constant at Replacement Level, and There Is No Migration or Momentum

The most basic description of population change identifies three fundamental building blocks: births, deaths, and migrants. Put simply, when the balance of these components deviates from zero, the size of the population will change.

The usefulness of this description is limited, however, because raw numbers are not good indicators of the magnitude of these events. Understanding magnitude is

helpful because it can provide information about likely future trends in each component and, consequently, about population growth itself.

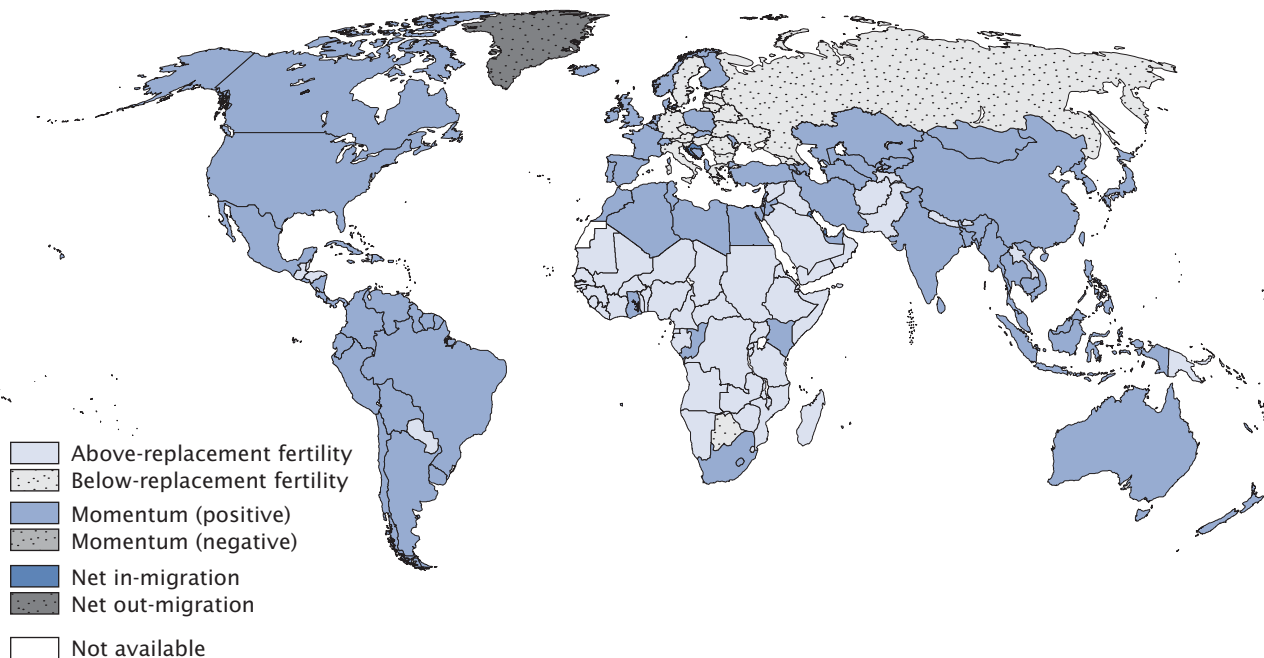

To produce such a description, the raw numbers of births, deaths, and migrants can be expressed as rates — i.e., in terms of the size of the population that contributes to each event type. Hence, we use women of childbearing age (typically between ages 15 and 49) to express births, and the entire population to express deaths and migrants.

Next, the level at which each component will not affect the size of a

population is identified. For fertility, this is the *replacement level*, or the level of fertility at which each successive generation of women produces just enough offspring so that it is matched in number by daughters surviving to reproductive age. Similarly, a constant level of mortality and number of deaths will contribute to the stability in the size of a population. For migration, constant size will be encouraged when immigration equals emigration (i.e., net migration is zero). In the end, change in population size can then be described in terms of deviations from these levels.

Figure 6.

The Major Component of Population Change by Country: 2002 Fertility and population momentum were the principal drivers of population growth in 2002.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

One outcome of this modification to the original description is that a

change in the size of a population (either growth or decline) may now

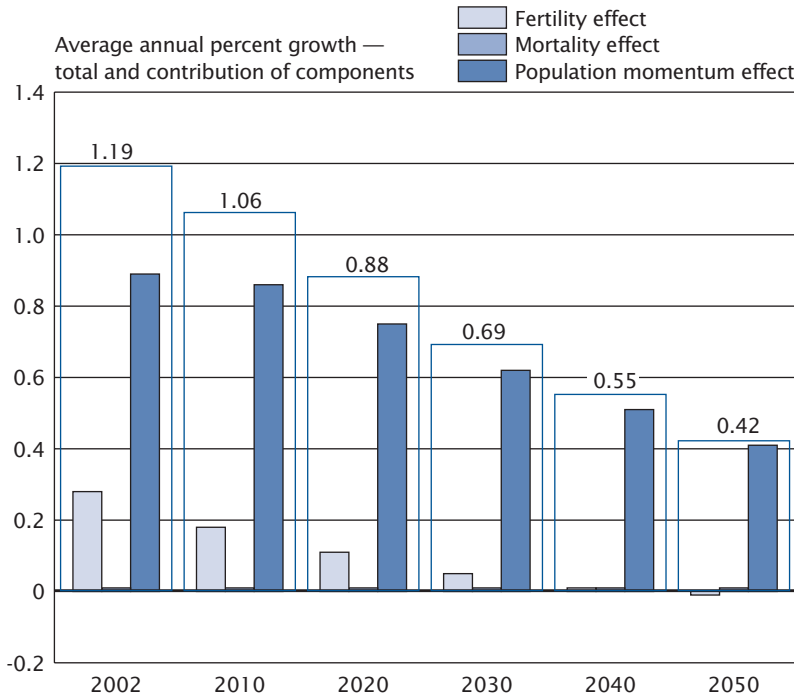

occur even if fertility is at replacement, mortality is constant, and the population itself is closed to migration. The cause of this is an abundance (or dearth) of women in their childbearing years relative to the rest of the population.

In practice, this abundance (or dearth) is commonly caused by past deviations of fertility from the replacement level. Hence, this phenomenon has been labeled *population momentum*. Over time, sustained replacement-level fertility and constant mortality in a population closed to migration will cause these cohorts to come into balance with the rest of the population and the expected zero population growth will result.

Population Momentum Is Expected to Gradually Become the Sole Driver of Global Population Growth

In 2002, population momentum (i.e., the relatively large numbers of childbearing women) was the principal driver of world population growth. Above-replacement fertility played a lesser role and mortality decline played almost no

Figure 7.
The Components of Yearly Global Population Growth: 2002-2050
Fertility's overall contribution to global population growth is projected to cease by 2050.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

role at all (Figure 7). At the country level, population momentum was dominant in most of Asia and the Americas, whereas above-replacement fertility was the principal driver in Sub-Saharan Africa. Below-replacement fertility

was the primary cause of change in Europe (Figure 6).²

Over the next 50 years, the role of population momentum is likely to

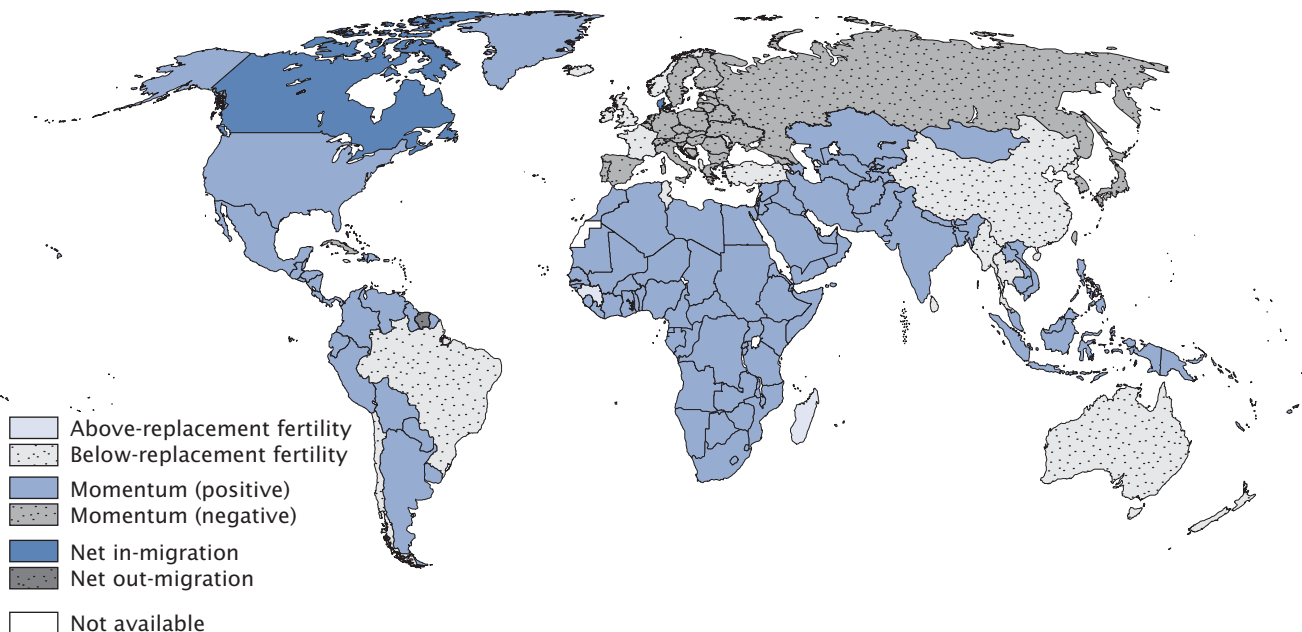

²This disaggregation of the components of growth builds on previous work by Christenson and Johnson (2002) and Knodel (1999).

become increasingly dominant (Figure 7). By 2050, it is expected to become the principal driver of growth in Asia, Africa, and the Americas, and of *decline* in Europe due to the relatively few women of childbearing age compared to the large numbers of elderly people (Figure 8).

Figure 8.

The Major Component of Population Change by Country: 2050

In 2050, population momentum will encourage increases in population size for much of the world but decreases in population size for many European countries.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

FERTILITY AND POPULATION GROWTH

In 2002, the Women of the Globe Needed to Have an Average of 2.3 Children in Their Lifetime to Assure the Replacement of the Globe's Population

Childbirth contributes positively to global population growth. Put simply, if the number of births is greater than the number of deaths, the size of the globe's population will grow.

A useful way to express the rate at which women have children is the Total Fertility Rate (TFR). The TFR is the average number of children that would be born per woman if all women lived to the end of their childbearing years and bore children according to a given set of

age-specific fertility rates. Thus, a TFR of 3 means that we would expect the average woman in a population to have three births in her lifetime.

In the context of population growth, another useful concept is the *replacement level of fertility*: the level of fertility at which each successive generation of women produces exactly enough offspring so that the same number of women survive to have children themselves. In general, therefore, the higher the level of mortality in a population, the higher the replacement level of fertility will be.

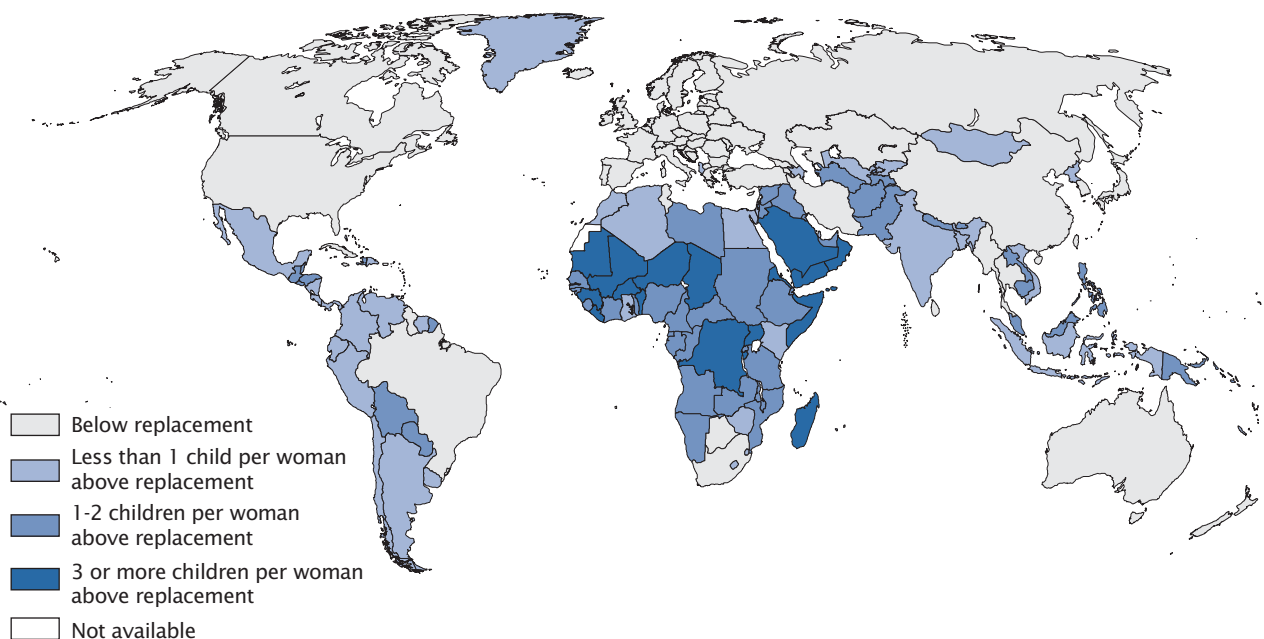

It is often said that fertility is at replacement when the TFR is

2.1 births per woman. In fact, this is the replacement level of a relatively developed country. In 2002, the actual replacement level of fertility for the globe as a whole was 2.3 children per woman. For the nations of the globe, the replacement level ranged from a low of just over 2 children per woman in several more developed countries to a high of 3.4 children per woman in Mozambique (U.S. Census Bureau, International Programs Center, unpublished tables).

Over the next five decades, Census Bureau projections indicate that the replacement level of fertility for the globe will decline gradually to reach 2.1 children per woman by 2050.

Figure 9.

Total Fertility Rate Relative to the Replacement Level for Each Country Across the Globe: 2002 In 2002, fertility levels were highest in the countries of Sub-Saharan Africa and the Near East, and lowest in the more developed countries.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

For the nations of the globe, many more are expected to approach the low of just over 2 children per woman, while the maximum national average is projected to decline to approximately 2.5 children per woman (U.S. Census Bureau, International Programs Center, unpublished tables).

The Globe Is Currently in the Midst of a Remarkable Decline in Fertility

In 2002, the globe’s TFR was 2.6 births per woman, about three-tenths of a child per woman above the replacement level (Figure 10). If current trends persist, the gap between the actual level of fertility and the replacement level will decrease gradually, with the actual level dipping below replacement in 2043.

Figure 10.
Global Fertility Levels Relative to Replacement Level: 2002-2050
The level of global fertility is projected to drop below replacement by mid-century.

Note: Global total fertility rates underlying figure 10 were derived by calculating weighted age-specific fertility rates from country-and-age-specific births and numbers of women.
 Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

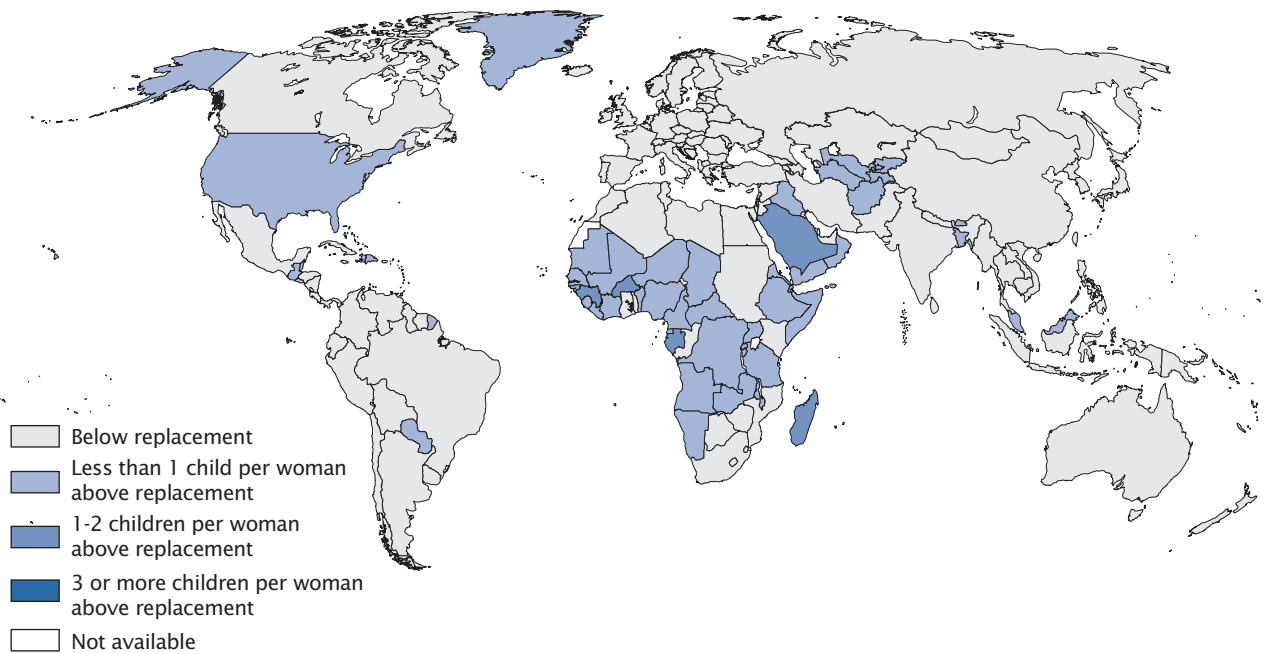

At the country level, fertility was below replacement in almost all of the more developed world and in some countries in the less developed world in 2002. Still, the majority of less developed

countries had fertility rates above replacement (Figure 9). If current trends continue, the number of countries with above-replacement fertility is expected to decline gradually over the coming

five decades. In addition, in countries where fertility continues above replacement, the gap between the actual and replacement levels is expected to shrink (Figure 11).

Figure 11.

Total Fertility Rate Relative to the Replacement Level for Each Country Across the Globe: 2050
In the next 50 years, country-to-country differences in fertility are expected to persist despite a general trend toward convergence.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

MORTALITY AND POPULATION GROWTH

Mortality Contributes to Population Change by Affecting the Number of People Who “Exit” a Population and by Determining the Replacement Level of Fertility

Whereas childbirth is the natural input mechanism behind global population change, death is the natural output mechanism. Put simply, if the number of deaths is greater than the number of births, the size of the globe’s population will decrease.

A useful way to express the level of mortality of a population is *life expectancy at birth*. Life

expectancy at birth is the average number of years a group of people born in the same year can be expected to live if mortality at each age remains constant in the future.

In the context of population growth, the level of mortality has two effects on our understanding of how the size of a population changes. First, a change in the level of mortality will encourage a change in the size of the population — i.e., a declining rate will indicate fewer deaths than in the previous year, whereas an increasing rate will indicate more deaths. Second, as mentioned in the

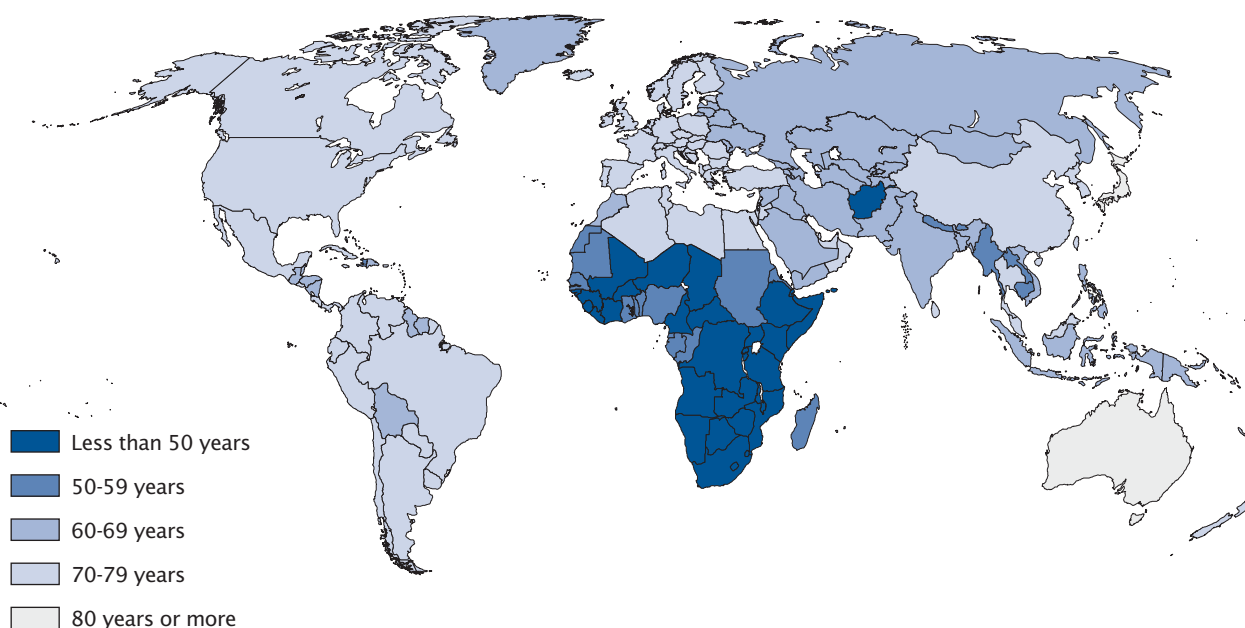

previous section, a higher level of mortality will create a higher replacement level of fertility — i.e., a higher level of fertility that will allow each successive generation of women to produce exactly enough offspring so that the same number of women survive to have children themselves.

Declining mortality most strongly influenced population growth at the end of the 19th century and the beginning of the 20th century (Bongaarts and Bulatao, 1999). Currently, the great majority of countries are experiencing only gradual declines in mortality.

Figure 12.

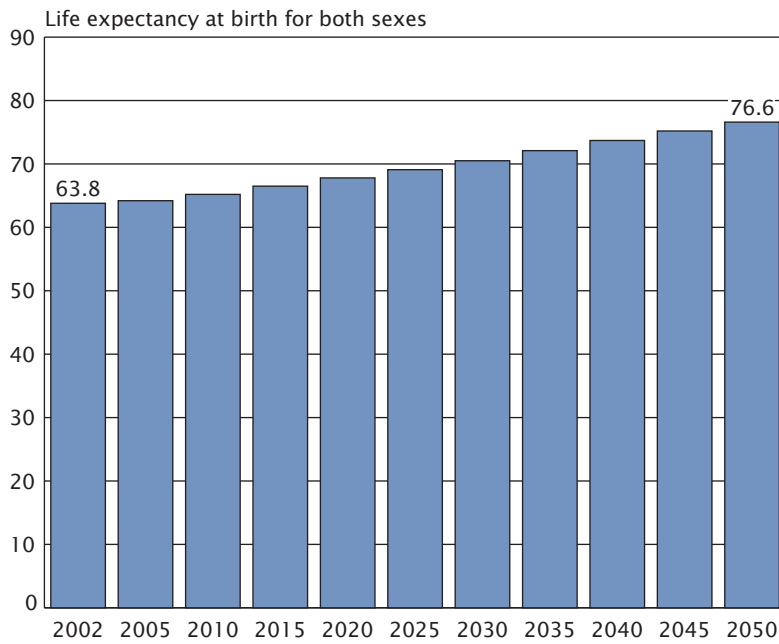

Life Expectancy at Birth Across the Globe: 2002

Sub-Saharan African countries had by far the lowest life expectancy at birth of any region on the globe in 2002.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

Figure 13.
World Life Expectancy at Birth: 2002-2050
Global life expectancy at birth is projected to increase gradually through 2050.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

However, there are several countries where the AIDS pandemic is causing mortality to rise quickly (see the fourth section of this report). As a result, the fertility level needed to maintain the balance between births and deaths is also changing quickly.

Life Expectancy at Birth Is Generally in a Gradual Upward Trend

In 2002, the overall life expectancy at birth in the world was 63.8 years. Countries with the highest levels of life expectancy at birth in 2002 were predominantly those of Europe and North America (Figure 12). Most of the countries with the lowest levels, in contrast, were in Sub-Saharan Africa. This latter fact is in part due to the effects of the HIV/AIDS pandemic.

U.S. Census Bureau projections indicate that the global level of life expectancy at birth will increase slowly but steadily to 76.6 years in

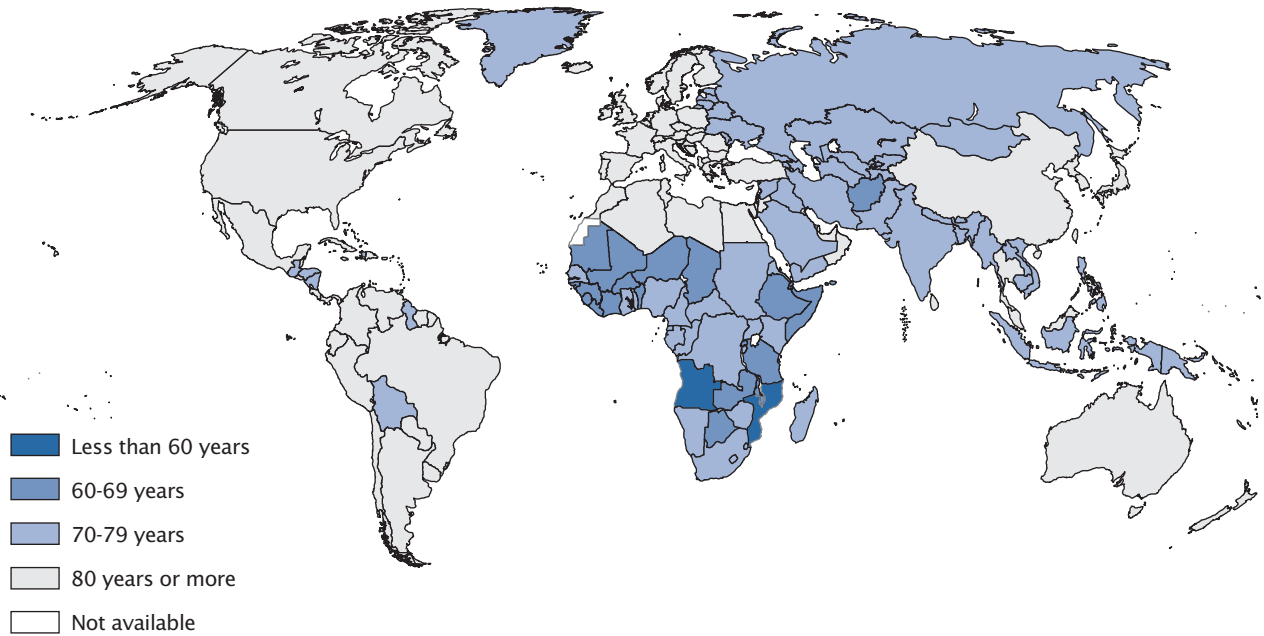

2050 (Figure 13). The levels for most countries are expected to mirror this gradual upward trend, with countries with lower life

expectancies enjoying substantially faster improvements on average than countries with higher life expectancies in 2002 (Figure 14).

Figure 14.

Life Expectancy at Birth Across the Globe: 2050

In the next 50 years, current disparities between countries in levels of life expectancy at birth are expected to decrease.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

MIGRATION AND POPULATION GROWTH

The Relationship Between Migration and Population Change Is Different From the Relationship Between Fertility or Mortality and Population Change

The relationship between migration and change in the size of a population is different from the effects of fertility and mortality in two respects. First, by definition, migration will not affect global population change. Every person who leaves one country must necessarily

enter another, so net world migration will always equal zero.

Second, migration is a far less predictable phenomenon than fertility or mortality. Whereas fertility and mortality can be considered basic human experiences, migration is more a social phenomenon. As a result, the number of births and deaths, as well as the ages at which women give birth and at which individuals die, tend to vary less than the numbers and ages of people who migrate. For this reason, the

data that are available to estimate the effect of migration on change in the size of a population are likely to be much less dependable, and projections of migration are especially problematic.

Despite these differences, migration is an important component of population change for many countries. If net migration, the difference between the numbers of people entering and leaving an area, is positive, the size of the population will grow, all else constant.

Table 3.

The Top Net Senders and Receivers of Migration: 2002

In 2002, net migration to the United States was three times higher than the next highest receiving country.

Top ten net senders			Top ten net receivers		
Rank	Country	Net migration	Rank	Country	Net migration
1	Mexico	-280,000	1	United States	1,040,000
2	China	-230,000	2	Afghanistan	300,000
3	Tanzania	-180,000	3	Canada	190,000
4	Congo (Kinshasa)	-150,000	4	Germany	180,000
5	Philippines	-130,000	5	Russia	140,000

Source: U.S. Census Bureau, International Programs Center, International Data Base.

While the Flow of Migrants in 2002 Was an Interesting Phenomenon, the Typical Effect of Net Migration on Population Change Was Small to Moderate

In 2002, there was a shift across national boundaries of approximately 3 million people. Mexico was the largest sender of people, having a net outflow of 280,000 people into other countries, including the United States (Table 3). China was the next largest sender, transferring approximately 230,000 people to other countries.

As Figure 15 shows, almost every net sender of migrants was a less developed country.

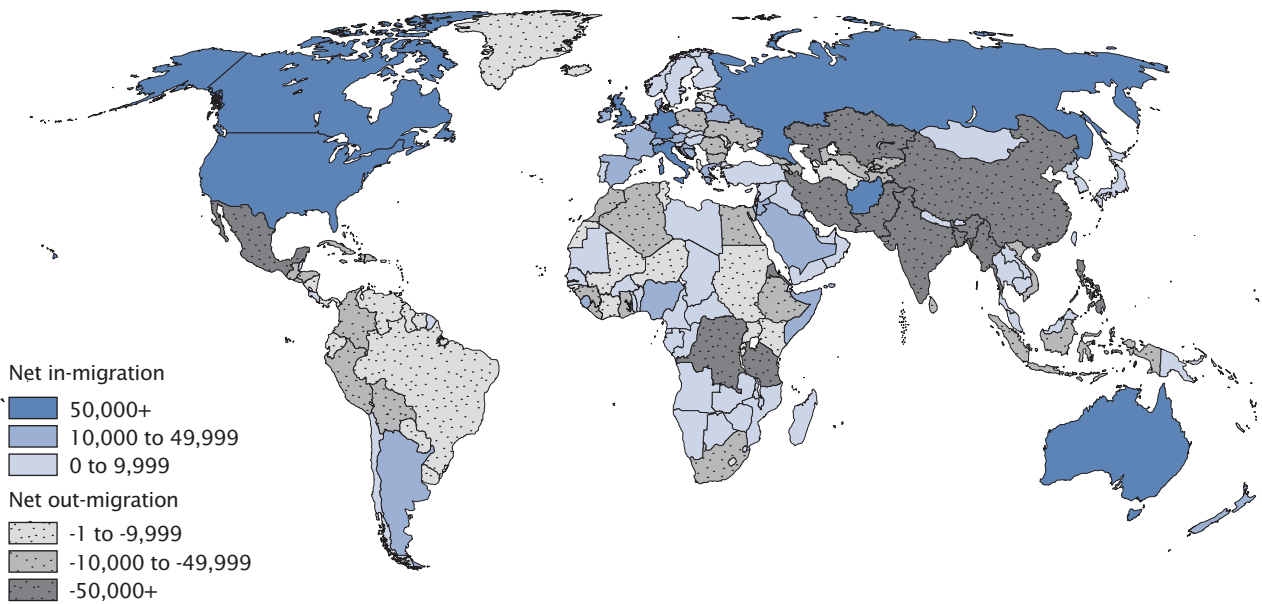

On the other side of the equation, the United States absorbed about one-third of the total net in-migration (total net migration for receiving countries) in 2002. Six of the remaining nine top ten net receivers (Table 3) were also more developed countries, the exceptions being Afghanistan, Singapore, and East Timor. Afghanistan and East Timor made the list in 2002 due to the return

of refugees, and Singapore because of its proximity to China, the largest net-sending country.

In relative terms, the countries where net migration had the most impact on population size in 2000 (whether positive or negative) were either island nations or nations with recent experience of military conflict (Table 4). For the majority of larger countries, however, the relative effect of net migration was small to moderate (Figure 16).

Figure 15.

THE FUTURE OF POPULATION GROWTH

The Globe's Population Is Expected to Grow to Approximately 9.1 Billion in 2050

The task of producing long-term population projections is fraught with difficulties. It requires that very broad assumptions be made regarding future trends in the underlying components of population change: fertility, mortality, and migration. (See Appendix B for details about the actual assumptions used in producing the projections in this volume.) In addition, the effects of these assumptions cumulate over time so that seemingly small adjustments can have substantial impacts on the resulting projections. For this reason, long-term population projections should be used with caution.

Nevertheless, the exercise of producing long-term projections can provide valuable insight into the likely development of phenomena that have important policy implications. Furthermore, population projections provide a concrete measure that can be used in subsequent analyses to evaluate the methods used to produce the projections and the assumptions that lie behind them.

The U.S. Census Bureau's long-term projections indicate that the globe's population will grow to approximately 9.1 billion in 2050, an increase of over 45 percent compared to its size in 2002.

The largest gains in population between 2002 and 2050 are projected to be in Sub-Saharan Africa

and the Near East (Figure 17). In these regions, many countries are expected to more than double in size by 2050, with some more than tripling.

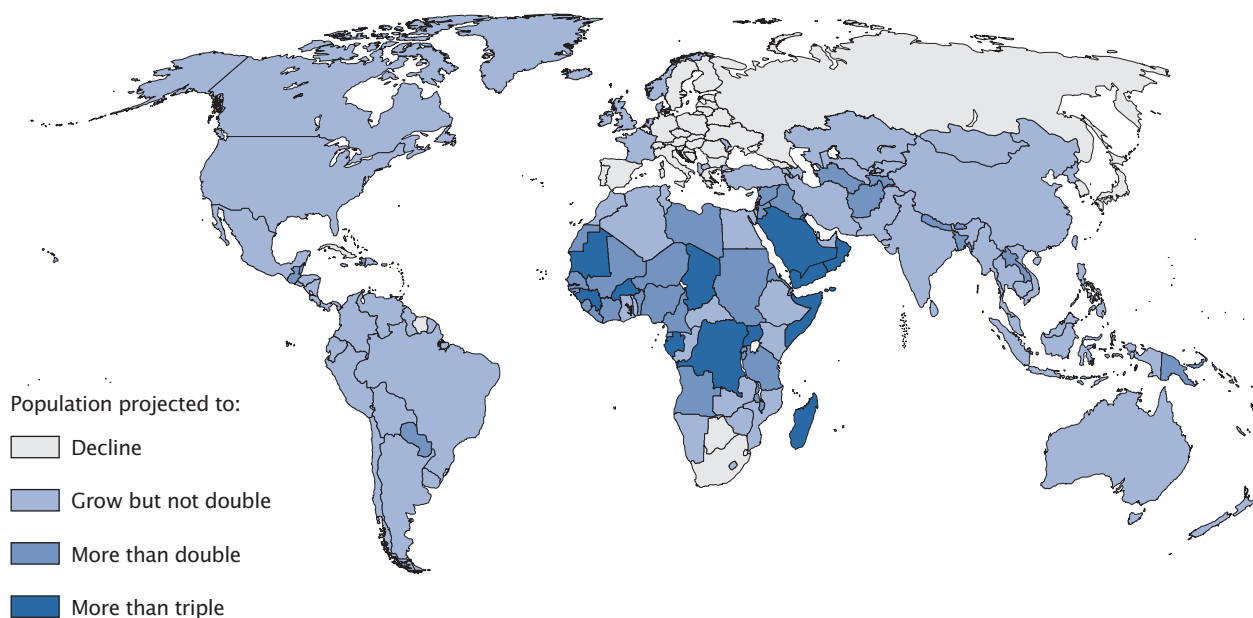

More moderate gains are expected in that time period for North Africa, the Americas, Asia, and the Pacific. Although some countries in these regions are expected to more than double in size, the typical country is likely to experience a smaller increase.

On the opposite end of the spectrum, a majority of the countries in Europe and the New Independent States of the former Soviet Union are expected to experience a decline in population between 2002 and 2050.

Figure 17.

Population Change Around the Globe: 2002-2050

The loss of population in Europe and the NIS over the next five decades is expected to be more than offset by population gains in the rest of the world.

GLOBAL POPULATION COMPOSITION

The age-sex composition of a society's population has significant implications for the current and future development of that society. As we saw in the previous section, the age-sex structure can cause a population to grow even when the levels of fertility and mortality suggest equilibrium or even decline. In addition, the age-sex composition of a population has its own direct implications for public policy.

*This section on **Global Population Composition** begins with a description of the current age-sex composition of populations around the globe. We then discuss the mechanics behind population structure, look at current levels and trends, and finally, look toward the future of population composition around the globe.*

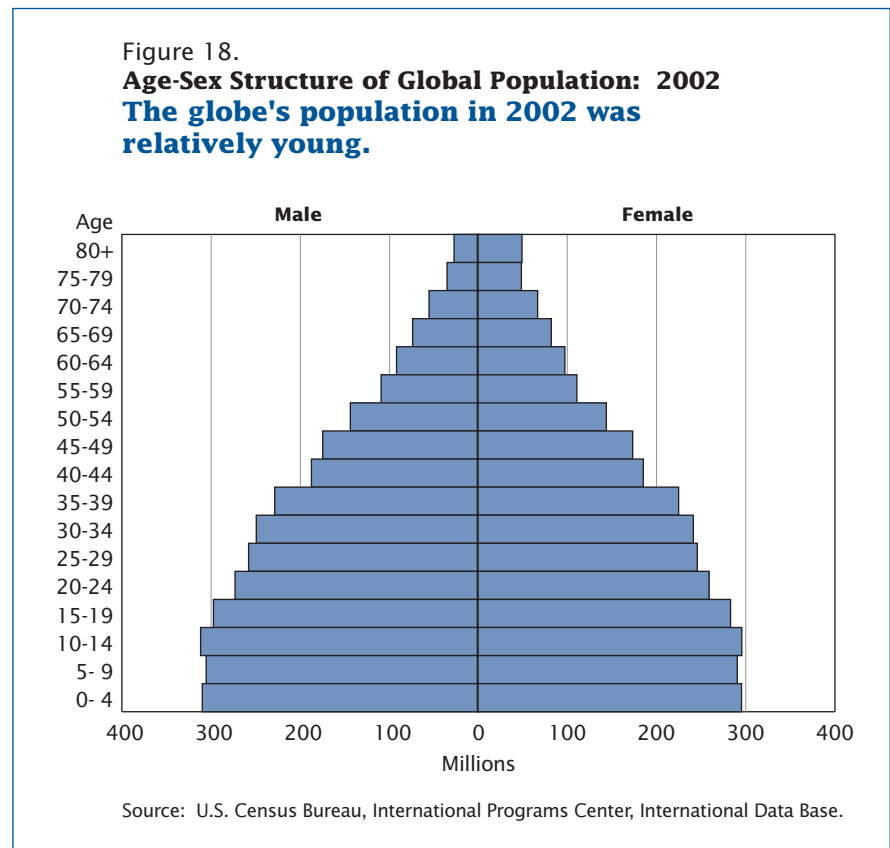

THE COMPOSITION OF GLOBAL POPULATION

A Global View of Population Composition in 2002 Hid Some Striking Regional Differences

The age-sex composition of the globe's population in 2002 is depicted in Figure 18. This pyramid illustrates the following characteristics:

- The number of men and women on the globe was approximately equal.
- Men outnumbered women up through the 50-54 age group, after which women outnumbered men.
- The largest age group for both males and females was ages 10-14, followed closely by ages 0-4, and then ages 5-9.
- Each successively older age group beginning with ages 15-19 was progressively smaller.

As the pyramids in Figure 19 illustrate, however, population age-sex structure varied across major world regions. First, although men outnumbered women in all of Asia, the Near East, and North Africa, women outnumbered men in the developed world, Eastern Europe and the NIS, and Latin America and the Caribbean. In addition, although women typically outnumbered men in the older age groups, the exact age at which this transition occurred varied widely across regions, from a low in Latin

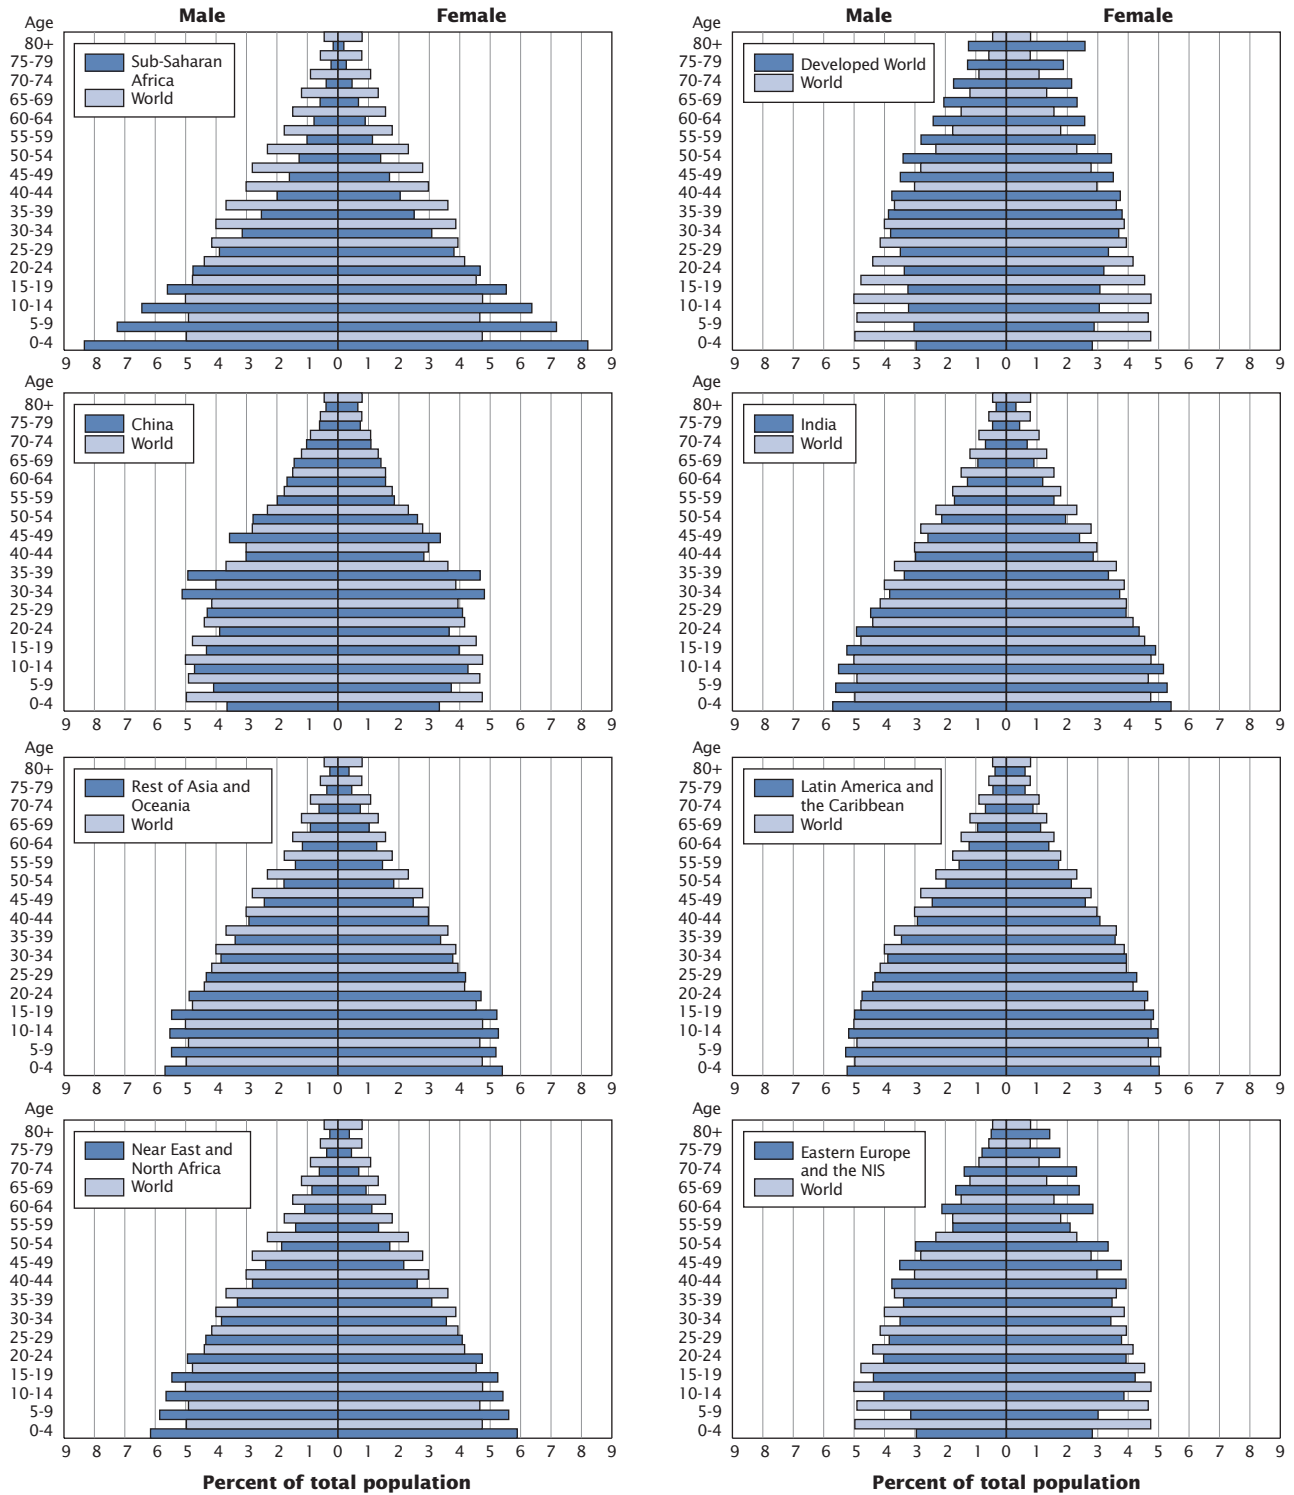

America and the Caribbean (the 30-34 year-old age group) to the extreme in India, where women never outnumbered men.

In terms of the age structure of populations, regions comprising less developed countries tended to have the highest percentages of their populations under age 15. In Sub-Saharan Africa, the Near East and North Africa, and for Asia and the Pacific excluding China and India, the largest proportion of the

population was 0 through 4 years old. In contrast, in more developed world regions and China, older ages composed the largest population groups. Finally, whereas the populations of less developed regions decreased in size progressively as age increased, the patterns in the developed world, Eastern Europe and the NIS, and China were more irregular and much larger proportions of population were ages 65 and higher.

Figure 19.

Population Pyramids by Region and Selected Countries: 2002

THE MECHANICS OF AGE-SEX COMPOSITION

The Age-Sex Composition of a Population Is Determined by the Age- and Sex-Specific Patterns of Fertility, Mortality, and Migration

In one sense, the mechanics that determine the age-sex composition

of a population are the same as those that drive change in the size of a population: fertility, mortality, and migration. In the case of age-sex composition, however, not only the level of each component but also the age- and sex-specific

patterns that make up those levels are important.

Demographic Transition Theory and the Age-Sex Composition of Populations

Demographers who study historical trends in age-sex composition have identified a general progression of changes in fertility, mortality, and population composition through which populations have typically passed in the modern era. These ideas are articulated in the study *Demographic Transition Theory* (Davis, 1945). Although this theory has been criticized as being too general to encompass the variety of national experiences, it still is a useful tool from which to begin to explain the very broad changes that have occurred and that are expected to occur in the age-sex composition of populations around the globe.

Demographic Transition Theory begins with the observation that, at one time, most currently developed societies had very high levels of both fertility and mortality and a corresponding low rate of growth (stage 1). As a result, populations were quite young and stayed relatively small. A pyramid of such a population would have a narrow triangular shape with very few people at the older ages.

According to the theory, the second stage of the demographic transition consists of a substantial drop in levels of mortality, especially among the very young. Since fertility levels stay high, the result is a rapid increase in population, especially at

the younger ages. A pyramid of a population at this stage would be triangular in shape with a wide base due to large cohorts of people at the youngest ages and progressively smaller cohorts at each successive age group.

which the population grows and a more even distribution of the population across age groups. A pyramid of a population at the end of this stage would be more rectangular in shape. At this time, however, the population in the older age groups would be increasingly dominant.

Population at Stage 1 of the Demographic Transition

Population at the End of Stage 3 of the Demographic Transition

Population in Stage 2 of the Demographic Transition

The next change that begins to affect populations is a decline in the level of fertility (stage 3), which causes a slowing of the rate at

Demographic Transition Theory does not offer a complete explanation of what determines the age-sex composition of populations. The most glaring omission is the effect of migration on population structure. In addition, it is not sensitive to potentially important local conditions that can affect the age- and sex-specific mortality or fertility levels of a population. Nevertheless, Demographic Transition Theory provides a useful basis from which to begin describing the age-sex composition of populations across the globe.

A Population's Demographic History Leaves Marks on Its Age-Sex Composition

In the following sections, examples are given of the ways that the three components of change can influence the age-sex composition of a population. When considering these examples, it may be helpful to compare the hypothetical composition to a population that is distributed equally across all age-sex groups, whose pyramid would be perfectly rectangular. Alternatively, one may compare the composition to one of the classical structures as put forth in Demographic Transition Theory. (See textbox on preceding page.)

Fertility and Age-Sex Composition

An interesting biological fact is that, on average, between 103 and 107 boys are born for every 100 girls. Although populations may deviate slightly from these proportions, long-run trends show that they tend to maintain these averages. As a result, males outnumber females at the bottom of most population pyramids.

In terms of the age-structure of populations, a decrease in the overall level of fertility will reduce the size of the younger cohorts of a population relative to the size of the older cohorts (all else constant). Changes in age-specific fertility rates can also have interesting effects. Baby booms, or uncharacteristically large age cohorts within a population, are created when large proportions of the women in a population have

Bulge in a population pyramid due to a baby boom (United States, 2000)

children in the same years, typically due to some critical event (e.g., the end of a war). The shape of the population pyramid of the United States in 2000 (above), especially at ages 35-54, reflects, in part, the effects of the post-World War II baby boom.

Mortality and Age-Sex Composition

Another interesting phenomenon is that males tend to die at higher rates at all ages than do females. For this reason, the advantage in numbers that males typically have at birth tends to erode and eventually be lost at higher ages.

Most changes in mortality experienced by a population typically affect people in certain age-sex groups more than others. For example, a reduction in deaths from infectious and parasitic diseases typically affects younger people the most. Conversely, a reduction in deaths from chronic and degenerative diseases tends to affect older people more than the young.

An unusual absence of adult males in a population (Sudan, 1990)

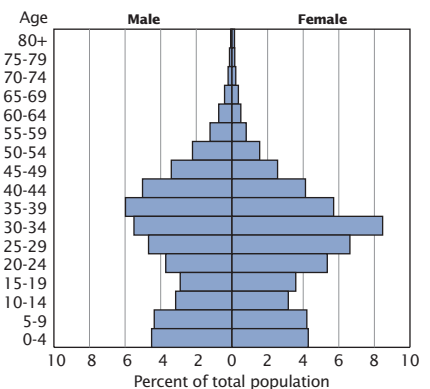

In more extreme cases, the effects of mortality are less regular. For example, the mortality from war tends to have its strongest effect on the young male population. The pyramid of Sudan in 1990 (above) may have been caused by such mortality. Likewise, the AIDS pandemic is already having marked effects on some young-adult populations (see the section on AIDS later in this volume).

Migration and Age-Sex Composition

As with population growth, the effect that migration will have on the eventual age-sex composition of a population is difficult to predict. Nevertheless, several patterns of age- and sex-specific migration have been observed.

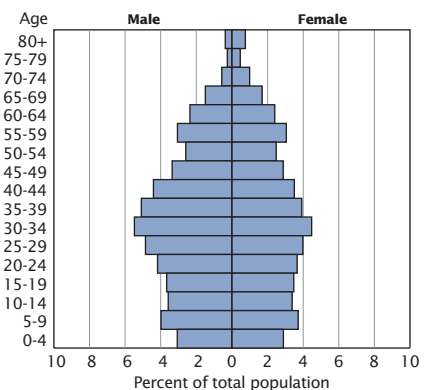

Pyramid of a labor migration-receiving territory (Northern Mariana Islands, 2000)

First, quite often people who migrate are looking for employment. In this case, the great majority of movers will be young adults. The pyramid of the Northern Mariana Islands (above) shows the effect that a massive influx of labor migrants can have.

The effect of massive refugee movements on the age-sex composition of a population is somewhat less predictable. Refugees can be of all ages and of both sexes. The pyramid of the population of Bosnia and Herzegovina during the conflict in 1995 (below) strongly indicates the outflow of women and children from the country.

Pyramid reflecting serious effects of migration (Bosnia and Herzegovina, 1995)

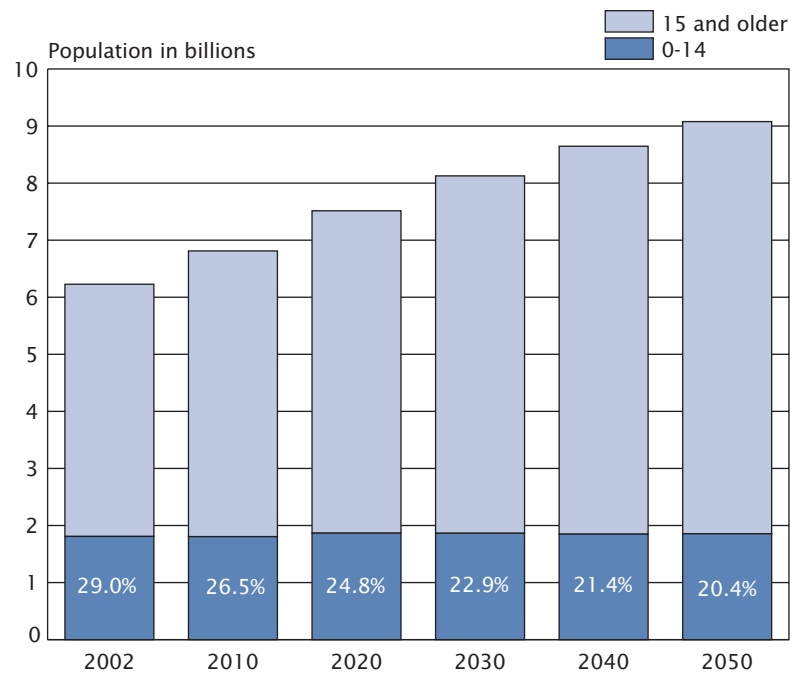

CHILDREN AROUND THE GLOBE

Three Out of Every Ten People on the Earth in 2002 Were Under the Age of 15

In 2002, the globe held approximately 1.8 billion people under the age of 15 (Figure 20). This was just under 30 percent of the total population.

Over the next 50 years, the total number of children on the globe is not projected to increase substantially. As a result, their percentage of the total global population is expected to fall to approximately 25 percent by 2020 and to 20 percent by 2050 (Figure 20). This trend is primarily due to the substantial decline in fertility rates across the globe and the attendant aging of the population.

Figure 20.
Global Population 0-14 Years of Age Compared to Total Global Population: 2002-2050
The percent of children across the globe is projected to decline by one-third over the next five decades.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

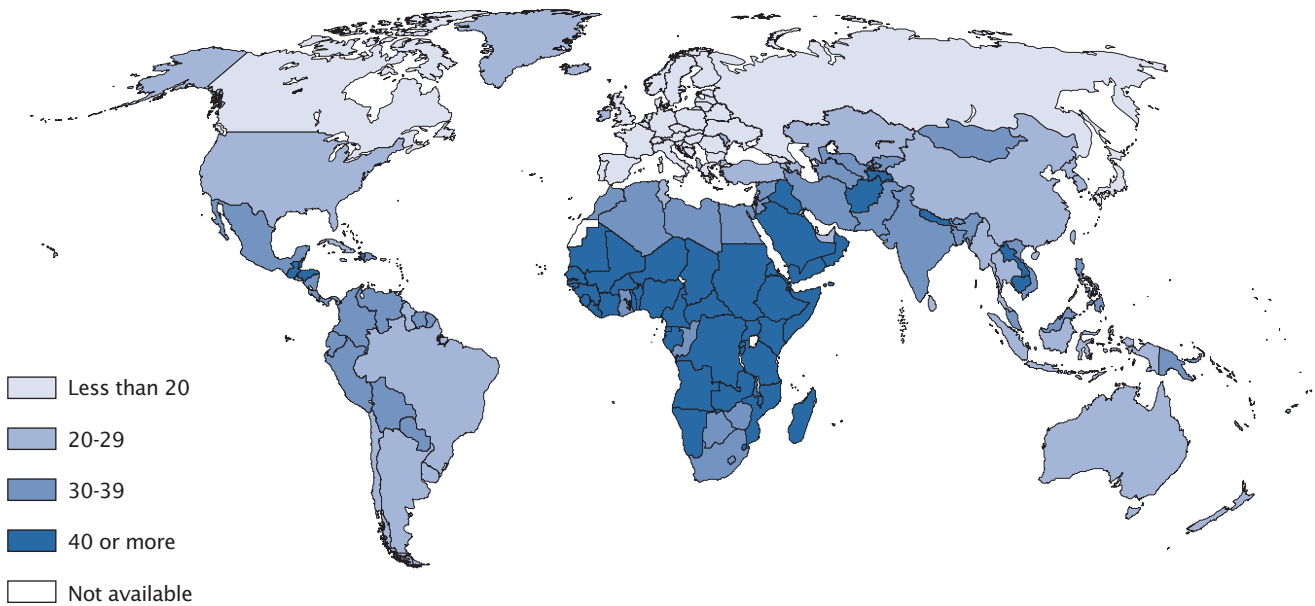

The Population Ages 0-14 Is Expected to Grow Slowly and Even to Decline in Many Parts of the Globe Over the Next Quarter Century

In 2002, children (ages 0-14) as a percentage of the total population

ranged from a high of 51 percent in Uganda to a low of 14 percent in Italy. As Figure 21 shows, the region where the percentage of children was most consistently high was Sub-Saharan Africa, whereas the percentage of children was generally low in the more developed countries.

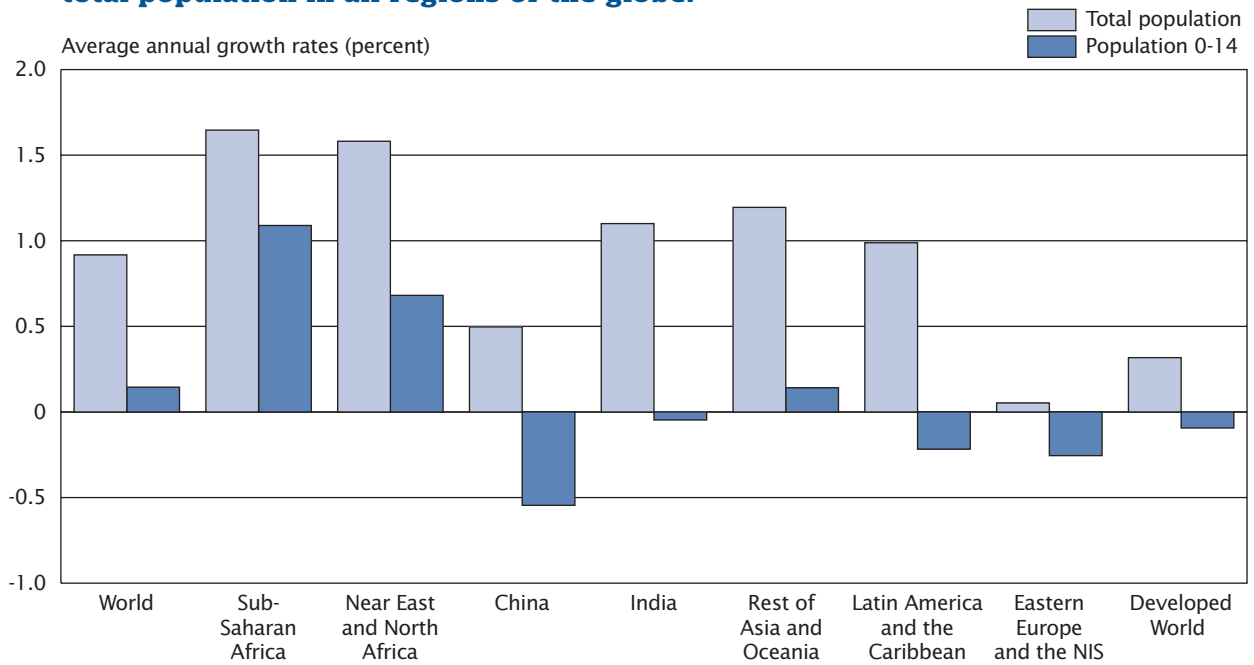

Between 2002 and 2025, the population ages 0-14 is projected to grow much more slowly or decline compared to the total population (Figure 22). As a result, children as a percentage of the total population are expected to decline consistently across the globe (Figure 23).

Figure 21.
Children (Ages 0-14) as a Percent of the Total Population by Country: 2002
In 2002, children were most prominent in Sub-Saharan Africa and parts of the Near East, and least prominent in Europe.

One Out of Every Four People on the Earth in 2002 Was Between the Ages of 15 and 29

In 2002, the globe held approximately 1.6 billion people between the ages of 15 and 29 (Figure 24). This was approximately 26 percent of the total population.

Over the coming five decades, the total number of youth on the globe is projected to increase slightly (Figure 24). Still, their percentage of the total global population is expected to fall to approximately 23 percent by 2020 and to 20 percent by 2050. As with the trends in the child population, this is primarily due to past declines in fertility across the globe and the attendant aging of the population.

Figure 24.
Global Population 15-29 Years of Age Compared to Total Global Population: 2002-2050
The percent of youth across the globe is projected to decline steadily over the next 50 years.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

Over the Next Two Decades, the Population Ages 15-29 Is Expected to Grow in Some Parts of the World and to Decline in Others

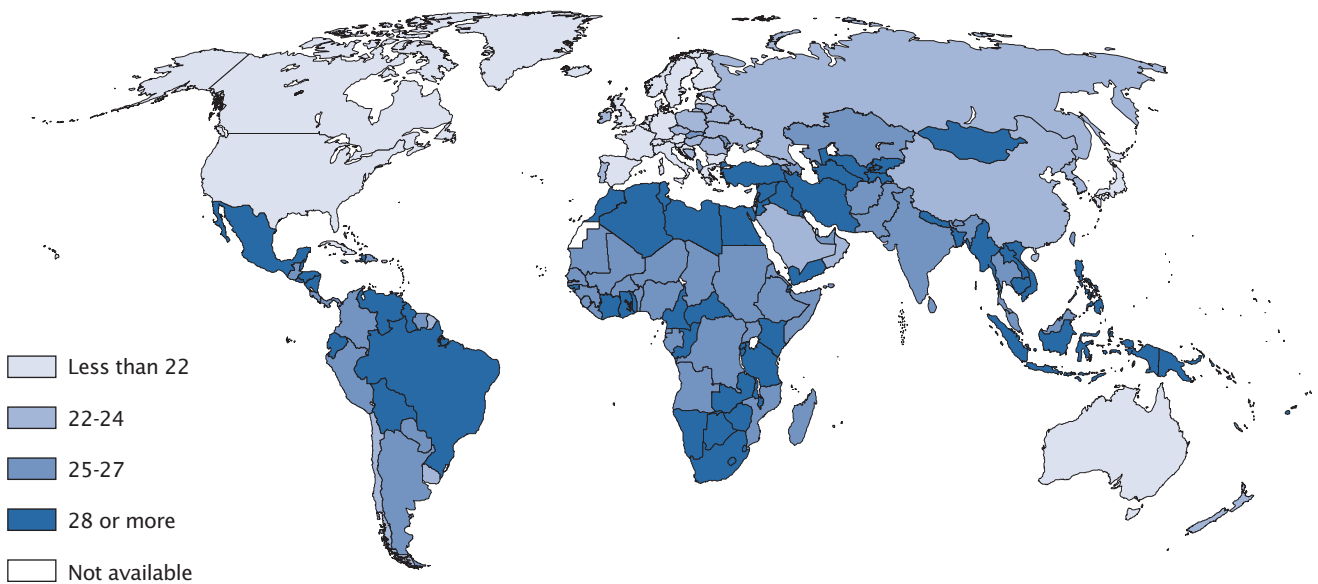

In 2002, youth as a percentage of the total population ranged from a high of 35 percent in Grenada to a low of 14 percent in Monaco. As Figure 25 shows, the percentage of

youth was predominantly higher in Africa and much of Asia, but generally low in the countries of the Developed World and in Eastern Europe and the new independent states of the former Soviet Union.

Over the 2002-2025 period, the change in the population ages 15-29 is expected to vary by region,

growing faster than the total population in Sub-Saharan Africa while declining in China, Eastern Europe, and the Developed World (Figure 26). As a result, youth as a percentage of the total population are likely to decline everywhere across the globe except in Sub-Saharan Africa (Figures 25 and 27).

Figure 25.
Youth (Ages 15-29) as a Percent of the Total Population by Country: 2002

WOMEN OF CHILDBEARING AGE AROUND THE GLOBE

One Out of Every Four People on the Earth in 2002 Was a Woman of Childbearing Age

In 2002, the globe held approximately 1.6 billion women between the ages of 15 and 49 (Figure 28). This was approximately 52 percent of the total female population.

Between 2002 and 2050, the number of women in their childbearing years is projected to increase gradually by over 0.4 billion. Still, women in their childbearing years as a percentage of the total female population are expected to decline gradually to approximately 50 percent in 2020 and to 45 percent by 2050 (Figure 28), due primarily to historical declines in fertility and the subsequent aging of the population.

Figure 28.
Global Women of Childbearing Age Compared to Total Female Population: 2002-2050
The percent of women in their childbearing years is projected to decline gradually over the next five decades.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

Over the Next Two Decades, the Female Population Ages 15-49 Is Expected to Grow Rapidly in Some Parts of the World and to Decline in Others

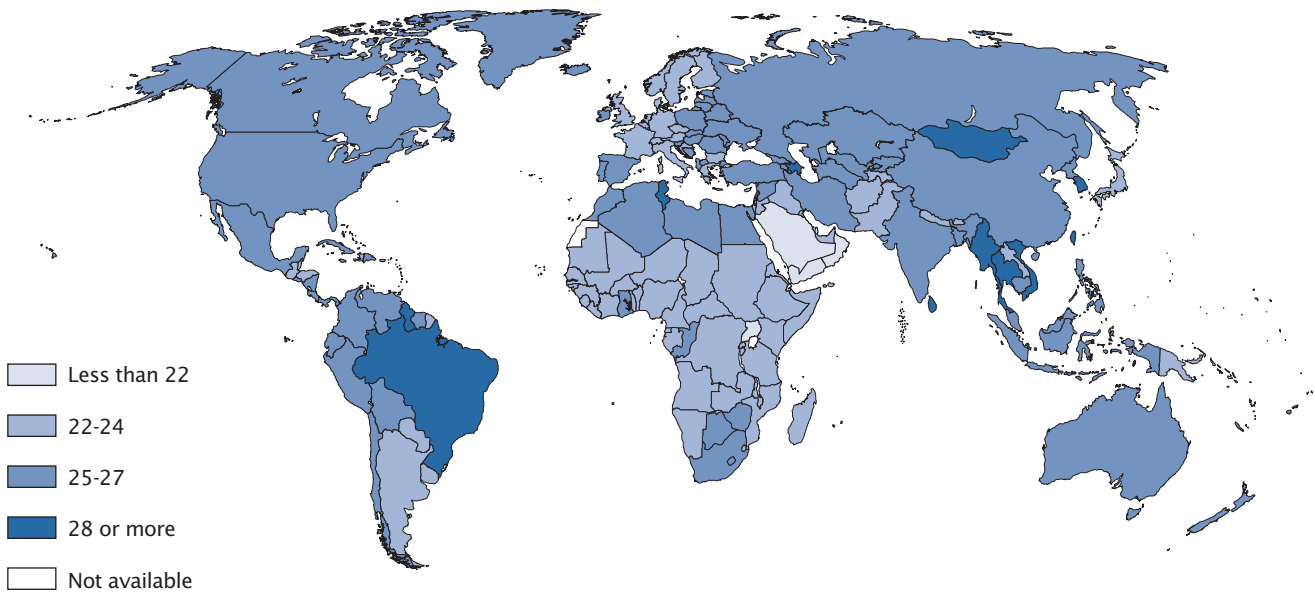

In 2002, women in their childbearing years as a percentage of the total population ranged from a high of 36 percent in the Northern Mariana Islands to a low of

18 percent in Qatar. As Figure 29 shows, women in their childbearing years generally comprised large proportions of the populations of countries in North Africa, Latin America, Eastern Europe and the NIS, and parts of Asia, and low proportions in Sub-Saharan Africa and the Near East.

Over the next two decades, the change in female population ages

15-49 is expected to vary by region, growing substantially faster than the total population in Sub-Saharan Africa while declining in China, Eastern Europe and the NIS, and the Developed World (Figure 30). However, the resulting levels within individual countries are difficult to predict based on these regional trends (Figure 31).

Figure 29.
Women of Childbearing Age (Ages 15-49) as a Percent of the Total Population by Country: 2002
In 2002, the relative size of the population composed of women of childbearing age was low in most of Sub-Saharan Africa but moderate to high in other world regions.

THE WORKING-AGE POPULATION AROUND THE GLOBE

Roughly 2 Out of Every 3 People on the Earth in 2002 Were Between the Ages of 15 and 64

In 2002, the globe held 4.0 billion people between the ages of 15 and 64 (Figure 32). This was approximately 64 percent of the total population.

Over the next five decades, the total number of people ages 15-64 on the globe is projected to increase to 5.7 billion (Figure 32). However, the percentage of total global population composed of people of labor force age is expected to rise only slightly to nearly 66 percent in 2010 and then to decline slightly to about 63 percent in 2050. As with the patterns of growth discussed earlier, this is due primarily to historical declines in fertility and the subsequent aging of the population.

Figure 32.
Population Ages 15-64 Compared to Total Global Population: 2002-2050
The working-age population at the global level is expected to increase by over 40 percent by 2050.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

Over the Next Two Decades, the Population Ages 15-64 Is Expected to Grow Significantly in Most of the Less Developed World

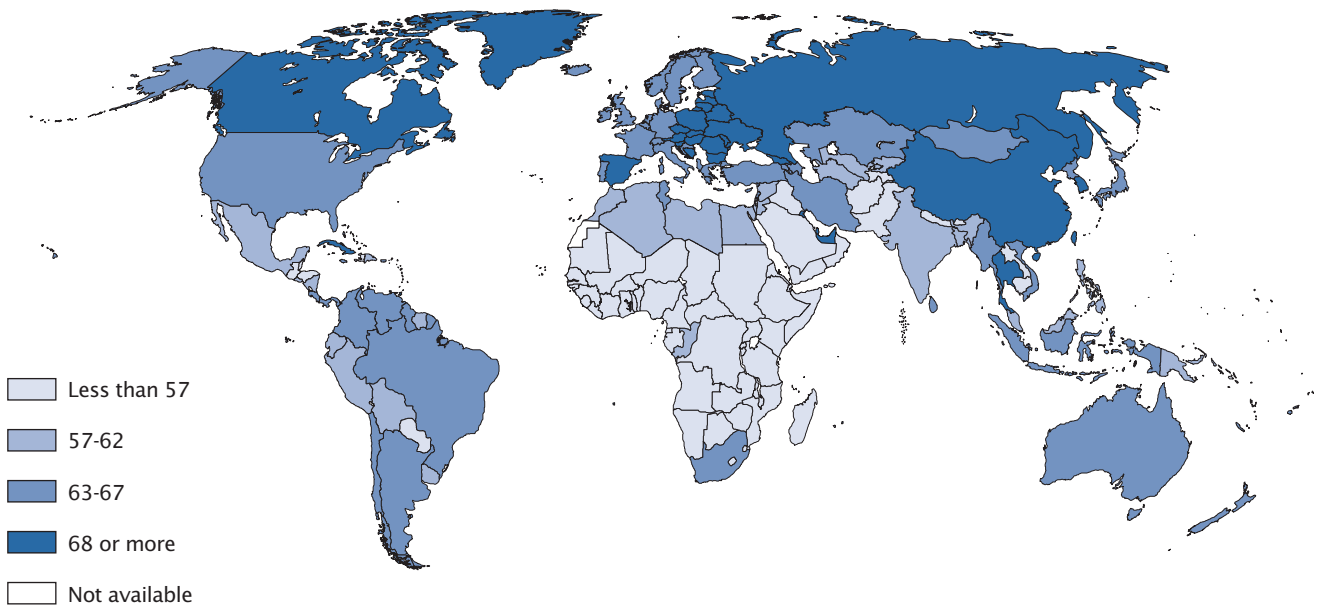

In 2002, the working-age population as a percentage of the total population ranged from a high of 75 percent in Singapore to a low of 47 percent in Uganda. As Figure 33 shows, the places where

the proportions in the age range 15-64 were most consistently high were in the Developed World, Eastern Europe and the New Independent States, and parts of Asia, whereas the percentage in the labor force ages was generally low in Sub-Saharan Africa.

Between 2002 and 2025, the population of labor force age is

projected to grow more rapidly than the population as a whole in all regions except the developed world, Eastern Europe and the NIS, and China (Figure 34). As a result, the population ages 15-64 as a percentage of the total population is expected to increase slightly in all regions except these three.

Figure 33.
Working-Age Population (Ages 15-64) as a Percent of the Total Population by Country: 2002
In 2002, the percent of the population ages 15-64 was higher in China and lower in Sub-Saharan Africa than other world regions.

Countries with relatively large projected labor force age populations are scattered across the globe.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

One Out of 14 People on the Earth in 2002 Was Age 65 or Over

In 2002, the globe held 440 million people age 65 or over (Figure 36). This was approximately 7 percent of the total population.

In the future, the size of the elderly population is projected to increase rapidly, almost doubling by 2020 and more than tripling by 2050. Similarly, the relative size of the elderly population is expected to grow to over 9 percent in 2020 and to almost 17 percent by 2050. Again, as with the patterns of growth discussed earlier, this is due primarily to historical declines in fertility and the general aging of the population.

Figure 36.
Global Elderly Population Compared to Total Population: 2002-2050
The number of elderly is expected to grow very rapidly during the coming five decades.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

The Population Ages 65 and Over Is Expected to Grow Very Rapidly in All Parts of the World

In 2002, the elderly as a percentage of the total population ranged from a high of 22 percent in Monaco to a low of 1.7 percent in Mayotte. As Figure 37 shows, this percentage was typically higher in

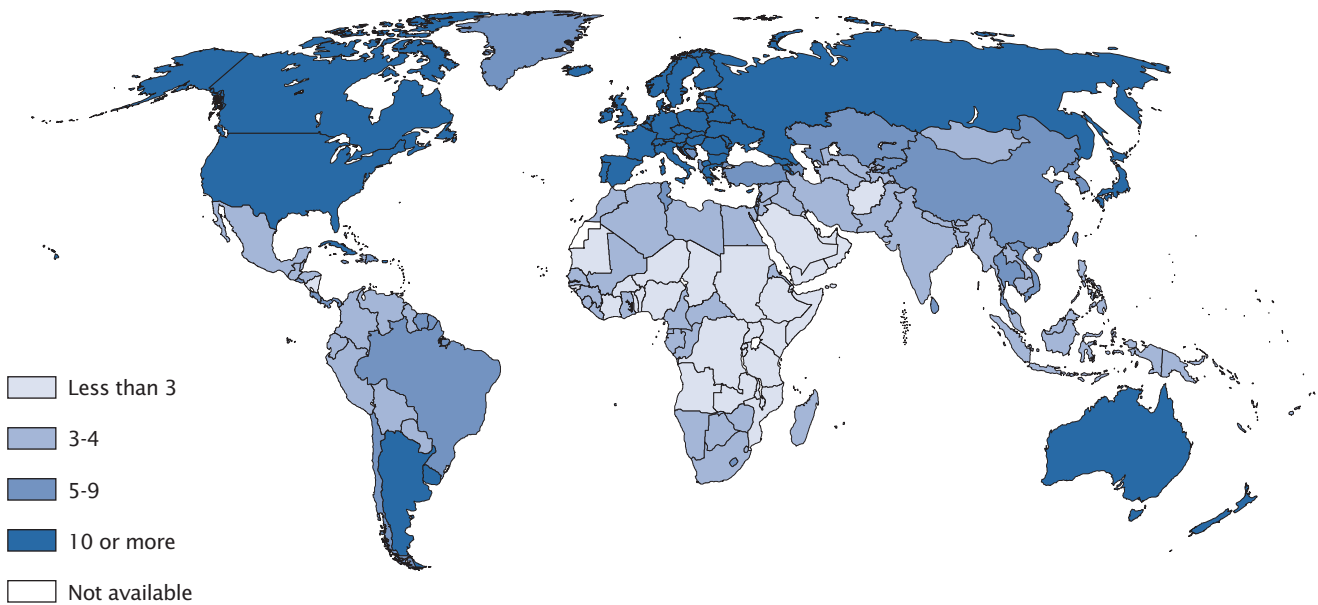

Eastern Europe and the New Independent States of the former Soviet Union, North America, Western Europe and the other countries making up the Developed World, whereas the percentage was generally very low in Africa and the Near East.

Over the next quarter century, the elderly population is projected to

grow much more quickly than the total population in all parts of the world (Figure 38). As a result, the elderly as a percentage of the total population are expected to increase over much of the globe, but especially in Eastern Europe and the Developed World (Figure 39).

Figure 37.

THE FUTURE COMPOSITION OF POPULATION

The Aging of the Population of the Globe Is a Nearly Universal Phenomenon

A comparison of the age-sex composition of the globe's population in 2002 and 2050 is depicted in Figure 40. This pyramid illustrates the following characteristics:

- In contrast to 2002, women are likely to outnumber men in 2050. The differential is expected to be approximately 1 percent.
- Increasing female dominance in the total population is associated primarily with growth in the elderly population between 2002 and 2050.
- In 2050, the population ages 80 and over is projected to make up a considerable proportion of the global total.

As the pyramids in Figure 41 illustrate, these global patterns are expected to be exaggerated in some regions of the world, while Sub-Saharan Africa's age-sex structure is likely to resemble the composition of the globe in 2002. For example, women are expected to outnumber men in 2050 by as much as 9 percent in Eastern Europe and the NIS, but men are expected to still outnumber women in India and the Near East and North Africa.

As for the age structure of the population, Census Bureau projections indicate the 0-4 age group will still be the largest cohort in Sub-Saharan Africa and the Near East and North Africa, whereas people ages 80 and above is likely to become the largest age group in the Developed World and China.

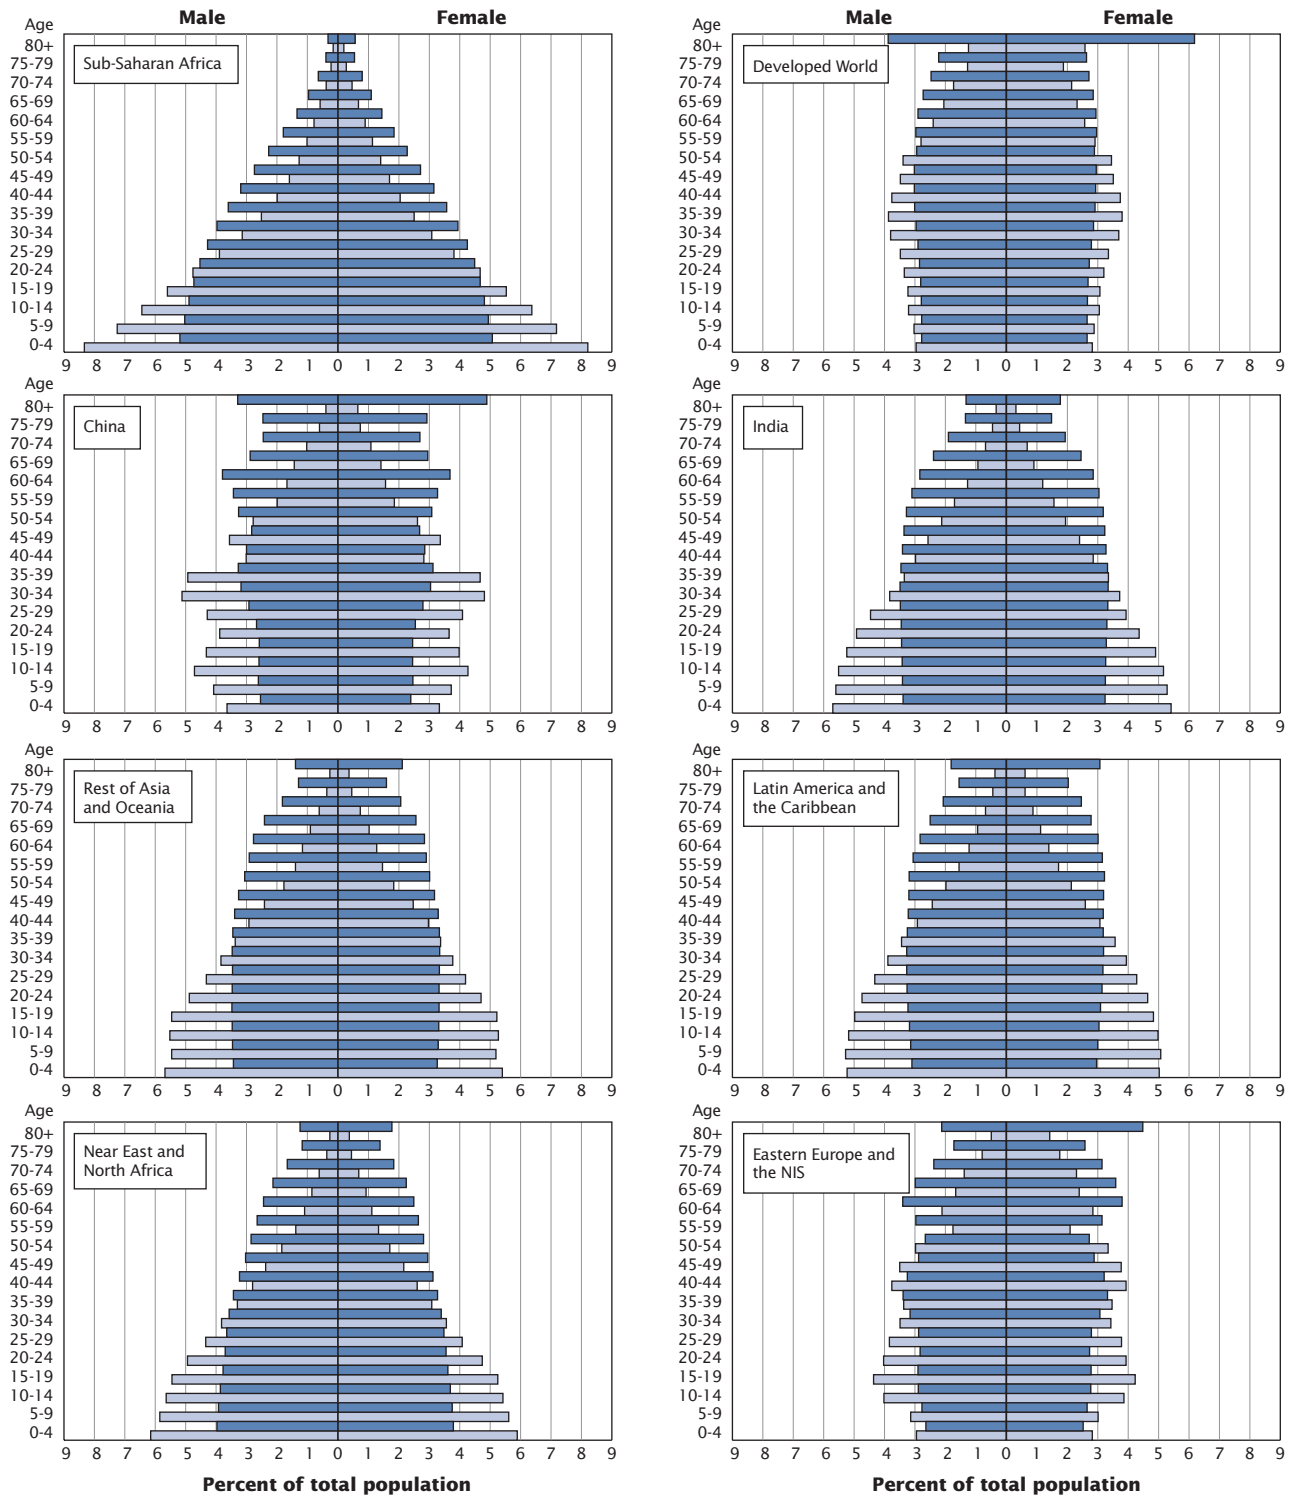

Finally, the regularity of the decrease in the size of successive

cohorts of older people that was the norm in the less developed world in 2002 is expected to give way in 2050 to more irregular patterns in the sizes of successive cohorts and to increased size of the older age groups.

Figure 41.

CONTRACEPTIVE PREVALENCE IN THE DEVELOPING WORLD

The first section of this report underscored the importance of looking at national population growth as the outcome of the interplay of current and future fertility, mortality, and migration, on the one hand, and population age structure — its built-in momentum — on the other. In the first half of the 21st century, a country's fertility level will be key to understanding its long-term growth potential and the way in which its age composition evolves. Regional fertility levels will help

dictate the extent to which some world regions grow relative to others.

*This section on **Contraceptive Prevalance in the Developing World** summarizes currently available information about levels and trends in a principal determinant of fertility level in that part of the world likely to see the greatest population growth during the first decades of this millennium. It also presents a new estimate of unmet need for contraception in the developing world.*

Contraceptive Prevalence Matters

Over the past three decades, developing countries have made substantial progress toward improving maternal and child health, providing reproductive health services to couples, and bringing fertility and mortality levels into line with national goals. While the HIV/AIDS pandemic has had a dramatic impact on the health, growth, and composition of seriously affected populations, fertility remains the dominant factor dictating the future size, growth, and composition of most developing nations.

Of the many factors considered important in understanding variation in fertility over time and from one population to the next, contraceptive prevalence is considered key in many developing countries. Over 20 years ago, Bongaarts (1976, 1981, 1982) observed that as a country passes through the demographic transition from high to lower fertility, four “proximate determinants” of fertility account for most of the difference between natural fertility and the observed total fertility rate. These factors include changes in marriage patterns, changes in postpartum infecundability (due to changing breastfeeding patterns), increased reliance on family planning to space or limit births, and changes in rates of induced abortion. Bongaarts argued, and considerable empirical evidence provides support to the proposition, that contraceptive prevalence becomes increasingly important in understanding fertility change as the fertility transition proceeds (Figure 42).

Figure 42.

Conceptual Model of the Changing Contribution of Contraception and Other Proximate Determinants to Fertility Decline

The relative importance of factors determining fertility level varies with phase of fertility transition.

Source: Bongaarts (1982).

From a demographic standpoint, then, contraceptive prevalence levels are integral to understanding recent trends, current levels, and perhaps the future direction of fertility in developing countries.

In 1994, 180 nations met at the International Conference on Population and Development (ICPD) in Cairo and adopted a Programme of Action which included among its major goals improving reproductive health and making family

planning services universally available to couples in all countries (United Nations, 1995a). The first 5-year review of progress made in achieving the objectives of the ICPD indicates that additional effort is required to meet these objectives (United Nations, 1999a).

This section reflects the importance attached to contraceptive prevalence around the world, from both demographic and reproductive health standpoints.

The Fertility Transition Reflects Changing Marriage Patterns and Increased Control of Fertility Within Marriage

The combined effects of rising age at marriage and the growing use of family planning to postpone the onset of childbearing or limit family size within marriage is illustrated with data from four developing countries in Figures 43 through 46.

Since at least the 1970s, young women in Africa, Asia, and Latin America have increasingly delayed first marriage for reasons such as the pursuit of education and, more generally, with changing roles of women and their participation in the labor force. Mean age at first marriage has been relatively low in Africa; relatively high in Asia, the Pacific, and in Latin America and the Caribbean (United Nations, 1987:100). But it has been rising in all developing regions. Postponing marriage may lead to smaller family size because couples have fewer years of childbearing (United Nations, 1987:101) and/or because women who delay the onset of childbearing also choose to have smaller families.

Figure 43.
Trend in Percent of Women Ages 20-24 Never Married, Selected Developing Countries Over the past 25 years age at marriage has risen or stabilized ...

Figure 44.
Contraceptive Prevalence and Total Marital Fertility Rate, Selected Developing Countries
... while couples' use of contraception has lowered fertility within marriage.

Source: U.S. Census Bureau, International Programs Center. Age-specific marital fertility rate calculations are based on fertility from the International Data Base and proportions married from Kenya (1980), Kenya and Macro International (1990, 1994, 1999), Jordan (1979), Anderson (1984), Zou'bi et al. (1992), Jordan and Macro International (1998), Philippines (1979), Concepcion (1991), Philippines and Macro International (1994, 1998), POPLAB Staff (1980), Colombia and IRD/Westinghouse (1988), and Colombia and IRD/Macro International (1991, 1995). Contraceptive prevalence estimates are from Table A-13.

Figure 43 shows the increase in the percentage of women ages 20-24 never married in Kenya and Jordan since the late 1970s, and the stabilization of this percentage in the Philippines and Colombia.

While delayed marriage may account for part of the decline in fertility rates in developing countries during the 1980s and 1990s, decreasing marital fertility is typically related to increases in contraceptive use within marriage. Figure 44 shows the inverse relationship between total marital fertility — the number of births a woman would have over her reproductive lifetime if subject to the age-specific fertility rates of married women ages 15-49 — and contraceptive use of married women for Kenya, Jordan, the Philippines, and Colombia.

As a result of both delayed marriage and use of contraception within marriage, the number of births a woman has during her reproductive lifetime has fallen dramatically over the past few decades throughout the developing world. For example, a woman could expect to have eight births in Kenya in the late 1970s but just over four today (Figure 45).

Countries With Higher Contraceptive Use Are Likely to Have Lower Fertility

While family planning does not explain all country-to-country variation in fertility levels, the relationship between the two variables is strong. For 94 countries of Africa, Asia and the Pacific, and Latin America and the Caribbean with survey data collected on contraceptive use in the 1990s, a 1-percentage point increase in use of any method of contraception is associated with a 0.06 birth decrease in total fertility rate (TFR). A 1-percentage point increase in modern method prevalence³ is also associated with a 0.06 birth decrease in TFR (Figure 46).

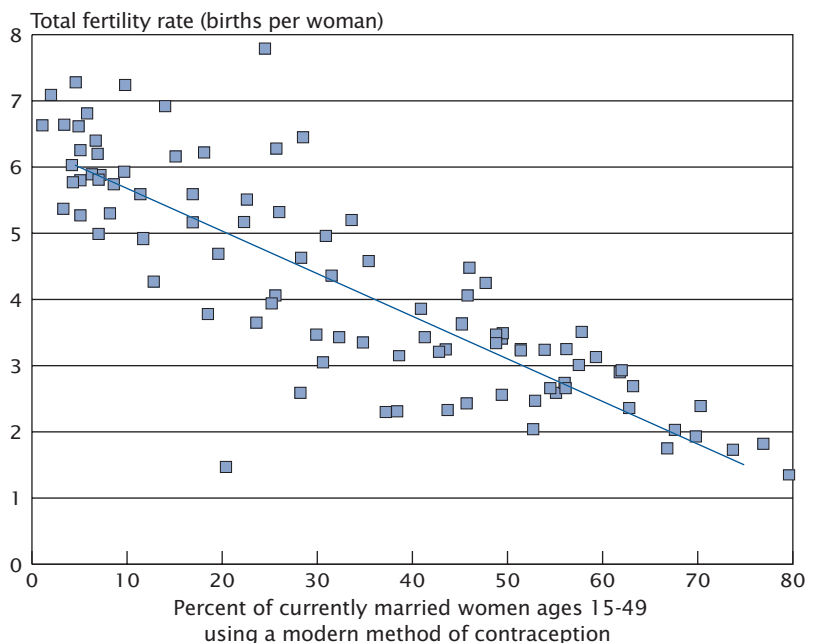

³ Contraceptive prevalence rate refers to the percentage of a population — generally women of reproductive age or married women of reproductive age — using contraception. Modern method prevalence refers to the percentage using a “modern” method of contraception — condoms, pills, IUDs, vaginal methods, injectables, and sterilization. “Traditional” methods and traditional method prevalence refer to such methods of contraception as periodic abstinence, withdrawal, douche, and prolonged breastfeeding as well as folk methods.

Smaller Proportions of Women in Sub-Saharan Africa Rely on Family Planning Than Women in Other Developing Regions

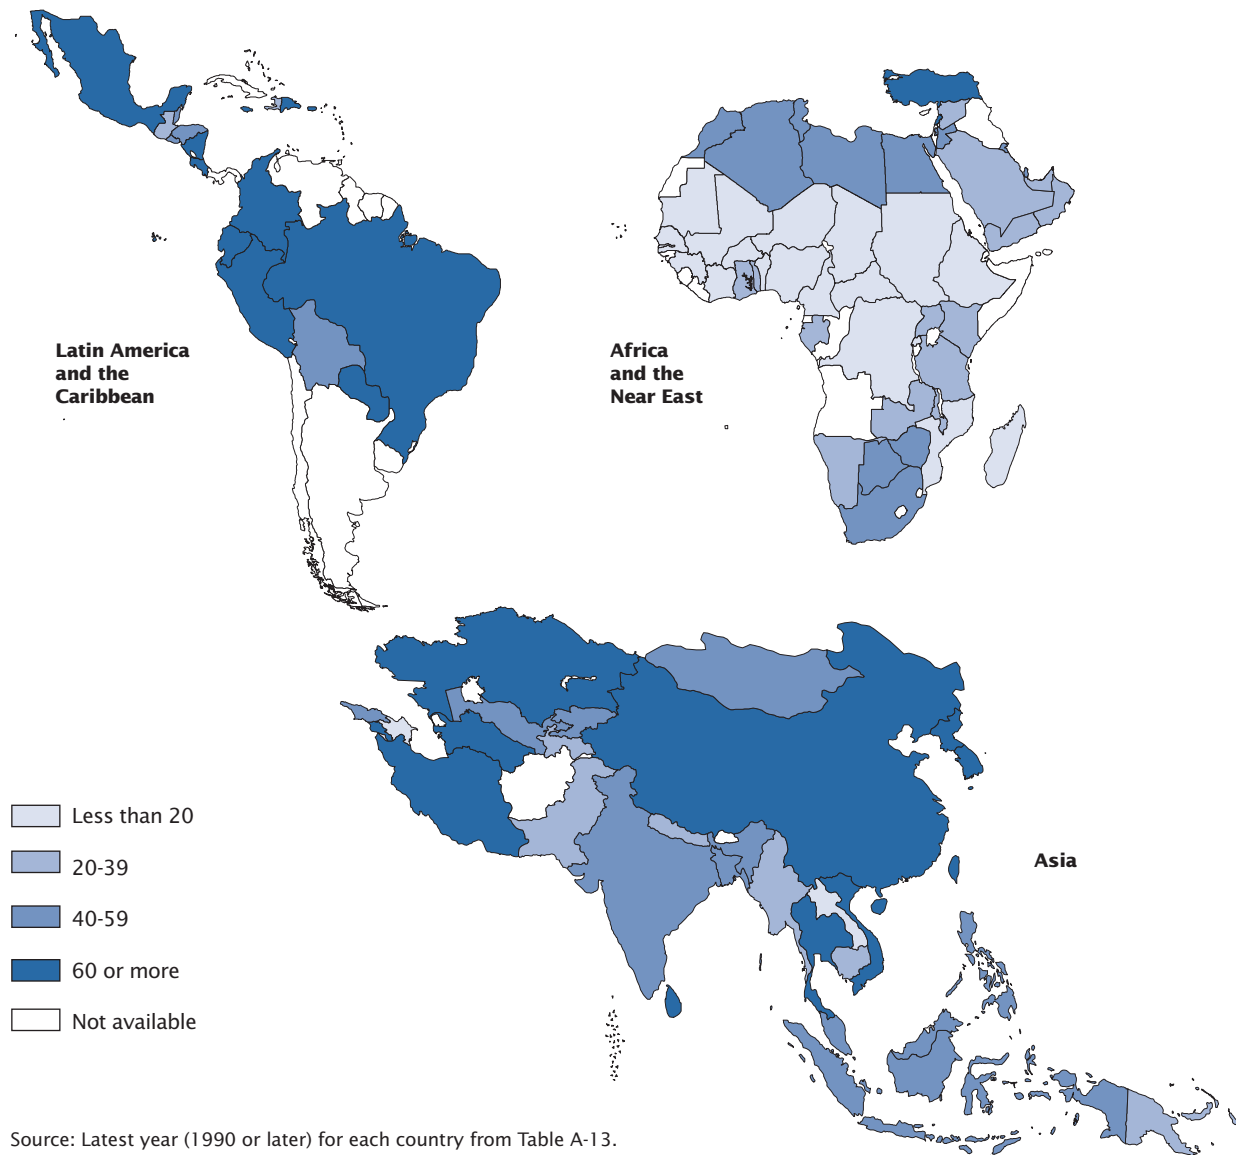

Figure 47 shows contraceptive prevalence (any method) at the national level for Africa, Asia, and Latin America. In general, Sub-Saharan African countries have lower prevalence levels than other

developing regions. About 1 in 9 Sub-Saharan African countries has a prevalence level for married women ages 15-49 as high as the median level for all developing countries (44 percent, based on estimates from 96 countries with surveys conducted in the 1990s, see Appendix Table A-13).

In contrast, 6 in every 10 countries in the Near East and North Africa

have a prevalence rate as high or higher than the median level for all developing countries with data, as do 7 in 10 of the developing countries making up Asia (including the Asian New Independent States of the former Soviet Union) and the Pacific. Nine in 10 of the countries of Latin America and the Caribbean exceed the median prevalence level for developing countries.

Figure 47.
Percent of Currently Married Women of Reproductive Age Using Some Method of Contraception: 1990 or Later
Contraceptive prevalence varies across countries and regions.

Unmarried Women as Well as Married Women Rely on Contraception in Some Countries

The contraceptive prevalence rate (CPR) is meant to provide a meaningful measure of the extent to which women at risk of pregnancy and childbirth are taking steps to avoid pregnancy at a point in time. In some countries, married women of reproductive age are not the only population subgroup at risk. In those countries, the CPR calculated either for all women, or for sexually active unmarried women as well as for married women, provides a more useful measure of the inhibiting effects of contraception on fertility. Expanding the focus to at-risk unmarried women also provides a better understanding of the actual number of women in a country in need of reproductive health services.

Figures 48a and 48b illustrate the utility of recognizing unmarried users of contraception as well as married users in the Philippines. From 1993 to 1998, overall prevalence increased from 40 percent to over 46 percent of currently married women, and the CPR for all women also increased. However, contraceptive prevalence rates for unmarried women changed very little. In both years, a small percentage of unmarried women, generally those ages 30 and over, reported use of contraception.

Figure 48a.
Age-Specific Contraceptive Prevalence Rates for Subgroups of Women, the Philippines: 1993

Source: Kenya and Macro International (1999). Rates for unmarried women calculated at the U.S. Census Bureau, International Programs Center.

A different situation exists in Kenya. The 1993 DHS showed contraceptive prevalence rising among women in each age group from 15-19 through 30-34, to a level of just under 40 percent, then declining at older ages (Figure 48c). Unlike women in the Philippines, however, younger unmarried Kenyan women used contraception in roughly the same proportions as their married counterparts. From a demographic standpoint, failing to recognize the level and trend in contraceptive prevalence among unmarried Kenyan women would tend to misstate the fertility-inhibiting effects of contraception in this population.

The importance of measuring the CPR among unmarried women as well as for married women is apparent in Figure 48d, which shows that about 30 percent of unmarried, sexually active Kenyan women ages 15-19 and nearly 60 percent of unmarried, sexually active Kenyan women ages 25 and above used contraception.

Considering population subgroups separately helps clarify the nature of the need for reproductive health services in some countries, helps quantify total demand, and suggests the extent to which the needs of specific groups of women (such as the 70 percent of sexually-active, unmarried women ages 15-19 in Kenya who are not using contraception) are perhaps not being met.

Available information on contraceptive prevalence for currently married women for all countries is presented in appendix Tables A-13 and A-14. Statistics on contraceptive prevalence for all women of reproductive age may be found in appendix Tables A-15 and A-16.

Higher Method Effectiveness Typically Accompanies Higher Prevalence

The fertility-inhibiting effect of family planning use is augmented in most contexts because increases in prevalence tend to be accompanied, over time, by shifts toward use of more effective methods. Not only do higher proportions of currently married women (and of all women) of reproductive age adopt family planning to control their childbearing, but the methods they choose tend to be those which are more effective. Modern methods of contraception tend to be increasingly preferred by couples to traditional methods. Figures 49-51 illustrate this relationship in two countries, Kenya and Egypt.

Over the past 20 years, Kenyans have increasingly adopted family planning to delay the onset of childbearing after marriage or after the birth of a first or second child, to space births, or to limit family size. During the 1989-93 period, for example, ideal family size³ for married women fell by about one child, from 4.8 to 3.9 children per woman. During the same period, the percentage of women with three living children who said they wanted to stop having children rose from 33 percent to 47 percent.

Contraceptive prevalence (all methods) for currently married Kenyan women rose from 17 percent in 1984 to 27 percent in 1989 to 39 percent in 1998. As Figure 49 shows, these increases occurred throughout the reproductive age range. Figure 50 shows that overall increases were accompanied by two kinds of method shift among contraceptive users. The first was a general shift toward more effective methods over time: The proportion

³ Ideal family size refers to a survey-based measure of mean family size preference in a population. See, for example, Kenya and Macro International (1989:50).

Proportion of Married Women of Reproductive Age Using Contraception Who Rely on Modern Methods by Contraceptive Prevalence Rate (All Methods), Developing Countries: 1990 or Later
In general, countries with higher prevalence have a method mix favoring more effective methods.

Source: Most recent survey data for developing countries from Table A-13.

of women practicing contraception who relied on traditional methods declined from over 40 percent in 1984 to under 20 percent in the 1990s. The second change was in method preference among users of modern methods. From 1984 to 1998, an increasing share of modern-method users relied on injectables (shown in the figure as part of “other modern” methods); a decreasing share, on the IUD.

Egypt illustrates the case of a population where couples, having adopted more effective, modern methods of contraception over time, collectively chose a different method mix but did not return to traditional methods.

Between the first half of the 1980s and the middle of the 1990s, Egypt’s total fertility fell from about five births per woman to less than four. During the same period, contraceptive prevalence rose from 30 percent of currently married women in 1984 to 47 percent in 1992-1995. During the 1984-88 period, women in the age range 20-44 adopted contraception in increasing numbers, with greater use of the IUD accounting for much of this rise. During the 1988-92 period, family planning use expanded from this base, and the IUD became the method of choice for an increasing proportion of users (Figure 51). Traditional methods continued to be used, but by about the same small fraction of all users over the 1984-1995 period.

The combination of (1) increased adoption of modern methods of contraception with increasing prevalence by populations where overall prevalence is relatively low and traditional method utilization is significant, and (2) relatively low traditional method use as a fraction of all-method CPR by populations which have already reached moderate overall CPR levels is reflected in

the cross-sectional relationship shown in Figure 52. This figure shows the proportion of users relying on modern methods as a proportion of all users for 93 developing countries with survey data collected during the 1990s.

Use of more effective methods is associated with higher prevalence. In most countries where 50 percent or more of currently married women practice family planning,

70 percent of couples using contraception rely on modern methods.

As Figure 53 shows, countries in Latin America and Asia are more likely to have relatively high modern-method prevalence than are countries in Sub-Saharan Africa or the Near East. Again, using survey data collected in the 1990s, median modern-method prevalence for countries in Latin America and the Caribbean is 58 percent; for Asia

and the Pacific, 46 percent; for the Near East and North Africa, 33 percent; and for Sub-Saharan Africa, 7 percent. The median proportion of users relying on modern methods is over 80 percent for Latin America and the Caribbean, Asia and the Pacific; over 70 percent for the Near East and North Africa; and just under 65 percent for Sub-Saharan African countries.

Increased Use of Contraception Is Accompanied by a Continued Unmet Need for Family Planning

In its 1999 review of progress made toward achieving the goals of the International Conference on Population and Development, the United Nations noted that substantial progress has been made in extending family planning and reproductive health services to couples in need of these services throughout the developing world (United Nations, 1999a:10). The United Nations also estimated that over half of all couples in developing countries are now using some form of contraception.

At the same time, substantial numbers of women who would prefer to control their fertility — either by limiting the number of children they have or by controlling the onset or spacing of wanted births — are not currently using contraception. These women are considered to have “unmet need for family planning.”

Women who would like to postpone their next pregnancy but are not using contraception, and women whose last pregnancy was mistimed, are considered to have unmet need for family planning for spacing purposes. Women who want no more children and are not using contraception, as well as women whose last pregnancy was unwanted, are defined as having unmet need for family planning to limit fertility.

Figure 54 shows levels of unmet need for both spacing and limiting for 56 countries that conducted Demographic and Health Surveys in the 1990s. Unmet need has been and continues to be a more pervasive problem in Sub-Saharan Africa than in other world regions. In over half the Sub-Saharan African countries shown in Figure 54, at least one fourth of married women ages

15-49 were considered to have unmet need for contraception.

Generally smaller percentages of women at risk have unmet need for family planning in the Central Asian republics of the former Soviet Union, the countries of the Near East and North Africa, and Latin America and the Caribbean. The median percentage of married women with unmet need for either spacing or limiting is 26 percent for the Sub-Saharan African region (based on countries shown in Figure 54), compared to 12 percent to 15 percent for the other listed world regions. The developing countries of Asia exclusive of the Asian NIS but including India have an intermediate median level of unmet need of about 18 percent of married women of reproductive age.

Over 100 Million Developing Country Women Have Unmet Need for Family Planning Services

If, instead of focusing on percentages of women with unmet need, absolute numbers of married women with unmet need are considered, the geographic locus of need changes dramatically. The same change in perspective permits a better picture of the magnitude of the challenge to the

health care community at national, regional, and global levels.

By combining the latest available estimates of percentages of married women of reproductive age (MWRA) for each country with unmet need figures taken from Demographic and Health Surveys, it is possible to estimate numbers of MWRA with unmet need for the current year.⁵

About 112 million married women in these developing regions have unmet need for family planning in 2002. This figure excludes MWRA in China, for which no estimate is available.⁶ It includes nearly 28 million women in Sub-Saharan Africa, over 7 million women in the Near East and North Africa, 65 million women in Asia (excluding China, Japan, and the Asian NIS), over 10 million women in Latin America and the Caribbean, and 1.5 million women in the eight Asian New Independent States.

⁵ MWRA with unmet need is calculated as the product of (1) percent of MWRA with unmet need from the latest DHS and (2) projected number of MWRA from the International Data Base of the U.S. Census Bureau. The median unmet need for countries of a region with a survey estimate is used to calculate total number of women with unmet need for any country lacking its own estimate.

⁶ Ross, Stover, and Willard (1999:75) indicate that unmet need in China is negligible.

Moreover, it should be noted that these figures do not include the unmet need for contraceptive services and products among unmarried women, nor do they take into account the possible need for more effective contraceptives among users of traditional and folk methods.

Unmet Need for Family Planning Influences Global Population Increase Through Fertility Levels

Contraceptive prevalence levels are integral to an understanding of recent trends and current levels of fertility in developing countries. The success or failure of individual nations in addressing unmet need for contraception, in turn, helps determine future fertility levels and also future population growth in the developing world and globally.⁷ At the same time, reductions in unintended pregnancies occurring because of unmet need will contribute to achieving the reproductive health goals adopted by the world community of nations in Cairo in 1994.

⁷ One recent study estimated that meeting unmet need would reduce the total fertility rate by about 18 percent for a group of countries in Africa, Asia, and Latin America (Westoff and Bankole, 1995).

THE AIDS PANDEMIC IN THE 21ST CENTURY

*This section of **Global Population Profile: 2002** provides an update on one of the key international health and demographic events of our time, and a source of some of the uncertainty associated with demographic change in the coming decades — the worldwide HIV/AIDS pandemic.*

This section of the report assesses the impact of AIDS on mortality, population growth, and

population structure in those parts of the world most seriously affected. It reviews the current status of the HIV/AIDS epidemics in Africa, Asia, and Latin America and describes the alternative demographic futures facing affected countries represented by the experience of a number of Sub-Saharan African countries.

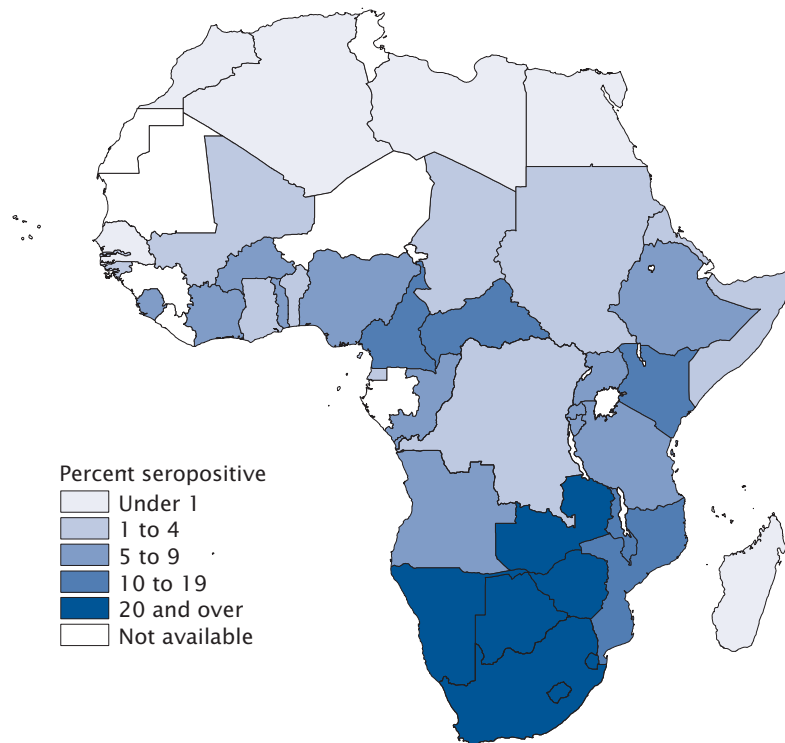

The AIDS pandemic in the 21st century continues to have devastating impacts on populations, particularly in the developing world. Since the beginning of the epidemic two decades ago, more than 20 million people have died of AIDS. Twice that many — 40 million — are now living with HIV. Barring some major breakthrough, most of these people are expected to die during the next 10 years or so. In 2001, the Joint United Nations Programme on AIDS (UNAIDS) estimated that 5 million people were newly infected with HIV.

The AIDS Pandemic in the 21st Century Continues to Have Its Greatest Impact in the Developing World

Over 90 percent of people infected with the Human Immunodeficiency Virus (HIV), which causes AIDS, live in the developing world. The Joint United Nations Programme on HIV/AIDS (UNAIDS) expects that this “proportion will continue to rise in countries where poverty, poor health systems, and limited resources for prevention and care fuel the spread of the virus” (UNAIDS, 1999).

Over 70 percent of the global total of HIV-positive people, 28.5 million out of 40 million, live in Sub-Saharan Africa, even though this region contains only 11 percent of the global population. Nine percent of all adults in Sub-Saharan Africa are HIV positive, compared to 0.6 percent of adults in the United States. Since the beginning of the epidemic, over 15 million Africans have died from AIDS; 2.2 million AIDS deaths occurred there in 2001.

Figure 55.
Adult HIV Prevalence in Africa: December 2001
In 12 countries, more than one-tenth of the adult population 15-49 years of age is infected with HIV.

Source: UNAIDS/WHO (2002).

Southern and eastern Africa have been the most severely affected regions. According to the latest UNAIDS/WHO figures, seven countries have an estimated adult (ages 15-49) HIV prevalence of 20 percent or greater: Botswana, Lesotho, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe

(UNAIDS/WHO, 2002). In these countries, all in southern Africa, at least one adult in five is living with HIV. An additional five countries, Cameroon, Central African Republic, Kenya, Malawi, and Mozambique, have adult HIV prevalence levels higher than 10 percent (Figure 55).

The HIV/AIDS epidemics in southern Africa started later but they have been explosive, such as in Botswana, where HIV prevalence among pregnant women⁸ in Francistown increased from 7 percent in 1991 to 44 percent in 2000.

The two success stories in Sub-Saharan Africa continue to be Uganda and Senegal. HIV prevalence among pregnant women in Uganda continues to decline in most sentinel surveillance sites. In Kampala, HIV prevalence declined from its peak of 30 percent in 1993 to 11 percent in 2000. In Dakar, AIDS control programs have managed to keep HIV prevalence at very low levels (Figure 56).

In comparison, HIV prevalence levels among pregnant women in Asia are relatively low. HIV prevalence exceeds 1 percent in only three countries: Burma, Cambodia, and Thailand. However, even these epidemics differ. In Thailand, another success story, and Cambodia, HIV prevalence is declining in some areas and stabilizing at low levels in other areas. In Burma, HIV prevalence rates fluctuated at low levels into the mid-1990s and show a slight increase since then.

In Latin America and the Caribbean, the HIV/AIDS epidemics vary from those that are concentrated among injecting drug users (Argentina and Uruguay) and men who have sex with men (Peru and Mexico) to epidemics that seem to be driven by heterosexual transmission. The last include those in the Bahamas, Haiti, Honduras, and Guyana, the countries with the highest HIV prevalence levels

⁸ In this report, "pregnant women" refers to those pregnant women attending antenatal clinics.

Figure 56.
HIV Seroprevalence for Pregnant Women in Selected Urban Areas of Africa, Asia, and Latin America: 1985-2001

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

among pregnant women in the region. In Brazil, already strong HIV prevention programs were augmented in recent years by advances in provision of antiretrovirals to all those HIV positive, thereby lessening the effects of AIDS mortality on the population.

In Sub-Saharan Africa, More Women Than Men Are HIV Positive

At the end of 2001, UNAIDS estimated that 58 percent of all HIV infections in Sub-Saharan Africa were among women. Peak HIV prevalence among women occurs at a younger age than among men: around age 25 compared to age 35-40. As Figures 57 and 58 show for Rwanda and Zambia, younger women tend to have higher levels of HIV infection than men of their same age.

Several studies have shown that HIV prevalence among pregnant women attending antenatal clinics provides a reasonable overall estimate of HIV prevalence in the general adult population, although it underestimates the rate among all women while overestimating it among men. This is shown for Zambia in Figure 58.

Mortality Patterns Are Driven by HIV Prevalence Patterns

Median survival time with HIV/AIDS is estimated to be around 10 years. In South Africa, by 2020, death rates for adults at ages 20-45 are likely to be much higher than they would have been without AIDS. Among those under age 60, mortality for women is projected to peak during the ages of 30-34, earlier than the peak projected for men: 40-44 years (Figure 59).

At the Beginning of the 21st Century, the Population Growth Rate in Botswana Is Now Negative Due to AIDS Mortality⁹

Other countries with sharply reduced growth rates include several additional African countries: Lesotho, Malawi, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe (Figure 60).

The negative population growth seen in Trinidad and Tobago in 2002 reflects the impact of out-migration and AIDS mortality. The underlying non-AIDS growth rate for Trinidad and Tobago is nearly -0.6 percent.

In Asia, AIDS mortality has slightly lowered population growth rates in Burma, Cambodia, and Thailand.

In Figures 60 through 71, two series of data are shown for each of the 51 seriously affected countries where AIDS is having an impact on demographic indicators. The first series, "With AIDS," shows what has happened and what is projected to happen in each country because of AIDS mortality and its demographic consequences. In this work, fertility is assumed to be unaffected by HIV/AIDS, though numbers of births decrease as a result of mortality-induced reductions in women of reproductive age. Second, a hypothetical "Without AIDS" series shows what the Census Bureau's modeling work indicates would have happened if a country had not been affected by the HIV/AIDS epidemic. This modeling takes into account not only lower death rates but also associated changes to a country's age-sex structure and, indirectly, the combined effects of lower mortality and changing population composition on demographic indicators.

⁹ Refer to Tables 5 and 6 for country-specific indicators.

Figure 60.
Population Growth Rates With and Without AIDS for Selected Countries: 2002
Botswana is now experiencing negative population growth. In South Africa, growth is now less than half what it might have been in 2002 without AIDS.

Figure 61.
Population Growth Rates With and Without AIDS for Selected Countries: 2010
By 2010, Botswana, Mozambique, Lesotho, Swaziland, and South Africa, are all expected to experience negative population growth due to AIDS.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

By the Year 2010, Five Countries Are Projected to Show Negative Population Growth Because of AIDS Mortality

The growth rate for Botswana is projected to be suppressed and by 2010 it will be -2 percent. In South Africa it is projected to be -1.4 percent and in Swaziland -0.4 percent. This negative population growth is due to the high levels of HIV prevalence in these countries and relatively low fertility. Previously, most HIV/AIDS experts never expected HIV prevalence rates to reach such high levels for any country. By the end of 2001, adult HIV prevalence had reached an estimated 39 percent in Botswana, 20 percent in South Africa, and 33 percent in Swaziland (UNAIDS/WHO, 2002). By 2010, Zimbabwe and Namibia are projected to experience a growth rate of close to zero. Without AIDS, these countries would have had a growth rate of 2 percent or greater (Figure 61).

In Latin America and the Caribbean, the Bahamas and Guyana are projected to see the greatest relative impact, with growth rates reduced from 1 percent to 0.5 percent. Trinidad and Tobago's already negative population growth, due to out-migration, is projected to decline further due to AIDS mortality.

In Asia, growth rates are projected to be slightly lower in Burma, Thailand, and Cambodia due to HIV/AIDS.

Table 5.
Demographic Characteristics With and Without AIDS: 2002

AIDS Mortality Is Likely to Produce Population Pyramids That Have Never Been Seen Before

In countries with projected negative population growth—Botswana, Lesotho, Mozambique, South Africa, and Swaziland—population pyramids will have a new shape, “the population chimney.” The implications of this new population structure are not clear. By 2020, men between the ages of 15 and 44 are likely to outnumber women in each of the 5-year age cohorts. This may influence men to seek sexual relationships with younger and younger women. This factor in turn may increase HIV infection rates among younger women. Current evidence (Glynn et al., 2001) indicates that, indeed, older men are infecting younger women. As these women marry, their partners are then at increased risk of HIV infection. This vicious cycle could result in even higher HIV infection levels (Figure 62).

Figure 62. **Population by Age and Sex With and Without AIDS for South Africa: 2002, 2010, and 2020**
Population structures of badly affected countries are likely to be radically altered by HIV.

**Population by Age and Sex With and Without AIDS
 for Uganda: 2002, 2010, and 2020**
**The population structure of Uganda is probably
 only slightly altered by HIV.**

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

In Countries With Moderate Epidemics, AIDS Mortality Is Likely to Have Less Effect on the Population Structure

For example, in Uganda, the greatest relative differences in future population size by cohort are evident in the youngest age groups and among people 30-50 years of age in 2002 and 2010. However, the population pyramid maintains its traditional shape in 2020 (Figure 63).

AIDS Mortality Is Causing Falling Life Expectancies at Birth

Already, life expectancies in Sub-Saharan Africa have fallen dramatically from levels they likely would have reached without AIDS. In Botswana, life expectancy is now 34 years instead of 72. In Zimbabwe, life expectancy is 40 years instead of 69. In fact, seven countries in Sub-Saharan Africa (Angola, Botswana, Lesotho, Malawi, Mozambique, Rwanda, and Zambia) have life expectancies below 40 years. Each of the countries, except for Angola and Mozambique, would have had an estimated life expectancy of 50 years or more without AIDS (Figure 64).

In Latin America and the Caribbean, the impact on life expectancy is not as great as in Sub-Saharan Africa because of lower HIV prevalence levels. However, life expectancy is still lower than it would have been without AIDS. In the Bahamas, life expectancy is now 66 years instead of 74; in Haiti, it is 51 instead of 59.

Thailand, Cambodia, and Burma have lost 2 to 5 years of life expectancy.

Figure 64.
Life Expectancy at Birth With and Without AIDS for Selected Countries: 2002
In Botswana, nearly 40 years of life expectancy have been lost due to AIDS.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

Figure 65.
Life Expectancy at Birth With and Without AIDS for Selected Countries: 2010
By 2010, Botswana and Swaziland are likely to see life expectancy reduced by over 40 years.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

In Less Than 10 Years, Some Countries Are Projected to See Life Expectancies Fall to Near 30 Years of Age, Levels Not Seen Since the Beginning of the 20th Century

Among countries in Southern Africa that would have approached or exceeded life expectancies of 70 years of age by 2010 in the absence of AIDS, several are likely to see life expectancies fall to around 30:

- Botswana—27 years
- Namibia—34 years
- Swaziland—33 years

Other countries are likely to see life expectancies fall to 30-40 years instead of 50-60 years (Figure 65).

By 2010, AIDS mortality is projected to continue to result in lower life expectancies in Latin America, the Caribbean, and Asia. Life expectancies are projected to be 10-14 years lower in Honduras, the Bahamas, and Guyana than they would have been without AIDS. They are likely to be 2 years lower in Thailand and 4 years lower in Cambodia and Burma.

The Most Direct Impact of AIDS Is the Increase in the Number of Deaths in Affected Populations

Crude death rates, the number of people dying per 1,000 population, have already been affected by AIDS.

In Africa, HIV epidemics have had their greatest impact in the eastern and the southern regions. Adult HIV prevalence is 20 percent or higher in seven countries and 10 percent to 20 percent in an additional five countries. In many of these countries, reports indicate the presence of the HIV virus since the early 1980s.

As a result of these high levels of HIV infection over several years, estimated crude death rates including AIDS mortality are greater by 50 percent to 500 percent in eastern and southern Africa over what they would have been without AIDS. For example, in Kenya, with an adult HIV prevalence of 15 percent at the end of 2001, the crude death rate in 2002 was estimated to be more than two and a half times as high (16 deaths per 1,000 population) as it would have been without AIDS (6 deaths per 1,000 population). In South Africa, with an estimated 20 percent adult HIV prevalence at the end of 2001, the crude death rate in 2002 was also over twice as high as it would have been without AIDS (17 deaths per 1,000 population compared with 7, as shown in Figure 66).

In Asia and Latin America, estimated crude death rates in 2002 were also higher than they would have been without AIDS, especially in Haiti and the Bahamas.

Figure 66. **Crude Death Rates With and Without AIDS for Selected Countries: 2002**
Crude death rates are four times as high in Zimbabwe as they would have been without AIDS.

Figure 67.

Crude Death Rates With and Without AIDS for Selected Countries: 2010

By 2010, crude death rates are projected to be ten times as high in Botswana and seven times as high in Swaziland as they would have been without AIDS.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

In Many Sub-Saharan African Countries, Crude Death Rates Are Projected To Be Higher in 2010 Than in 2002, Even Though Mortality Due to Non-AIDS Causes Is Likely to Decline

In Botswana, the crude death rate is likely to increase from 29 deaths per 1,000 population in 2002 to 43 in 2010 (Tables 1 and 2). In South Africa, the crude death rate is likely to increase from 17 deaths per 1,000 population to 30; in Zimbabwe, from just under 21 to over 27. In the absence of the AIDS pandemic, crude death rates in 2010 for these three countries that are now projected to range from 27 deaths per 1,000 population to 43 would have ranged, instead, from 4 to 7 (Figure 67).

In Latin America and the Caribbean, Honduras and Guyana are likely to see crude death rates in 2010 twice as high as they would have been without AIDS.

In Asia, crude death rates in 2010 are projected to be somewhat higher with AIDS than they would have been without AIDS. In Thailand, the crude death rate with AIDS is likely to be just over 7 deaths per 1,000 population, or about 12 percent higher than the level without AIDS. In Cambodia, the crude death rate is expected to be between 8 and 9 deaths per 1,000 population, a level 26 percent higher than the projected level without AIDS.

In Some Sub-Saharan African Countries, Infant Mortality Rates Are Now Higher Than They Were in 1990¹⁰

AIDS mortality has reversed the declines in infant mortality rates that occurred during the 1980s and early 1990s. Over 30 percent of all children born to HIV-infected mothers in Sub-Saharan Africa are likely to be HIV positive, either through the birth process or due to breastfeeding. The relative impact of AIDS on infant mortality is likely to depend on both the levels of HIV prevalence in the population and the infant mortality rate from other causes. In 1990,¹¹ the infant mortality rate in Zimbabwe was 52 infant deaths per 1,000 live births; in 2002 it is 66. In South Africa, the infant mortality rate in 1990 was 51 infant deaths per 1,000; in 2002 it is 60. Without AIDS, infant mortality in Zimbabwe and South Africa would likely have been 35 infant deaths per 1,000 and 39, respectively (Figure 68).

In western and central Africa, where epidemics are generally less severe, infant mortality rates are still higher than they would have been without AIDS. The increase ranges from less than 1 percent in Mali to about 13 percent in Côte d'Ivoire and Rwanda.

In countries most affected by AIDS in Latin America, the Caribbean, and Asia, infant mortality rates are also higher than they would have been without AIDS. In Latin America and the Caribbean, infant mortality rates are 2 percent to 6 percent higher. In Asia, infant mortality is less than 1 percent higher in Thailand and 4 percent higher in Cambodia.

¹⁰ U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

¹¹ Figures for 1990 also include AIDS mortality.

Figure 68.
Infant Mortality With and Without AIDS for Selected Countries: 2002
AIDS doubles infant mortality in some Sub-Saharan African Countries.

Figure 69.
Infant Mortality With and Without AIDS for Selected Countries: 2010
By 2010, nearly 60 infants out of every 1,000 live births are expected to die in Botswana from AIDS.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

In Five Countries of Sub-Saharan Africa, More Infants Are Likely to Die From AIDS in 2010 Than From All Other Causes

In Botswana, Swaziland, and Zimbabwe, twice as many infants are likely to die from AIDS in 2010 as from all other causes; in South Africa and Namibia, more infants are likely to die from AIDS than from all other causes. In 46 of the 51 countries examined, overall infant mortality rates are projected to decline between 2002 and 2010. However, in 43 of these 46 countries, infant mortality due to AIDS is projected to increase over the same period, offsetting the greater drop that would otherwise have been achieved. Moreover, in the five countries with projected overall increases, the entire change can be attributed to increases in AIDS mortality among infants. Without the effect of AIDS, infant mortality would have been projected to decline in these countries (Figures 68 and 69).

In 37 Sub-Saharan African Countries, Under-5 Mortality Rates in 2002 Were Higher Than They Would Have Been Without AIDS

The impact of HIV/AIDS on under-5 mortality is highest among countries that had substantially reduced under-5 mortality due to other causes and where HIV prevalence is high. Many HIV-infected children survive their first birthdays, only to die before the age of 5. In Botswana, more than 70 percent of under-5 mortality is due to AIDS. In Zimbabwe and Swaziland, over half of all deaths among children under 5 are due to AIDS (Table 1 and Figure 70).

The impact of HIV/AIDS in Latin America and the Caribbean has been generally less severe than in Sub-Saharan Africa. For the 11 seriously-affected countries in this region (shown in Table 1), AIDS contributed between 3 child deaths per 1,000 births and 11 per 1,000 in 2002. AIDS accounted for 7 percent to 27 percent of under-5 deaths occurring in these countries.

For Burma, Cambodia, and Thailand, AIDS accounted for 4 percent to 7 percent of under-5 deaths in 2002.

Figure 70.
The Under-5 Mortality Rate With and Without AIDS for Selected Countries: 2002
AIDS deaths among children under 5 years of age are resulting in higher mortality rates.

Figure 71.
The Under-5 Mortality Rate With and Without AIDS for Selected Countries: 2010
Over 80 percent of deaths among children under 5 years of age in Botswana in 2010 are likely to be due to AIDS.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

In the Absence of Prevention of Mother-to-Child Transmission, Under-5 Mortality Rates in 2010 Are Projected to Be Much Higher With AIDS Than They Would Have Been Without AIDS

In Botswana, where under-5 mortality rates in 2010 may have been below 30 deaths per 1,000 live births without AIDS, over 120 children per 1,000 live births born are likely to die before their fifth birthday in 2010. Of that total, over 80 percent are likely to be due to AIDS. In many of the countries in southern Africa, over 50 percent of under-5 deaths are likely to be due to AIDS. In Malawi and Zambia, where under-5 mortality rates due to other causes are already high, AIDS mortality is likely to increase those rates by 30 percent or more (Figure 71).

In Trinidad and Tobago, 40 percent of under-5 deaths are likely to be due to AIDS. In a number of other countries in Latin America and the Caribbean, one-third of under-5 deaths are likely to be due to AIDS.

In Burma, Cambodia, and Thailand, under-5 mortality rates are likely to be 1 percent to 6 percent higher with AIDS mortality than they would have been without AIDS.

Populations in Most Sub-Saharan African Countries Are Projected to Increase, in Spite of the High Levels of Mortality. The Exceptions Are Botswana, Lesotho, Mozambique, South Africa, and Swaziland

Although AIDS mortality has resulted in lower growth rates, fertility is still high and population growth is still positive in most countries affected by AIDS. Such is the case for Uganda. However, the population in the most severely affected countries, such as Botswana and South Africa, is projected to decline over time, in that the population, by 2050, is likely to be lower than it was in 1990, even if current AIDS control programs result in lowering future HIV incidence and prevalence (Figure 72).

Figure 72.
Change in Population of Selected African Countries With and Without AIDS: 1990-2050
The populations of Botswana and South Africa are projected to decline over the next few decades whereas in Uganda, population growth is projected to continue.

Source: U.S. Census Bureau, International Programs Center, International Data Base and unpublished tables.

At the Beginning of the 21st Century, AIDS Is the Number One Cause of Death in Africa and Is Number Four Globally¹²

Just 20 years ago when AIDS first appeared, few would have predicted the current state of the pandemic, particularly in Sub-Saharan Africa. That over 30 percent of adults would be living with HIV/AIDS in any country was unthinkable. Yet, this is the current situation in four countries. In seven Sub-Saharan African countries, at least one out of five adults is living with HIV/AIDS and in an

additional five Sub-Saharan African countries, one out of ten adults is HIV positive (UNAIDS/WHO, 2002).

Many individuals and governments have difficulty grasping the reality of these high prevalence levels, and the resulting AIDS mortality is difficult to comprehend. The magnitude of the current epidemic in HIV infection and the low likelihood of an effective vaccine or even widespread availability of therapeutic medication strongly suggest that many more millions of individuals are likely to die of AIDS over the next decade than have over the past two decades. Many of the southern African countries are only beginning to see the

impact of these high levels of HIV prevalence.

Thailand, Senegal, and Uganda are notable success stories. In Thailand and Uganda, concerted efforts at all levels of civil society have turned around increasing HIV prevalence rates. In Senegal, programs put into place early in the epidemic have kept HIV prevalence rates low. These successes can be repeated but doing so would take time. Hence, the current burden of disease, death, and orphanhood is likely to be a problem in many countries of Sub-Saharan Africa for the foreseeable future.

¹² See WHO (1999).

APPENDIX A. DETAILED TABLES

New estimates and projections of population and vital rates are made for each issue of this report based on the latest information available. Sometimes the latest information requires making a revision to estimated data for the past as well as new projections for the future.

Therefore, the user is cautioned against creating time series of population or the components of population change from previous issues of this report.

NA Data not available. See Appendix B.

¹The category "currently married women" includes women in consensual unions.²Estimates are based on component projections for the female population and the percent of women who are married or in consensual unions in each 5-year age group from the most recent source in the International Data Base. Countries without cohort-component projections are omitted. These are Cook Islands, Federated States of Micronesia, Wallis Futuna, and Western Sahara. Region and world subtotals are sums of country data and therefore exclude countries for which data are not available. Region and world subtotals in this table, and in later tables where countries have been excluded, will not match corresponding population totals in Tables A-1 through A-5.³Marital status by 5-year age groups not available. For these countries, numbers of currently married women are estimated using marital status data from another country in the region.⁴Numbers of currently married women are estimated using marital status data from former Czechoslovakia.⁵Data for the United States include Armed Forces overseas.Note: Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Z Less than 500.

Note: Countries without cohort-component projections are omitted. These are Cook Islands, Federated States of Micronesia, Wallis and Futuna and Western Sahara. Region and world subtotals are sums of country data and therefore exclude countries for which data are not available. For this reason, region and world subtotals will not match corresponding population totals in Tables A-1 through A-5. Data for the United States include Armed Forces overseas. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Z Less than 500.

Note: Countries without cohort-component projections are omitted. These are Cook Islands, Federated States of Micronesia, Wallis and Futuna, and Western Sahara. Region and world subtotals are sums of country data and therefore exclude countries for which data are not available. For this reason, region and world subtotals will not match corresponding population totals in Table A-1 through A-5. Data for the United States include Armed Forces overseas. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Note: Countries without cohort-component projections are omitted. These are Cook Islands, Federated States of Micronesia, Wallis and Futuna and Western Sahara. Region and world subtotals are sums of country data and therefore exclude countries for which data are not available. For this reason, region and world subtotals will not match corresponding population totals in Tables A-1 through A-5. Data for the United States include Armed Forces overseas. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Z Less than 500.

Note: Countries without cohort-component projections are omitted. These are Cook Islands, Federated States of Micronesia, Wallis and Futuna and Western Sahara. Region and world subtotals are sums of country data and therefore exclude countries for which data are not available. For this reason, region and world subtotals will not match corresponding population totals in Tables A-1 through A-5. Data for the United States include Armed Forces overseas. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

NA Data not available.

Note: World and regional TFRs are weighted averages of country rates using total populations as weights. Countries lacking data for a specific year are excluded from the calculation of a regional rate for that year. For some regions, especially for 1990, regional TFR may not be representative of the region. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Z Less than 0.5 per 1,000.

¹Infant mortality rate is the probability of dying between birth and exact age 1. Rates shown in Table A-11 are infant deaths per 1,000 live births.

²Child mortality (ages 1 to 4) is the probability of dying between exact age 1 and exact age 5 (i.e., between the first and fifth birthdays). Child mortality rates shown in Table A-11 are the numbers of child deaths at ages 1 to 4 per 1,000 children surviving to exact age 1. Under-5 mortality is the probability of dying between birth and exact age 5 (after birth, before the fifth birthday).

Note: Regional rates are weighted means of country rates. Countries lacking data for a specific year are excluded from the calculation of a regional rate for that year. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

NA Data not available.

Note: Regional life expectancies are weighted means of country-specific values using total population as weight. Countries lacking data for a specific year are excluded from the calculation of a regional life expectancy for that year. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

NA Data not available.

Z Less than 0.05 percent.

Note: Data refer to currently married women (and women in consensual and visiting unions) ages 15 to 49 years unless coverage is unknown or is otherwise specified in the remarks. "Other methods" refer to unspecified methods or modern and traditional methods reported together. Countries with no data available are omitted from the table. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Remarks:

1. Data refer to women exposed to the risk of pregnancy (currently married nonpregnant women who consider themselves to be fecund).
2. Data refer to ages 15 to 44.
3. Data refer to ages 15 to 50 years.
4. Data refer to sedentary population.
5. Data refer to ever-married women.
6. Data refer to ages under 50 years.
7. "Other modern" refers to injection and traditional refers only to rhythm.
8. Total prevalence rate refers to all women in union, while data by method are based on fecund women in union.
9. Total prevalence rate refers to currently married women, while data by method are based on exposed women.
10. Data refer to ages 12 to 49 years.
11. "Other modern methods" include douche, which is not reported separately.
12. Data refer to Northern Sudan only.
13. Data refer to ever-married women and unmarried women who have had a child.
14. Traditional includes all methods other than pill and IUD.
15. Data are from a national survey that implies that dramatic demographic changes are occurring in Libya, reflected in, for example, the reported proportion of women ages 25-29 currently married being less than 40 percent.
16. Data refer to nationals only.
17. Excludes breastfeeding.
18. Data refer to ages 14 to 49 years.
19. The traditional methods include all other methods not clearly designated as modern.
20. Data by method were recalculated because some women reported using more than one method.
21. Sum of method-specific rates exceeds total prevalence rate because some women reported using more than one method.
22. Data refer to ages 15 to 45 years.
23. Data refer to the former Yemen Arab Republic (Sana'a).
24. With technical assistance from PAPCHILD.
25. Data refer to ages under 56 years.
26. Data refer to ages 10 to 49 years.
27. Age range is not specified.
28. Contraceptive prevalence figures are based on adjusted service statistics data reported in Banister (1995) rather than from the 1992 Fertility Survey by the State Family Planning Commission.
29. Figure shown for pill refers to pill and injectables.
30. Data exclude Jammu and Kashmir, North-East Frontier Agency, and offshore islands.
31. Data exclude North-East Frontier Agency, offshore islands, and Assam.
32. Data refer to sample of husbands and wives.
33. Data refer to Peninsular Malaysia only.
34. Data exclude the northern and eastern provinces.
35. Data refer to women who have ever been either married or in a consensual union.
36. Data refer to ages 20 to 49 years.
37. Total prevalence rate refers to currently married women, while data by method are based on ever-married women.
38. "Other modern" methods include withdrawal, which is not reported separately.
39. Total prevalence rate refers to women in union, while data by method are based on all respondents, regardless of marital status.
40. Data refer to ages 20 to 44 years.
41. Data refer to women who married in 1974 and 1978.
42. Data refer to ages 20 to 40 years.
43. Data refer to the Flemish population only.
44. Data refer to ages 21 to 40.
45. Data refer to ages under 45 years.

Remarks—Con.

46. Data refer to ages 18 to 44 years.
47. Data refer to women in their first marriage.
48. Data refer to ages 21 to 49 years.
49. Data refer to Federal Republic of Germany.
50. Data refer to ages 18 to 49 years.
51. Data refer to ages 20 to 39.
52. Data refer to all women ages 18 to 44 years.
53. Data refer to ages 16 to 49 years.
54. Data refer to ages 18 to 37 years.
55. Data refer to ages 21 to 37 years.
56. Data refer to ages 18 to 42.
57. Data are for women born in 1945, 1950, ... 1965, and 1968 only. These women were 20, 23, 28, and 43 at the time of the 1988 survey.
58. From unpublished tables, Swiss Federal Statistical Office, Family and Fertility Survey 1994-95.
59. Data refer to ages 16 to 40 years.
60. Data refer to ages 16 to 39 years.
61. Abstinence is not included here as a method of contraception.
62. Data for 1970 and 1977 are available for Czechoslovakia.
63. Data refer to ages under 35 years.
64. Data refer to ages under 40 years.
65. Data refer to ages 15 to 39 years.
66. Data refer to ages 18 to 41 years.
67. Data refer to all sexually active women.
68. Data for 1976 are available for Yugoslavia SFR.
69. May include women over age 50 years.
70. Data refer to women who "had sexual intercourse [during the 4 weeks prior to the survey but were] not pregnant."
71. Data refer to ages 18 to 34.
72. "Other modern" methods refer to female barrier methods.
73. Estimate.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

Census	- Census data.
CDC	- Centers for Disease Control family health, contraceptive prevalence, or other health survey data.
CPS	- Contraceptive Prevalence Survey program data (Westinghouse Health Systems or the Centers for Disease Control).
DHS	- Demographic and Health Survey data.
IPPF	- Contraceptive Prevalence Survey data collected under the auspices of International Planned Parenthood Federation, Western Hemisphere Region, Inc.
Lucas	- Lucas and Ware (1981).
Nguyen	- Nguyen et al. (1996).
PAPCHILD	- League of Arab States, Pan Arab Project for Child Development data.
PC	- Population Council. Data from this source usually refer to program service statistics, sometimes with an estimate for private sector contraceptive use. Such data are often unreliable unless confirmed by an independent source such as a nationwide contraceptive prevalence or fertility survey.
Ross	- Ross, Stover, and Willard (1999).
SPC	- South Pacific Commission.
SS	- Service statistics based on number of family planning acceptors or amount of supplies distributed and assumptions about discontinuation rates. See also PC.
Survey	- A nationwide survey conducted by a national government or independent organization, but not related to CPS, DHS, or WFS.
UNESCAP	- United Nations Economic and Social Commission for Asia and the Pacific.
USAID	- U.S. Agency for International Development, mission reports.
UN83	- United Nations (1984).
UN91	- United Nations (1992).
UN94	- United Nations (1994).
UN96	- United Nations (1996).
UN98	- United Nations (1999c).
UN01	- United Nations (2002).
WFS	- World Fertility Survey data.

NA Data not available.

Z Less than 0.05 percent.

Notes: Data usually refer to currently married women (and women in consensual and visiting unions). Exceptions are noted in the remarks below. Countries with no data available by age are omitted from Table A-14. Direct access to this table and the International Data Base is available through the Internet at www.census.gov/ipc/www.

Remarks:

1. Data refer to women exposed to the risk of pregnancy (currently married women who consider themselves to be fecund).
2. Rates by age refer to nonsingle women.
3. Data refer to Northern Sudan only.
4. Data refer to the former Yemen Arab Republic (Sana'a).
5. With technical assistance from PAPCHILD.
6. Data exclude Jammu and Kashmir, North-East Frontier Agency, and offshore islands.
7. Data exclude North-East Frontier Agency, offshore islands, and Assam.
8. Estimate for 15-19 years based on one case.
9. Data shown refers to Peninsular Malaysia only.
10. Base for rates by age excludes pregnant women.
11. Data refer to all sexually-active women ages 15 to 44 years.
12. Data refer to the Flemish population only.
13. Rate shown for ages 20 to 24 years refers to ages 21 to 24 years.
14. Rate shown for ages 15 to 19 years refers to ages 18 to 19 years.
15. Data are for single-year birth cohorts within 5-year age groups shown. Data for women age 23 at the time of the 1988 survey are reported in lieu of a figure for age group 20 to 24; data for women age 28, in lieu of a figure for age group 25 to 29; data for women age 33, in lieu of a figure for age group 30 to 34; data for women age 38, in lieu of a figure for age group 35 to 39; data for women age 43, in lieu of a figure for age group 40 to 44.
16. From unpublished tables, Swiss Federal Statistical Office, Family and Fertility Survey 1994-95.
17. Data shown for ages 40 to 44 years refers to ages 40 to 41 years.
18. Nonresponse is reported to be in excess of 20 percent for ages 35 to 49 and is, overall, 29.3 percent for the source survey.
19. Rate shown for ages 20 to 24 years refers to ages 18 to 24 years.

Source: U.S. Census Bureau, International Programs Center, International Data Base.

Census	- Census data.
CDC	- Centers for Disease Control family health, contraceptive prevalence, or other health survey data.
CPS	- Contraceptive Prevalence Survey program data (Westinghouse Health Systems or the Centers for Disease Control).
DHS	- Demographic and Health Survey data.
PAPCHILD	- League of Arab States, Pan Arab Project for Child Development data.
Survey	- A nationwide survey conducted by a national government or independent organization, but not related to CPS, DHS, or WFS.
WFS	- World Fertility Survey data.

NA Data not available.

Z Less than 0.05 percent.

Note: Data refer to all women ages 15 to 49 years unless coverage is unknown or is otherwise specified in the remarks. Figures shown for traditional methods may include modern methods not reported separately. Countries with no data available are omitted from the table.

Remarks:

1. Data refer to ages 15 to 47 years.
2. Data refer to ages 15 to 44 years.
3. Data refer to ages 18 to 44 years.
4. Sum of method-specific rates exceeds total prevalence rate because some women reported using more than one method.
5. Data refer to ages 16 to 49 years.
6. "Other modern" includes injection, diaphragm, and female sterilization.
7. Data refer to ages 18 to 49 years.

Source: U.S. Census Bureau, International Programs Center, unpublished tables. Sources are as follows:

- | | | |
|--------|---|--|
| CDC | - | Centers for Disease Control family health, contraceptive prevalence, or other health survey data. |
| CPS | - | Contraceptive Prevalence Survey program data (Westinghouse Health Systems or the Centers for Disease Control). |
| DHS | - | Demographic and Health Survey data. |
| Survey | - | A nationwide survey conducted by a national government or independent organization, but not related to CPS, DHS, or WFS. |

- Survey - A nationwide survey conducted by a national government or independent organization, but not related to CPS, DHS, or WFS.

APPENDIX B.
POPULATION PROJECTIONS AND
AVAILABILITY OF DATA

Making Population Projections

Making a cohort-component population projection is a multi-step process whose complexity lies not in the calculations — computer programs now handle this quickly and painlessly — but, rather, in deriving the projection inputs, or assumptions. Gathering the base data, assessing their quality, adjusting them as necessary using demographic techniques, and assessing their comparability among countries are all necessary to ensure the success of the projection process. Once the base estimates are derived, the researcher also must make reasonable and consistent assumptions about the future course of fertility, mortality, and international migration. Regional and world populations are obtained by first projecting each country's population separately and then combining the results to derive aggregated totals.

This section (adapted from Arriaga and Associates, 1994) briefly summarizes the process of preparing population projections by the cohort component method at the International Programs Center of the U.S. Census Bureau. Further details and complete references for specific methods mentioned can also be found in Arriaga and Associates (1994).

The Cohort Component Method

Cohort-component population projection follows each group of people of the same age and gender throughout its lifetime, exposing it to assumed mortality, fertility, and migration. An initial, or base year, population disaggregated by age and sex is exposed to estimated age-sex-specific chances of dying as determined by projected mortality levels and age patterns. Once deaths are estimated, they are subtracted from each age group,

yielding the next older age group in the next time period. Fertility rates are projected and applied to the female population of childbearing age to estimate the number of births every year. Each cohort of children born is also followed through time and survivors are calculated after exposure to mortality. Finally, the component method takes into account in-migrants who are incorporated into the population and out-migrants who leave the population. Migrants are added to or subtracted from the population at each specific age. The whole procedure is repeated for each year of the projection period, resulting in the projected population by age and sex, as well as birth and death rates, rates of natural increase, rates of population growth, and other summary measures of fertility, mortality, and migration for each year.

Base Data on Population

For many developed countries, base data on population are taken from population registers or current official estimates prepared by the national statistical offices based on a census for an earlier year. For developing countries, the base population for a projection is based on census data. However, census enumerations are not perfect, and reported data on the population age and sex structure may be affected by age misreporting and by underenumeration of people of certain ages. If the projection starts with errors in the base year, such errors will be carried throughout the projection period and will have an impact on the projected number of births as well.

Consequently, before being accepted to serve as a base for the projections, a population must be evaluated to detect errors and adjusted as necessary to correct them. Various methods have been

developed to detect age misreporting, including analysis of digit preference, age ratios, and sex ratios. Techniques have been developed for making any needed corrections. Depending on the country-specific data problems, mild smoothing or strong smoothing techniques may be recommended.¹³ The base population age and sex structures for most developing countries in this report are at least slightly smoothed for the population ages 10 years and over.

Special attention is given to possible underenumeration of the youngest age groups, 0-4 years and 5-9 years, because errors in these ages may have a significant impact on the total projection. Suppose, for example, that children age 0-4 years were undercounted in the base population. In the projection, not only would the surviving cohorts of these children be smaller than they should be, but when the female cohorts reached reproductive ages, their number of births would also be underestimated. The completeness of enumeration of individuals in the youngest age groups is evaluated by checking for consistency between the number counted and the estimated levels of fertility and mortality during the 10-year period prior to the census date, as children of these ages represent the survivors of births during that period.

Base Data on Mortality

When vital registration data are available and complete (which is usually the case only in developed countries), it is easy to construct life tables using microcomputer programs, and thereby to derive both a level and an age pattern of mortality suitable for the projection

¹³ Arriaga and Associates (1994: 39-42).

process. For most developing countries, however, it is necessary to estimate mortality some other way. Data on deaths may be available from vital statistics registers, as well as from surveys or censuses that include questions concerning deaths during a specific period of time, for example, deaths of any household members during the past year. If registered deaths can be evaluated and adjusted for errors, they can be used to obtain valuable information about the level and pattern of mortality.

Several techniques have been developed for estimating underregistration of deaths.¹⁴ Some of them are based on the assumption that the population is “stable.” A stable population is one in which there has been no migration, and neither fertility nor mortality has changed in the past. Other techniques, developed more recently, do not require the assumption of stability. Some methods may be applied to estimate mortality during the first years of life.¹⁵ They are based on data on children ever born and children surviving, by age of mother.

Like mortality in infancy and childhood, mortality in adult ages can be estimated indirectly when reliable data are not available to measure it directly. Two principal techniques have been developed to estimate adult mortality based on information collected in censuses or surveys: the orphanhood technique, based on the number of people whose mother or father has died; and the widowhood technique, based on the number of people whose first spouse has died. Both provide an estimate of

survivorship levels between two adult ages for a period of time prior to the year of data collection. However, these techniques are seldom used for the base mortality patterns of the projections in this report because the reference period to which the estimated mortality pertains is not well defined.

Base Data on Fertility

As in the case of mortality, procedures for estimating fertility depend on the availability of data and on the level and type of detail of the information. For cases where vital registration is complete, fertility can be measured directly using classical procedures. Most developing countries, however, do not have reliable vital statistics, so techniques have been developed to measure fertility indirectly based on census or survey information.

Using the age structure of the population, the crude birth rate is sometimes estimated by the rejuvenation technique, in which the population at the youngest ages is “reverse survived” to determine the number of births from which they are survivors. This technique is attractive because it does not require the collection of data related specifically to fertility. However, the reliability of the estimate depends on the quality of both the census data on age and the survival ratios used for the rejuvenation.

Under certain circumstances, census data by age can be used to obtain not only a crude birth rate but age-specific fertility rates as well. This is done by using the own-children technique based on information on children and women by single years of age. This technique requires data linking individual children to their natural mothers.

Other techniques, such as the Rele technique, use census data by age to calculate the net reproduction rate or total fertility rate based on the relationship of children of specified ages to the number of women in childbearing ages.

Finally, and most importantly for many developing countries, many censuses and surveys include questions related specifically to fertility, for example, the number of children women have had and whether they had a birth in the year preceding the inquiry. Responses to such questions can be used to estimate fertility indirectly. Some techniques to do this include the P/F (Parity/Fertility) ratio method developed by Brass, based on the average number of children ever born to women in 5-year age groups and women’s age pattern of fertility derived from births in the year preceding the census or survey; and the Arriaga technique, which is similar to the P/F ratio method but links data for more than one date. While the Brass P/F ratio method assumes constant fertility in the past, the Arriaga method does not. All of these methods can be used to estimate the age-specific fertility rates required for making component population projections.

Base Data on International Migration

Although migration is sometimes an important component of population change, it is not generally well recorded except in some European countries, such as Sweden and the Netherlands, that maintain complete and detailed population registers. Some countries collect information on arrivals and departures of passengers at the official borders of the national territory, but such data are seldom processed in a way that renders them useful for statistical

¹⁴ For example, the Preston-Coale technique, the growth balance technique developed by Brass, and the Bennett-Horiuchi technique.

¹⁵ For example, the Brass technique and modifications developed by Trussell, Sullivan, and Feeney; the Palloni-Heligman technique, and the Johnson technique.

purposes. Even in countries with otherwise excellent statistical systems, information on international migration is often unreliable. The primary source of information on immigration for purposes of population projections is census data on place of birth of the foreign-born population. To detect emigration as well, in order to calculate the net movement in or out of a country, it is necessary to find data for the countries in which the emigrants have settled (since they are the foreign immigrants of that country). In addition, special migration flows, such as refugee movement, are incorporated by considering reported numbers of refugees from the United Nations High Commissioner on Refugees, country sources, and media reports. Thus, most data on international migration are educated guesses at best, especially since not only total numbers but also age and sex distributions of the migrants are required for the projection process.

Assumptions About the Future

Once levels of mortality, fertility, and migration have been determined for the base year of the projection, each component must be projected into the future. Although the procedure for doing this is mechanical, care must be taken in determining projected levels, trends, and patterns by age. Not only must the assumptions be appropriate for the particular country in question, but consistent assumptions must be made when projections are being carried out for more than one country.

An expected increase in contraceptive prevalence is implicit in the assumptions about future fertility declines for most developing countries. For many developed countries, future fertility levels are projected to experience only minor

change, either slight decreases or slight increases.

In general, mortality is expected to continue to decline in most countries, as economic development occurs and health care improves. A particular exception relates to the impact of acquired immune deficiency syndrome (AIDS) on the mortality of some countries, where mortality levels in the next decade are expected to increase. (For a description of the method used to incorporate the impact of AIDS mortality on selected populations, see Appendix C.) While there is no single "right" way to make assumptions about the future, the following procedures are those recommended and generally used by the Census Bureau for the projections presented in this report.

Projecting Mortality and Fertility

To project mortality and fertility, available data on past trends in life expectancy at birth and total fertility rate are considered. The trend in future levels of these indicators can be approximated using a logistic function.

Life expectancy at birth is projected by fitting a fixed-slope logistic curve to the most recent estimate of life expectancy at birth.¹⁶ If estimates of total fertility rates are available for more than one date in the past, a logistic function can be fitted to these data. The results of the logistic function must be carefully scrutinized, however, to ensure that they yield an acceptable future target for the individual country's circumstances.

¹⁶ The fixed-slope model of change in sex-specific life expectancy at birth in a population assumes that future change follows a fixed logistic curve from its initial level. The relationship is based on empirical research undertaken at the International Programs Center, U.S. Census Bureau, in 1998-1999.

In some instances, no data on past trends in fertility are available to which a logistic curve can be fitted. When trend data are not available for estimating future changes using a logistic function, the past experience of other countries serves as a guideline to determine the pace of future change.

Recent population and socioeconomic trends and policies of each country are taken into account to determine if the projected trends are plausible. For example, for mortality, information concerning programs of public health are considered in judging the results. For fertility, factors such as trends in age at marriage, the proportion of women using contraception, the strength of family planning programs, and any foreseen changes in women's educational attainment or in their labor force participation in the modern economic sector are considered.

The next task is to determine an age pattern of mortality and fertility for each of the projected values, since these patterns tend to vary as overall levels change. For each level of projected life expectancy at birth, a set of central death rates is estimated using an iterative interpolation process. The interpolation is logarithmic and uses a set of central death rates for the base year and a "limit" set of rates with very low mortality. Life tables constructed with the interpolated rates correspond to the life expectancies at birth projected previously. Age-specific fertility rates for each projected level of total fertility rate are interpolated between the set for the base year and an ultimate pattern of fertility derived at the International Programs Center using empirical data for countries with low fertility.

Once mortality and fertility have been tentatively projected for each

country according to its particular circumstances, the estimates are compared with projected values for other countries in the same region and with those for other regions. Differences are evaluated to make sure they exist for valid reasons that can be explained by known peculiarities of the particular countries.

Finally, in recent years the Census Bureau has concluded that distinctive mortality assumptions must be made for selected countries in this report because of the death risk due to AIDS. Using methodology that takes into account the effect of AIDS, country projections have been prepared that assess its impact on future populations in countries where the infection is significant (see Appendix C).

Projecting International Migration

Assumptions about future migration are generally much more speculative than assumptions about fertility and mortality. International migration may occur as a result of changing economic conditions, political unrest, persecutions, famines, and other extreme conditions in the countries of origin. Thus, individuals may be attracted by economic opportunities perceived to be available in more industrialized societies. And refugees may flee in large numbers looking for better or more stable lives elsewhere.

Due to the unpredictability of conditions such as crop failure, emerging violence, and war, migration forecasts are subject to large errors. If migration is known to have a negligible impact on a country's current growth rate, future migration is often assumed to be nil. If a country's migration is known to be significant, the estimated number of migrants during the past is frequently held constant in projecting

to the near future. The age and sex composition of international migrants depends on the situation in each country. If information is not available, model patterns by age and sex are sometimes used.

Regional and World Aggregations

As new data are obtained, world population projections are updated and published biennially in this profile series.¹⁷ The national projections presented in this report were updated for any country for which significant new information was received since the preparation of the previous profile. For most countries, the cutoff for receipt of new information was the end of calendar year 2001.

Due to the differing nature of the base data for each country, there is no standard starting date for each country's projection. The projection period for several countries started as recently as 1996, when the base information was current to that date. In contrast, the projection period for many African countries (and a few countries in other regions as well) started as long ago as the 1970s, or even before, although information for a later date on one or more of the variables may have been taken into account when deriving parameter estimates for the early years of a projection. "New" information for a country whose projection base year is in the 1970s may pertain to the 1980s or 1990s, superseding the 1970s data available for a previous round. Thus, total populations in the revised projections may change for any year in the past.

¹⁷ Projections are made by the cohort component method for all but 4 small countries or territories with a combined population in 1998 of about 400,000 people, or 0.01 percent of the world total. For these small countries, total populations and vital rates are projected, but not age and sex distributions.

When the projected population for any individual country changes, so does the aggregated total for the corresponding region and for the world. New aggregations are made for world regions and world totals, combining the latest projected data for all countries, and superseding previously projected world and regional totals given in previous reports.

The differing starting dates complicate aggregations not only of total population but of vital rates and other measures as well. For this reason, regional and global aggregations of crude birth and death rates, life expectancy at birth, infant mortality rates, and age-sex distributions of the population generally can be presented only for the latest and future years for which all countries have a projected estimate for each variable. In this report, such measures are always shown for 2002.

Recency of Base Data for the Projections

The first two sections of this appendix described methods for evaluating base data and making projections, without reference to the data situations actually encountered in the various countries. This section reviews the availability of data for the current round of projections as presented in this report.

Census Cycles, Ongoing Survey Programs, and Demographic Data Availability

This report presents population estimates and projections for 227 countries or areas of the world. These estimates and projections are based, in turn, on population data published in the wake of the 1990 round of censuses and, less frequently, the 2000 round of censuses. They are also based on published vital statistics and

survey results, which accounts for the greater recency of fertility and mortality data compared with population data.¹⁸

Of the 227 countries and areas covered, 154 have data on population size, 180 have information on fertility, and 165 have information on mortality pertaining to some date since 1990 (Tables B-1, B-2, and B-3). Data availability has continued to improve since the publication of the previous edition in this series (*World Population Profile: 1998* (WP98)). For example, fewer countries now have population data available only prior to 1990. The number of countries lacking more recent data has fallen from 87 (as reported in WP98) to 73 at mid-2002, when the analytical work for WPO2 was completed.

While the current round of projections draws on population data for 1995 or later for only about 1 in 6 countries, they incorporate new fertility data for half of all countries and new mortality data for about 40 percent of all countries. As tables B-2 and B-3 show, the proportion of more developed countries with relatively recent fertility and mortality data is substantially higher than that for less developed countries. This reflects the general availability of complete vital statistics data from registration systems for more developed countries and the lack of such data for many developing countries.

Differences in Recency of Data by Development Status

Perhaps more important than the number of countries with recent information on population size,

¹⁸ Data on fertility and mortality tend to be more recent than data on population size largely because of the wealth of information being generated by the Demographic and Health Surveys program, the Reproductive Health Surveys program, the Centers for Disease Control, and similar multi-country survey programs.

fertility, and mortality is the proportion of the world's population covered by such information.

Again, as tables B-1 through B-3 show, over 80 percent of the global population lives in countries with population data as recent as 1990; over half, in countries with fertility data since 1995; nearly half, in countries with mortality data since 1995. Ninety-nine percent of the populations of more developed countries live in countries for which the current round of estimates and projections incorporates data for 1995 or later. For less developed countries the corresponding figures are 47 percent for fertility data and 36 percent for mortality data. Tables B-1 through B-3 show how the recency of data varies by geographic region as well as by development status.

Recency of Information on Contraceptive Prevalence

In the population projections presented in this report, information on the prevalence of family planning is not used directly as input in the computer model. Nevertheless, knowledge of the extent of contraceptive use and the strength of national family planning programs are important considerations when projecting future levels and age patterns of fertility required for cohort-component projections.

Recent data on the current use of family planning methods are gathered primarily by surveys such as the DHS program of Macro International, Inc. and the various family health and contraceptive prevalence surveys of the U.S. Centers for Disease Control. There are also important regional survey programs in Europe and the Middle East. In addition, some countries conduct other national surveys, either for the specific purpose of gathering information on family planning or for other purposes,

such as the monitoring of maternal and child health. These surveys often include questions about contraceptive use.

Of the 172 countries in developing regions, 84 (49 percent) have gathered information on family planning for some date since 1995 (Table B-4). About 1 in 3 more developed countries has contraceptive data for this period.

It is primarily the larger countries that gather information on contraceptive use, as shown by the larger proportions of populations than of countries covered by available data. While 49 percent of less developed countries have contraceptive data available since 1995, these countries represent 65 percent of the LDC population globally. Similarly, the 31 percent of more developed countries with data since 1995 account for 59 percent of the world's MDC population.

Data for the United States

The estimates and projections presented in this report take into account the population count from Census 2000, vital statistics and immigration data made available after 2000, and include the Armed Forces overseas. However, the projections for the United States presented in this report are interim projections, prepared without undergoing a full and final Census Bureau review. These estimates and projections also feed into those for North America, more developed countries as a group, the Developed World (the grouping used in most of the figures of the report), and the world as a whole.

New U.S. projections will be released in 2004 and will be available through the Internet at www.census.gov/population/www/projections/

APPENDIX C.
POPULATION PROJECTIONS
INCORPORATING AIDS

Background

Although it has been clear for a number of years that mortality estimates and projections for many countries would have to be revised due to AIDS mortality, the lack of accurate empirical data on AIDS deaths, the paucity of data on HIV infection among the general population, and the absence of tools to project the impact of AIDS epidemics into the future have all hampered these efforts. Currently, although the accuracy of data on AIDS deaths has not substantially improved, knowledge of HIV infection has expanded and modeling tools have become available to project current epidemics into the future.

The methodology used to project AIDS mortality into the future for this report follows generally the method adopted for *World Population Profile: 1994*, *World Population Profile: 1996*, and *World Population Profile: 1998* with continuing modifications. The method consists of the following steps:

1. Establishing criteria for selecting countries for which AIDS mortality will be incorporated into the projections.
2. For each selected country, determining the empirical epidemic trend and a point estimate of national HIV prevalence.
3. Modeling the spread of HIV infection and the development of AIDS in the population, generating alternative scenarios ranging from super high to low AIDS epidemics, and producing the seroprevalence rates and AIDS-related, age-specific mortality rates which correspond to each epidemic.
4. Using the empirical levels and trends (from step 2) to establish a factor representing each country's position on a continuum between

super high and low epidemics (from step 3), and the derived factor to generate a unique interpolated epidemic curve.

5. Using weighted country total adult seroprevalence to determine the appropriate location on the interpolated total country epidemic curve from step 4. This curve establishes the likely beginning date of the epidemic in the country in question, the progression of the epidemic up to the date of the last empirical data point, and the projection of HIV seroprevalence into the future.
6. Interpolate AIDS-related mortality rates, by age and sex, associated with the estimated speed and level of HIV from epidemic results for the period 1990 to 2010.

In the sections that follow, each of these steps is described, and the method is illustrated.

Country Selection Criteria

The International Programs Center, U.S. Census Bureau, maintains the *HIV/AIDS Surveillance Data Base*. This data base is a compilation of aggregate data from HIV seroprevalence and incidence studies in developing countries. Currently, it contains over 72,000 data items drawn from over 6,500 publications and presentations. As a part of the biannual updating of the data base, new data are reviewed for inclusion into a summary table which, for each country, lists the most recent and best study of seroprevalence levels for high- and low-risk populations in urban and rural areas.¹⁹

¹⁹ High risk includes samples of prostitutes and their clients, sexually-transmitted disease patients, or other persons with known risk factors. Low risk includes samples of pregnant women, volunteer blood donors, or others with no known risk factors. For a more complete description of the selection criteria, see U.S. Census Bureau (2002).

A review of the data in the summary table suggested that a reasonable cut-off point for selection would be countries which had reached 5 percent HIV prevalence among their low-risk urban populations, or, based on recent trends, appeared to be likely to reach this level in the near future. In addition, countries were selected that had national HIV prevalence above 1 percent, as estimated by UNAIDS for year-end 1999.

A total of 51 countries met these criteria for the incorporation of AIDS mortality in the projections. Thirty-seven of these countries were in Africa. The African countries are as follows (newly added countries in italics):

Angola
Benin
Botswana
Burkina Faso
Burundi
Cameroon
Chad
Central African Republic
Côte d'Ivoire
Congo (Brazzaville)
Congo (Kinshasa)
Djibouti
Eritrea
Ethiopia
Gabon
Ghana
Guinea
Guinea-Bissau
Kenya
Lesotho
Liberia
Malawi
Mali
Mozambique
Namibia
Niger
Nigeria
Rwanda
Senegal
Sierra Leone
South Africa
Swaziland

Tanzania
Togo
Uganda
Zambia
Zimbabwe

Outside of Africa, the following countries met the criteria:

The Bahamas
Barbados
Belize
Burma
Cambodia
Dominican Republic
Guatemala
Guyana
Haiti
Honduras
Panama
Trinidad and Tobago
Suriname
Thailand

Empirical Epidemic Trends

For 50 of the countries meeting the selection criteria, staff members reviewed the HIV seroprevalence information available in the HIV/AIDS Surveillance Data Base to establish urban seroprevalence trends over time (Table C-1, col. 1-4) and to establish the estimated prevalence for the whole country (Table C-1, col. 5). The two data points judged to be most representative for the urban low-risk population were identified and used to calculate the annual change between the dates of the two studies. National prevalence figures were based on year-end 1999 estimates prepared by the World Health Organization and the United Nations Joint Programme on HIV/AIDS. Table C-1, column 6 contains the corresponding estimate for year-end 2001.

Alternative Scenarios

To project the impact in the selected countries, five alternative epidemic scenarios were developed,

corresponding to low, medium, high, higher, and super high AIDS epidemics. The highest scenarios were added this round to incorporate the very explosive HIV epidemics in southern Africa, and those epidemics where there is little difference between the urban and rural HIV prevalence levels. These scenarios were developed using iwgAIDS, which is a complex deterministic model of the spread of HIV infection and the development of AIDS in a population. This model was developed under the sponsorship of the Interagency Working Group (iwg) on AIDS Models and Methods of the U.S. Department of State (Stanley et al., 1991).

All five of these epidemic scenarios incorporate increasing levels of behavior change in the form of increased condom use. This assumption corresponds to actual changes in behavior that are now beginning to occur in some countries. In addition, all five epidemics exhibit plateauing and subsequent declines in prevalence in the later stages of the epidemic, particularly in urban areas.

Interpolation of a Unique Epidemic

The empirical urban trend from each country was used to interpolate among the five epidemic scenarios to derive an epidemic trend line matching the observed HIV seroprevalence increase between the two points. Thus, both the level and the rate of increase of the urban epidemic were matched through this procedure and resulted in an interpolation factor used in subsequent steps (Figure C-1).

Projected Total Seroprevalence

At this point in the estimation procedure, no direct linkage has been made to the total country prevalence or to a particular calendar

year in this country's epidemic. The next step accomplishes these tasks. The total-country adult prevalence estimate (Table C-1, col. 5) was matched with the one implied using the interpolation factor. From this comparison, an "offset" figure was calculated, corresponding to the number of years of difference between the start of the epidemics in the five scenarios, and the empirical epidemic at the reference date (Figure C-2). The resulting projected epidemics for the 1990 to 2010 period for selected countries in Africa are shown in Figure C-3.

AIDS-Related Mortality Rates

Based on the "interpolation factor" and the "offset" described above, AIDS-related age-sex-specific mortality rates (n^m_x values) at 5-year intervals from 1990 to 2010 were interpolated and added to non-AIDS n^m_x values for the same period.²⁰ Population projections were prepared with the combined n^m_x values as input, using the Rural-Urban Projection (RUP) program of the U.S. Census Bureau.

The future course of the AIDS pandemic is uncertain, but the projections require that some assumptions be made. It was assumed that the epidemics would peak in 2010, with no further growth in HIV infection after that year. AIDS mortality was assumed to decline from the level reached in 2010 to nil by 2070, thus implying a return to "normal" mortality levels in the latter year. To implement the projection process, life tables for 2070, assuming no AIDS mortality, were used.

²⁰ Non-AIDS n^m_x values were derived by making standard assumptions concerning the improvement in mortality conditions.

Table C-1.
Empirical Seroprevalence Data for Urban and Rural Areas for Selected Countries

NA Data not available.

¹Country-specific "modeling" was undertaken for Thailand and Uganda.

²Burma military recruit data.

³Estimated percentage shown in column 5 for Djibouti is for 1995.

⁴The decimal part of dates shown refers to the timing of seroprevalence estimates within calendar years. For example, 1995.00 is January 1, 1995; 1994.50 is June 30, 1994 (midyear 1994).

Source: Urban and rural data are from U.S. Census Bureau, International Programs Center, HIV/AIDS Surveillance Data Base, January 2000. Estimated seropositive percentages at the national level are from UNAIDS (2000), UNAIDS/WHO (2000), and Burton and Mertens (1998).

The Special Case of Uganda

Prevalence levels for pregnant women in major urban areas in Uganda appear to have peaked in the early 1990s, with rather dramatic declines subsequently. Infection levels of nearly 30 percent were detected in 1992; by 1996, HIV prevalence rates had declined by nearly 50 percent (Table C-1). Although discussion of the causes of these declines is still underway, it appears clear that a substantial change has occurred. Consequently, the approach described above needed to be modified to conform to the empirical evidence of declining HIV prevalence rates.

To handle this epidemiological pattern in Uganda, the 1990-2010 period was divided into a rising epidemic period (1990-1995), a transition period (1995-2005), and a period of a relatively low and stable epidemic (2005-2010). This classification is represented in Figure C-4. Mortality rates corresponding to the rising epidemic and the stable epidemic were separately derived, and the transition between the two was accomplished

by linear interpolation between the two epidemics.

The Special Case of Thailand

Modeling activities have also been undertaken for Thailand with the support of the Interagency Working Group. The AIDS epidemic in Thailand has substantial injecting drug use components, while those in Africa do not (WHO/GPA, 1993). For Thailand, AIDS-related mortality rates from recent epidemiological and demographic projections (TNESDB, 1994) were added to the non-AIDS nmx values for the 1990 to 2010 period.

Caveats and Limitations

In developing the methodology for these projections, the International Programs Center has attempted to maximize the use of both the empirical data and the modeling tools available. However, much is unknown about the dynamics of AIDS epidemics in countries around the world, and the methodology is necessarily imprecise. The actual path of AIDS epidemics in the countries that were selected will undoubtedly differ from the course projected. As epidemics

grow, future behavior changes and interventions being implemented in countries around the world may alter that course.

What if AIDS epidemics do not peak in 2010 as assumed? Will entire populations become infected with HIV and eventually die from AIDS? The simulations used for this report and available epidemiological and behavioral evidence suggest that this will not happen in any population. Variations in sexual behavior help to ensure that the majority of the population in countries around the world is not at high risk of HIV infection. And when substantial proportions of the population are at lower risk of infection, a plateau in HIV seroprevalence after an initial rise is likely. Indeed, some of the countries with high HIV seroprevalence levels are beginning to show evidence of this plateau effect. However, as evidenced in our projections, population declines are possible in countries with a sustained widespread epidemic, particularly in the presence of low fertility levels.

APPENDIX E. GLOSSARY

Age structure. The distribution of a population according to age, usually by 5-year age groups.

Age-specific fertility rate. The number of births during a year to women in a particular age group, usually per 1,000 women in a 5-year age group at midyear.

Aging. An increase in the proportion of the population in the older ages. May also be measured as an increase in the median age of the population.

AIDS. Acquired immune deficiency syndrome.

Base population. The population, usually by age and sex, for the initial year of a projection.

Birth rate. The average annual number of births during a year per 1,000 population at midyear. Also known as the crude birth rate.

Children ever born. The total number of births a woman has had, regardless of whether the children are living or dead at the time of the inquiry.

Children surviving. The number of children a woman has had that are still living at the time of the inquiry.

Cohort. A group of individuals born in the same calendar year or group of years. Also referred to as a birth cohort.

Cohort component method. See component method.

Component method. A method of estimating or projecting a population in which separate components of population change (fertility, mortality, and migration) are used to derive the total population. When such projections are made also by age and sex, the procedure is known as the cohort component method.

Components of change (of population). Fertility, mortality, and migration.

Contraception. The conscious effort by couples to regulate the number and spacing of births. Also known as family planning.

Contraceptive prevalence rate. The percentage of women, men, or couples that use contraception. Unless otherwise stated, contraceptive prevalence rate in this report refers to currently married women of reproductive age (normally defined as the range 15-49 years) who use contraception.

Crude birth rate. See birth rate.

Crude death rate. See death rate.

Currently married women. Women age 15-49 either formally married or living in union with a man (consensual unions). Same as "married women of reproductive age."

Death rate. The average annual number of deaths during a year per 1,000 population at midyear. Also known as the crude death rate.

Dependency ratios. A population's dependency ratio, also known as the age dependency ratio and the **total dependency ratio**, is the combined child population (people under age 15) and elderly population (people ages 65 and above) per 100 people ages 15-64 (people "of labor force age"). The **youth dependency ratio** is the number of people under age 15 per 100 people ages 15-64. The **elderly, or old age, dependency ratio** is the number of people 65 and over per 100 people 15-64. Dependency ratios are also referred to as support ratios.

Dependent age groups. People under age 15 and people 65 years of age or older.

Development category. The classification of regions into "less developed" and "more developed" according to their general level of economic development. In this report, countries are classified according to the grouping used by the United Nations. See references to these terms in the Glossary for details.

DHS. Demographic and Health Surveys, an ongoing program of household surveys implemented by Macro International, Inc. and collaborating organizations. Most DHS surveys are funded by the U.S. Agency for International Development.

Family planning. See contraception.

Growth rate. The average annual percent change in the population, resulting from a surplus (or deficit) of births over deaths and the balance of migrants entering and leaving a country. The rate may be positive or negative. Also known as population growth rate or average annual rate of growth.

HIV. Human immunodeficiency virus. The virus that causes AIDS.

Indirect estimation. The use of special techniques to estimate demographic measures (such as fertility and mortality) when information is not adequate for measuring them directly.

Infant mortality rate. The number of deaths of infants under 1 year of age from a cohort of 1,000 live births. Denoted ${}_1q_0$ or IMR, it is the probability of dying between birth and exact age 1.

IUD. Intrauterine device, a method of contraception.

iwgAIDS. Interagency Working Group on AIDS.

Less developed countries. The “less developed” countries include all of Africa, all of Asia except Japan, the Transcaucasian and Central Asian republics of the New Independent States, all of Latin America and the Caribbean, and all of Oceania except Australia and New Zealand. This category matches the “less developed country” classification employed by the United Nations. “Less developed” countries are also referred to in the report as “developing” countries.

Life expectancy at birth. The average number of years a group of people born in the same year can be expected to live if mortality at each age remains constant in the future.

Life table. A statistical table that follows a hypothetical cohort of 100,000 people born at the same time as they progress through successive ages, with the cohort reduced from one age to the next according to a set of death rates by age until all people eventually die.

Married women of reproductive age (MWRA). Women age 15-49 either formally married or living in union with a man (consensual unions). Same as “currently married women.”

Median age. The midpoint age that separates the younger half of a population from the older half.

Modern methods of contraception. Condoms, IUD’s, pills, vaginal methods (spermicides, diaphragms, or caps), injectables, and voluntary sterilization of a woman or her partner.

More developed countries. The “more developed” countries and areas include all of North America and Europe (including the Baltics

and the four European republics of the NIS (Russia, Ukraine, Belarus, and Moldova)) plus Japan, Australia, and New Zealand. This category matches the “more developed” classification employed by the United Nations.

Natural increase. The difference between the number of births and the number of deaths.

Net migration rate. The difference between the number of migrants entering and those leaving a country in a year, per 1,000 midyear population. May also be expressed in percent. A positive figure is known as a net immigration rate and a negative figure as a net emigration rate.

New Independent States (NIS). Fifteen nations formed from the former Soviet Union. The Commonwealth of Independent States (CIS) refers to these countries excluding the three Baltic nations of Latvia, Estonia, and Lithuania.

Pandemic. A global epidemic.

Projections. Data on population and vital rates derived for future years based on statistics from population censuses, vital registration systems, or sample surveys pertaining to the recent past, and on assumptions about future trends.

Rate of natural increase. The difference between the crude birth rate and the crude death rate.

Replacement level fertility. The level of fertility at which a cohort of women give birth to just enough children so that their daughters just “replace” them in the population, given current levels of mortality in that population. A population closed to migration and having constant, replacement level fertility would, in the long run, remain constant in size. While many

low-mortality populations would attain replacement level fertility at a total fertility rate of about 2.10 births per woman, higher-mortality populations would reach replacement level fertility at higher total fertility rates.

Sentinel surveillance.

Surveillance conducted through “watchpost” sites that provide access to populations that are of particular interest or represent a larger population.

Seroprevalence. The percentage of a population testing positive for infection in a blood test. In the context of this report, the percentage testing positive for antibodies to HIV.

Total fertility rate. The average number of children that would be born per woman if all women lived to the end of their childbearing years and bore children according to a given set of age-specific fertility rates.

Traditional methods of

contraception. Periodic abstinence, rhythm, withdrawal, douche, prolonged breastfeeding, and folk methods. Also known as natural methods.

UNAIDS. The United Nations Joint Programme on HIV/AIDS.

Under-5 mortality. Number of deaths of children under 5 years of age from a cohort of 1,000 live births. Denoted 5q0, it is the probability of dying between birth and exact age 5.

Underenumeration. In a census, the erroneous counting of fewer people in a population than actually belong to it.

Underregistration. In a vital registration system, the failure to register all vital events that occur in a population.

Unmet need for family planning. Nonuse of contraception among women who would like to regulate their fertility, measured as the proportion of currently married women of reproductive age not using contraception but wishing either to postpone the next wanted birth or to prevent unwanted

childbearing after having achieved their desired number of children.

Vital events. Births and deaths.

Vital rates. Birth rates and death rates.

Vital registration. The recording of vital events for legal, administrative, and statistical purposes.

WHO. World Health Organization.

WHO/GPA. World Health Organization/Global Programme on AIDS.

INTERNATIONAL PROGRAMS CENTER

Population Division, U.S. Census Bureau

The International Programs Center (IPC) conducts demographic and socioeconomic research on all countries of the world. We estimate and project population for all countries, study trends in key demographic indicators, conduct specialized research on topics such as population aging, the prevalence of HIV/AIDS, gender issues, and the socioeconomic status of population in transition economies. IPC also provides technical assistance and training to national statistical offices and other agencies worldwide. Our work is funded by other U.S. and foreign government agencies, international organizations, and businesses.

Research results are issued as working papers, publications, and electronic databases. Single copies of most reports are available at no cost.

RECENT PUBLICATIONS

An Aging World 2001.

International Population Reports Series P-95, No. 01-1. Focuses on the numbers, proportions, and growth rates (past, current, and projected) of the world's elderly, as well as socioeconomic characteristics of older populations in 52 nations comprising 77 percent of the world's population.

International Briefs. A series of short, country and regional reports summarizing demographic and selected socioeconomic information. The most recent issues include "Global Population at a Glance: 2002 and Beyond;" "Gender and Aging: Caregiving;" and "Gender and Aging: Mortality and Health."

Most current and all future IPC publications will be available via Internet, at www.census.gov/ipc/www/publist.html

DATABASES AND MICROCOMPUTER APPLICATIONS

International Data Base (IDB).

Contains tables of demographic and socioeconomic data for all countries of the world. An Internet version is available for online access and the entire database may be downloaded from the Internet.

HIV/AIDS Surveillance Data Base.

Incorporates extant seroprevalence data obtained from scientific literature and from presentations at international conferences. As with the IDB, an Internet version is available for online access and the entire database may be downloaded from the Internet.

Integrated Microcomputer

Processing System (IMPS). Contains software packages that perform the major tasks in survey and census data processing. IMPS may be downloaded from the Internet.

Census and Survey Processing

System (CSPro). CSPro is a Windows-based system for survey and census data processing. It also may be downloaded from the Internet.

Population Analysis with Microcomputers/Population Analysis Spreadsheets (PAS).

Two-volume publication which: (1) explains the concepts behind frequently-used demographic techniques; and (2) includes a microcomputer spreadsheet diskette set and documentation for use with Excel or Lotus 1-2-3. The PAS spreadsheets may also be downloaded from the Internet.

Rural-Urban Projections program

(RUP). The software used by the International Programs Center to make population projections for both countries and subnational regions. RUP is available either

with *Population Analysis with Microcomputers* or may be downloaded from the Internet.

TECHNICAL ASSISTANCE AND TRAINING

The International Programs Center provides technical assistance and applied training in sampling, techniques of data collection and data processing, statistical and demographic analysis, analysis of gender statistics and data on aging, geographic information systems, and data dissemination at the request of other governments and international organizations. In addition to English, the staff is able to work in Spanish, French, Arabic, Italian, Portuguese, Chinese, and Russian.

FURTHER INFORMATION

For more information about the International Programs Center or its products, please write to:

International Programs Center
Population Division
Washington Plaza II
U.S. Census Bureau
Washington, DC 20233-8860

or contact us via FAX (301-457-3034) or Internet e-mail (ipc@census.gov). IPC's Web site is located at www.census.gov/ipc/www/index.html

For additional information about on-site technical assistance and both in-country and Washington-based workshops, please contact Peter Way, Chief, International Programs Center (301-763-1390; FAX: 301-457-3033). Inquiries about IPC technical assistance or training should be sent to ipcta@lists.census.gov.
