

Work Task D6
System Monitoring for Riparian
Obligate Avian Species

Jonathan Bart, Matthew Voisine,
John Swett

Approach

Goals

Objectives

Methods

Broad goal

Fulfill the requirement to “monitor riparian, obligate bird species covered under the LCR MSCP to document long-term trend and habitat use.”

Study area

NV

AZ

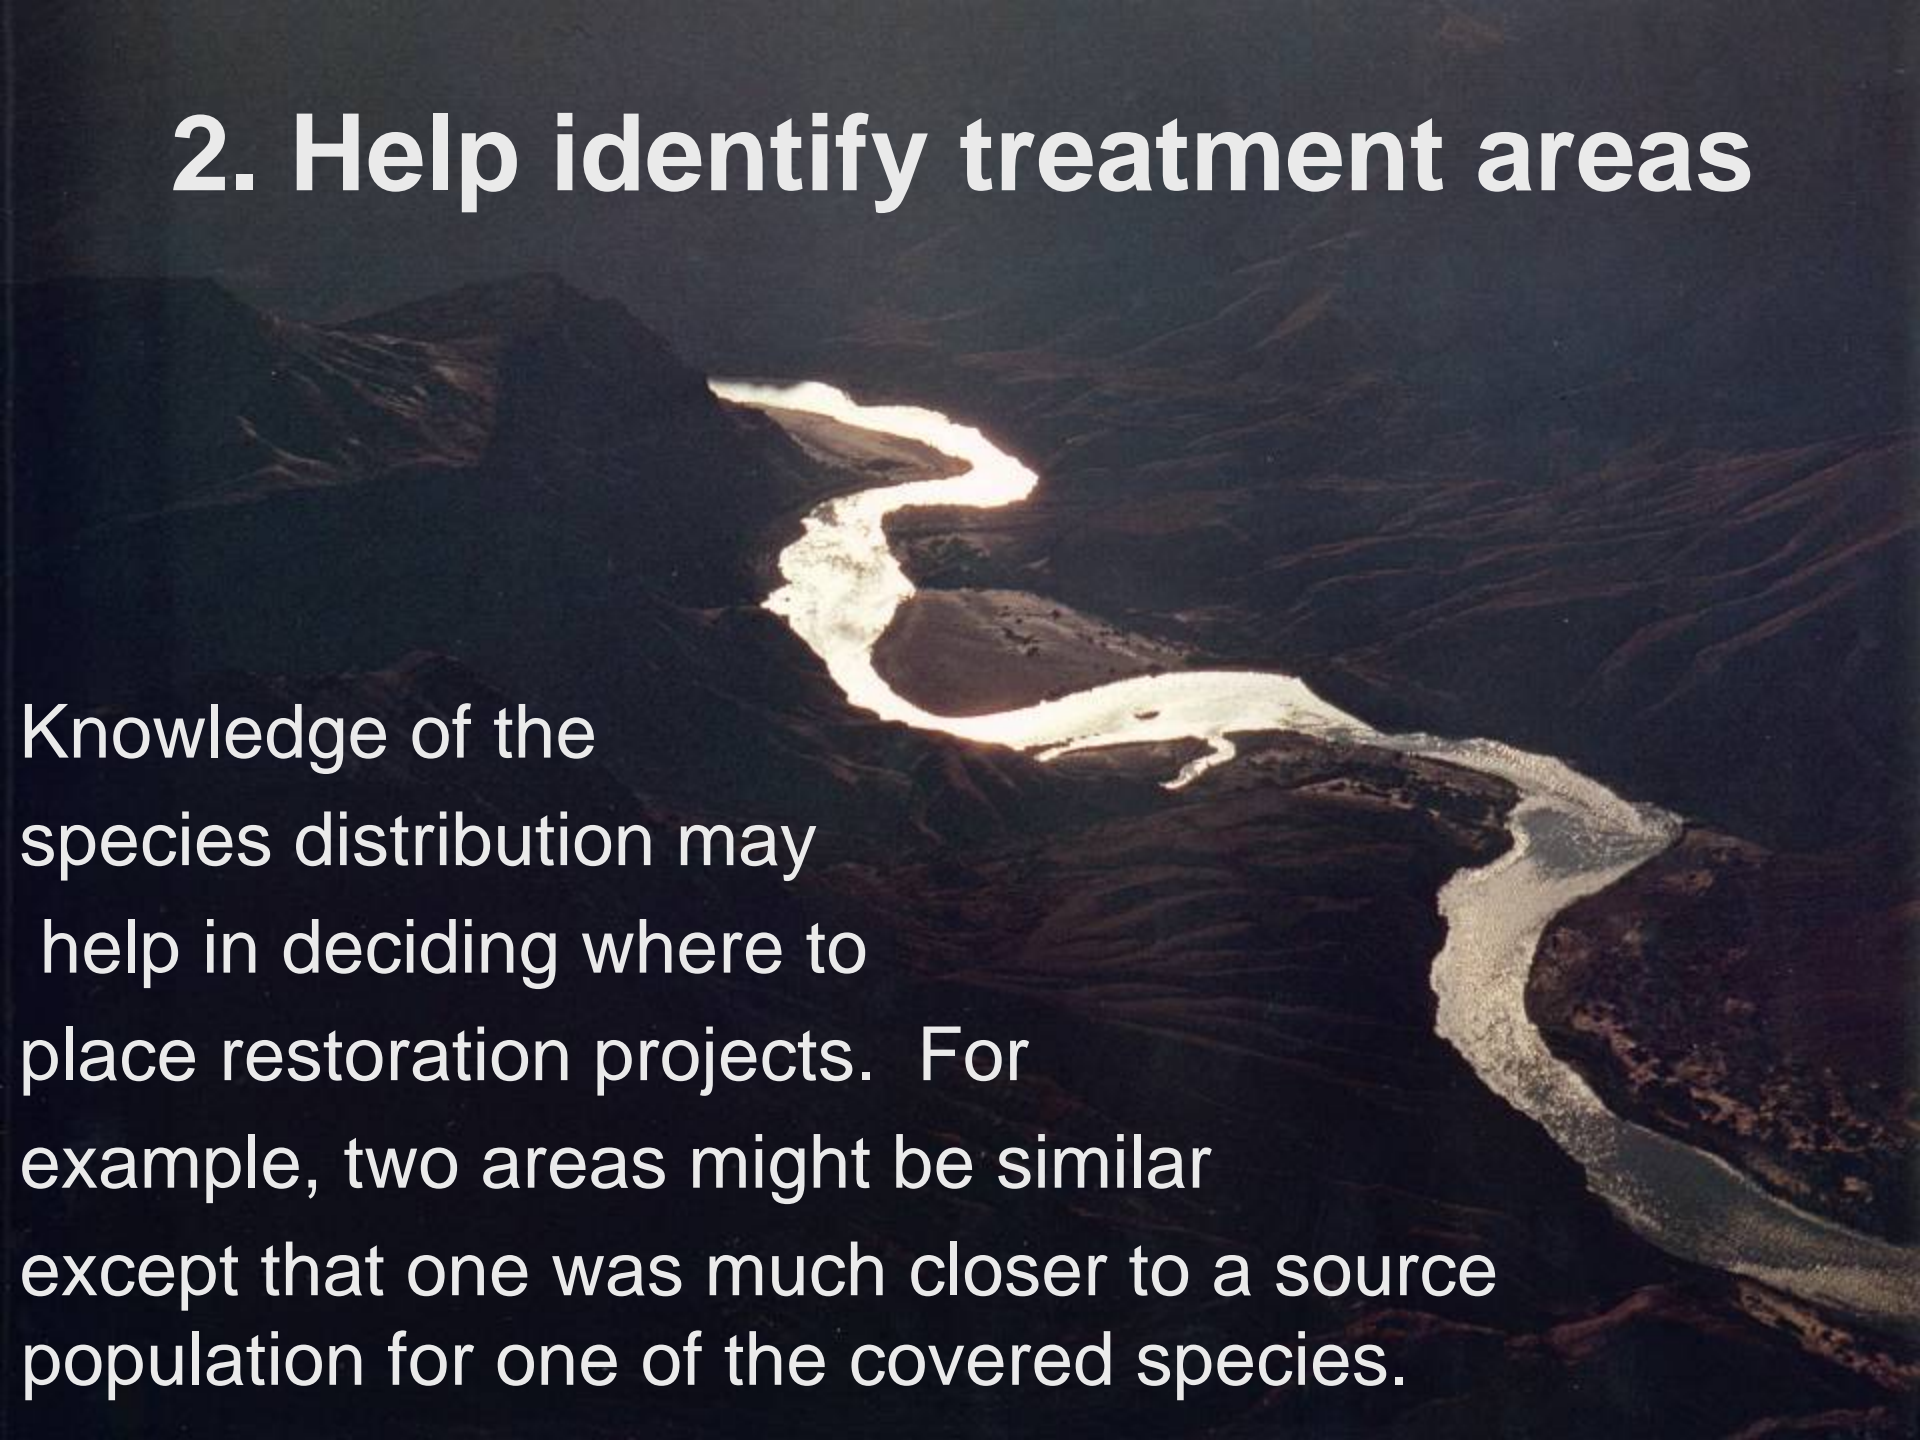

1. Define needed habitat

The conservation measures include the creation of habitat for each of the 6 focal species for this project. Carrying out this measure will require detailed description of the habitat to be created.

2. Help identify treatment areas

An aerial photograph of a winding river in a dark, hilly landscape. The river is illuminated from above, creating a bright, glowing path that meanders through the dark terrain. The hills are dark and textured, with the river's path clearly defined by the light. The overall scene is dramatic and highlights the natural beauty of the landscape.

Knowledge of the species distribution may help in deciding where to place restoration projects. For example, two areas might be similar except that one was much closer to a source population for one of the covered species.

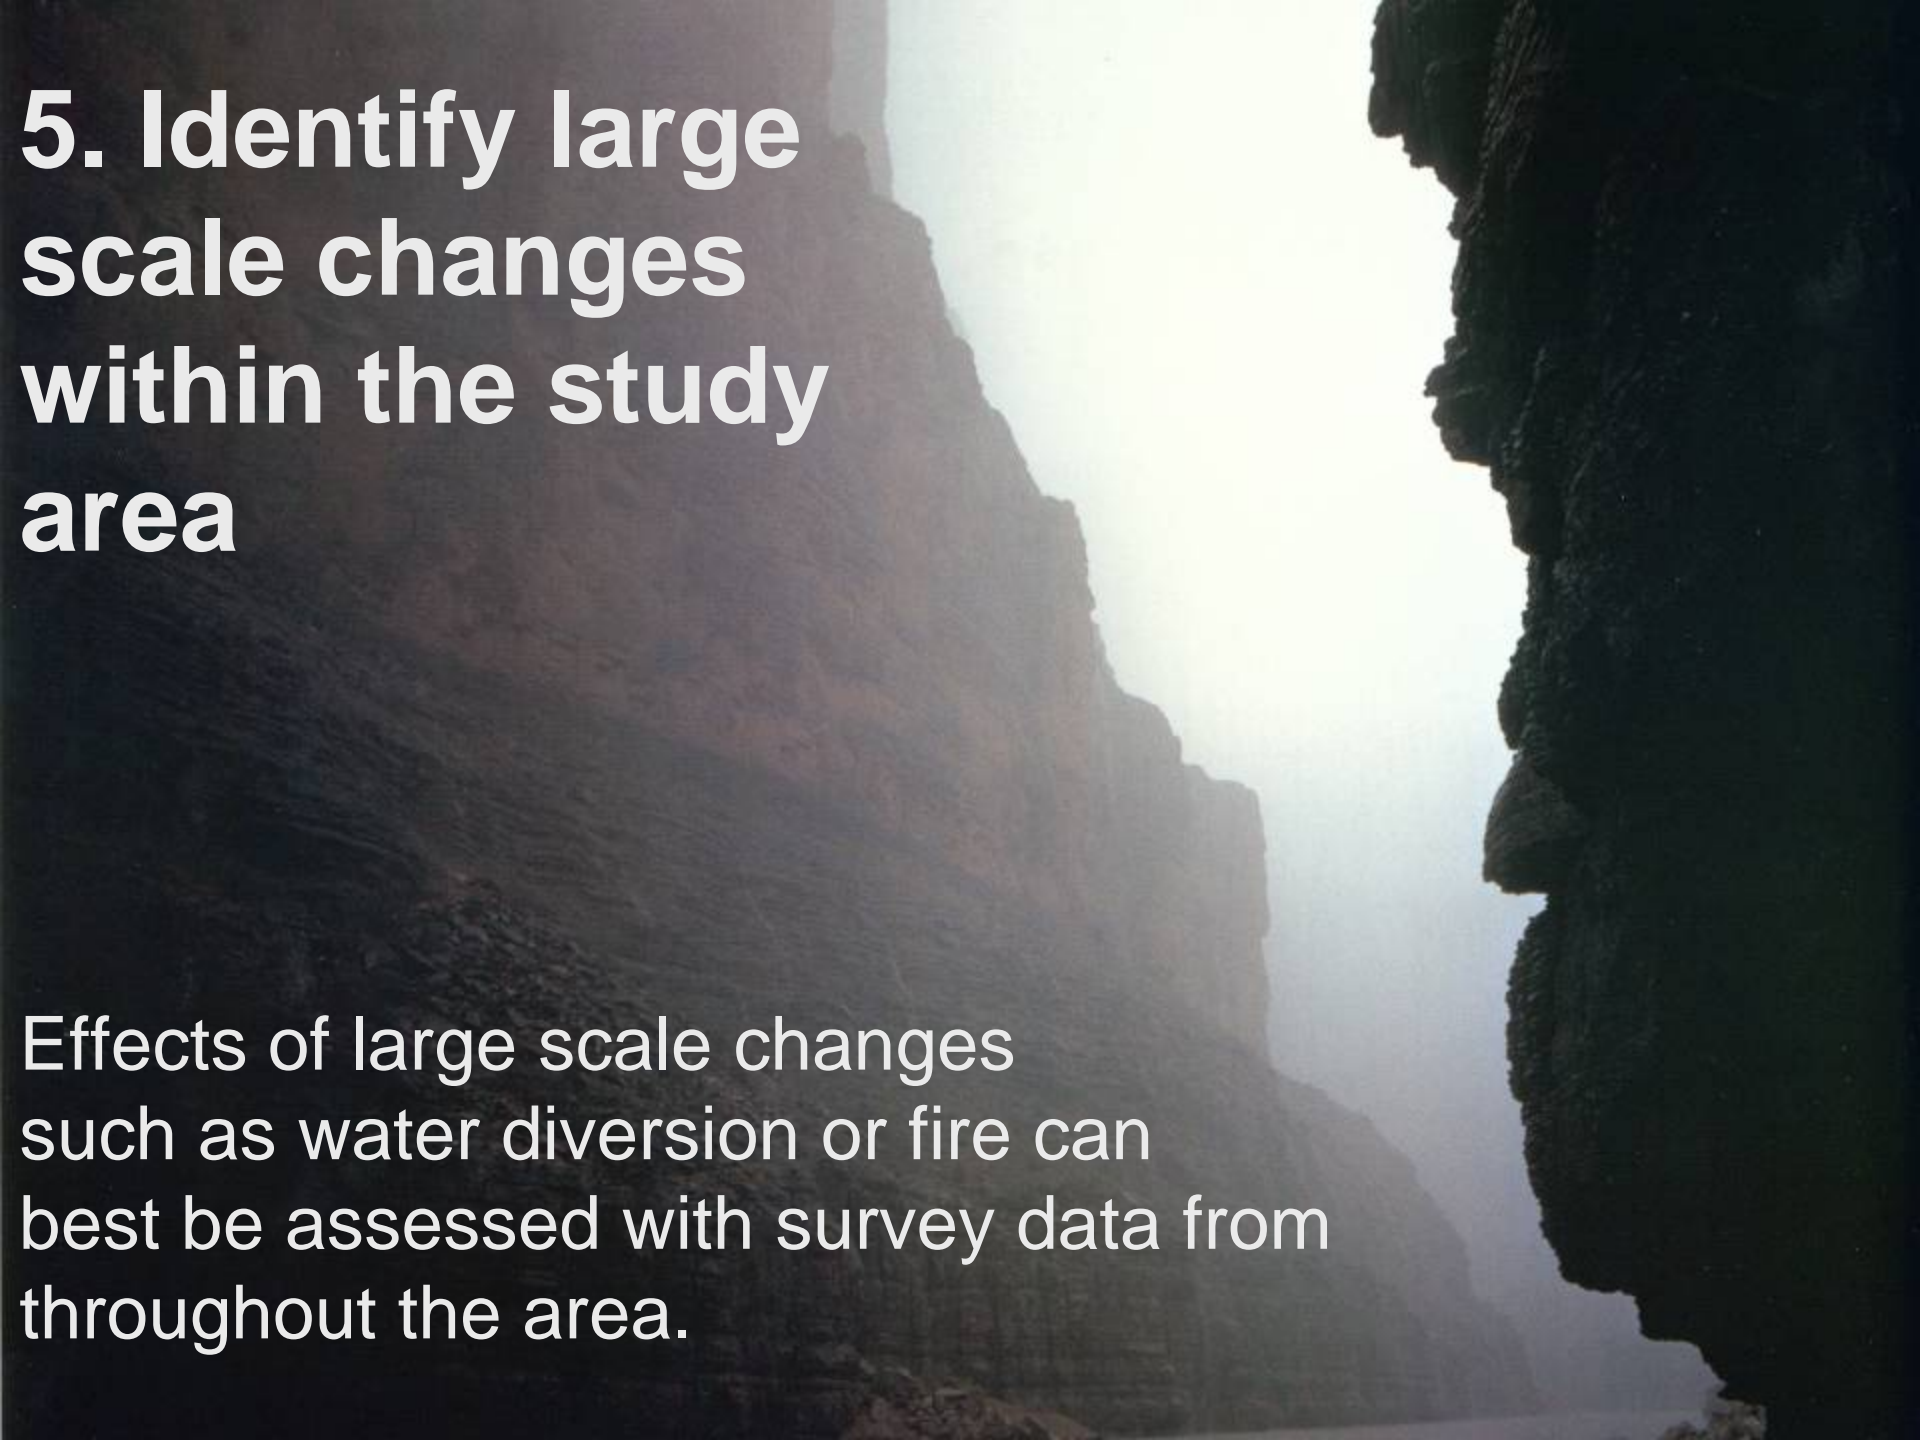

3. Help evaluate treatments

Response to a restoration project might be positive but weaker than expected. Surveys across the study area and surrounding areas, however, might show that populations were generally in decline.

4. Identify off-site treatment impacts

A dramatic landscape photograph featuring a dark, jagged mountain peak on the left side. The sky is a deep, dark purple, and a bright, jagged lightning bolt strikes down from the top center towards the right side of the frame. The overall mood is intense and stormy.

Surveys throughout the study area might show that birds were being drawn into the treated areas from nearby areas and that no increase had occurred in the population throughout the study area.

A dramatic landscape photograph of a canyon. The sky is bright and hazy, while the rock formations are dark and silhouetted against the light. The canyon walls are steep and layered, with some horizontal ledges. The overall mood is somber and majestic.

5. Identify large scale changes within the study area

Effects of large scale changes such as water diversion or fire can best be assessed with survey data from throughout the area.

6. Contribute to status assessments

One reason for choosing the covered species is that concern for them exists. In the future, status assessments may be needed to determine whether they warrant protection under the ESA or similar rules. Data from the study area will be of high value in any such analysis.

Summary

1. Define needed habitat
2. Help identify treatment areas
3. Help evaluate treatments
4. Identify off-site treatment impacts
5. Assess changes at larger scales
6. Contribute to status assessments

Objectives (qualitative)

- Define high-quality habitat (goals 1-3)
 - identify most important habitat parameters (criteria)
 - establish desired ranges for each (standards)
- Assess population size and trends (goals 4-6)
 - within treated areas
 - throughout the study area

Setting quantitative objectives

- **In theory**
 - Accuracy target is fixed and stated at outset
 - **Determine the needed sample size**

- **Usual reality**

**Predicted
accuracy**

**Resources
available**

- **Our approach: Largely resource driven**
 - Thus, predicted accuracy will be discussed after discussing methods

Initial resource levels

- **PI available as needed for design, one week of initial field work, periodic consultation with field team, data management, analysis, and preparation of reports**
- **One four-person team available full-time throughout the breeding season to conduct bird surveys and record habitat measurements**

Overview of Methods - 1

- **Planning**
 - Literature review & consultation with experts
 - Build GIS project (habitat, roads, etc)
 - Week of exploratory field work (PI)
 - Stratify study area and select point locations
- **Field work**
 - Conduct point counts
 - Intensive study of selected pairs
 - Delineate territories

Overview of Methods - 2

Analysis

- **Point counts**
 - **Use in combination with BBS data for temporal variation**
 - **Explore “panel designs”**
 - **Recommend sample sizes and allocation of effort for long-term program**
 - **Combine with GIS habitat layers from landscape level habitat analyses**
- **Intensive habitat data**
 - **Tailor measures to each species**
 - **Use hypothesis-testing approach**
 - **Carry out sensitivity analyses**

Planning

- **Statistical population: territorial pairs of the 6 focal species (excludes migrants)**
- **Review species accounts (BOR), BNAs, other literature and reports**
- **Confer with Ken Rosenberg, Chuck Hunter, Troy Corman, etc.**
- **Build the GIS project for landscape analyses**
- **Week(s) of field work, unstructured but thorough coverage of study area**
- **Stratify study area, determine sampling intensity, select point count locations**

Field work

- **Detailed daily work schedule developed**
- **600 point counts**
 - Only for the 6 focal species
 - Estimate distance, especially $<> 50$ m
 - Record “song/no song” in each 30 sec interval
- **Select 60 territories (10/species)**
 - Visit each 3 times for 1 hr/visit to map boundaries and record substrate, behavior, and songs
 - Record habitat data at 5+ locations (next slide)
 - Select nearby non-utilized areas and collect similar habitat data

Habitat measurements

- Will be designed after review of literature on focal species and consultation with experts
- Potential different variables for different species
- Define hypotheses about habitat to be tested
- Clearly non-utilized areas in the territories will be excluded

Analysis – point counts

- Population size \hat{Y}

$$\hat{Y} = 2A \frac{\bar{y}}{P_s} = 2A \frac{\sum W_h \bar{y}_h}{0.00785 P_s} \hat{y}$$

A = size (km²) of the study area

\bar{y} = mean N of singing birds (males) per point count

P_s = Probability that a male sings during a point count

W_h = Proportion of study area in stratum h

0.00785 = area covered by a 50-m point count

Variance is derivable using standard survey sampling methods

Analysis – Point counts

- **Population trend**
 - Point counts for density in the study area; Breeding Bird Survey data for variance in temporal trends
 - Panel designs (i.e., “partial replacement” strategies)
 - Will probably recommend fixed radius plots and methods to estimate detection rates
 - Power to detect trend vs. sample size curves will be derived

Analysis – data from focal birds

- Estimate $P(\text{song})$ during time budget (P_s)
- Identify critical habitat parameters and ranges
 - Variables used by the species for nesting, foraging, or as perches (from t-b data)
 - Variables for which value appears to matter (from used/non-used comparison)
 - Variables as “different” from one another as possible
- Will probably use multivariate methods for habitat analyses, but which ones still uncertain

Schedule

<u>Planning</u>	<u>Training</u> <u>Recon</u>	<u>Time budgets</u>		<u>Analysis</u> <u>reports</u> - - - -
	<u>Point cts</u>	<u>Habitat</u>		
April	May	June		July

Phenology
