# FERTILITY TABLES FOR BIRTH COHORTS BY COLOR

Robert L. Heuser, *Division of Vital Statistics*

## INTRODUCTION

The tables in this volume present fertility data for actual groups or cohorts of women as they pass through their childbearing years of 14 through 49. The tables contain data for calendar years 1917-73. The data will be updated annually in *Vital Statistics of the United States*, Volume I, Natality, beginning with the 1974 data year. These data have been prepared as a revision and extension of the cohort fertility rates developed by Pascal K. Whelpton and Arthur A. Campbell.<sup>1</sup> The set of rates in this volume utilizes revised population estimates prepared by the U.S. Bureau of the Census for this purpose, and has been extended to include data for the two major color groups, white and all other,<sup>2</sup> as well as for all women.

This work has been done in collaboration with Arthur A. Campbell,<sup>3</sup> who provided invaluable assistance in developing the methods and gave advice at all stages of the project. A detailed description of the methods used in estimating the basic data, the births and populations, is included in appendixes I and II.

The cohort approach<sup>4</sup> refers to the study of the fertility of the same women at successive ages, the cumulative effect of this fertility at successive ages, and the completed family size of these women. A cohort consists initially of female babies born during a 12-month period centered on January 1; subsequently it consists of the survivors of these babies. A cohort is identified by the year of the date on which the births are centered. For example, women born from July 1, 1923, to June 30, 1924, centering on January 1, 1924, constitute the cohort of 1924. Since these women retain this designation throughout their childbearing years, there is a fixed relationship between the cohort identification year, the age of the member of the cohort, and the calendar year to which the fertility measure refers, and by knowing any two of these factors the third can be derived. This relationship is: cohort identification year plus age equals calendar year of the fertility measure.

Four cohort measures are shown in this volume. The central birth rates are similar to the age-specific birth rates computed annually for many geographic areas. Cumulative birth rates, the sum of central birth rates for specified cohorts, show the number of children ever born up to the indicated age. The cumulative rate at age 50, assumed to be the end of childbearing, is considered to be the completed fertility rate. The parity distribution shows a proportional distribution of all women in the cohort by parity (the number of children they have borne alive). Birth probabilities show the probability that a woman of a given age and parity will have a child in the next year. The computations of these rates are described in appendix III.

In addition to these cohort measures total fertility rates for each calendar year are shown. The total fertility rate shows the implications for completed family size of a given set of central birth rates. It states the number of births a hypothetical cohort of 1,000 women would have if they experienced the central birth rates of a given calendar year throughout their reproductive ages. It is the sum of the central birth rates for each single year of age in a given calendar year, and is age-adjusted in that it is based on the assumption that there are the same number of women (1,000) at each year of age.

The central birth rates have been computed using numbers of births adjusted for underregistration for all years and numbers of women adjusted for underenumeration for all censuses and for misstatement of age in all censuses except that of 1970. An additional adjustment was made so that the number of women more adequately represented the population of cohorts in calendar years as described in appendix I. These rates differ somewhat from the age-specific birth rates shown in volumes of *Vital Statistics of the United States*, for which the numbers of births have been adjusted for underregistration only through 1959 and the annual population estimates were used without the adjustments for cohorts or for underenumeration.

The data presented in this volume are intended to represent a general model of fertility trends over time and the numbers should not be taken as precise values. Small differences and fluctuations may not represent real changes because of the estimation required to obtain the births and female populations for all years and the cumulative birth rates for 1917. Comparisons of these rates with the earlier cohort rates for all women prepared by Whelpton and Campbell have been made and they appear to be reasonable. A comparison between the methods used by Whelpton and Campbell and those used for this volume is presented in appendix IV.

<sup>1</sup>National Office of Vital Statistics: Fertility tables for birth cohorts of American women, by P.K. Whelpton and A.A. Campbell. *Vital Statistics—Special Reports*, Vol. 51, No. 1. Public Health Service, Washington, D.C., Jan. 29, 1960.

<sup>2</sup>As used in this report, the term "all other" refers to the combined grouping of all races other than white.

<sup>3</sup>Deputy Director, Center for Population Research, National Institute for Child Health and Human Development, National Institutes of Health.

<sup>4</sup>For further discussion of the cohort approach to fertility analysis, see *Cohort Fertility*, by P.K. Whelpton, Princeton, Princeton University Press, 1954, and Chapter 13, "Cohort Fertility," in *Trends and Variations in Fertility in the United States*, by C.V. Kiser, W.H. Grabill, and A.A. Campbell, Cambridge, Harvard University Press, 1968.

## LIST OF DETAILED TABLES

In each case, table A is for all women, and color is shown in separate tables designated B and C for white women and all other women, respectively.

TABLE 10A. BIRTH PROBABILITIES FOR ALL WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958--CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "0 PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

PARITY AND COHORT	DIAGONAL LINE FOR JANUARY 1	EXACT AGE												
		15	16	17	18	19	20	21	22	23	24	25	26	
2 PARITY

TABLE 10A. BIRTH PROBABILITIES FOR ALL WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958—CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "0 PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

TABLE 10A. BIRTH PROBABILITIES FOR ALL WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958--CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "0 PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

PARITY AND COHORT	DIAGONAL LINE FOR JANUARY 1	EXACT AGE												
		27	28	29	30	31	32	33	34	35	36	37	38	
7 AND HIGHER PARITY--CON.

TABLE 10A. BIRTH PROBABILITIES FOR ALL WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958--CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "C PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

PARITY AND COHORT	DIAGONAL LINE FOR JANUARY 1	EXACT AGE											
		39	40	41	42	43	44	45	46	47	48	49

TABLE 10B. BIRTH PROBABILITIES FOR WHITE WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958--CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "0 PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

TABLE 10B. BIRTH PROBABILITIES FOR WHITE WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958--CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "0 PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

TABLE 10C. BIRTH PROBABILITIES FOR ALL OTHER WOMEN FOR EACH YEAR 1917-73 BY AGE AND PARITY FOR EACH COHORT FROM 1868 TO 1958—CON.

(PROBABILITIES ARE THE NUMBER OF BIRTHS PER 1,000 WOMEN IN SPECIFIED PARITY AND EXACT AGE GROUP. FIGURES FOR "0 PARITY" SHOW THE PROBABILITY OF FIRST BIRTHS TO "C PARITY" WOMEN, THOSE FOR "1 PARITY" SHOW THE PROBABILITY OF SECOND BIRTHS TO "1 PARITY" WOMEN, ETC. BASED ON CENTRAL BIRTH RATES AND PARITY DISTRIBUTIONS)

PARITY AND COHORT	DIAGONAL LINE FOR JANUARY 1	EXACT AGE

## APPENDIX I

### METHOD OF ESTIMATING NUMBERS OF WOMEN

Estimates of the female population for single years of age 14 through 49 by color (white and all other) for 1917-73 were prepared for this report by the U.S. Bureau of the Census. The estimates have been corrected for net census undercount and are consistent within cohorts from year to year. The methods of estimation are summarized in the first three sections. The last section describes the adjustment to obtain appropriate denominators for central birth rates of cohorts.

#### 1950

The corrected estimates begin with a 1950 female population corrected for net census undercount and misstatement of age. The white population benchmark was developed from estimates for native U.S. white females prepared by Coale and Zelnik and presented in *New Estimates of Fertility and Population in the United States*.<sup>5</sup> These estimates were converted to figures for total white females by assuming that the percent of net census undercount was the same for foreign-born females as for native females by 5-year age groups. Single year of age data for foreign-born females were estimated by osculatory interpolation. Comparable data for the population of all other races were not available from this source. The 1950 benchmark for this segment of the population was developed from estimates prepared by Coale and presented in "The Population of the United States in 1950 Classified by Age, Sex and Color—A Revision of Census Figures;"<sup>6</sup> single year of age data were estimated by osculatory interpolation.

#### 1951-73

In carrying the female population forward from 1950, white and all other women were treated in a similar manner. Components of change (births, deaths, and immigration) consistent with *Current Population Reports*, Series P-25, No. 310, were used to carry the population forward to 1960. The 1960 census count of females was corrected for undercount using data presented by Siegel and Zelnik in "An Evaluation of Coverage in the 1960 Census of Population by Techniques of Demographic Analysis and by Composite Methods"<sup>7</sup> and carried forward to July 1. Since

the two sets of estimates for 1960 were very close, the corrected census estimates were used with no adjustment of earlier years for error of closure. The 1960 estimates were carried forward to 1973 using unpublished data on components of change. Estimates for 1970 are consistent with data from the 1970 census.

#### 1917-49

In carrying the 1950 population backward through time, the two color groups were treated differently due to the basic character of the available data. However, the estimates appear to be mutually consistent, since a review of the ratios of the native white population to the population of all other races by age showed them to be reasonable.

For the white population, benchmarks similar to that for 1950 were available for 1940, 1930, 1920, and 1910. Estimates for each year from 1950 back to 1940 were obtained by reviving the population using data on components of change consistent with those in *Current Population Reports*, Series P-25, No. 98. The estimates for 1940 to 1950 were adjusted pro rata by cohort for the error of closure. Unpublished data were used to revive the population from 1940 to 1930 and then from 1930 to 1920 and on to 1917. The data developed in this way for intervening years were adjusted for the error of closure as described for 1940 to 1950.

For the population of all races other than white there were no benchmarks similar to that for 1950 available for 1940, 1930, and 1920. Therefore the revived estimates of the population were not adjusted for errors of closure for the census years. The 1950 corrected population was revived to 1940 using components of change consistent with P-25, No. 98. Before 1940, estimates of the components of change were not available for the population of all other races and survival rates developed from appropriate life tables were used. No adjustment was made for immigration for 1917 to 1940. For the last 15 years of this period there was virtually no immigration of all other females. The relatively small number of immigrants in the years from 1917 to 1924 was not taken into account in the absence of appropriate age data.

#### Adjustment for Denominators of Central Birth Rates of Cohorts

These estimates of the numbers of women in single-year cohorts were further adjusted to represent more adequately the denominators of central birth rates of cohorts in calendar years.

Essentially, what is wanted for the denominator of a central birth rate for age  $x$  in calendar year  $y$  is the average number of women who are between exact ages  $x$  and

<sup>5</sup>Coale, A.J. and Zelnik, M.: *New Estimates of Fertility and Population in the United States*. Princeton. Princeton University Press, 1963.

<sup>6</sup>Coale, A.J.: The population of the United States in 1950 classified by age, sex and color - A revision of census figures. *J. Am. Stat. A.* 50 (269), Mar. 1955.

<sup>7</sup>Siegel, J.S. and Zelnik, M.: An Evaluation of Coverage in the 1960 Census of Population by Techniques of Demographic Analysis and by Composite Methods, prepared for the American Statistical Association, Aug. 1966.

$x+1$  (that is, current age  $x$  or age  $x$  last birthday) during year  $y$ . Ideally, to obtain such a denominator an estimate is made for the population age  $x$  on every day of the year and is averaged for the result. Figure I shows how to approximate this ideal. It shows the date of birth of three cohorts (1919, 1920, and 1921) plotted against the date at which age 20 or 21 is attained during the year 1940. The horizontal distance between the lines for the 20th and 21st birthdays and the beginning or end of 1940 (shaded portion of the figure is the length of time in 1940 that women born on a particular date (vertical axis) are in current age 20. Assuming that the survivors of the 1920 cohort were distributed evenly with respect to the date that age 20 was attained, they spent an average of 75 percent of 1940 in this year of age. In addition, half of the women in the cohorts of 1919 and 1921 were 20 years old during one or more days in 1940 (again assuming an even distribution of birthdays). They spent an average of 25 percent of 1940 at current age 20. Since only half of the women in the cohorts of 1919 and 1921 were 20 years old in 1940, the weight applied to them is half of 25 percent, or 12.5 percent. Therefore, the denominator for a central birth rate at age  $x$  in year  $y$  is  $.125 P_{y-x-1} + .75 P_{y-x} + .125 P_{y-x+1}$ , where  $P$  represents the female population of the designated cohort on July 1, of year  $y$ .

Figure 1. Date in 1940 on which age 20 or 21 is attained by women in the cohorts of 1919, 1920, and 1921.

## APPENDIX II

### METHOD OF ESTIMATING NUMBERS OF BIRTHS

In order to compute the central birth rates it was necessary to have the number of births in each year from 1917 through 1973, corrected for underregistration, classified by age of mother (single years of age from 14 through 49), live-birth order (each order through the seventh, and eighth and higher orders combined), and color (white and all other). The numbers of registered births tabulated by age, birth order, and color were adjusted to

- Distribute births of unknown age of mother and live-birth order.
- Distribute births of each order by single years of age of mother for years when births were tabulated only for 5-year age groups.
- Estimate "registered" births before 1933 for States not in the birth-registration area.
- Adjust for underregistration of births.

These adjustments were made separately for white and all other births, which were added to obtain total births.

The methods of making these adjustments are described below.

#### Distributing Births With Unknown Characteristics

*Age.*—Births to women of unknown age were distributed within each birth-order group like births to women of known age.

*Birth order.*—Among States for which tabulations of births by age and order were available, births of unknown order were distributed within each age group (single years of age where available or 5-year age groups) like births of known order. From 1939 through 1962, births to residents of Massachusetts, the only State not classifying births by order, were assumed to have the same distribution by order within each age group as births to residents of Connecticut. For 1930-38, births in Massachusetts and other States not classifying births by order were added to other births of unknown order in the United States and distributed, within each age, like births of known order.

#### Distributing Births by Single Year of Age of Mother When Births Were Tabulated Only for 5-Year Age Groups

Births of each order were distributed among single years of age within 5-year age groups like births in as nearly adjacent a year for which single year of age data were available. The years distributed and the year providing the single year of age pattern are:

<i>Years distributed</i>	<i>Pattern year</i>
1942-43-----	1944
1939-41-----	1938
1917-23-----	1924

Estimated births in States not in the birth-registration area in 1924-32 were distributed among single years of age like births in registration-area States.

#### Estimating "Registered" Births in 1917-32 for States Not in the Birth-Registration Area

Data by age and by birth order for States in the birth-registration area (BRA) were used to estimate numbers of births for States not in the birth-registration area (non-BRA). Estimates of white births were made for all non-BRA States. However, estimates of all other births were not made for eight States with small numbers of all other women (less than 2,500 women 15-44 years of age in the 1920 census). The procedures used are summarized as follows:

- a. Calculate rates by age and by order for each BRA State for each year 1917-33.
- b. Using rates for 1933, select a guide State for the non-BRA State in 1932. The guide State is the BRA State where rates are most like those of the non-BRA State.
- c. Estimate rates by age and by order for 1932 for the non-BRA State, assuming the same relationship between the guide and the estimated State as was observed in 1933. There are now rates for all States in 1932.
- d. Estimate "registered" births for non-BRA States.
- e. Distribute the age and order marginals obtained in step d to get numbers of births by single year of age by birth order.
- f. Repeat steps b-e using rates for 1932 to estimate data for 1931, 1931 to estimate 1930, and so on until numbers of registered births by single year of age of mother, live-birth order, and color have been estimated for each year back to 1917.

These procedures are described in detail below.

a. *Rates by age and by order for BRA States 1917-33.*—For each State registered births with unknown age of mother were distributed within 5-year age groups like births to women of known age. Births of unknown order were similarly distributed. Births to Mexicans were classified as white for all years except 1930-34. Since the number of births identified as Mexican was large enough in some States to significantly affect the proportions of births tabulated as other than white, an adjustment was made. An expected proportion of births of "other races" (races other than white and Negro), excluding Mexicans, for each year from 1930 through 1934 was obtained by straight-line interpolation between proportions for 1928-29 and 1935-36. This was done for each of 11 States with large Mexican populations. The difference between the actual and the expected number of births of "other races" was assumed to be

Mexican births. It was further assumed that the distribution of these births by age and by order was the same as for all births other than white. The estimated numbers of Mexican births were subtracted from all other births and added to white births.

Numbers of females by 5-year age groups for each State were estimated by linear interpolation between censuses of 1910, 1920, 1930, and 1940. Estimates for 1915, 1925, and 1935 were obtained by interpolating cohortwise between censuses. For example, age 25-29 in 1925 is the average of age 20-24 in 1920 and 30-34 in 1930. Estimates for 1917-19, 1921-24, 1926-29, and 1931-33 were the results of linear interpolation within 5-year age groups between data for 1915, 1920, 1925, 1930, and 1935.

Birth rates by age are the number of births to women in a given 5-year age group per 1,000 women of those ages. Rates were computed for the age groups 15-19 through 45-49 years. The rate for ages 15-19 is the number of births to women under 20 per 1,000 women 15-19 years of age. Rates by order are the number of births in each order per 1,000 women 15-44 years of age.

b. *Selecting guide States.*—The birth rates by age and by order for a non-BRA State were compared with the rates for each BRA State using the measure

$$S = \sum_{\text{all } i} \left[ \frac{\left( \text{Rate}_{\text{BRA State}} - \text{Rate}_{\text{non-BRA State}} \right)^2}{\text{Rate}_{\text{non-BRA State}}} \right]_i$$

where  $i$  is each age and order group. The BRA State for which  $S$  was the smallest was chosen as the guide State to estimate rates for the non-BRA State in the previous year. The guide States are shown in tables I and II.

c. *Estimate rates for non-BRA States.*—Assume the ratios of rates for the non-BRA State to the rates for its guide were the same in the year being estimated as they were for the next year, when rates for all States (actual or estimated) were available. This is done for each age and order group. The rate for each group,  $r$ , is computed as follows:

$$\text{Rate}_{\text{non-BRA State}, i, Y_e} = \left( \frac{\text{Rate}_{\text{non-BRA State}}}{\text{Rate}_{\text{guide State}}} \right)_{i, Y_{e+1}} \times \text{Rate}_{\text{guide State}, i, Y_e}$$

where  $Y_e$  is the year being estimated. The implied assumption in this procedure is that the rates for the non-BRA State changed by the same percent as for the guide State between  $Y_e$  and  $Y_{e+1}$ .

d. *Estimate "registered" births for non-BRA States.*—"Registered" births by age and by order are estimated by multiplying the rates obtained in step c by the populations obtained in step a. "Registered" births by age and by order for the United States are the sum of the estimates for non-BRA States and the registered births for the BRA States.

e. *Distribute age and order marginals into age-order cells.*—A first estimate of the age-order distribution of the estimated number of "registered" births in the United States was obtained by using a percent distribution of births in the BRA. This estimate was adjusted first to the control totals for each birth order and then to the control totals for each age group. (The control totals were the numbers estimated in step d.) After each pair of "rakings," first to birth order and then to age controls, the difference between the birth-order controls and the sum of the estimates over all age groups was computed for each birth order. The raking procedure was continued until the absolute difference between the control and the estimate was less than 100 for each birth order.

The numbers that have been obtained for the 15-19 year age group are really for all ages under 20 (see step a). To estimate the under 15 age group (assumed to be age 14) the ratio  $\frac{\text{Under 15}}{\text{Under 20}}$  was calculated for the BRA and applied to the estimated births under 20 years of age in the United States. This was done for each birth order.

All 5-year age groups 15-19 through 45-49 were distributed by single years of age as described in the previous section.

Adjusting for Underregistration of Births

There have been three nationwide tests of birth registration completeness (BRT), in 1940, 1950, and 1964-68. These three tests are the basis for estimating the completeness of registration in other years.

The 1950 BRT provided the most detailed results. Data are available for each State by place of delivery (in or out of hospital) and for the United States by age of mother<sup>8</sup> and birth order. The 1940 BRT provided the same information for States, but for the United States no figures were available by birth order. Estimates were made by assuming that for each 5-year age group the relationship by birth order was the same in 1940 as in 1950. Results from these two tests, made in connection with the censuses, may be found in *Vital Statistics of the United States, 1950*, Volume I, Chapter 6.

The 1964-68 BRT was conducted on a sample basis primarily to obtain current national estimates of registration completeness by race. This test is described and the results are shown in "Test of Birth Registration Completeness 1964 to 1968," *Census of Population and Housing, 1970*, Evaluation and Research Program, PHC(E)-2. The test produced estimates for births occurring in and out of hospitals for the United States but not for States. Data by age of mother and birth order are not available.

The methods of estimating registration completeness and numbers of births adjusted for underregistration for nontest years are described below.

1951-73.—Control totals for these years were obtained using national estimates of registration completeness for births in and out of hospital from the 1950 and 1964-68 BRT's. Percents of registration completeness for 1951-65 were obtained by linear interpolation between the test re-

sults. The 1964-68 test results were assumed to apply for 1966, the midpoint of the test period, and for later years.

Since age of mother and birth-order data were not available for the 1964-68 BRT, it was assumed that the relationships by these characteristics were the same for all years as in 1950. The first estimates of the number of births adjusted for underregistration obtained using the 1950 percents by age and order were adjusted to the control totals.

1941-49.—For each State the number of births adjusted for underregistration in each of the years between 1940 and 1950 was estimated by assuming a linear trend between the 1940 and 1950 percents of births registered for births in and out of hospital. The national control was the sum of the State estimates. (These are the same totals used by Whelpton and Campbell and are shown in *Vital Statistics of the United States, 1949*, Part I, and elsewhere.)

The numbers of registered births in each year were adjusted using the 1950 percents by age and order. These first estimates were then adjusted to the control totals. This, in effect, assumed a linear change in the registration completeness by age and order.

1917-39.—The total number of births adjusted for underregistration used as control totals for these years are the estimates prepared by P.K. Whelpton and shown in table 1 of "Births and Birth Rates in the Entire United States, 1909-48," *Vital Statistics—Special Reports*, Vol. 33, No. 8.<sup>9</sup> For each of these years it was assumed that the relationships in registration completeness by age and order were the same as in 1940. After the estimates of underregistration for 1940 were applied to the number of "registered" births in 1917-39, the results were adjusted to meet the control totals.

<sup>8</sup>Registration completeness figures from the BRT for 5-year age of mother groups were used for each single year of age within the age group.

<sup>9</sup>National Office of Vital Statistics: Births and birth rates in the entire United States, 1909-48, by P.K. Whelpton. *Vital Statistics—Special Reports*, Vol. 33, No. 8. Public Health Service, Washington, D.C., Sept. 29, 1950.

## APPENDIX III

### METHOD OF COMPUTING COHORT FERTILITY MEASURES

#### Central Birth Rates

Central birth rates represent the number of births occurring to women at age  $x$  (described in appendix II) divided by the number of women of age  $x$  (described in appendix I). Such rates were computed for all color groups (total, white, and all other) by single year of age 14 through 49 by live-birth order,<sup>10</sup> first through seventh and eighth and higher combined, for each calendar year 1917 through 1973. After the central birth rates were computed, two adjustments were made as described below.

*Adjustment to central birth rates of 1899 and 1900 cohorts.*—The rates computed for the 1899 and 1900 cohorts appeared to be inconsistent with the rates for preceding and succeeding cohorts, those for the 1899 cohort being too low and those for the 1900 cohort being too high. This probably represented the tendency for some women in the co-

<sup>10</sup>No central birth rates are computed for second and higher orders at age 14 or at fifth and higher orders at ages 15-19; an asterisk is shown in the tables for these age-order cells. Before computation of central rates, the few births reported at these ages and orders are added to the youngest age permitted for each order (age 15 for second through fourth orders and age 20 for fifth and higher orders). In addition, the few births reported to women aged 50 and over were added to the number for age 49.

hort of 1899 to report age as the two right-hand digits of the calendar year when giving information for the birth certificate. Such misreporting was not important for women in the 1901 cohort, perhaps because it raised their age rather than lowering it.

It was assumed that the sum of the births assigned to the 1899 and 1900 cohorts in any calendar year was correct. That is, it was necessary only to redistribute the births already assigned to the two cohorts, subtracting some from the 1900 cohort and adding the same number to the 1899 cohort. This redistribution was done separately for the births of each order because it was found that the misreporting of age was much greater for the higher order births than for those of lower order.

The corrections for each order were calculated on the basis of the sums of central birth rates for the 1898 cohort, the 1899 and 1900 cohorts combined, and the 1901 cohort for 1917 and later years. It was assumed that these sums formed a regular progression, described by a second-degree polynomial that passed through the sums of the rates for the cohorts of 1898 and 1901 and the average of the sums for the 1899 and 1900 cohorts. This procedure yielded a larger sum for the 1899 cohort and a smaller sum for the 1900 cohort. Table III shows the original and corrected sums

Table III. Sums of central birth rates in 1917 and later years by color and live-birth order, as originally computed for the cohorts of 1898 to 1901 and as revised for the cohorts of 1899 and 1900

Color and live-birth order	Sum of original rates				Sum of revised rates		Percent deviation of revised from original	
	1898	1899	1900	1901	1899	1900	1899	1900
White-----	2,487.7	2,445.1	2,594.1	2,448.5	2,526.1	2,513.1	3.3	-3.1
First-----	689.3	734.4	785.1	784.6	743.9	775.6	1.3	-1.2
Second-----	599.5	593.1	612.0	583.3	605.3	599.8	2.1	-2.0

Eighth and higher-----	147.1	132.8	147.3	128.5	143.2	136.9	7.8	-7.1
All other-----	2,585.1	2,661.4	3,035.0	2,838.3	2,806.0	2,890.4	5.4	-4.8
First-----	510.7	610.6	702.0	735.5	618.8	693.8	1.3	-1.2
Second-----	455.9	479.4	513.9	488.9	491.1	502.2	2.4	-2.3
Third-----	386.2	383.0	411.2	378.4	398.4	395.8	4.0	-3.7
Fourth-----	296.5	289.5	326.1	295.3	308.0	307.6	6.4	-5.7
Fifth-----	226.0	219.6	258.5	230.2	238.3	239.8	8.5	-7.2
Sixth-----	187.0	179.9	215.6	188.6	197.5	198.0	9.8	-8.2
Seventh-----	144.1	140.4	166.9	143.7	153.7	153.6	9.5	-8.0
Eighth and higher-----	378.7	359.0	440.8	377.7	400.1	399.7	11.4	-9.3

of central birth rates for the 1899 and 1900 cohorts with the rates for the 1898 and 1901 cohorts by order of birth for white and all other women.

The number of births to be subtracted from the 1900 cohort and added to the 1899 cohort in each year was found by multiplying the original number of births of each order by the ratio

$$\frac{\text{revised sum of central rates after January 1, 1917}}{\text{original sum of central rates after January 1, 1917}}$$

computed from rates for the 1900 cohort.

This adjustment was applied to white and all other births separately. The revised total number of births for these cohorts is the sum of the revised numbers for the two color groups. After adjustment of the number of births, central birth rates for total women were recomputed for all years.

*Adjustment for erratic age pattern of central birth rates.*—The central birth rates computed and adjusted as described above were graphed for selected calendar years. These graphs revealed a sawtooth pattern by age, with the peaks at ages ending with 0, 5, 2, and 8. This age preference was more pronounced for women of all other races than for white women and was stronger for the higher order births. The problem had largely disappeared by the early 1930's for the rates for white women and by the late 1940's for the rates for all other women.

To smooth the rates, a three-term average of the central rates was computed for each of the color groups and for the total. The averages were computed within each calendar year using the single year of age rates. For example, the final rate for age 23 was the average of the rates for ages 22, 23, and 24. (The rates for ages 13 and 50 are considered to be zero.) Although the age preference had disappeared by about 1950, the averaging was continued for later years to give a consistent series; it has little effect on the rates for recent years.

### Cumulative Birth Rates

Cumulative birth rates by a given exact age represent the total childbearing experience of women in a cohort up to that age. The cumulative birth rate at age 50, assumed to be the end of childbearing, is considered to be the completed fertility rate of a cohort.

*Cohorts of 1903-59.*—For the cohorts of 1903 through 1959 central birth rates are available from age 14 through the age attained in 1973 (the latest year for which data are included in this report). For these cohorts the cumulative birth rates up to specified ages are the sums of central birth rates for ages 14 forward. That is, the sum of the central birth rates of a cohort during current ages  $x$  and younger is referred to as the cumulative birth rate by exact ages  $x+1$  and is said to relate to January 1 of a given year. For example, the cumulative birth rate by exact age 30 for the 1910 cohort is the sum of the central birth rates for the 1910 cohort for the years 1924 (when its members were age 14) through 1939 (when they were age 29). This is the cumulative birth rate for exact age 30 on January 1, 1940.

*Cohorts of 1863-1902.*—Since the cohorts of 1902 and earlier reached age 14 before 1917, the first year for which central birth rates are available, it was not possible to obtain cumulative birth rates for them simply by summing central birth rates. Instead, the cumulative birth rates for these cohorts for ages attained by January 1, 1917, were estimated by other means, and cumulative rates for subse-

quent years were then obtained by adding central birth rates for 1917 and later years.

Cumulative birth rates up to January 1, 1917, were estimated using 1910 census data on children ever born for women classified in 5-year age groups from 15-19 through 50-54. The census data may be considered as relating to 5-year cohort groups, for current ages rather than exact ages.

Before the census data on children ever born could be used, it was necessary to make certain adjustments. The procedures followed are outlined below in subsections 1-3. The estimation of cumulative birth rates for January 1, 1917, is outlined in subsections 4 and 5.

1. *Estimating numbers of children ever born, by order of birth, from parity distributions for each age group.*—Published tables for the 1910 census do not give numbers of children ever born by order of birth; these numbers must be derived from distributions of women by parity (number of children ever born). The number of births of each order to women reporting number of children ever born was found by cumulating the number of women of each successive parity from the highest parity down to the parity for the order of birth desired. For example, the number of first births was obtained by adding the numbers of women who had borne one or more children. Similarly, the number of fifth births was determined by adding women of fifth and higher parities. The numbers of births of eighth and higher orders were determined by subtracting the calculated numbers for the first seven orders from the published total number of children for all birth orders combined. This was done for the two color groups separately and the results were added to get the total births.

2. *Allowing for births to ever-married women for whom number of children ever born was not reported in 1910 and 1940.*—Reports on the number of children born were not obtained for significant proportions of ever-married women in the 1910 and 1940 censuses (table IV). For native white women and all Negro women in 1940 the U.S. Bureau of the Census estimated the ratio of the fertility of these non-reporters to that of reporters, by age, on the basis of tabulations of number of children under 5 years of age living with mother. Using a similar procedure, these ratios, called "fertility indexes," were computed for white and all other women for 1940; they are shown in table V. The fertility indexes for 1940 were used to estimate the total number of

Table IV. Percent of ever-married women not reporting number of children ever born, by age and race, 1910 and 1940

Age	Native white		Negro	
	1910	1940	1910	1940
15-19 years-----	23.3	22.0	24.4	20.8
20-24 years-----	12.1	15.5	14.0	17.0
25-29 years-----	7.5	12.9	10.4	15.4
30-34 years-----	6.1	11.6	9.6	14.2
35-39 years-----	5.5	11.4	7.8	14.5
40-44 years-----	5.4	11.1	8.6	14.4
45-49 years-----	5.5	11.3	8.1	14.2
50-54 years-----	6.0	11.6	9.5	14.3

Table V. Fertility indexes by age and color, 1940

[Index is the number of children under 5 years living with mother per 1,000 ever-married women for nonreporters divided by the number for reporters]

Age	White	All other
15-19 years-----	.490	.581
20-24 years-----	.649	.695
25-29 years-----	.746	.712
30-34 years-----	.817	.804
35-39 years-----	.810	.821
40-44 years-----	.840	.829
45-49 years-----	(1)	(1)
50-54 years-----	(1)	(1)

<sup>1</sup>Not available; assumed to be the same as for 40-44 years.

children ever born to the nonreporters in 1910 and hence to reporters and nonreporters combined.

To estimate the number of births of each order to nonreporters, it was assumed that the fertility indexes were constant by order of birth within each age group. This assumption implies that for each age group the parity distribution among women who have given birth was the same for reporters as for nonreporters of children ever born and, therefore, that the difference in the fertility of the two groups was the result of differences in the proportion of ever-married women with no children. Since the fertility of nonreporters was lower than that of reporters, this assumption implies that there were relatively more women with no children among the nonreporters than among the reporters.

The estimates of number of children ever born for white and all other women were added to obtain estimates for all women.

3. *Converting census-based rates from current ages to exact ages.*—The parity distributions published by the Bureau of the Census are by current age of woman, i.e., age at last birthday. In order to use the census-based cumulative fertility rates to supplement the rates based on vital statistics, it was necessary to convert the census rates to an exact age basis. This was done by multiplying the 1910 census-based rates for ages 45-49 and younger by the following ratios, which were derived from vital statistics rates:

$$\frac{\text{cumulative rate for order } N \text{ by exact ages } x \text{ to } x+4}{\text{cumulative rate for order } N \text{ by current ages } x \text{ to } x+4}$$

Ratios were computed for each 5-year age group 15-19 through 45-49 in each fifth year from 1925 through 1955. The ratios used for the adjustment were the averages of the available ratios for these years.

Adjustment ratios applied to the rates for first, second, and third births to all women are shown in table VI. At the younger ages a difference of 6 months makes a substantial difference in the number of children ever born. The cumulative first birth rates by exact ages 15-19, for example, are 25 to 28 percent below the cumulative rates by current ages 15-19 (or, what is assumed to be the same concept, by exact ages 15½-19½). The census-based cumulative rates estimated for exact ages should be regarded as relating to

Table VI. Ratio of cumulative birth rates for exact ages to cumulative birth rates for current ages used to convert 1910 census-based birth rates for all women, by age of mother and live-birth order

Age	Live-birth order		
	1	2	3
15-19 years-----	.7312	.6180	.5206
20-24 years-----	.9188	.8663	.8114
25-29 years-----	.9742	.9473	.9251
30-34 years-----	.9908	.9774	.9642
35-39 years-----	.9965	.9916	.9847
40-44 years-----	.9992	.9985	.9969
45-49 years-----	1.0000	.9998	.9997
50-54 years-----	1.0000	1.0000	1.0000

a date 6 months before the census was taken. The 1910 census date was April 15, 1910, so the cumulative rates by exact age relate to October 15, 1909.

These adjustments were done for each color group and for the total.

4. *Estimation of cumulative birth rates for 5-year cohort groups as of January 1, 1917.*<sup>11</sup>—The method used for births of each order from first through seventh and for eighth and higher orders combined is summarized below:

(a). The cumulative rate by exact age attained on October 15, 1909, was estimated for each 5-year age group from 15-19 through 50-54, as just described.

(b). The cumulative rate by exact ages 15-19 was obtained for the cohorts of 1903-07 as of January 1, 1922, by adding central birth rates for these cohorts for the period 1917-21 and averaging them.

(c). The cumulative rate by exact ages 15-19 was estimated for the cohorts of 1898-1902 as of January 1, 1917, by straight-line interpolation between the rate for 15-19 as of October 15, 1909, mentioned in step (a), and the rate for 15-19 as of January 1, 1922, obtained in step (b).

(d). The cumulative rate by exact ages 20-24 was obtained for the cohorts of 1898-1902 as of January 1, 1922, by adding the cumulative rate by ages 15-19 as of January 1, 1917, obtained in step (c), and their central birth rates for 1917-21.

<sup>11</sup>The cumulative rates for 5-year cohort groups are defined as the average of the rates of each cohort in the group by the ages reached on a specified date. For example, the cumulative rate for the cohorts of 1898-1902 by exact ages 15-19, reached on January 1, 1917, is the average of the following cumulative rates for single cohorts:

Cumulative rate by exact age—	For the cohort of—
19 -----	1898
18 -----	1899
17 -----	1900
16 -----	1901
15 -----	1902

Such rates are referred to as cumulative rates for the cohorts of 1898-1902 by ages 15-19 or by January 1, 1917.

Table VII. Estimated cumulative first birth rates for all women by exact ages attained on January 1, 1917, for the cohorts of 1863-1902, and figures on which estimates are based

Age	Cumulative birth rate by exact age on			Sum of central birth rates 1917-21	Cohorts to which the 1917 rates relate
	October 15, 1909 <sup>1</sup>	January 1, 1922 <sup>2</sup>	January 1, 1917 <sup>3</sup>		
15-19 years---	44.9	63.2	55.7	330.0	1898-1902
20-24 years---	344.4	385.7	368.8	279.5	1893-1897
25-29 years---	592.8	648.3	625.5	118.0	1888-1892
30-34 years---	706.7	743.5	728.4	40.2	1883-1887
35-39 years---	762.8	768.6	766.2	13.3	1878-1882
40-44 years---	795.2	779.5	785.9	2.3	1873-1877
45-49 years---	816.5	788.2	799.8	0.2	1868-1872
50-54 years---	826.0	800.0	810.7	...	1863-1867

<sup>1</sup>Estimated by correcting the 1910 census data on number of children ever born for nonreporting and for underreporting and converting the results from a current to an exact age basis. The latter adjustment of 1/2 year of age causes the rates to relate to a date 1/2 year earlier than the census of April 15, 1910.

<sup>2</sup>The rate for ages 15-19 relates to the cohorts of 1903-07 and is based entirely on vital statistics for 1917-21. Rates for other ages are obtained by adding central birth rates for the appropriate cohort group in 1917-21 to the cumulative rate estimated for January 1, 1917.

<sup>3</sup>Estimated by straight-line interpolation between October 15, 1909, and January 1, 1922.

(e). The cumulative rate by exact ages 20-24 was estimated for the cohorts of 1893-97 as of January 1, 1917, by straight-line interpolation between the rate for 20-24 as of October 15, 1909, mentioned in step (a), and the rate for 20-24 as of January 1, 1922, obtained in step (d).

The process described in steps(c)-(e) was repeated for each earlier group of cohorts. The cumulative rate on January 1, 1922, was always estimated by adding central birth rates in 1917-21 to the cumulative rate by the ages reached on January 1, 1917. The cumulative rate on January 1, 1917, was always estimated by straight-line interpolation between cumulative rates by the same exact ages for preceding cohorts on October 15, 1909, and following cohorts on January 1, 1922. The cumulative rates by 1917 and 1922 for first births to all women obtained by this method are shown in table VII. The cumulative rates for all orders combined is the sum of the rates for the first through the seventh and the eighth and higher orders. These procedures were applied to rates for each color group and for the total.

5. *Estimation of cumulative birth rates for single-year cohorts, 1863-1902.*—After estimates had been obtained for cumulative birth rates by January 1, 1917, for 5-year cohort groups (1863-67 through 1898-1902), estimates were derived for single cohorts. Two requirements were imposed on these estimates: they must be consistent with the estimates already derived for 5-year cohort groups, and they must be at approximately the same level as comparable rates for nearby cohorts.

To meet the above requirements, two interpolation procedures were applied. One was applied to the cumulative rates on January 1, 1917, for the more recent groups at the young childbearing ages whose cumulative rates should differ substantially from cohort to cohort. For example, the cohorts of 1903-07 had a cumulative first birth rate of 63.2 by January 1, 1922. This number is an average of five quite different rates for five different cohorts at five different ages. The extent to which these rates for single cohorts would be expected to differ from each other can be seen

from the following first birth rates for all women derived from vital statistics for the cohorts of 1903 through 1907:

Cohort	Exact age on January 1, 1922	Cumulative first birth rate on January 1, 1922
1907-----	15	3.8
1906-----	16	15.7
1905-----	17	42.3
1904-----	18	92.0
1903-----	19	162.0
1903-07-----	15-19	63.2

To derive such rates for single cohorts in earlier groups, it was assumed that the rate for any single cohort at a given age and birth order is a constant multiplied by the average rate for the next five cohorts at the same age and birth order and that the constant is the same for all cohorts in a given 5-year cohort group. For example, the first birth rate of 3.4 for the 1902 cohort at age 15 is equal to .9655 times the average of the cumulative rate at age 15 for the cohorts of 1903-07. Similarly, the rate of 143.1 for the 1898 cohort at age 19 is equal to the same factor (.9655) times the average of the cumulative rate at age 19 for the cohorts of 1899-1903. Such constants were found for each 5-year cohort group by means of a series of approximations which will not be described. Basically, the algebra is fairly simple, but the derivation of the formulas is too long to warrant a detailed description. The above method was used to derive estimates of cumulative rates on January 1, 1917, for the following cohorts and birth orders:

Cohort	Birth orders
1898-1902-----	1-4
1893-1897-----	1-8 and higher
1888-1892-----	3-8 and higher
1883-1887-----	6-8 and higher
1878-1882-----	8 and higher

Among earlier cohorts than those shown above, the cumulative rates for single cohorts on January 1, 1917, did not differ sufficiently from each other to warrant the use of the rather elaborate interpolation procedure described. For these earlier groups, cumulative rates for single cohorts on January 1, 1917, were found by osculatory interpolation between values for 5-year cohort groups.

These interpolation procedures were applied to the cumulative birth rates of each order for both color groups and for the total. The cumulative rates for all orders combined for each single year of age is the sum of rates for each of the orders.

### Parity Distribution

A parity distribution is a distribution of all the women in a cohort on a per 1,000 basis by the number of children they have ever borne up to a specified exact age. The proportions are computed by subtracting the cumulative birth rates for adjacent orders of birth. The cumulative birth rate for birth order  $N$  may be interpreted as the proportion of women who have had at least  $N$  children (or who have had  $N$  or more children). By subtracting the proportion of women who have had  $N+1$  or more children from the proportion who have had  $N$  or more children, one finds the proportion of women who have *exactly*  $N$  children.

The proportion of zero-parity women is found by subtracting the cumulative first birth rate from 1,000. The proportions of women at parities 1-6 are found from the following formula:

Proportion at  $N$  parity =

(cumulative rate, order  $N$ ) - (cumulative rate, order  $N+1$ ).

The proportion of women at seventh and higher parities is the cumulative birth rate for seventh order births.

Since no central birth rates are computed for second and higher orders at age 14 or for fifth and higher orders at ages 15-19, there are no cumulative birth rates for second and higher orders at age 15 or for fifth and higher orders at ages 16-20. Consequently, there can be no figures shown in the parity distributions for second and higher parities at age 15 or for fifth and higher parities at ages 16-20.

### Birth Probabilities

The age-parity-specific birth probability shows the probability that a woman who has attained  $N$  parity by exact age  $x$  will have an  $(N+1)$ th birth during age  $x$ . The probabilities are computed using the central birth rates and the parity distributions. The general formula for the probability for age  $x$ , parity  $N$  is

$$\frac{\text{Central rate, order } N+1}{\text{Proportion of women, parity } N} \quad 1,000$$

Since there are no figures for the proportion of women at second and higher parities at age 15 and at fifth and higher parities at ages 16-20, there are no birth probabilities for these groups. In addition, no probability is computed if the proportion of women in an age-parity group is less than 10.0 per 1,000, and an asterisk is shown in the tables.

## APPENDIX IV

### COMPARISON OF METHODS WITH THOSE OF WHELPTON AND CAMPBELL

With only a few exceptions the methods used by Whelpton and Campbell<sup>12</sup> for the estimation of the numbers of births and for the computation of central and cumulative birth rates have been used in the preparation of estimates for this report. The differences are described in this appendix.

#### Numbers of Births

The only methodological difference in the estimation of the numbers of births involves the estimates for States not in the birth-registration area (BRA) for 1917-32. Both procedures utilized guide States which were in the BRA in estimating births for States not in the BRA. Whelpton and Campbell selected one set of guide States for the whole period 1917-32. The guide States used in this report were allowed to change in each year. The new method gives, in effect, only different distributions of births by age and by order. Although the estimates were generally lower than Whelpton and Campbell's, this is not a factor in the final estimates since the new figures for the United States were adjusted to the totals prepared by Whelpton and Campbell.

Since Whelpton and Campbell did not prepare estimates by age and by order for white and all other births separately, no comparison between the two methods can be made by color. For the total, however, the numbers are very close. By age group the new estimates are all within 2 percent of the Whelpton and Campbell estimates except for ages 45-49, the least important age group. For the 45-49 age group the difference was 2 percent or less for 1929-32, 3 percent for 1920, 1923-24, and 1928, 4 to 5 percent for 1925-27, 6 to 7 percent for 1921-22, and 8 to 9 percent for 1917-19. For all the years where the difference was 3 percent or greater except one (1918), the new estimates were lower than those of Whelpton and Campbell. By birth order the new estimates are within 3 percent of the Whelpton and Campbell estimates for all orders in all years.

#### Central Birth Rates

The central birth rates were computed in the same manner as had been done by Whelpton and Campbell, including the adjustment to the cohorts of 1899 and 1900. One additional step was taken in the computation of central birth rates for this report—the 3-year average of central birth rates to remove the sawtooth pattern as described in

<sup>12</sup>National Office of Vital Statistics: Fertility tables for birth cohorts of American women, by P.K. Whelpton and A.A. Campbell. *Vital Statistics—Special Reports*, Vol. 51, No. 1. Public Health Service, Washington, D.C., Jan. 29, 1960.

appendix III, "Central Birth Rates," "Adjustment for erratic age pattern" (page 456).

#### Cumulative Birth Rates

The estimation of cumulative birth rates for January 1, 1917, involved many steps. Each of the steps, as described by Whelpton and Campbell, was applied to the data for the white population and for the population of all other races. However, the resultant parity distributions for the "all other" women did not appear reasonable—for all ages over 30 nearly 25 percent of the women were at one parity. An examination of the steps used to derive the cumulative birth rates showed the problem to be in a "consistency ratio" relating vital statistics and census cumulative rates. This ratio was used to adjust the census data on children ever born for the omission of births to single women and for the understating of births to ever-married women.

These two factors were posited as accounting for the observed excess of the vital statistics over the census cumulative rates. Whelpton and Campbell used the average of the ratios for 1940 and 1950 to adjust the 1910 census-based cumulative birth rates. However, when ratios were computed for white and all other women separately, those for all other women were not consistent with the logical bias in the census. That is, for all other women for orders 2 and 3, ages 30 and over, and orders 4 and 5, ages 35 and over, the census-based cumulative birth rates were higher than the vital statistics cumulative rates. When the "consistency ratios" (average of 1940 and 1950 ratios) were applied to the 1910 census-based cumulative rates, the result was to increase the rate for first births and to decrease the rate for second births. This yielded an unreasonably high proportion of one-parity women. Since the census rates were higher than vital statistics rates for both 1940 and 1950 for these groups, it was decided not to use any "consistency ratios" on the 1910 census cumulative rates. This resulted in more reasonable parity distributions for January 1, 1917.

A comparison of the new cumulative birth rates for all women with those computed by Whelpton and Campbell for 1940, 1950, and 1960 shows very close agreement. The 1940 rates reflect, in part, the estimated cumulative birth rates for January 1, 1917. For all three years the new rates are within 3 percent of the Whelpton and Campbell rates with two exceptions. At ages 15-19 the new rates were an average of 10 percent higher. The higher orders for younger women (ages 20-24, orders 3 and higher, and ages 25-29, orders 7 and higher) had differences in the same direction ranging up to 10 percent.
