STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 64.90 years for total males and 73.41 for total females. This State ranks 45th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00089—out of every 1,000 reaching their 21st birthday, 0.89 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,831 will complete the first year of life and enter the second, 96,629 will reach age 21, and 58,306 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,169 will die in the first year of life, 86 in the 22d year, and 2,652 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,585. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,585 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,298,916 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,341,114.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,585 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,629 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,298,916) in column 6 is the total number of years lived after attaining age 21 by the 96,629 reaching that age. This number of years divided by the number of persons (5,298,916 divided by 96,629) gives 54.84 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: ALABAMA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE
(1)	(2)	(3)	(4)	(5)	(6)	(7)
x to x +1	q_x	l_x	d_x	L_x	T_x	$\mathring{e}_x$

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.05 years for total males and 74.03 for total females. This State ranks 43d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00111—out of every 1,000 reaching their 21st birthday, 1.11 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,373 will complete the first year of life and enter the second, 96,935 will reach age 21, and 60,639 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,627 will die in the first year of life, 108 in the 22d year, and 2,901 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,881. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,881 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,349,823 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,402,841.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,881 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,935 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,349,823) in column 6 is the total number of years lived after attaining age 21 by the 96,935 reaching that age. This number of years divided by the number of persons (5,349,823 divided by 96,935) gives 55.19 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: ALASKA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.57 years for total males and 75.04 for total females. This State ranks 31st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00092 —out of every 1,000 reaching their 21st birthday, 0.92 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,289 will complete the first year of life and enter the second, 97,027 will reach age 21, and 63,527 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,711 will die in the first year of life, 89 in the 22d year, and 2,392 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,983. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,983 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,452,585 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,503,867.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,983 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,027 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,452,585) in column 6 is the total number of years lived after attaining age 21 by the 97,027 reaching that age. This number of years divided by the number of persons (5,452,585 divided by 97,027) gives 56.20 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: ARIZONA, 1969-71

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.68 years for total males and 74.97 for total females. This State ranks 27th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00082—out of every 1,000 reaching their 21st birthday, 0.82 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,166 will complete the first year of life and enter the second, 97,017 will reach age 21, and 62,260 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,834 will die in the first year of life, 80 in the 22d year, and 2,552 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,977. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,977 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,447,180 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,497,068.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,977 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,017 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,447,180) in column 6 is the total number of years lived after attaining age 21 by the 97,017 reaching that age. This number of years divided by the number of persons (5,447,180 divided by 97,017) gives 56.15 as the average remaining lifetime at age 21 for females in this State.

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.19 years for total males and 75.37 for total females. This State ranks 17th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00081—out of every 1,000 reaching their 21st birthday, 0.81 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,501 will complete the first year of life and enter the second, 97,517 will reach age 21, and 63,104 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,499 will die in the first year of life, 79 in the 22d year, and 2,487 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,478. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,478 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,477,415 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,536,772.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,478 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,517 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,477,415) in column 6 is the total number of years lived after attaining age 21 by the 97,517 reaching that age. This number of years divided by the number of persons (5,477,415 divided by 97,517) gives 56.17 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: CALIFORNIA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.40 years for total males and 75.93 for total females. This State ranks 12th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00085—out of every 1,000 reaching their 21st birthday, 0.85 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,366 will complete the first year of life and enter the second, 97,335 will reach age 21, and 65,243 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,634 will die in the first year of life, 83 in the 22d year, and 2,411 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,293. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,293 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,536,643 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,592,710.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,293 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,335 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,536,643) in column 6 is the total number of years lived after attaining age 21 by the 97,355 reaching that age. This number of years divided by the number of persons (5,536,643 divided by 97,355) gives 56.88 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: COLORADO, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 69.04 years for total males and 75.94 for total females. This State ranks 8th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00061—out of every 1,000 reaching their 21st birthday, 0.61 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,502 will complete the first year of life and enter the second, 97,706 will reach age 21, and 63,812 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,498 will die in the first year of life, 60 in the 22d year, and 2,729 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) —Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,676. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,676 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,532,599 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,593,529.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,676 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,706 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,532,599) in column 6 is the total number of years lived after attaining age 21 by the 97,706 reaching that age. This number of years divided by the number of persons (5,532,599 divided by 97,706) gives 56.62 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: CONNECTICUT, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.29 years for total males and 74.07 for total females. This State ranks 41st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00051—out of every 1,000 reaching their 21st birthday, 0.51 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,327 will complete the first year of life and enter the second, 97,425 will reach age 21, and 58,687 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,673 will die in the first year of life, 49 in the 22d year, and 2,710 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,401. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,401 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,352,767 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,407,289.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,401 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,425 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,352,767) in column 6 is the total number of years lived after attaining age 21 by the 97,425 reaching that age. This number of years divided by the number of persons (5,352,767 divided by 97,425) gives 54.94 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: DELAWARE, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

DISTRICT OF COLUMBIA
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 60.92 years for total males and 70.52 for total females. This State ranks 51st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00082—out of every 1,000 reaching their 21st birthday, 0.82 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,443 will complete the first year of life and enter the second, 96,173 will reach age 21, and 51,985 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,557 will die in the first year of life, 78 in the 22d year, and 2,298 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,134. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,134 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,019,424 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,051,553.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,134 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,173 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,019,424) in column 6 is the total number of years lived after attaining age 21 by the 96,173 reaching that age. This number of years divided by the number of persons (5,019,424 divided by 96,173) gives 52.19 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: DISTRICT OF COLUMBIA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.61 years for total males and 74.96 for total females. This State ranks 27th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00084—out of every 1,000 reaching their 21st birthday, 0.84 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,112 will complete the first year of life and enter the second, 96,927 will reach age 21, and 63,395 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,888 will die in the first year of life, 81 in the 22d year, and 2,218 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,887. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,887 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,447,659 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,495,823.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,887 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,927 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,447,659) in column 6 is the total number of years lived after attaining age 21 by the 96,927 reaching that age. This number of years divided by the number of persons (5,447,659 divided by 96,927) gives 56.20 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: FLORIDA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 64.27 years for total males and 73.01 for total females. This State ranks 48th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00084—out of every 1,000 reaching their 21st birthday, 0.84 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,045 will complete the first year of life and enter the second, 96,841 will reach age 21, and 56,136 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,955 will die in the first year of life, 81 in the 22d year, and 2,526 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,800. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,800 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,254,286 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,301,309.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,800 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,841 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,254,286) in column 6 is the total number of years lived after attaining age 21 by the 96,841 reaching that age. This number of years divided by the number of persons (5,254,286 divided by 96,841) gives 54.26 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: GEORGIA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 71.02 years for total males and 76.79 for total females. This State ranks 1st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00063—out of every 1,000 reaching their 21st birthday, 0.63 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,498 will complete the first year of life and enter the second, 97,689 will reach age 21, and 66,020 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,502 will die in the first year of life, 61 in the 22d year, and 2,451 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,659. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,659 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,617,818 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,678,677.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,659 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,689 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,617,818) in column 6 is the total number of years lived after attaining age 21 by the 97,689 reaching that age. This number of years divided by the number of persons (5,617,818 divided by 97,689) gives 57.51 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: HAWAII, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.20 years for total males and 76.10 for total females. This State ranks 14th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00081—out of every 1,000 reaching their 21st birthday, 0.81 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,441 will complete the first year of life and enter the second, 97,366 will reach age 21, and 66,217 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,559 will die in the first year of life, 79 in the 22d year, and 2,573 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,327. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,327 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,553,419 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,610,010.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,327 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,366 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,553,419) in column 6 is the total number of years lived after attaining age 21 by the 97,366 reaching that age. This number of years divided by the number of persons (5,553,419 divided by 97,366) gives 57.04 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: IDAHO, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

ILLINOIS
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.48 years for total males and 73.96 for total females. This State ranks 37th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00076—out of every 1,000 reaching their 21st birthday, 0.76 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,083 will complete the first year of life and enter the second, 97,079 will reach age 21, and 59,350 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,917 will die in the first year of life, 74 in the 22d year, and 2,764 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,042. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,042 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,346,390 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,396,252.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,042 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,079 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,346,390) in column 6 is the total number of years lived after attaining age 21 by the 97,079 reaching that age. This number of years divided by the number of persons (5,346,390 divided by 97,079) gives 55.07 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: ILLINOIS, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

INDIANA
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.23 years for total males and 74.72 for total females. This State ranks 24th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00073—out of every 1,000 reaching their 21st birthday, 0.73 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,317 will complete the first year of life and enter the second, 97,329 will reach age 21, and 61,101 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,683 will die in the first year of life, 70 in the 22d year, and 2,717 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,294. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,294 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,417,442 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,472,174.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,294 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,329 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,417,442) in column 6 is the total number of years lived after attaining age 21 by the 97,329 reaching that age. This number of years divided by the number of persons (5,417,442 divided by 97,329) gives 55.66 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: INDIANA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

IOWA
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.83 years for total males and 76.50 for total females. This State ranks 7th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00066 —out of every 1,000 reaching their 21st birthday, 0.66 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,434 will complete the first year of life and enter the second, 97,504 will reach age 21, and 66,412 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,566 will die in the first year of life, 64 in the 22d year, and 2,543 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,472. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,472 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,592,472 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,650,333.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,472 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,504 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,592,472) in column 6 is the total number of years lived after attaining age 21 by the 97,504 reaching that age. This number of years divided by the number of persons (5,592,472 divided by 97,504) gives 57.36 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: IOWA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE
(1)	(2)	(3)	(4)	(5)	(6)	(7)

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.83 years for total males and 76.54 for total females. This State ranks 6th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00069—out of every 1,000 reaching their 21st birthday, 0.69 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,485 will complete the first year of life and enter the second, 97,586 will reach age 21, and 66,724 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,515 will die in the first year of life, 67 in the 22d year, and 2,512 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,552. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,552 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,594,800 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,654,351.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,552 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,586 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,594,800) in column 6 is the total number of years lived after attaining age 21 by the 97,586 reaching that age. This number of years divided by the number of persons (5,594,800 divided by 97,586) gives 57.33 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: KANSAS, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

KENTUCKY
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.22 years for total males and 74.31 for total females. This State ranks 39th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00077—out of every 1,000 reaching their 21st birthday, 0.77 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,285 will complete the first year of life and enter the second, 97,186 will reach age 21, and 60,790 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,715 will die in the first year of life, 75 in the 22d year, and 2,713 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,148. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,148 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,378,933 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,431,499.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,148 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,186 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,378,933) in column 6 is the total number of years lived after attaining age 21 by the 97,186 reaching that age. This number of years divided by the number of persons (5,378,933 divided by 97,186) gives 55.35 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: KENTUCKY, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

LOUISIANA
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 64.85 years for total males and 72.88 for total females. This State ranks 47th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00083—out of every 1,000 reaching their 21st birthday, 0.83 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,856 will complete the first year of life and enter the second, 96,797 will reach age 21, and 55,814 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,144 will die in the first year of life, 80 in the 22d year, and 2,725 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,758. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,758 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,244,045 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,288,134.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,758 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,797 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,244,045) in column 6 is the total number of years lived after attaining age 21 by the 96,797 reaching that age. This number of years divided by the number of persons (5,244,045 divided by 96,797) gives 54.18 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: LOUISIANA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.24 years for total males and 74.85 for total females. This State ranks 21st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00048—out of every 1,000 reaching their 21st birthday, 0.48 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,275 will complete the first year of life and enter the second, 97,293 will reach age 21, and 61,148 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,725 will die in the first year of life, 46 in the 22d year, and 2,673 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,271. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,271 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,431,313 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,485,029.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,271 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,293 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,431,313) in column 6 is the total number of years lived after attaining age 21 by the 97,293 reaching that age. This number of years divided by the number of persons (5,431,313 divided by 97,293) gives 55.82 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MAINE, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

MARYLAND
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.47 years for total males and 74.17 for total females. This State ranks 36th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00069—out of every 1,000 reaching their 21st birthday, 0.69 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,326 will complete the first year of life and enter the second, 97,421 will reach age 21, and 58,907 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,674 will die in the first year of life, 66 in the 22d year, and 2,785 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,388. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,388 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,360,897 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,416,927.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,388 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,421 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,360,897) in column 6 is the total number of years lived after attaining age 21 by the 97,421 reaching that age. This number of years divided by the number of persons (5,360,897 divided by 97,421) gives 55.03 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MARYLAND, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

MASSACHUSETTS
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.12 years for total males and 75.45 for total females. This State ranks 15th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00051—out of every 1,000 reaching their 21st birthday, 0.51 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,467 will complete the first year of life and enter the second, 97,730 will reach age 21, and 62,418 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,533 will die in the first year of life, 50 in the 22d year, and 2,679 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,705. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,705 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,484,175 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,544,725.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,705 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,730 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,484,175) in column 6 is the total number of years lived after attaining age 21 by the 97,730 reaching that age. This number of years divided by the number of persons (5,484,175 divided by 97,730) gives 56.12 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MASSACHUSETTS, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.09 years for total males and 74.48 for total females. This State ranks 29th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00072—out of every 1,000 reaching their 21st birthday, 0.72 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,240 will complete the first year of life and enter the second, 97,274 will reach age 21, and 60,306 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,760 will die in the first year of life, 70 in the 22d year, and 2,687 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,239. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,239 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,394,276 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,447,694.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,239 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,274 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,394,276) in column 6 is the total number of years lived after attaining age 21 by the 97,274 reaching that age. This number of years divided by the number of persons (5,394,276 divided by 97,274) gives 55.45 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MICHIGAN, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

MINNESOTA
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 69.38 years for total males and 76.80 for total females. This State ranks 2d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00061—out of every 1,000 reaching their 21st birthday, 0.61 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,564 will complete the first year of life and enter the second, 97,676 will reach age 21, and 66,760 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,436 will die in the first year of life, 59 in the 22d year, and 2,574 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,646. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,646 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,619,018 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,680,339.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,646 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,676 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,619,018) in column 6 is the total number of years lived after attaining age 21 by the 97,676 reaching that age. This number of years divided by the number of persons (5,619,018 divided by 97,676) gives 57.53 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MINNESOTA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE
(1)	(2)	(3)	(4)	(5)	(6)	(7)

MISSISSIPPI
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 64.06 years for total males and 72.40 for total females. This State ranks 49th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

[1]Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00103—out of every 1,000 reaching their 21st birthday, 1.03 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,434 will complete the first year of life and enter the second, 96,096 will reach age 21, and 57,054 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,566 will die in the first year of life, 100 in the 22d year, and 2,640 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,046. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,046 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,207,211 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,239,767.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,046 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,096 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,207,211) in column 6 is the total number of years lived after attaining age 21 by the 96,096 reaching that age. This number of years divided by the number of persons (5,207,211 divided by 96,096) gives 54.19 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MISSISSIPPI, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

MISSOURI
STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.88 years for total males and 74.66 for total females. This State ranks 26th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table of Contents

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93
2	Minnesota	72.96	69.38	76.80	73.04	69.46	76.87	(1)	(1)	(1)

[1] Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x *to* $x+1$) —The year of age shown in column 1. is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x) —This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00078—out of every 1,000 reaching their 21st birthday, 0.78 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x) —This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,217 will complete the first year of life and enter the second, 97,158 will reach age 21, and 61,779 will live to age 75.

Column 4—Number dying (d_x) —This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,783 will die in the first year of life, 76 in the 22d year, and 2,672 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x *and* T_x) — Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x, shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,120. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,120 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,414,198 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,466,315.

Column 7—Average remaining lifetime ($\mathring{e}_x$) —The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,120 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,158 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,414,198) in column 6 is the total number of years lived after attaining age 21 by the 97,158 reaching that age. This number of years divided by the number of persons (5,414,198 divided by 97,158) gives 55.73 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MISSOURI, 1969-7

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE
(1)	(2)	(3)	(4)	(5)	(6)	(7)
x to $x+1$	q_x	l_x	d_x	L_x	T_x	$\mathring{e}_x$
